1 SAP HANA Search Developer Guide

With the SAP HANA platform, your users can search tables and views much like they would when searching for information on the Internet. In SAP HANA, you can either query data using OData service definitions, directly with SQL queries, or via the built-in procedure `sys.esh_search()`. You build your UIs using SAPUI5.

Prerequisites

Before enabling search, note the following prerequisites:

- Your SAP HANA database must contain column-oriented tables.
- A valid data type must be assigned to each column. The data types of the columns determine how you can query your data.

Context

In SAP HANA, you can search on single or multiple columns of almost any visible data type. In addition to standard string search, SAP HANA also supports full-text search.

During a full-text search, the SAP HANA search engine examines both structured text, such as author and date attributes, and unstructured text, such as body text. Unlike a string search, the sequence of words and characters used for a text search is not critical for finding matches. A full-text index enables this functionality by analyzing and preprocessing the available text semantically. This includes normalization, tokenization, word stemming, and part of speech tagging.

Procedure

To enable search in SAP HANA, proceed as follows:

1. Define the persistency and indexing.
2. Create your search models.
3. Access your data using full-text search.
4. Create your search UI.

Related Information

[Defining the Persistency and Indexing \[page 7\]](#)

[Creating Search Models \[page 29\]](#)

[Accessing Data Using Full-Text Search \[page 156\]](#)

[Creating Search UIs With SAPUI5 \[page 474\]](#)

2 Defining the Persistency and Indexing

The first task when developing a search application is to define the persistency of your data before you can index the data for a search.

Context

There are two ways to define database tables, views and indexes, and search-related settings.

- **Programming model A**
You can use Core Data Services (CDS) with its annotations syntax.
- **Programming model B**
You can use the SQL syntax.

i Note

We recommend using programming model A: CDS search annotations.

Procedure

1. Define the persistency for your data.
Create database tables, which store the data that you want to search for. Create views to model your data. Views are also needed for the OData service definitions in the CDS programming model.
2. Define indexes and choose the columns which you want to search in.
Use a powerful set of properties to set up all search related functions you want to use, for example the search mode FUZZY or text analysis.

Related Information

[Creating Full-Text Indexes Using CDS Annotations \[page 8\]](#)

[Creating Full-Text Indexes Using SQL \[page 11\]](#)

2.1 Creating Full-Text Indexes Using CDS Annotations

CDS uses a SQL-like syntax to define full-text indexes and fuzzy search indexes in the `technical configuration` part of an entity definition.

Procedure

1. You use the `technical configuration` part of the entity definition (in an `.hdbcds` or `.hdbdd` file) to create full-text indexes and fuzzy search indexes.

CDS entities are used to define database tables. The elements of an entity describe the columns of the table. For more information, see *SAP HANA Developer Guide For SAP HANA XS Advanced Model* and *SAP HANA Core Data Services CDS Reference*.

2. Add a `technical configuration` part to the entity definition.
3. Define the full-text index or fuzzy search index inside the **technical configuration** part. You use syntax similar to SQL syntax to define the indexes.

Example

Sample Code

Example for the Technical Configuration for Full-Text Indexes:

After the entity block, you define the indexes in the `technical configuration` block for each column that you want to search in.

```
Entity award
{
  key id:           Integer;
  title:            String(500);
  abstract:         LargeString;
  institutionName:  String(100);
  institutionCountry: String(100);
  institutionState: String(10);
  institutionZip:   String(20);
  institutionCity:  String(100);
  institutionStreet: String(100);
  programOfficer:  String(100);
}
technical configuration
{
  fulltext index fti_title      on (title)           fast preprocess off
                                                    language detection ('en')
                                                    fuzzy search index on;

  fulltext index fti_abstract  on (abstract)        fast preprocess off
                                                    language detection ('en')
                                                    fuzzy search index on;

  fulltext index fti_institutionName on (institutionName);
  fulltext index fti_programofficer on (programOfficer);
  fuzzy search index            on (institutionCity);
};
```

Sample Code

Example for the Technical Configuration for Complex Types:

Example of the `technical configuration` block with index definitions for complex types.

```
type contentType
{
  title:           String(500);
  abstract:       LargeString;
};

type institutionType
{
  institutionName: String(100);
  institutionCountry: String(100);
  institutionState: String(10);
  institutionZip: String(20);
  institutionCity: String(100);
  institutionStreet: String(100);
};

Entity award
{
  key id:           Integer;
  content:         contentType;
  institution:      institutionType;
  programOfficer:  String(100);
}

technical configuration
{
  fulltext index fti_title           on (content.title)      fast preprocess
off                                                                           language
detection ('en')                                                             fuzzy search
index on;
  fulltext index fti_abstract       on (content.abstract)  fast preprocess
off                                                                           language
detection ('en')                                                             fuzzy search
index on;
  fulltext index fti_institutionName on (institution.institutionName);
  fulltext index fti_programofficer  on (programOfficer);
  fuzzy search index                 on (institution.institutionCity);
};
```

Sample Code

Example for the `SearchIndex` Annotation for Full-Text Indexes (Repository/XS Classic):

```
entity myEntity
{
  key id: String(100);
  author: String(100);
  abstract: LargeString;
  content: LargeString;
  languagecode: String(2)
}

technical configuration
{
  fulltext index fti_abstract on (abstract) fast preprocess off
```

```

fulltext index fti_content    on (content);
fuzzy search index          on (author);
};
language column 'languagecode'
fuzzy search index on;

```

Sample Code

Example for the `SearchIndexes` Annotation for Structured Types (Repository/XS Classic):

```

type languageType
{
  code: String(2);
  name: String(100);
};

type documentType
{
  author: String(100);
  abstract: LargeString;
  content: LargeString;
  language: languageType;
};

entity documents
{
  key id: Integer;
  document: documentType;
}

technical configuration
{
  fulltext index fti_abstract on (document.abstract) fast preprocess off
  language column
'document.language.code'
  fuzzy search index on;

  fulltext index fti_content on (document.content);
  fuzzy search index on (document.author);
};

```

[Full-Text Index Parameters \[page 22\]](#)

[SAP HANA Developer Guide for XS Advanced Model](#)

2.2 Creating Full-Text Indexes Using SQL

When you create a TEXT or SHORTTEXT column in a table, SAP HANA automatically creates a corresponding full-text index. For columns of other data types, however, you have to manually create and define any required full-text indexes.

Context

A full-text index is an additional data structure that is created to enable text search features on a specific column in a table. Conceptually, full-text indexes support searching on columns in the same way that indexes support searching through books.

To create a full-text index, proceed as follows:

Procedure

1. Determine the columns for which you require an index.
2. Use the CREATE FULLTEXT INDEX statement to create an index with the specified index name.

```
CREATE FULLTEXT INDEX <index_name> ON <tableref> '(' <column_name> ')'  
[<fulltext_parameter_list>]
```

3. Specify any of the following additional parameters for the full-text index:

```
LANGUAGE COLUMN <column_name>  
LANGUAGE DETECTION '(' <string_literal_list> ')'  
MIME TYPE COLUMN <column_name>  
FUZZY SEARCH INDEX <on_off>  
PHRASE INDEX RATIO <on_off>  
CONFIGURATION <string_literal>  
SEARCH ONLY <on_off>  
FAST PREPROCESS <on_off>  
TEXT MINING <on_off>  
TEXT MINING CONFIGURATION <string_literal>  
TEXT MINING CONFIGURATION OVERLAY <string_literal>  
TEXT ANALYSIS <on_off>  
MIME TYPE <specified mime type, e.g. application/pdf>  
TOKEN SEPARATORS <\/;,. :- _ () [] <> ! ? * @ + { } = " & >  
To set the synchronization, specify one of the following parameters:  
| SYNC  
| ASYNC  
| ASYNC FLUSH [QUEUE] EVERY n MINUTES  
| ASYNC FLUSH [QUEUE] AFTER n DOCUMENTS  
| ASYNC FLUSH [QUEUE] EVERY n MINUTES OR AFTER m DOCUMENTS
```

If you do not specify any parameters, the default values are used.

i Note

For a complete list of available parameters, see [Full-Text Index Parameters \[page 22\]](#).

The system creates a separate, hidden full-text index column for each source column that you have specified. You can now create queries to search these columns.

Results

You can check the parameters of an existing full-text index using the `SYS.FULLTEXT_INDEXES` monitoring view.

Example

You want to create a full-text index `i1` for table `A`, column `C`, with the following characteristics:

- Synchronous processing
- Fuzzy search index disabled
- Languages for language detection: English, German, and Korean

To create the index, you use the following syntax:

```
CREATE FULLTEXT INDEX i1 ON A(C) FUZZY SEARCH INDEX OFF
                                SYNC
                                LANGUAGE DETECTION ('EN','DE','KR')
```

Related Information

[Full-Text Index Types \[page 12\]](#)

[Synchronization \[page 16\]](#)

[Full-Text Index Parameters \[page 22\]](#)

2.2.1 Full-Text Index Types

SAP HANA automatically creates full-text indexes for columns of type `TEXT` and `SHORTTEXT(n)`. For other column types, you must manually create any required full-text indexes.

Characteristic	TEXT/BINTEXT	SHORTTEXT (n)	Manually Created
SQL data type exposed to user	NCLOB	NVARCHAR(n)	Original data type

Characteristic	TEXT/BINTEXT	SHORTTEXT (n)	Manually Created
Data returned by SELECT	Original text data (returns normalized data if the SEARCH_ONLY parameter is ON)	Original data	Original data
SQL insertion mode	SYNC or ASYNC	SYNC	SYNC or ASYNC
Drop index	Yes (via drop column)	Yes (via drop column)	Yes
Text search via CONTAINS	Yes	Yes	Yes
SQL string search	Not possible	Possible	Depends on underlying data type
Change parameters of full-text index	Partially	Partially	All (with rebuild)
Rebuild index	No	No	Yes
Base type can be changed	No	No	No (no dependency between base-column and index available)

2.2.1.1 TEXT or BINTEXT Indexes

In a SAP HANA database, when you create a table that contains large text or binary documents, you can define the columns with the TEXT or BINTEXT data type. This data type allows you to query textual data and present content excerpts in search hit lists. You can also reconstruct the document and display its original textual content.

i Note

Embedded document filters can automatically extract text and metadata from most popular document formats, including Adobe PDF, Microsoft Office, OpenDocument, email, HTML, XML, and plain text.

Archive file formats, which may contain nested sub-files, are not supported. This includes ZIP and RAR files, as well as personal email folders like PST files.

When you create a TEXT/BINTEXT column and insert content, SAP HANA extracts and processes the text from the original document and then automatically generates a full-text index for the column. To create this full-text index, SAP HANA replaces the original data in the column with the processed text. This text is then returned with the data type NCLOB. The original data is no longer available.

If you insert new entries in the TEXT/BINTEXT column, the full-text index is automatically updated.

Limitations

The TEXT/BINTEXT data types have the following search-relevant limitations:

- SQL string searches are not supported.

- The SQL functions `CONCAT` and `JOIN` are not supported.
- `TEXT` columns cannot be converted to other data types.
- The `LIKE` predicate is not supported.

For `TEXT`/`BINTEXT` columns, SAP HANA does not support the following SQL expressions:

- `HAVING`
- `WHERE` with strings or non-alphanumeric characters
- `ORDER BY`
- `GROUP BY`
- Aggregate expressions (`COUNT`, `MIN`, `MAX`, etc.)
- `JOIN ON`

Changes to `TEXT`/`BINTEXT` Indexes

`TEXT`/`BINTEXT` full-text indexes are automatically generated and you do not specify names for them; therefore, you cannot directly manipulate them. However, when you create, alter, or drop a table column, the same change is automatically applied to the full-text index for that column.

By using the `ALTER TABLE` statement to affect changes on the index, you can alter the following parameters:

- `PHRASE INDEX RATIO`
- `FUZZY SEARCH INDEX`
- `LANGUAGE DETECTION`

Example

Sample Code

```
CREATE COLUMN TABLE <tablename>
(
  k int primary key,
  content TEXT
  FAST PREPROCESS OFF
  PHRASE INDEX RATIO 0.77
)
```

2.2.1.2 `SHORTTEXT(n)` Indexes

If the tables in your SAP HANA database contain columns with text strings that are relatively short in length, you can define those columns with the `SHORTTEXT(n)` data type. The `SHORTTEXT(n)` data type enables both SQL string search and full-text search capabilities.

SAP HANA preprocesses the text in the column and stores that preprocessed text as a full-text index in a hidden column attached to the original column. When queried, the text in the full-text index returns with the

NVARCHAR data type. The original text is still available; however, search queries are performed, by default, on the text in the index.

When you create a column table and define a column with the data type SHORTTEXT(n), as in the following example, a full-text index is automatically generated. Whenever new entries are then inserted in the column, the full-text index is automatically and synchronously updated.

Example

```
CREATE COLUMN TABLE <tablename>
(
    k int primary key,
    content SHORTTEXT(100)
                                FAST PREPROCESS OFF
                                SEARCH ONLY ON
)
```

Changes to SHORTTEXT(n) Indexes

SHORTTEXT(n) full-text indexes are automatically generated and you do not specify names for them; therefore, you cannot directly manipulate them. However, when you create, alter, or drop a table column, the same change is automatically applied to the index for that column.

When using the ALTER TABLE statement to affect changes on the index, you can only alter the following parameters:

- PHRASE INDEX RATIO
- FUZZY SEARCH INDEX

i Note

You cannot change the length of the original text and you cannot convert SHORTTEXT(n) to another data type.

2.2.1.3 Manually Created Indexes

If the tables in your SAP HANA database contain extensive columns that are frequently queried but do not have automatically generated full-text indexes, meaning they are not TEXT or SHORTTEXT(n) type columns, you can improve search performance by manually creating full-text indexes.

To manually create a full-text index, the column must have one of the following SQL data types:

- VARCHAR
- NVARCHAR
- ALPHANUM

- CLOB
- NCLOB
- BLOB

When you manually create an index, the system attaches a hidden column to the specified column. This hidden column contains textual data that SAP HANA Preprocessor has extracted from the text in the source column. The original text in the source column remains unchanged. Search queries are then performed on the hidden column; however, they always return the original text. Depending on the data type that is assigned to a source column, string search may be possible.

You can manually create an index directly after creating a table or you can create the index later. Once you create an index for a column, the system automatically processes any text that is inserted into this column and adds the processed text to the index. Processing for manually created indexes can be performed synchronously or asynchronously.

You can specify different parameters when you create a full-text index. If parameter changes are required later, you can change the values for the existing index directly or re-create the index with the parameters that you want to change.

Related Information

[Creating Full-Text Indexes Using SQL \[page 11\]](#)

[Altering Full-Text Index Parameters \[page 21\]](#)

[Synchronization \[page 16\]](#)

[Full-Text Index Parameters \[page 22\]](#)

2.2.2 Synchronization

Full-text indexes in a SAP HANA database must be created and updated in synchronization with the corresponding columns. This synchronization can be either synchronous or asynchronous.

Synchronous

In SAP HANA, indexes of the type TEXT and SHORTTEXT(n) are synchronous. Text preprocessing is automatically performed when a column is created or new text is inserted and the full-text index is then automatically updated. The system cannot transport any data to the proper database tables until text preprocessing is complete.

Asynchronous

If you manually create a full-text index, you can specify whether the index is synchronous or asynchronous. By default, manually created indexes are asynchronous. Text preprocessing is not initially performed when the

table or column is created or whenever new text is inserted. In this case, inserting the results of the text preprocessing and writing the original data do not occur at the same time. Therefore, the full-text information may not be immediately available for searching.

To handle asynchronous processing of text, SAP HANA uses queues.

2.2.2.1 Queues

The queue is a mechanism used to enable a full-text index to operate asynchronously. This means that when you insert new entries into the column, the text is not made available in the column until it is preprocessed.

When you insert new entries, the queue sends the text to the preprocessor for analysis. It returns a serialized instance of a DAF (document analysis format) object, which is then processed further by the HANA column store. The result is stored in the full-text index.

The SAP HANA queue manager automatically creates a queue when you create an asynchronous full-text index or when the index server is started and the queue manager finds the information that a specific queue is needed. The queues are always created on the server on which the table is stored.

Every entry in the queue has one of the following processing states:

- New
- Preprocessing
- Preprocessed
- Indexing
- Error

If the original column entry is modified or deleted during text processing, the queue is notified and, if necessary, the entry is preprocessed again.

i Note

The content of the queue is not made persistent at any stage. If the HANA index server process fails, the queue data is lost and the queue manager automatically restarts the process for those entries that were not already processed. Any incomplete text preprocessing is restarted from the beginning.

Flush Scheduling

When you create an asynchronous full-text index, you can specify when documents are removed from the queue after they are preprocessed and inserted into the full-text index; this is called flushing. You can schedule flushing based on either time or the number of documents. To do this, when you create the full-text index, define one of the following clauses with the `ASYNC` parameter:

- `FLUSH EVERY (n) MINUTES`
- `FLUSH AFTER (n) DOCUMENTS`
- `FLUSH EVERY (n) MINUTES OR AFTER (m) DOCUMENTS`

i Note

You cannot specify negative values for minutes or documents.

To determine when the queue of an existing full-text index is flushed, see the `FLUSH_EVERY_MINUTES` and `FLUSH_AFTER_ROWS` attributes in the view `FULLTEXT_INDEXES`.

Related Information

[Manipulating Queue Processing \[page 18\]](#)

2.2.2.2 Encoding of the Synchronization Modes

The synchronization mode of an index is encoded in two attributes in the `SYS.FULLTEXT_INDEXES` view.

If you want to know which synchronization mode is set for an index, you can check and encode the values of the `FLUSH_EVERY_MINUTES` and `FLUSH_AFTER_DOCUMENTS` attributes in the `SYS.FULLTEXT_INDEXES` view.

Sync Mode Clause	Value of Attribute <code>FLUSH_EVERY_MINUTES</code>	Value of Attribute <code>FLUSH_AFTER_DOCUMENTS</code>
<code>SYNC</code>	0	-1
<code>ASYNC</code>	-1	-1
<code>ASYNC FLUSH EVERY n MINUTES (n>0)</code>	n	-1
<code>ASYNC FLUSH AFTER n DOCUMENTS (n>0)</code>	-1	n
<code>ASYNC FLUSH EVERY n MINUTES OR AFTER m DOCUMENTS</code>	n	m

2.2.2.3 Manipulating Queue Processing

By default, queues are active initially and run automatically based on the parameters you specify when creating the full-text index. However, if necessary, you can manually manipulate the processing of an existing queue.

Context

To manipulate the processing of a queue, the following commands are available:

- `FLUSH`
Updates the full-text index with the documents in the queue which have already been processed and removes them from the queue.
- `SUSPEND`
Suspends the full-text index processing queue
- `ACTIVATE`
Activates the full-text index processing queue if it has been suspended

To manipulate the processing of a queue:

Procedure

1. Identify which queue process you want to manipulate by using the monitoring view `M_FULLTEXT_QUEUES`. For information about the specific content of the view, see *SAP HANA System Tables and Monitoring Views*.
2. Use the `ALTER FULLTEXT INDEX` statement to flush, suspend, or reactivate the queue.

Use the following syntax:

```
ALTER FULLTEXT INDEX <index name> FLUSH|SUSPEND|ACTIVATE QUEUE
```

Related Information

[SAP HANA System Tables and Monitoring Views: M_FULLTEXT_QUEUES](#)

2.2.3 Text Analysis

Text analysis is a feature enabled with the full-text index to discover and classify entities in your documents.

Text analysis provides a vast number of possible entity types and analysis rules for many industries in many languages. You do not have to deal with this complexity when analyzing your individual set of documents. The language modules included with the software contain system dictionaries and provide an extensive set of predefined entity types. The extraction process can extract entities using these lists of specific entities. It can also discover new entities using linguistic models. Extraction classifies each extracted entity by entity type and presents this metadata in a standardized format. You can also customize the text analysis process and even define your own entity types.

Individual text analysis options are grouped into text analysis configurations, which are stored in SAP HANA in an XML format. The system includes a number of predefined configurations. You can use any of these, or create your own custom text analysis configurations. To use your own text analysis extraction dictionaries and extraction rules, you need to create a custom text analysis configuration.

Related Information

[SAP HANA Text Analysis Developer Guide](#)

2.2.4 Dropping Full-Text Indexes

If you want to delete a full-text index that you manually created, for example, because it is referenced only rarely or preprocessing is too time-consuming, you can drop the full-text index. For TEXT or SHORTTEXT full-text indexes, you cannot drop the full-text index; instead, you must delete the related column in the table.

Context

You also need to drop full-text indexes when adding or removing index parameters. As parameters cannot be added to or removed from an existing full-text index, if you want to change parameters, you must first drop the full-text index and then create a new index with the new parameters.

To drop a full-text index, you use the DROP FULLTEXT INDEX statement:

```
DROP FULLTEXT INDEX <index_name>
```

i Note

Before you can drop a full-text index, you must remove the relationship between the source table and any existing \$TA tables (for text analysis). To do so, use the following statement:

```
ALTER TABLE SCHEMA <$TA_table> DROP <name_constraint>
```

The name constraint must be the same as originally used when adding the constraint. For more information, see *Text Analysis*.

[Altering Full-Text Index Parameters \[page 21\]](#)

[SAP HANA Text Analysis Developer Guide](#)

2.2.5 Altering Full-Text Index Parameters

You can alter a full-text index after it is created. Altering an index includes changing the values of the parameters and altering the parameters by replacing the index. It can also be used to invoke text mining initialization.

Procedure

- To alter the parameters of a full-text index, use the `ALTER FULLTEXT INDEX` statement.

You can only use this statement to alter the following parameters:

- Fuzzy search index
- Phrase index ratio
- Text mining on/off (sets flag only, doesn't invoke text mining initialization)
- Text mining configuration (also invokes text mining initialization)
- Text mining configuration overlay (also invokes text mining initialization)

Example syntax:

```
ALTER FULLTEXT INDEX <index_name>  
PHRASE INDEX RATIO <parameter value>  
FUZZY SEARCH INDEX <on_off>  
ALTER FULLTEXT INDEX <index_name>  
TEXT MINING CONFIGURATION <config_name>
```

- To alter any other parameter, you must replace the existing full-text index as follows:
 - a. Delete the existing full-text index by using the `DROP FULLTEXT INDEX` statement.
 - b. Create a new index using the new parameter values.

[Full-Text Index Parameters \[page 22\]](#)

2.2.6 Full-Text Index Parameters

The content and behavior of a full-text index is configured by the use of both default and user-specified parameters. To view the configuration of a full-text index, you use the `SYS.FULLTEXT_INDEXES` view.

i Note

Note that the parameters inside the `SYS.FULLTEXT_INDEXES` view are written with underscores. When using the parameters in SQL no underscores are to be used.

In SAP HANA, full-text indexes are configured using the following parameters:

Parameter	Description
LANGUAGE COLUMN	<p>Specifies the language used for analyzing the document. If no language is specified, the language is detected automatically. The detected language is stored in text attribute <code>TEXT_AE</code> and can be queried via <code>LANGUAGE(columnName)</code>.</p> <p>Example values: 'EN', 'KO', 'DE'</p> <p>With this option, you can refer to a column of the same database table where the language for the document is stored.</p> <p>The column is read by the queue. Language columns in base tables should be of type <code>NVARCHAR/ VARCHAR(m)</code>.</p> <p>The language is specified using either ISO 639-1 (2 character) codes or ABAP (1 character) codes. Valid ISO 639-1 (2 character) language codes are listed in the <code>SYS.M_TEXT_ANALYSIS_LANGUAGES</code> view.</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>The valid ISO 639-1 language codes can be displayed using the following SQL statement:</p> <pre>SELECT * FROM "SYS"."M_TEXT_ANALYSIS_LANGUAGES"</pre> </div> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>Specify the "neutral" language (two-letter code "UD") to perform only basic analysis on the document, such as tokenization, case normalization, and umlaut conversion. You may want to do this when a document is in a language not listed in the <code>SYS.M_TEXT_ANALYSIS_LANGUAGES</code> view (for example, Chechen or Somali). No entities will be extracted unless you have custom rules or dictionaries written in the neutral language. See the <i>SAP HANA Text Analysis Developer Guide</i> for additional information.</p> </div> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>The list in the <code>SYS.M_TEXT_ANALYSIS_LANGUAGES</code> view includes a number of languages which are known for language detection but which are not explicitly supported for text analysis processing. For these languages, text analysis will fall back to "neutral" processing. For non-whitespace languages where neutral processing cannot work, text analysis will return an empty result. See the <i>SAP HANA Text Analysis Language Reference Guide</i> for more details on specific language support.</p> </div>
MIME TYPE COLUMN	<p>This column holds a mimetype indicator that is used for preprocessing. If this is empty or invalid, auto detection is used.</p> <p>Valid MIME types are listed in the <code>SYS.M_TEXT_ANALYSIS_MIME_TYPES</code> view.</p> <p>Example values: 'text/plain', 'text/html', 'application/pdf'</p>

Parameter	Description
MIME TYPE	<p>Specifies the default MIME type used for preprocessing (see <code>MIME TYPE COLUMN</code>). If both <code>MIME TYPE</code> and <code>MIME TYPE COLUMN</code> are set, and if the corresponding cell for the <code>MIME TYPE COLUMN</code> is null, the value of parameter <code>MIME TYPE</code> is used for preprocessing.</p> <p>Example: You can specify <code>MIME TYPE 'application/pdf'</code> if the table contains only pdf content.</p>
LANGUAGE DETECTION	<p>Specifies the set of languages to be used for automatic language detection. If reliable language detection cannot be performed, the first language in the list will be used as the default language.</p> <p>This option is used to limit the languages for text analysis.</p> <p>Valid languages are listed in the <code>SYS.M_TEXT_ANALYSIS_LANGUAGES</code> view, and can be displayed using the following SQL statement:</p> <pre>SELECT * FROM "SYS"."M_TEXT_ANALYSIS_LANGUAGES".</pre> <p>Example: LANGUAGE DETECTION ('EN', 'DE', 'JA') The language is specified in the ISO 639-1 (2 characters) and not in the ABAP format (1 character with conversion exit)</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>Only the <code>LANGUAGE COLUMN</code> parameter accepts SAP/ABAP codes. The <code>LANGUAGE DETECTION</code> parameter only accepts ISO 639-1 codes.</p> </div> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>In addition, you may specify the "neutral" language code ("UD") as the first language in the <code>LANGUAGE DETECTION</code> list. This causes "neutral" language processing to be used when the actual language cannot be determined automatically.</p> </div> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>In addition, you may specify the "all supported" language code ("**") in the <code>LANGUAGE DETECTION</code> list. This causes all languages which are explicitly supported for text analysis processing to be considered for language detection. See the <i>SAP HANA Text Analysis Language Reference Guide</i> for more details on specific language support.</p> </div>

Parameter	Description
FAST PREPROCESS	<p>Specifies whether fast preprocessing should be performed.</p> <p>Default: FAST PREPROCESS ON</p> <p>With fast preprocessing, the language detection just returns the default language, which is 'EN'. Linguistic analysis is skipped, and only a simple tokenizer is used. This simple tokenizer does not work for languages which do not use spaces as word separators (like Japanese). It cannot handle binary documents either.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note</p> <p>The parameter combination FAST PREPROCESS ON + [LANGUAGE COLUMN OF LANGUAGE DETECTION OR TEXT ANALYSIS ON] is not allowed.</p> </div>
FUZZY SEARCH INDEX	<p>If this option is enabled, a special index is created for fuzzy search. This index accelerates fuzzy search, but uses additional memory.</p>
SEARCH ONLY	<p>If set to ON, the original content is not stored in the text attribute. You can get a reconstructed version of the document, but it may deviate from the original content. It is not possible to show the document in its original formatting when using the highlight function or to retrieve the HTML-converted data from the text attribute. The document will use less memory however.</p> <p>If the text attribute is created via a manually created full-text index, the source attribute that contains the original data is not affected by this setting.</p>
SYNC	<p>Insert/Update calls do not return until all documents have been preprocessed and inserted into the fulltext index.</p>
ASYNC	<p>Insert/Update calls return before all documents are preprocessed and inserted into the index. However, preprocessing and insertion into index starts immediately upon insert/update call.</p>
ASYNC FLUSH EVERY n MINUTES	<p>Like ASYNC, but insertion into fulltext index takes place every n minutes instead of immediately upon insert/update call. Preprocessing still starts immediately.</p>
ASYNC FLUSH AFTER m DOCUMENTS	<p>Like ASYNC, but insertion into fulltext index takes place after m new documents have inserted/updated instead of immediately upon insert/update call. Preprocessing still starts immediately.</p>

Parameter	Description
ASYNC FLUSH EVERY n MINUTES OR AFTER m DOCUMENTS	<p>Like ASYNC, but insertion into fulltext index takes place every n minutes or after m new documents have been inserted/updated instead of immediately upon insert/update call. Preprocessing still starts immediately.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>Note that DELETE commands do not reduce the document count, e.g. if you use FLUSH AFTER 5 DOCUMENTS, insert four documents, delete one and afterwards insert one more document, the fulltext index gets updated as in total five documents where inserted.</p> </div>
CONFIGURATION	<p>Specifies the text analysis options to be used. The options are bundled into a single file with the <code>.hdbtextconfig</code> file extension, referred to as a text analysis configuration file. You can create your own custom configurations with the SAP HANA repository, the HANA deployment infrastructure or the <code>TEXT_CONFIGURATION_CREATE</code> stored procedure. Or you can use one of the following predefined text analysis configurations delivered by SAP:</p> <ul style="list-style-type: none"> • LINGANALYSIS_BASIC • LINGANALYSIS_STEMS • LINGANALYSIS_FULL • EXTRACTION_CORE • EXTRACTION_CORE_VOICEOFCUSTOMER • EXTRACTION_CORE_ENTERPRISE • EXTRACTION_CORE_PUBLIC_SECTOR • GRAMMATICAL_ROLE_ANALYSIS <p>Specify the package path to the configuration file, the configuration file name, and file extension as follows: <code>[<package-path>::]<configuration-name>[.hdbtextconfig]</code></p> <p>The file extension defaults to <code>.hdbtextconfig</code>. Omit the package path and file extension when using a predefined configuration. For example: <code>CONFIGURATION 'EXTRACTION_CORE'</code></p> <p>If a custom configuration was created in a package, such as when using the SAP HANA repository, you must specify the full package path when using that configuration. For example: <code>CONFIGURATION 'acme.com.ta.config:MY_TA_CONFIGURATION'</code></p> <p>This parameter requires the setting <code>TEXT ANALYSIS = ON</code>.</p>
PHRASE INDEX RATIO	<p>Stores information about the occurrence of words and the proximity of words to one another. If a phrase index is present, phrase searches are sped up (e.g. <code>SELECT * FROM T WHERE CONTAINS (COLUMN1, "cats and dogs")</code>).</p> <p>The float value is between 0.0 and 1.0. 1.0 means that the internal phrase index can use 100% of the memory size of the fulltext index.</p>

Parameter	Description
TEXT_ANALYSIS	<p>This parameter enables the creation of the \$TA table. Text analysis may occur even when TEXT_ANALYSIS_OFF is specified, depending on the other indexing parameters that are specified.</p> <p>If set to ON, the FAST_PREPROCESS parameter is automatically set to OFF.</p> <p>Text analysis can extract entities such as persons, products, or places from documents, and thus enriches the set of structured information in SAP HANA. You can use these additional attributes, which are stored in a new table, when creating models (views) for analytics and search scenarios to enable improved analytics and search in SAP HANA.</p>
TOKEN_SEPARATORS	<p>A set of characters used for token separation. Only ASCII characters are considered.</p> <p>Default values are <code>\ / ; , . : - _ () [] < > ! ? * @ + { } = " &</code></p> <p>If for example "-" is removed from the default token separators set, a chemical formula like "CH₃-CH₂-CH₃" won't get split into "CH₃", "CH₂" and "CH₃". It will remain one token.</p>
TEXT_MINING	<p>If set to ON, text mining capabilities will be enabled on the indexed column. Text mining initialization will be called for the document data in that column when the table is loaded or when that data has changed.</p>
TEXT_MINING_CONFIGURATION	<p>States the name of the configuration file for text mining created with the SAP HANA repository, with the SAP HANA deployment infrastructure, or with the TEXT_CONFIGURATION_CREATE stored procedure. Default is DEFAULT.textminingconfig. Custom configuration files for text mining can be specified by name.</p>
TEXT_MINING_CONFIGURATION_OVERLAY	<p>This parameter specifies literal text mining configuration data that should override the text mining configuration file. The format is the same as in the configuration file, typically a small subset of parameters. This allows parameter experimentation without requiring creation of configuration files for each case.</p>

2.2.6.1 Memory Consumption of Full-Text Index Parameters

In SAP HANA, certain full-text index parameters can have a significant impact on memory consumption based on how they are defined.

The following full-text index parameters can have a significant impact on memory consumption:

Parameter	Memory Impact Details
PHRASE INDEX RATIO	If the value is greater than 0.0, there is additional memory overhead. The maximum memory consumption is the memory consumption of the full-text index multiplied by the parameter value.
FUZZY SEARCH INDEX	To increase response times for fuzzy search, when enabled, this parameter creates additional in-memory structures. For text-type columns, fuzzy search indexes require approximately 10% of the memory size of the column.
TEXT ANALYSIS	If this parameter is set to ON, an additional table is created for storing structured data extracted from the source text for text analysis. The amount of extracted data depends on the data in the source column, the text analysis rules, and the structure of the results. In certain cases, the memory consumption of the extracted data could exceed the memory consumption of the source data.

3 Creating Search Models

To search for data you have to model it first.

Context

Depending on which persistency you have chosen, you have various options for modelling your data:

- Using CDS search annotations
If you use the CDS search approach, you define the search models either in the `hdbdd` file (XS Classic) or `hdbcds` file (XS Advanced) using search-specific annotations.
- Using the built-in procedure `sys.esh_config()`
If you use the built-in procedure `sys.esh_config()`, you define the search models in a metadata document that contains the columns of the join view, SQL view, or table function that are relevant to search.
- Using attribute views
If you use the SQL search approach, you create an attribute view in the SAP HANA modeler using the tables that you want to enable for the search. Create joins and add the attributes that you want to use to search and display. You can also join additional attributes derived from the text analysis.

[Modeling With Attribute Views \[page 154\]](#)

3.1 Definition of Searchable Database Objects

Search is possible in one of the following database objects only:

- SQL views
- SQL views with parameters
- CDS views
- table functions

Search configurations for other database objects like single tables or calculation views cannot be created.

i Note

For SQL views with parameters and for table functions, parameters of SQL type (N) VARCHAR are allowed only.

Usually a searchable database object contains more than one table: one anchor table and many detail tables.

Anchor Table: The first table is called the 'anchor table'. The anchor table defines the object that is searched as, for example, a customer or a document. Each row of the anchor table defines a searchable object that is identified by a unique key. This key is called the anchor key. It is defined using the `@EnterpriseSearch.key` annotation and it usually equals the primary key of the table. All anchor key columns have to be part of the anchor table, they have to be defined as `NOT NULL` columns, and these columns have to be added to the view.

Detail Tables: All other tables are called 'detail tables'. These tables are joined to the anchor table either by one-to-one joins, by one-to-many joins, or by many-to-many joins. Examples of detail tables are the authors of a document, the addresses of a customer, the purchase orders of a customer, or even the line items of these purchase orders.

3.1.1 Examples for Searchable Database Objects

The following basic example shows the definition of searchable database objects like a view, a view with parameters, and a table function.

Sample Code

Examples for Searchable Database Objects

```
/* anchor table */
create column table customer
(
  cust_id    integer primary key,
  name      nvarchar(100)
);

/* detail table */
create column table address
(
  cust_id    integer,
  addr_id    integer,
  street     nvarchar(100),
  city       nvarchar(100),
  country    nvarchar(2),
  valid_from date,
  valid_to   date,
  primary key (cust_id, addr_id)
);

/* definition of a view */
create view v_customer
as select c.cust_id, addr_id, name, street, city, country, valid_from,
valid_to
from customer c left outer join address a on c.cust_id = a.cust_id;

/* definition of a view with parameters */
create view vp_customer(in country nvarchar(2), in valid nvarchar(8))
```

```

as select c.cust_id, addr_id, name, street, city, country, valid_from,
valid_to
from customer c left outer join address a on c.cust_id = a.cust_id
where country = :country and valid_from <= to_date(:valid, 'YYYYMMDD') and
valid_to >= to_date(:valid, 'YYYYMMDD');

/* definition of a table function */
create function tf_customer(in country nvarchar(2), in valid nvarchar(8))
returns table
(
  cust_id      integer,
  addr_id      integer,
  name         nvarchar(100),
  street       nvarchar(100),
  city         nvarchar(100),
  country      nvarchar(2),
  valid_from   date,
  valid_to     date
)
LANGUAGE SQLSCRIPT SQL SECURITY INVOKER AS
BEGIN
  return
  select c.cust_id, addr_id, name, street, city, country, valid_from,
valid_to
  from customer c left outer join address a on c.cust_id = a.cust_id
  where country = :country and valid_from <= to_date(:valid, 'YYYYMMDD')
and valid_to >= to_date(:valid, 'YYYYMMDD');
END;

```

3.1.2 Search-Read-Breakup

A search in SAP HANA is processed as a two-step approach. It is broken up into a search step and a read step.

The **search step** is the first step of a search. It takes all search criteria (for example, the search terms entered by the user), searches all matching objects in the view and identifies their anchor keys. The set of unique anchor keys defines the objects that are returned in the search response. There is one response object for each distinct anchor key.

The **read step** is the second step of a search. The input to this step is the set of unique anchor keys that have been found in the search step. The read step fetches all values that are needed to build the search response. This includes the values of all response columns, snippets, highlighted text, and whyfound information.

As there is only one response object for each anchor key, the response columns (columns with a presentation mode other than NONE), snippets, and highlighted text are limited to columns coming from a one-to-one join. To return columns coming from a one-to-many join, these columns have to be defined either as language-dependent columns (with no more than one value for each language), as multi-value columns or as columns of a subobject.

3.1.3 Rules for Creating Searchable Views

To enable a search in a database object, a temporary join view has to be created internally during search runtime based on the definition of the database object. This is automatically done by the SQL interpreter and the join views are never visible to the user.

Search returns correct results only if this transformation of the database object to the join view is possible. Otherwise the `CONTAINS ()` predicate that is internally used in the search query results in a SQL error (or, in some cases, may not return correct results).

Database objects can be transformed to join views only if they follow the rules below:

- The searchable database object is of one of the supported database object types:
 - SQL views
 - SQL views with parameters
 - CDS views
 - table functions
- The searchable database object is created on top of the following database objects only:
 - Column tables (created as CDS entities or via `CREATE (COLUMN) TABLE` statements)
 - Projection views created on top of column tables using `CREATE PROJECTION VIEW` statement
 - Views and table functions created on top of the above database objects
- Other database objects are not allowed. This includes, for example, column views created with the `CREATE COLUMN VIEW` statement, attribute views, calculation views, and row tables.
- The searchable database object and all the objects it uses do not use any of the following features:
 - Calculated columns. This includes functions like `CAST ()` and `SUBSTRING ()`. This also includes columns with masked column values.
 - `DISTINCT`, `GROUP BY`, `ORDER BY` and aggregation functions like `COUNT ()`, `MIN ()`, `MAX ()`, and so on.
 - `UNION`, `UNION ALL`, `INTERSECT`, and `EXCEPT` operations are not supported.
- Join conditions have to follow the rules below:
 - Inner joins and left outer joins only
 - Equi-joins only
 - `AND` between join conditions only, no `OR`-ed conditions
 - Cyclic outer joins are not allowed
 - No joins over calculated columns
 - Additional filters for constant values on the right table are allowed (`col = 'x'`)
- The names of all view columns have to be valid OData identifiers
 - The maximum length of an OData identifier is 128 characters
 - The identifier has to start with a letter, an underscore, or a Unicode character from the categories L or NI
 - All other characters have to be letters, digits, underscores, or Unicode characters from the categories L, NI, Nd, Mn, Mc, Pc, or Cf
 - See the OData version 4.0 abnf construction rules for details

Example for Cyclic Outer Join

Cyclic outer joins, as shown in this example, are not allowed.

As soon as a left outer join defines a join condition that uses more than one table from the left side of the join, it is considered a cyclic outer join. This cyclic outer join definition cannot be processed by the search engine.

Sample Code

```
create view myview as
select ...
from tab1
left outer join tab2 on tab1.c1 = tab2.c1
left outer join tab3 on tab1.c2 = tab3.c2
left outer join tab4 on tab2.c3 = tab4.c3 and tab3.c4 = tab4.c4; -- left side
of join uses tab2 and tab3
```

Sample Code

```
create view myview as
select ...
from tab1
left outer join tab2 on tab1.c1 = tab2.c1
left outer join tab3 on tab1.c2 = tab3.c2 and tab2.c3 = tab3.c3; -- left side
of join uses tab1 and tab2
```

3.2 Modeling with CDS Annotations (XS Advanced)

To define a search model on XS Advanced, you need to use the CDS annotations.

SAP HANA supports the following annotations, which are important elements of the CDS documents used to define CDS-compliant catalog objects (these catalog objects are used to create search models):

- Search
- EnterpriseSearch
- EnterpriseSearchHana
- Hierarchy
- Semantics

You can use further configuration options by defining values on the metadata of these annotations directly, or on the higher view, entity, or element level.

For details on programming with XS Advanced see the *SAP HANA Developer Guide for SAP HANA XS Advanced Model*.

3.2.1 Annotation @Search

The `Search` annotation contains parameters that are used by the Enterprise Search runtime (`sys.esh_search()`) and that could also be used by other search runtimes.

Syntax

```
namespace sap.common;

annotation Search
{
    /* annotation at view level */
    searchable: Boolean;

    /* annotations at element level */
    defaultSearchElement: Boolean;

    ranking: String(6) enum {
        HIGH='HIGH';
        MEDIUM='MEDIUM';
        LOW='LOW';
    };

    fuzzinessThreshold: Decimal(3,2);

    termMappingDictionary: String(128);
    termMappingListID: array of String(32);

    fulltextIndex {
        required: Boolean;
    };
};
```

The ranking weights are defined as HIGH=1.0, MEDIUM=0.7, LOW=0.5.

Annotations on View Level

Annotation	Possible Values	Description
@Search.searchable	true, false	<p>Defines if a CDS view or entity is generally relevant for search scenarios.</p> <p>The annotation offers a general switch and a means to quickly detect whether a view is relevant or not.</p> <p>Set to true to enable @Search annotations. At least one column has to be defined as <code>defaultSearchElement</code>.</p>

Annotations on Element Level

Annotation	Possible Values	Description
@Search.defaultSearchElement	true, false	<p>Defines a column as full-text search column.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>At least one column has to be defined as default full-text search column. Search in views without default full-text search elements is not supported.</p> </div>
@Search.ranking	#HIGH #MEDIUM #LOW	Defines the ranking weight for a column ('HIGH' = 1.0, 'MEDIUM' = 0.7, 'LOW' = 0.5)
@Search.fuzzinessThreshold	0..1	<p>Defines the threshold for a fuzzy search.</p> <p>Default value is 1. This means that an exact search is performed.</p>

Annotation	Possible Values	Description
@Search.termMappingDictionary	string	<p>Defines the name of the term mapping table (format: <code>schemaname.tablename</code>), passed to the search option 'termMappingTable' of the <code>CONTAINS ()</code> predicate.</p> <div data-bbox="1007 600 1396 936" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>This annotation cannot be used if the <code>@EnterpriseSearch.searchOptions</code> annotation is used. In this case the term mapping definition has to be added to the search options string.</p> </div>
@Search.termMappingListID	array of strings	<p>Defines the names of the term mapping list IDs, passed to the search option 'termMappingListId' of the <code>CONTAINS ()</code> predicate.</p> <div data-bbox="1007 1126 1396 1462" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>This annotation cannot be used if the <code>@EnterpriseSearch.searchOptions</code> annotation is used. In this case the term mapping definition has to be added to the search options string.</p> </div>
@Search.fulltextIndex.required	true, false	<p>If set to <code>true</code>, a configuration fails if there is no full-text index defined for the element.</p> <div data-bbox="1007 1615 1396 1951" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>This annotation is checked during the validation of a search configuration only. This means that a search call does not fail if the full-text index has been removed from the column after writing the configuration to the database.</p> </div>

[FUZZY Search \[page 273\]](#)

[Term Mappings \[page 371\]](#)

3.2.1.1 Metadata on View- and Entity Level

On view and entity level you can specify additional metadata.

3.2.1.1.1 searchable

Defines if a CDS view or entity is generally relevant for search scenarios.

This annotation must be set if *SearchDetails* annotations are being defined for elements of the corresponding CDS view or entity.

The annotation offers a general switch and a way of quickly detecting whether or not a view is relevant.

3.2.1.2 Metadata on Element Level

On element-level via the `search` annotation those metadata can be specified which is relevant for all search scenarios.

3.2.1.2.1 defaultSearchElement

This annotation specifies that the element is to be considered in a full-text search (for example a `SELECT...`) where no columns are specified.

Such a search must not operate on all elements – for performance reasons, and because not all elements (e.g. internal keys) do qualify for this kind of access.

3.2.1.2.2 ranking

This annotation defines the ranking weight of a column that is used to calculate the overall score.

There are complementary aspects to ranking, where e.g. absolute values influence the ranking, without regard to the actual search terms.

Only one of the annotations `@EnterpriseSearchHana.weight` and `@Search.ranking` can be used for a column.

i Note

This annotation should be used only if the attribute is annotated with usage mode `FREESTYLE_SEARCH`.

The `ranking` attribute can have the following values:

Value	Description
HIGH	The attribute is of high relevancy; this holds usually for ID and their descriptions. 'HIGH' = 1.0
MEDIUM	The attribute is of medium relevancy; this holds usually for other, important attributes. 'MEDIUM' = 0.7
LOW	Although the attribute is relevant for freestyle search, a hit in this attribute has no real significance for a result item's ranking. 'LOW' = 0.5

i Note

Beginning with metadata calls to API version 5 (`/v5/$metadata`), the annotation `@EnterpriseSearchHana.weight` is always returned instead of `@Search.ranking`. 'HIGH', 'MEDIUM', and 'LOW' are returned as their numeric values.

3.2.1.2.3 fuzzinessThreshold

This annotation specifies the least level of fuzziness (with regard to some comparison criteria passed at runtime) the element has to have to be considered in a fuzzy search at all.

Related Information

[Fuzzy Score \[page 284\]](#)

3.2.1.2.4 termMappingDictionary

This annotation specifies the table/entity that holds the term mappings to be considered in the context of a fuzzy search on this view.

Term mappings are usually synonyms, but other semantic classes (like homonyms) and degrees of identity.

Related Information

[Term Mappings \[page 371\]](#)

3.2.1.2.5 termMappingListID

This annotation specifies one or multiple lists within the term mapping dictionary mentioned before.

The list is implemented as a column of the term mapping table, with the list ID as content of this column. This concept has the aim to enable overarching term mapping dictionaries while being able to separate domain-specific content at the same time.

Related Information

[Term Mappings \[page 371\]](#)

3.2.1.2.6 fulltextIndex.required

If the annotation `@Search.fulltextIndex.required` is set to `true`, a configuration fails if there is no full-text index defined for the element.

i Note

This annotation is checked during the validation of a search configuration only. This means that a search call does not fail if the full-text index has been removed from the column after writing the configuration to the database.

3.2.2 Annotation @EnterpriseSearch

You use the annotation `EnterpriseSearch` to define response attributes in your model.

Syntax

```
namespace sap.common;

using sap.common::CDSTypes.elementRef;

annotation EnterpriseSearch
{
    /* annotation at view level */
    enabled: Boolean;

    /* annotation at view level */
    hidden: Boolean;

    /* annotation at element level */
    key: Boolean;

    /* annotation at view level */
    fieldGroupForSearchQuery: array of {
        name : String(128);
        elements : array of elementRef;
    };

    /* annotation at element level */
    defaultValueSuggestElement : Boolean;

    /* annotation at element level */
    searchOptions : String(5000);

    /* annotation at element level */
    filteringFacet {
        default: Boolean;
        displayPosition: Integer;
        numberOfValues: Integer;
        "order" {
            by: String(30) enum {
                NUMBER_OF_HITS='NUMBER_OF_HITS';
                FILTER_ELEMENT_VALUE='FILTER_ELEMENT_VALUE';
            };
            byReference: elementRef;
            direction: String(4) enum {
                ASC='ASC';
                DESC='DESC';
            };
        };
        caseInsensitiveAggregation: Boolean;
        countNullValues: Boolean;
        noIntervals: Boolean;
    };

    /* annotation at element level */
    filteringAttribute {
        default: Boolean;
        displayPosition: Integer;
        caseInsensitiveAggregation: Boolean;
        countNullValues: Boolean;
    };
};
```

```

/* annotation at element level */
presentationMode: array of String(20) enum {
    DETAIL='DETAIL';
    HIDDEN='HIDDEN';
    IMAGE='IMAGE';
    SUMMARY='SUMMARY';
    THUMBNAIL='THUMBNAIL';
    TITLE='TITLE';
    LONGTEXT='LONGTEXT';
    NONE='NONE';
};

/* annotation at element level */
snippets {
    enabled:          Boolean;
    maximumLength:   Integer;
};

/* annotation at element level */
highlighted {
    enabled:          Boolean;
};
};

```

Annotations on View Level

Annotation	Possible Values	Description
@EnterpriseSearch.enabled	true, false	Has to be true. The view has to be defined as @Search.searchable and needs a valid anchor key definition.
@EnterpriseSearch.hidden	true, false	<p>If set to true, the view is not part of the default search scope of a federated search that is used if no SCOPE parameter is given in a search call. In other words, the view is not searched if the view name is not explicitly given in the SCOPE parameter.</p> <p>If this annotation is not given, the default value is false and the view is part of the default search scope.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.fieldGroupFor- SearchQuery	-	A field group defines a set of view columns that belong together. The field group is used in the query language to limit the search for a search term to the columns of the field group. For example: the field group 'name' that contains the columns 'firstName', 'lastName', 'companyName'.
@EnterpriseSearch.fieldGroupFor- SearchQuery.name	string	Defines the name of a field group. The name is used in the query language as a reference to the field group.
@EnterpriseSearch.fieldGroupFor- SearchQuery.elements	array of strings	Contains a list of column names. This defines the view columns that belong to the field group.

Annotations on Element Level

Annotation	Possible Values	Description
@EnterpriseSearch.key	true, false	<p>Defines a column that is part of the anchor key.</p> <p>All anchor key columns have to be part of the same database table and this has to be the first (i.e., the leftmost) table that is used in the view definition.</p> <p>The anchor key columns have to define a unique key of the anchor table. Usually the anchor key columns are identical to the primary key columns of the anchor table. In this case, a client column, annotated with <code>@EnterpriseSearch.client</code> set to <code>true</code>, can be omitted from the anchor key definition.</p> <div data-bbox="1007 1025 1396 1288" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>Like primary keys, anchor key columns must not contain NULL values. Therefore they should always be defined as <code>NOT NULL</code> to avoid unexpected search results.</p> </div> <div data-bbox="1007 1308 1396 1529" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>At least one column of the view has to be marked as the anchor key. Search in views without an anchor key is not supported.</p> </div>
@EnterpriseSearch.searchOptions	string	<p>Defines the search options string that is passed to the <code>CONTAINS ()</code> predicate when searching in the column.</p> <div data-bbox="1007 1686 1396 1883" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>Search options <code>emptyScore</code>, <code>emptyMatchesNull</code>, and <code>returnAll</code> are not allowed.</p> </div>

Annotation	Possible Values	Description
(Deprecated) @EnterpriseSearch.usageMode	#AUTO_FACET #SUGGESTION	<div data-bbox="1007 371 1402 674" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>This annotation is deprecated. It is replaced by the annotations @EnterpriseSearch.filteringFacet and @EnterpriseSearch.defaultValueSuggestElement.</p> </div> <p>In a view, the annotations @EnterpriseSearch.filteringFacet and @EnterpriseSearch.usageMode AUTO_FACET cannot be used at the same time.</p>
@EnterpriseSearch.filteringFacet.default	true, false	<p>Defines a column as a facet column.</p> <p>If set to <code>true</code>, a facet is automatically returned for this column in the search response if facets are enabled (with custom query option <code>facets=all</code>, for example).</p> <p>If set to <code>false</code>, a facet for this column is returned only if the facet is requested explicitly (by adding the column name to custom query option <code>facets as</code>, for example, <code>facets=AMOUNT, INSTITUTIONCOUNTRY</code>).</p> <p>If the annotation @EnterpriseSearch.filteringFacet.default is not given but any of the other filteringFacet annotations is used for a column, this implicitly also sets @EnterpriseSearch.filteringFacet.default to <code>false</code>.</p> <p>Beginning with Enterprise Search version 5, columns of CDS type hana.ST_POINT can also be defined as facet columns.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.filteringFacet.displayPosition	integer > 0	<p>Defines the sequence of facet columns in the search response.</p> <p>If the number of facets returned in the search response is limited to n (by setting the facets option to n, as, for example, facets=3), only the first n facets in the order defined by the display position are returned.</p> <p>The use of this annotation is optional. But as soon as it is used in a view definition, it has to be given for all facet columns.</p> <p>All facet columns of a leveled hierarchy have to be assigned to the same display position. For all other facet columns the display position has to be unique.</p> <p>If the displayPosition annotation is not used, facet columns are returned in a stable order so that consecutive calls to <code>sys.esh_search()</code> return the same sequence of facet columns.</p>
@EnterpriseSearch.filteringFacet.numberOfValues	integer > 0	<p>Defines the number of values that are returned in the facet.</p> <p>If this parameter is not given, 10 values are returned by default.</p>
@EnterpriseSearch.filteringFacet.order.by	#NUMBER_OF_HITS #FILTER_ELEMENT_VALUE	<p>Defines the sort criterion for facet columns.</p> <p>If set to <code>NUMBER_OF_HITS</code>, the facet is sorted by the number of distinct anchor objects belonging to each facet value. This is the default behavior.</p> <p>If set to <code>FILTER_ELEMENT_VALUE</code>, the facet is sorted by the value of the facet column.</p>

Note

The annotation cannot be used for spatial datatypes (`hana.ST_POINT`, `hana.ST_GEOMETRY`), as these cannot be sorted.

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filteringFacet.order.byReference</code>	string	<p>Defines the name of a column that is used as a sort criterion for a facet column.</p> <p>The facet is sorted by the contents of the column that is referenced by this annotation.</p> <p>For example, a facet that counts documents for month names can be sorted by the month number so that the UI displays the month names in the right sequence. In this case, the month name is defined as a facet column and this annotation references the view column that contains the number of the month.</p> <p>The referenced column cannot be defined as a language-dependent column.</p> <div style="border: 1px solid #0070C0; padding: 5px; background-color: #F0F0F0;"> <p>i Note</p> <p>Only one of the annotations <code>@EnterpriseSearch.filteringFacet.order.byReference</code> and <code>@EnterpriseSearch.filteringFacet.order.by</code> can be used.</p> <p>Interval facets (numeric columns and date columns) cannot be sorted by a reference to another column.</p> <p>For correct results, there has to be a 1-to-1 relationship between the facet value and the value of the referenced column.</p> </div>
<code>@EnterpriseSearch.filteringFacet.order.direction</code>	#ASC #DESC	<p>Defines whether the facet is sorted in an ascending or descending order.</p> <p>The default is in a descending order for a facet that is sorted by <code>NUMBER_OF_HITS</code>.</p> <p>In all other cases, the default is to sort in an ascending order.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.filteringFacet.caseInsensitiveAggregation	true, false	<p>If set to <code>true</code>, a case-insensitive aggregation of facet values is done.</p> <p>If not given or set to <code>false</code>, the default aggregation is case-sensitive.</p>
@EnterpriseSearch.filteringFacet.countNullValues	true, false	<p>If set to <code>true</code>, facets also return an anchor object count for NULL values.</p> <p>If not given or set to <code>false</code>, NULL values are not returned.</p> <p>NULL values are returned only for facets that show single values. If intervals are returned (for date, numeric or spatial SQL types), NULL values are not part of the facet.</p> <div data-bbox="1007 927 1398 1279" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>NULL values for facets are only returned for search calls to version 6 or higher (<code>'/v6/\$all/...'</code>).</p> <p>With older versions (<code>'/v5/\$all/...'</code>) NULL values for facets are never returned in the search response.</p> </div> <div data-bbox="1007 1294 1398 1444" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>This annotation cannot be used for classification properties.</p> </div>
@EnterpriseSearch.filteringFacet.noIntervals	true, false	<p>If set to <code>true</code>, date facets and numeric facets are returned as single values instead of intervals.</p> <p>If set to <code>false</code>, date facets and numeric facets are returned as intervals. This is the default behavior.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.filteringAttribute.default	true, false	<p><code>filteringAttribute</code> annotations can be used by search UIs to identify elements that are suitable for filter conditions but that shall usually not be displayed as facets.</p> <p>If needed by the UI, elements with <code>filteringAttribute</code> annotations can be explicitly requested as facets. To get the facet values, the element name has to be explicitly added to the facets option of the search call.</p> <p>If facets are requested with <code>facets=all</code> or <code>facets=n</code> (with $n > 0$), columns with <code>filteringAttribute</code> annotations are never returned.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p><code>filteringAttribute</code> and <code>filteringFacet</code> annotations cannot be used at the same time for an element.</p> </div>
@EnterpriseSearch.filteringAttribute.displayPosition	integer > 0	<p>Defines the sequence of facet columns in the search response.</p> <p>Only if the element is explicitly requested as a facet column.</p> <p>See <code>@EnterpriseSearch.filteringFacet.displayPosition</code> for details.</p>
@EnterpriseSearch.filteringAttribute.caseInsensitiveAggregation	true, false	<p>If set to <code>true</code>, a case-insensitive aggregation of facet values is done.</p> <p>If not given or set to <code>false</code>, the default aggregation is case-sensitive.</p> <p>Only if the element is explicitly requested as a facet column.</p>
@EnterpriseSearch.defaultValueSuggestElement	true, false	<p>Defines a column that is used to calculate suggestions, if set to <code>true</code>.</p>

Annotation	Possible Values	Description
(Deprecated) @EnterpriseSearch.presentationMode	#DETAIL #HIDDEN #IMAGE #SUMMARY #THUMBNAIL #TITLE #LONGTEXT #NONE	<p>i Note</p> <p>Beginning with Enterprise Search API version 20405, this annotation is replaced by annotation @UI and others to define the UI behavior. Columns with @UI annotations are returned by default if the query option \$select is not used to define the response columns of a search.</p> <p>In a single view either the presentation mode annotation or the @UI annotations can be used.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.snippets.enabled	true, false	<p data-bbox="1007 371 1366 427">Enables snippet calculation for a column.</p> <p data-bbox="1007 456 1390 689">Only snippets for columns with a presentation mode other than 'NONE' will be returned in the search result. The original column content is not returned if snippets are enabled. In other words, either a snippet or a column value are returned in the search result.</p> <p data-bbox="1007 719 1390 842">The column has to support text search. This means it needs a fulltext index or has to be of SQL type TEXT, BINTEXT or SHORTTEXT.</p> <div data-bbox="1007 869 1390 1055" style="background-color: #f0f0f0; padding: 10px;"> <p data-bbox="1031 880 1110 902">i Note</p> <p data-bbox="1031 936 1366 1032">This annotation must not be used for columns that are part of a 1:n join.</p> </div> <p data-bbox="1007 1077 1390 1245">Beginning with API version 4, this annotation is also allowed for columns that are part of a 1:n join if these columns are defined as multi-values or subobjects.</p> <p data-bbox="1007 1267 1390 1570">For <code>sys.esh_search()</code> calls up to API version 20302 (<code>/v20303/\$all?...</code>), snippets are always returned for all columns that have a snippets annotation, independent of presentation mode annotations. If a column has a presentation mode annotation, both the original column value and the snippet are returned in the search response.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.snippets.maxLength	integer > 0 and <= 5000	<p>Defines the maximum length of a snippet in characters.</p> <p>For columns with annotation <code>@EnterpriseSearch.snippets.enabled</code> set to <code>true</code> this annotation defines the maximum length of a snippet that is returned in the search response.</p> <p>The annotation also defines the maximum length of a snippet that is returned as part of the whyfound information. If the whyfound information contains a highlighted text, the maximum length parameter is ignored.</p> <p>The snippet returned will be as long as possible but it will never be longer than the given maximum length.</p> <p>Without this annotation a snippet has a maximum length of 5000 characters but the length of the snippet depends on the number of different tokens that are found in the column.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.highlighted.enabled	true, false	<p data-bbox="1007 371 1337 394">Enables highlighting for a column.</p> <p data-bbox="1007 423 1402 689">Only highlighting for columns with a presentation mode other than 'NONE' will be returned in the search result. The original column content is not returned if highlighting is enabled. In other words, either a highlighted text or a column value are returned in the search results.</p> <p data-bbox="1007 719 1382 808">It is possible to get both snippets and highlighted text in the search result by setting both annotations.</p> <p data-bbox="1007 837 1393 969">The column has to support text search. This means it needs a fulltext index or has to be of SQL type TEXT, BINTEXT or SHORTTEXT.</p> <p data-bbox="1007 999 1394 1160">Beginning with API version 4, this annotation is also allowed for columns that are part of a 1:n join if these columns are defined as multi-values or subobjects.</p> <p data-bbox="1007 1189 1388 1525">For <code>sys.esh_search()</code> calls up to API version 20302 (<code>/v20303/\$all?...</code>), highlighted text is always returned for all columns that have a highlighted annotation, independent of presentation mode annotations. If a column has a presentation mode annotation, both the original column value and the highlighted text are returned in the search response.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.client	true, false	<p>Defines the client column and is used by ABAP applications only.</p> <p><code>sys.esh_search()</code> takes the current client from the session context and adds it to any read access to the database object as an additional where condition. The ABAP application server automatically copies the current client to the session context for the primary database connection and for all secondary database connections.</p> <p>Beginning with API version 20301 the session variable <code>CDS_CLIENT</code> is preferred to get the client number. For older versions or if this variable is not defined, the session variable <code>CLIENT</code> is used. These session variables are automatically set by the ABAP database client.</p>
@EnterpriseSearch.displayOrder	integer >= 0	<p>Defines the order of the columns when displayed in the UI.</p> <p>Adding this annotation to a column does not change the search results. The value of this annotation is returned in the metadata document only and has to be processed by the UI.</p>

3.2.2.1 Metadata on View Level and Entity Level

On view level and entity level, you can specify additional metadata.

3.2.2.1.1 @EnterpriseSearch.enabled

Defines on the view level whether the view is suitable for integration into the Search application, and is therefore a precondition for all @EnterpriseSearch annotations on element level.

The distinction is necessary because usually there are normalized views for an object's nodes (which are still likely to be searchable via @Search), and also dedicated, extremely denormalized search views. This annotation makes the denormalized views explicit.

3.2.2.2 Metadata on Element Level

Metadata, which is relevant for all search scenarios, can be specified on element level via the `EnterpriseSearch` annotation.

3.2.2.2.1 snippets

The annotation specifies that if a hit is returned for one of the search terms, the element does not receive the actual content, but only an excerpt with the search terms being marked.

i Note

Note that if a fuzzy search is performed, the marked term is not necessarily identical to the search term.

Note also that for a *-only search, the snippet tokens will be taken from the beginning of the text.

Search queries using the `SNIPPETS` function return the data type `NVARCHAR`.

3.2.2.2.2 highlighted

The annotation specifies that if a hit is returned for one of the search terms, the element does not receive the actual content, but the original content with marked search terms.

i Note

Note that when a fuzzy search is performed, the marked term is not necessarily identical to the search term.

Note also that a *-only search will return no marked terms.

Given the definition of the fragment length at the `snippets` annotation, this is the same as `highlighted`, with an infinite fragment length.

3.2.2.2.3 key

Defines on the view level which are the semantic key attributes, i.e. how the search result item instance is defined.

Because of the massive denormalization common to the `EnterpriseSearch` views, this semantic key tends to be a real subset of the view's technical key. The latter defines the Cartesian product across all involved tables; `EnterpriseSearch.key` defines the key of the entity to be found. All elements annotated as `key` have to stem from the same data base table.

3.2.3 Annotation @EnterpriseSearchHana

The `EnterpriseSearchHana` annotation is not part of the CDS core annotations. It extends the search annotations defined by `EnterpriseSearch` and adds annotations, which are only available for SAP HANA CDS and which are used by the search runtime (`sys.esh_search()`).

Syntax

```
namespace sap.common;

using sap.common::CDSTypes.elementRef;

annotation EnterpriseSearchHana
{
  /* annotation at view level */
  identifier: String(127);

  /* annotation at element level */
  arbitraryCardinality: Boolean;

  /* annotation at view level */
  layoutStructuredObject: array of {
    layerId: String(20);
    arbitraryCardinality: Boolean;
    defaultExpand: String(20) enum {
      WHY_FOUND = 'WHY_FOUND';
      "ALL"      = 'ALL';
    };
    elementList: array of {
      element: elementRef;
      key: Boolean;
    };
  };
  /* annotation at element level */
  weight: Decimal(4,3);

  /* annotation at view or element level */
  uiResource {
    label {
      bundle: String(1000);
      key: String(100);
    };
  };
};
```

Annotations on View Level

Annotation	Values	Description
@EnterpriseSearchHana.layoutStructuredObject	-	<p>Defines a subobject of the anchor object.</p> <p>This means that the columns of the subobject come from a 1:n join and are returned in the search result as an array.</p>
@EnterpriseSearchHana.layoutStructuredObject.arbitraryCardinality	true	<p>Specifies that the subobject comes from a 1:n join and that there may be multiple subobject instances for a given anchor object.</p>
@EnterpriseSearchHana.layoutStructuredObject.defaultExpand	#ALL #WHY_FOUND	<p>Specifies which subobjects are returned in the search result.</p> <p>#ALL: all subobjects of an anchor object are returned.</p> <p>#WHY_FOUND: only the subobjects of the anchor object are returned that contain at least one of the search terms.</p> <p>If the annotation is not given, the default value is #ALL.</p>
@EnterpriseSearchHana.layoutStructuredObject.elementList	-	<p>Specifies the view columns that belong to the subobject.</p>
@EnterpriseSearchHana.layoutStructuredObject.elementList.element	string	<p>Contains the name of a view column that belongs to the subobject.</p>
@EnterpriseSearchHana.layoutStructuredObject.elementList.key	true, false	<p>Specifies if a column is part of the subobject's key. Used to identify the distinct subobjects of an anchor object.</p> <p>If there are no key columns defined for a subobject, all columns are used to identify the distinct subobjects.</p>

i Note

All key columns have to be of a SQL type that can be used in a group by clause.

Annotation	Values	Description
@EnterpriseSearchHana.layoutStructuredObject.layerId	string	Defines the name of the subobject.
@EnterpriseSearchHana.uiResourceLabel.bundle	string	<p>Defines the name of a resource bundle.</p> <p>Can be used by the search UI to load a view label.</p> <p>Info</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>i Note</p> <p><code>uiResource</code> annotations do not change the behavior of <code>sys.esh_search()</code>.</p> <p>They are only returned in the metadata of the search configuration, so a UI may use these values to get texts in the end user's language.</p> </div>
@EnterpriseSearchHana.uiResourceLabel.key	string	<p>Defines the name of a key in a resource bundle.</p> <p>Can be used by the search UI to load a view label.</p>

Annotations on Element Level

Annotation	Values	Description
@EnterpriseSearchHana.arbitraryCardinality	true, false	<p>Defines a column as a multi-value column. This means that the column comes from a 1:n join and that it is returned in the search result as an array.</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>i Note</p> <p>This annotation is only allowed for columns with an SQL type that can be used in a group by clause.</p> </div>

Annotation	Values	Description
@EnterpriseSearchHana.weight	DECIMAL(4,3) > 0	<p>Defines the ranking weight of a column that is used to calculate the overall score.</p> <p>Only one of the annotations @EnterpriseSearchHana.weight or @Search.ranking can be used for a column.</p> <div data-bbox="1007 645 1390 1025" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>For metadata calls up to API version 4 ('/\$metadata' or '/v4/\$metadata'), the annotation @Search.ranking is returned and the value given with @EnterpriseSearchHana.weight is rounded to 'HIGH', 'MEDIUM', or 'LOW'.</p> </div>

Annotation	Values	Description
@EnterpriseSearchHana.identifier	string	<p data-bbox="1007 371 1396 465">Defines the OData identifier of the view. The value has to be a valid OData identifier.</p> <p data-bbox="1007 495 1396 730">If an identifier is defined, the identifier is used instead of the original column name in all interfaces of <code>sys.esh_search()</code> including the metadata call. In other words, the internal column name is not visible to the users of <code>sys.esh_search()</code>.</p> <p data-bbox="1007 759 1396 815">If this annotation is not given, the column name is used as an identifier.</p> <div data-bbox="1007 837 1396 992" style="background-color: #f0f0f0; padding: 5px;"> <p data-bbox="1031 853 1114 875">i Note</p> <p data-bbox="1031 909 1377 965">An identifier cannot be equal to the name of a subobject.</p> </div> <div data-bbox="1007 1010 1396 1576" style="background-color: #f0f0f0; padding: 5px;"> <p data-bbox="1031 1025 1114 1048">i Note</p> <p data-bbox="1031 1081 1353 1137">Version-dependent Implementation</p> <p data-bbox="1031 1171 1377 1261">Identifiers are returned by the metadata call if the call is done with an API version of '/v20411' or higher.</p> <p data-bbox="1031 1283 1377 1552">For older versions ('/v20410' or lower) the column names are returned. The column names can also be used in calls to <code>sys.esh_search()</code> even if identifiers are defined to avoid inconsistencies between the metadata call and the search call.</p> </div> <div data-bbox="1007 1594 1396 1951" style="background-color: #f0f0f0; padding: 5px;"> <p data-bbox="1031 1610 1114 1632">i Note</p> <p data-bbox="1031 1666 1225 1688">Non-unique Names</p> <p data-bbox="1031 1722 1377 1951">When using identifiers, columns of different subobjects can share the same column name. Client applications have to be aware of this feature and have to use subobject names as prefixes to make references to columns unique.</p> </div>

Annotation	Values	Description
		<p>Example: Both subobjects 'customer' and 'supplier' can contain a column with the same identifier 'name'. To make names unique, the columns can be referenced as 'customer/name' and 'supplier/name' in the interface to <code>sys.esh_search()</code>.</p>
<p>@EnterpriseSearchHana.uiResource.la- bel.bundle</p>	<p>string</p>	<p>Defines the name of a resource bundle.</p> <p>Can be used by the search UI to load labels for view elements.</p> <div data-bbox="1007 837 1394 1308" style="border: 1px solid #ccc; padding: 10px;"> <p>i Note</p> <p><code>uiResource</code> annotations do not change the behavior of <code>sys.esh_search()</code>.</p> <p>They are only returned in the metadata of the search configuration, so a UI may use these values to get texts in the end user's language.</p> <p>To get the annotation, API version 5 or higher of the metadata call has to be used ('/v5/\$metadata').</p> </div>
<p>@EnterpriseSearchHana.uiResource.la- bel.key</p>	<p>string</p>	<p>Defines the name of a key in a resource bundle.</p> <p>Can be used by the search UI to load labels for view elements.</p>

Annotation	Values	Description
@EnterpriseSearchHana.numc	true, false	<p>Defines a column as an ABAP NUMC column (a numeric value padded with leading zeros).</p> <p>API version 20402 and higher: If a score function (linear, gaussian, logarithmic) is defined for this column, search in this column is done like in an integer column.</p> <p>API version 20404 and higher: Without score functions, a search in a NUMC column is done similar to an alphanumeric search limited to numeric characters.</p> <p>Interval facets are returned, if a facet is requested for a NUMC column.</p>

i Note

This annotation is allowed for `string` columns with a length of up to 18 characters only.

3.2.4 Other Annotations

This section shows the definition of annotations that are not 'owned' by search and that are mainly used to define other non-search-related aspects of a view. But these annotations also influence the behavior of the Enterprise Search runtime so they should also be used when defining search configurations.

The annotation definitions in this section are shown as subsets of the full CDS annotation definitions. The subsets of the annotations are needed to define the behavior of the Enterprise Search runtime in SAP HANA and they can also be used to define basic UI behavior. If other parts of the annotation definitions are needed, these can easily be added to the following CDS definitions by the application developers.

i Note

The annotations that are shown below have to be defined in `*.hdbcds` files. There has to be one file for each annotation, and the name of the file has to equal the name of the annotation (example: `Hierarchy.hdbcds`). All annotation definitions have to be added to the XS Advanced project because they have to be defined in the same SAP HANA DI container that is used to define the search views.

3.2.4.1 Annotation @Hierarchy

The `Hierarchy` annotation contains a subset of the hierarchy annotations defined as CDS core annotations. It contains only the annotations that are used by `sys.esh_search()`.

Syntax

```
namespace sap.common;
using sap.common::CDSTypes.elementRef;
annotation Hierarchy {
  /* annotation at view level */
  leveled : array of {
    name : String(127);
    levels : array of {
      element : elementRef;
    };
  };
};
```

Annotations on View Level

Metadata of Annotation Hierarchy

Annotation	Possible Values	Description
@Hierarchy.leveled	-	Defines a leveled hierarchy that is used to define leveled facets. Examples of leveled hierarchies: <ul style="list-style-type: none">• year, month, date• country, region, city
@Hierarchy.leveled.name	string	Defines the name of the hierarchy.
@Hierarchy.leveled.levels	-	Defines which elements of the view specify the levels of the hierarchy. The sequence in which the elements are specified also defines the level on which the elements appear in the hierarchy.

Annotation	Possible Values	Description
@Hierarchy.levelled.levels.element	string	Contains the name of an element that defines the specific hierarchy level.

i Note

If facets are requested with query option `facets=all`, the result contains only elements of the leveled hierarchy that are annotated with `@EnterpriseSearch.filteringFacet.default: true`.

If the name of the leveled hierarchy is explicitly requested in the query option `facets`, all levels of the leveled hierarchy are processed as facet columns, independent of the value of the `@EnterpriseSearch.filteringFacet.default` annotation.

3.2.4.2 Annotation @Semantics

The `Semantics` annotation contains a subset of the semantic annotations defined as CDS core annotations. It only contains the annotations that are currently used by `sys.esh_search()`.

Syntax

```
namespace sap.common;
using sap.common::CDSTypes.elementRef;
annotation Semantics {
  /* annotations at element level */
  languageReference : elementRef;

  businessDate {
    at : Boolean;
    "from" : Boolean;
    to : Boolean;
    createdAt : Boolean;
    lastChangedAt : Boolean;
  };
  systemDate {
    createdAt : Boolean;
    lastChangedAt : Boolean;
  };
};
```

```
contact {  
  birthDate : Boolean;  
};  
};
```

Annotations on Element Level

Annotation	Values	Description
@Semantics.amount.currencyCode	string	<p>Defines the name of a column that contains the currency count for the monetary amount that is stored in the annotated column.</p> <p>This annotation is used by classification search.</p>

Annotation	Values	Description
@Semantics.languageReference	string	<p>Defines the name of a column that contains the language code of the annotated column's content.</p> <p>If a column contains text in multiple languages, this annotation can be used to define the name of the column that contains the corresponding language code.</p> <p>The language code column may contain language codes in any format as, for example, 1-character SAP language codes or 2-character ISO 639-1 language codes. The language codes given in the language vector have to match the language codes stored in the language code column.</p> <p>The language code column has to be defined as a CDS type string.</p> <div data-bbox="1007 1055 1393 1570" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>The language code column cannot be part of the search result. In other words, <code>@EnterpriseSearch.presentationMode</code> annotations with a value other than <code>#NONE</code> cannot be used for language code columns. The value of the language code column is instead returned in the search result with the annotation <code>@com.sap.vocabularies.Search.v1.Language</code>.</p> </div> <div data-bbox="1007 1585 1393 1771" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>Key and client columns cannot be defined as language dependent columns.</p> </div>

Annotation	Values	Description
@Semantics.businessDate.at	true, false	Defines a column that contains a date or timestamp.
@Semantics.businessDate.from		
@Semantics.businessDate.to		
@Semantics.systemDate.createdAt		The annotations are valid for some CDS types only:
@Semantics.systemDate.lastChange- dAt		<ul style="list-style-type: none"> LocalDate, UTCTime, UTCTimestamp (SQL types DATE, SECONDDATE, TIMESTAMP): These types are always treated as a date or timestamp. The annotation is allowed, but does not change the behavior. String(8) - SQL type NVARCHAR (8) : The column is treated as a date column. Dates stored in the column have to be of format YYYYMMDD. Decimal(15,0) - SQL type DECIMAL (15) : The column is treated as a timestamp (similar to CDS type UTCTime). Time-stamps stored in the column have to be of format YYYYMMDDHHMMSS. Only years between 1000 and 9999 are supported. Decimal(21,7) - SQL type DECIMAL (21 , 7) : The column is treated as a timestamp (similar to CDS type UTCTimestamp). Time-stamps stored in the column have to be of format YYYYMMDDHHMMSS . NNNNNNN. Only years between 1000 and 9999 are supported.
@Semantics.contact.birthDate		
(Deprecated) @Semantics.business- Date.createdAt		
(Deprecated) @Semantics.business- Date.lastChangedAt		
		<p>The annotation changes the behavior of string and decimal columns so that esh_search() treats them like other date or timestamp columns:</p> <ul style="list-style-type: none"> Facets are returned as date intervals. Only valid dates or date patterns are searched in these columns (except for decimal columns that also

Annotation	Values	Description
		<p>accept decimal numbers as search terms).</p> <p>String columns accept the initial value of ABAP DATS columns ('00000000') as a search term.</p> <p>Decimal columns accept the initial value 0 as a search term.</p>
		<p>i Note</p> <p>Deprecated Annotations</p> <p>The annotations <code>@Semantics.businessDate.createdAt</code> and <code>@Semantics.businessDate.lastChangedAt</code> are deprecated. Use <code>@Semantics.systemDate.createdAt</code> and <code>@Semantics.systemDate.lastChangedAt</code> instead.</p>
<code>@Semantics.quantity.unitOfMeasure</code>	string	<p>Defines the name of a column that contains the unit of measure for the measured quantity that is stored in the annotated column.</p> <p>The referenced unit of measure column may contain any SAP unit of measure from table T006 of an ABAP system.</p> <p>This annotation is used by classification search.</p>

3.2.4.3 Annotation @Consumption

The `Consumption` annotation contains a subset of the semantic annotations defined as CDS core annotations. It contains only the annotations that are currently used by `sys.esh_search()`.

Syntax

Source Code

```
namespace sap.common;
using sap.common::CDSTypes.elementRef;
annotation Consumption
{
    /* annotation at element level */
    labelElement: elementRef;
};
```

Annotations

Annotation	Possible Values	Description
@Consumption.labelElement	string	<p>Defines the name of a column that contains a label belonging to a facet column.</p> <p>The label column may either be language-independent or language-dependent (with annotation <code>@Semantics.languageReference</code>).</p> <p>For each facet value, the label is additionally returned in the search response with the annotation <code>@com.sap.vocabularies.Common.v1.Text</code>.</p> <div data-bbox="1007 958 1398 1290"><p>i Note</p><p>If a label is defined for a facet column that is of a data type that usually returns intervals (as, for example, a numeric column), the facet will never be returned as intervals. It will always return single values and the corresponding labels.</p></div> <div data-bbox="1007 1305 1398 1776"><p>i Note</p><p>Warning</p><p>To get correct search results, there has to be a 1:1 relationship between every value in the facet column and the corresponding value in the label column.</p><p>For language-dependent labels, there has to be at most one label text in each language for every value in the facet column.</p></div>

3.2.4.4 Annotation @GenericPersistence

The `@GenericPersistence` annotation is used to define data models for classification search. These data models contain key-value-pairs. Values in this case may be simple values or intervals, optionally with units of measure stored in a separate column.

Sample Code

```
namespace sap.common;

using sap.common::CDSTypes.elementRef;

define annotation GenericPersistence
{
    /* annotations at element level */
    property: Boolean;
    propertyValue: array of elementRef;
};
```

Annotations on View Level

Metadata of Annotation Hierarchy

Annotation	Possible Values	Description
@GenericPersistence.property	true, false	true, if the column contains the key column of a key-value-pair used for classification search. If this annotation is set to true, at least one value column has to be defined using the @GenericPersistence.propertyValue annotation.

Annotation	Possible Values	Description
@GenericPersistence.propertyValue	array of strings	<p>Array of column names that defines one or more value columns of a key-value-pair used for classification search.</p> <p>The value columns of a key-value-pair may be of different SQL data types. In this case, it is possible to define more than one column as value column (one for each SQL type).</p> <p>If the value of the key-value-pair is an interval, this annotation contains the name of the lower boundary column only. The remaining columns of the interval are defined using the @Semantics.interval annotation.</p> <p>If a unit of measure column or a currency code column belongs to the value column, the annotations @Semantics.quantity.unitOfMeasure and @Semantics.amount.currencyCode are used on the value column to define these additional columns.</p> <p>This annotation may only be used if @GenericPersistence.property is set to true.</p>

3.2.4.5 Annotation @ObjectModel

The subset of the @ObjectModel annotation can be used to define UI behavior and is not used by the Enterprise Search runtime.

Sample Code

```
namespace sap.common;

using sap.common::CDSTypes.elementRef;

annotation ObjectModel
{
    /* annotations at element level */
    text {
        element : array of elementRef;
    };
};
```

```
};
```

3.2.4.6 Annotation @UI

The subset of the @UI annotation can be used to define UI behavior and is not used by the Enterprise Search runtime.

i Note

All columns with @UI annotations are returned as default response columns in the search result if the \$select query option is not used to define the response columns.

This means that only columns that are allowed to be used as response columns in the \$select query option can get a @UI annotation. Limitations for \$select and for @UI annotations are the same and are described for the \$select option only.

Sample Code

```
namespace sap.common;

using sap.common::CDSTypes.elementRef;

annotation UI
{
    /* annotations at element level */
    identification: array of {
        position:    DecimalFloat;
        importance : String(6) enum {
            HIGH='HIGH';
            MEDIUM='MEDIUM';
            LOW='LOW';
        };
        url: elementRef;
    };

    /* annotation at view level */
    headerInfo {
        typeName:      String(60);
        typeNamePlural: String(60);
        title {
            value: elementRef;
            url:   elementRef;
        };
        description {
            value: elementRef;
        };
    };

    /* annotations at element level */
    hidden:      Boolean;
    multiLineText: Boolean;
    textArrangement: String(13) enum {
        TEXT_FIRST='TEXT_FIRST';
        TEXT_LAST='TEXT_LAST';
        TEXT_ONLY='TEXT_ONLY';
        TEXT_SEPARATE='TEXT_SEPARATE';
    };
};
```

```
};
```

3.2.4.7 CDSTypes

The `CDSTypes.hdbcds` file contains a type definition for CDS type `ElementRef`. It will be used until SAP HANA CDS supports `ElementRef` as a built-in type.

Syntax

Code Syntax

```
namespace sap.common;
context CDSTypes
{
    type elementRef: String(127);
};
```

3.2.4.8 SAP

This annotation is used to define `@SAP.Common.Label` that may be needed to define multilingual labels for view columns.

Sample Code

```
namespace sap.common;

annotation SAP
{
    Common {
        Label: String(100);
    };
};
```

3.2.5 Technical Configuration to Define Full-Text Indexes and Fuzzy Search Indexes

CDS entities are used to define database tables. The elements of an entity describe the columns of the table.

The technical configuration part of the entity definition can be used to create full-text indexes and fuzzy search indexes, as it is shown in the example.

Related Information

[SAP HANA Developer Guide for XS Advanced Model](#)

[Example: Defining Fulltext Indexes and Fuzzy Search Indexes \[page 74\]](#)

3.2.5.1 Example: Defining Fulltext Indexes and Fuzzy Search Indexes

CDS for HDI/XS Advanced uses a SQL-like syntax to define fulltext indexes and fuzzy search indexes in the 'technical configuration' part of an entity definition.

Sample Code

Technical Configuration for Fulltext Indexes

```
Entity award
{
  key id:          Integer;
  title:           String(500);
  abstract:        LargeString;
  institutionName: String(100);
  institutionCountry: String(100);
  institutionState: String(10);
  institutionZip:  String(20);
  institutionCity: String(100);
  institutionStreet: String(100);
  programOfficer: String(100);
}
technical configuration
{
  fulltext index fti_title          on (title)          fast preprocess off
('en')                               language detection
                                         fuzzy search index
on
  fulltext index fti_abstract       on (abstract)      search only off;
('en')                               fast preprocess off
                                         language detection
                                         fuzzy search index
on
  fulltext index fti_institutionName on (institutionName) search only off;
  fulltext index fti_programofficer on (programOfficer) search only off;
  fuzzy search index                on (institutionCity);
};
```

Sample Code

Technical Configuration for Fulltext Indexes on Structured Types

```
type contentType
{
  title:          String(500);
  abstract:       LargeString;
};
```

```

type institutionType
{
  institutionName:   String(100);
  institutionCountry: String(100);
  institutionState:  String(10);
  institutionZip:    String(20);
  institutionCity:   String(100);
  institutionStreet: String(100);
};

Entity award
{
  key id:           Integer;
  content:          contentType;
  institution:      institutionType;
  programOfficer:  String(100);
}

technical configuration
{
  fulltext index fti_title           on (content.title)      fast preprocess
off
                                     language
detection ('en')
                                     fuzzy search
index on
                                     search only off;
                                     fast preprocess
                                     language
detection ('en')
                                     fuzzy search
index on
                                     search only off;
  fulltext index fti_institutionName on (institution.institutionName) search
only off;
  fulltext index fti_programofficer  on (programOfficer)      search
only off;
  fuzzy search index                  on (institution.institutionCity);
};

```

i Note

Limitations

It is not possible to define the flush interval of asynchronous full-text indexes.

It is not possible to set a fuzzy search mode without a fuzzy search index. The SQL statement `FUZZY SEARCH INDEX OFF FUZZY SEARCH MODE '<mode>'` is not available.

3.2.6 Creating a Term Mapping Table via CDS

If you use programming model A (CDS) you can use term mappings as well as with the SQL approach.

Context

You need to create a table for the term mappings in your `hdbdd` file:

Procedure

1. Inside the CDS file create a term mapping table as shown in the example below:

Sample Code

```
@Catalog.tableType: #COLUMN
entity myTermMappings
{
  key MAPPING_ID: String(32);
  LIST_ID: String(32) NOT NULL;
  LANGUAGE_CODE: String(2);
  TERM_1: String(200) NOT NULL;
  TERM_2: String(200) NOT NULL;
  WEIGHT: Decimal(3,2) NOT NULL;
};
```

2. To use the term mapping table on a certain column of a CDS view add the following search annotation to this column:

```
@Search: { termMappingDictionary: 'myTermMappings', termMappingListID: ['L1'] }
```

Related Information

[Term Mappings \[page 371\]](#)

3.2.7 Example: Defining Search Configurations

See the example code, which contains tables, view definitions, and models.

The example below shows the configuration of a search view that joins several tables of an awards database.

Anchor object and anchor key: The anchor object of the view is the award that is identified by the anchor key column called 'id'.

1:n joins: The data contains 1:n information that is joined to the award objects. The 1:n objects are defined as subobjects 'investigator' and 'programElement'. To see the difference in search results, the program reference is not defined as a subobject. Instead, 'programReferenceText' is defined as multi-value element.

Field groups: Some of the view elements are grouped as field groups 'award', 'investigator', and 'organization'. The 'award' group, for example, can be used to search for text in the award title, abstract, or id.

Leveled facets: Hierarchies are defined to return leveled facets 'instLocation' and 'organization'.

Snippets and highlighted text: Instead of the full abstract a text snippet shall be returned only. The award title shall be returned with highlighting if any of the search terms is found in the title. So the 'abstract' and 'title' columns re annotated with snippets and highlighted annotations and do not have a presentation mode annotation.

Sample Code

Search and EnterpriseSearch Annotations

```
namespace search;
using sap.common::Hierarchy;
using sap.common::Search;
using sap.common::EnterpriseSearch;
using sap.common::EnterpriseSearchHana;

```

3.2.8 Example: Defining Subobjects Within Subobjects

The previous example showed how to define subobjects using the annotation `@EnterpriseSearchHana.layoutStructuredObject`.

With this annotation, it is also possible to define subobjects within other subobjects. This is done by referencing embedded subobject definitions in the surrounding subobject using the annotation `childIds`.

The following example shows a code snippet of the definition of a subobject 'institution' that contains another subobject 'investigator'.

The annotation `@EnterpriseSearchHana.identifier` is used to get rid of the column name prefixes 'inv' and 'inst' in the subobjects. The name columns of the institution and the investigator show that identifiers can be the same for both columns while the real column names have to be different.

Sample Code

Defining a Subobject Within Another Subobject

```

...
@Search.searchable: true
@EnterpriseSearch.enabled: true

@EnterpriseSearchHana.layoutStructuredObject: [
  {
    layerId: 'institution', arbitraryCardinality: true, defaultExpand: #ALL,
    childIds: [ 'investigator' ],
    elementList: [ { element: 'instName' }, { element: 'instPhone' },
  { element: 'instCountry' },
    { element: 'instStateCode' }, { element: 'instState' },
  { element: 'instZip' },
    { element: 'instCity' }, { element: 'instStreet' } ]
  },
  {
    layerId: 'investigator', arbitraryCardinality: true, defaultExpand: #ALL,
    elementList: [ { element: 'invFirstName' }, { element: 'invLastName' },
  { element: 'invEmail' },
    { element: 'invRole' }, { element: 'invStartDate' },
  { element: 'invEndDate' } ]
  },
  {
    layerId: 'programElement', arbitraryCardinality: true, defaultExpand:
#ALL,
    elementList: [ { element: 'programElementCode' }, { element:
'programElementText' } ]
  } ]
...
@EnterpriseSearchHana.identifier: 'awards'

view awardssearch

```

```

as select from award a
...
@UI.identification: [ { position: 4 } ]
@Search.defaultSearchElement: true
@EnterpriseSearchHana.identifier: 'Name'
a.institutionName as "instName",
@EnterpriseSearchHana.identifier: 'Phone'
a.institutionPhone as "instPhone",
...
@UI.identification: [ { position: 40 } ]
@Search.defaultSearchElement: true
@EnterpriseSearchHana.identifier: 'FirstName'
i.firstName as "invFirstName",
@UI.identification: [ { position: 4 } ]
@Search.defaultSearchElement: true
@EnterpriseSearchHana.identifier: 'Name'
i.lastName as "invLastName",
...

```

3.2.9 Example: Using Annotations not Related to Search

The following example shows a search view configuration for products.

The configuration contains annotations that are not used by the Enterprise Search runtime in SAP HANA. Examples are the annotations `@UI.identification` and `@Semantics.quantity.unitOfMeasure`. These annotations are returned by a metadata call only and have no impact on the search results.

Sample Code

Using Other Annotations

```

namespace sample;

using sap.common::Search;
using sap.common::EnterpriseSearch;
using sap.common::EnterpriseSearchHana;
using sap.common::UI;
using sap.common::ObjectModel;
using sap.common::Semantics;

using ...;

@Search.searchable: true
@EnterpriseSearch.enabled: true
@EnterpriseSearchHana.identifier: 'products'
@EnterpriseSearchHana.uiResource.label.bundle: '/sap/search_resourcebundle/
resources.properties'
@EnterpriseSearchHana.uiResource.label.key: 'products'
@UI.headerInfo.title.value: 'Product'
@UI.headerInfo.description.value: 'ProductUUID'

view Products
as select from ...
{
  @EnterpriseSearch.key: true
  ProductUUID,

  @Search.defaultSearchElement: true
  @EnterpriseSearch.defaultValueSuggestElement: true
  @EnterpriseSearch.filteringFacet.default: true

```

```

Product,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 1 } ]
@EnterpriseSearchHana.uiResource.label.key: 'productdescription'
@EnterpriseSearch.defaultValueSuggestElement: true
ShortText,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 3 } ]
@EnterpriseSearchHana.uiResource.label.key: 'productcategory'
@EnterpriseSearch.defaultValueSuggestElement: true
ProductCategory,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 9 } ]
@EnterpriseSearchHana.uiResource.label.key: 'lastchangeddatetime'
@EnterpriseSearch.filteringFacet.default: true
LastChangedDateTime,

@Search.defaultSearchElement: false
@UI.identification: [ { position: 55 } ]
@Semantics.imageUrl: true
ProductPictureURL,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 12 } ]
@EnterpriseSearchHana.uiResource.label.key: 'height'
@EnterpriseSearch.filteringFacet.default: true
@Semantics.quantity.unitOfMeasure: 'DimensionUnit'
Height,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 13 } ]
@EnterpriseSearchHana.uiResource.label.key: 'width'
@EnterpriseSearch.filteringFacet.default: true
@Semantics.quantity.unitOfMeasure: 'DimensionUnit'
Width,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 14 } ]
@EnterpriseSearchHana.uiResource.label.key: 'depth'
@EnterpriseSearch.filteringFacet.default: true
@Semantics.quantity.unitOfMeasure: 'DimensionUnit'
Depth,

@Search.defaultSearchElement: true
@EnterpriseSearchHana.uiResource.label.key: 'dimensionunit'
@UI.hidden: false
DimensionUnit,

@Search.defaultSearchElement: true
@UI.identification: [ { position: 4 } ]
@EnterpriseSearchHana.uiResource.label.key: 'price'
@EnterpriseSearch.filteringFacet.default: true
@Semantics.quantity.unitOfMeasure: 'Currency'
Price,

@Search.defaultSearchElement: true
@EnterpriseSearchHana.uiResource.label.key: 'currency'
@EnterpriseSearch.filteringFacet.default: true
@UI.hidden: false
Currency
};

```

3.2.10 Defining Multilingual Text

UIs need to show text like, for example, view names and labels in the language of the end-user. With CDS there are multiple ways how multilingual texts can be defined.

Defining Texts in the Search Application

For applications that work with a defined set of search configurations only it makes sense to store all UI related texts in the application layer itself.

This means that standard translation mechanisms of the application's runtime environment are used and all text definitions can be stored in a single place.

Resource Bundles

Generic search applications do not know in advance in which views the search is done. In this case, the search application needs to get the UI texts based on information stored in the metadata of the search model.

To link the search model to multilingual text, it is possible to define resource bundles and resource keys for the view and for all view elements. This allows to put all texts of a given language in a separate file. The search application can access the files containing the translations to get the texts in the language of the user.

When using resource bundles, the application sitting on top of CDS and `sys.esh_search()` needs to implement functions to access the resource bundles to get the texts in the required language.

Sample Code

Using Resource Bundles

```
namespace sample;

using ...;

@Search.searchable: true
@EnterpriseSearch.enabled: true
@EnterpriseSearchHana.uiResource.label.bundle: '/sap/search_resourcebundle/
resources.properties'
@EnterpriseSearchHana.uiResource.label.key: 'products'

view Products
as select from ...
{
  @EnterpriseSearch.key: true
  ProductUUID,

  @Search.defaultSearchElement: true
  @EnterpriseSearchHana.uiResource.label.key: 'productdescription'
  ShortText,

  @Search.defaultSearchElement: true
  @EnterpriseSearchHana.uiResource.label.key: 'productcategory'
  ProductCategory,
```

```
...  
};
```

Storing Multilingual Texts in the Search Configuration

As an alternative to resource bundles, multilingual text for generic search applications can also be stored directly in the search configuration. This means that the search configuration and all available translations are maintained in a single place.

The search application gets back the text in the end-user's language as part of the output of the metadata call.

As a drawback, this approach does not allow to collect translations for separate languages in separate files.

The following example shows how to define text in the search configuration.

At the beginning of the configuration, there is the annotation `@EnterpriseSearchHana.translation` that defines all required text elements in multiple languages. The texts are assigned to placeholders ("id") that are later used in the search configuration to reference the translated texts. For each placeholder there is also a default text defined (the text that is given without a language).

All UI related annotations that are not processed by `sys.esh_search()` can use the placeholders to reference to translated text. During the metadata call the placeholders are replaced by the translated text in the best available language based on the language settings of the user.

Sample Code

Multilingual Text in the Search Configuration

```
namespace sample;  
  
using ...;  
  
@EnterpriseSearchHana.translation: [  
  { id: '$PRODUCT',  
    value: [ { text: 'Product' },  
             { language: 'en_US', text: 'Product' },  
             { language: 'de_DE', text: 'Produkt' } ]  
  },  
  { id: '$PRODUCTS',  
    value: [ { text: 'Product' },  
             { language: 'en_US', text: 'Products' },  
             { language: 'de_DE', text: 'Produkte' } ]  
  },  
  { id: '$SHORTTEXT',  
    value: [ { text: 'Product Description' },  
             { language: 'en_US', text: 'Description' },  
             { language: 'de_DE', text: 'Beschreibung' } ]  
  },  
  { id: '$PRODUCT_CATEGORY',  
    value: [ { text: 'Product Category' },  
             { language: 'en_US', text: 'Category' },  
             { language: 'de_DE', text: 'Kategorie' } ]  
  }  
]
```

```

@Search.searchable: true
@EnterpriseSearch.enabled: true
@UI.headerInfo.typeName: '$PRODUCT'
@UI.headerInfo.typeNamePlural: '$PRODUCTS'

view Products
as select from ...
{
  @EnterpriseSearch.key: true
  ProductUUID,

  @Search.defaultSearchElement: true
  @SAP.Common.Label: '$SHORTTEXT'
  ShortText,

  @Search.defaultSearchElement: true
  @SAP.Common.Label: '$PRODUCT_CATEGORY'
  ProductCategory,

  ...
};

```

3.3 Modeling with CDS Annotations (XS Classic)

To define a search model on XS Classic, you need to use the CDS annotations.

SAP HANA with XS Classic supports the following annotations, which are important elements of the CDS documents used to define CDS-compliant catalog objects (these catalog objects are used to create search models):

- Search
- EnterpriseSearch

You can use further configuration options by defining values on the metadata of these annotations directly, or on the higher view, entity, or element level.

3.3.1 Annotation @Search (XS Classic)

This annotation marks a view as searchable. You define the fuzziness threshold as well as the specifics of term mappings at element level.

Syntax

```

annotation Search
{
  /* annotation at view level */
  searchable: Boolean;
}

```

```

/* annotations at element level */
defaultSearchElement: Boolean;

ranking:          String(6) enum {
                  HIGH='HIGH';
                  MEDIUM='MEDIUM';
                  LOW='LOW';
                };

fuzzinessThreshold: Decimal(3,2);

termMappingDictionary: String(128);
termMappingListID:    array of String(32);
};

```

Annotations on View Level

Annotation	Possible Values	Description
@Search.searchable	true, false	<p>Defines if a CDS view or entity is generally relevant for search scenarios.</p> <p>The annotation offers a general switch and a means to quickly detect whether a view is relevant or not.</p> <p>Set to true to enable @Search annotations. At least one column has to be defined as <code>defaultSearchElement</code>.</p>

Annotations on Element Level

Annotation	Possible Values	Description
@Search.defaultSearchElement	true, false	<p>Defines a column as full-text search column.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p>i Note</p> <p>At least one column has to be defined as default full-text search column. Search in views without default full-text search elements is not supported.</p> </div>

Annotation	Possible Values	Description
@Search.fuzzinessThreshold	0..1	Defines the threshold for a fuzzy search. Default value is 1. This means that an exact search is performed.
@Search.ranking	#HIGH #MEDIUM #LOW	Defines the ranking weight for a column ('HIGH' = 1.0, 'MEDIUM' = 0.7, 'LOW' = 0.5)
@Search.termMappingDictionary	string	Defines the name of the term mapping table (format: <code>schemaname.tablename</code>), passed to the search option 'termMappingTable' of the <code>CONTAINS ()</code> predicate.
@Search.termMappingListID	array of strings	Defines the names of the term mapping list IDs, passed to the search option 'termMappingListId' of the <code>CONTAINS ()</code> predicate.

Related Information

[FUZZY Search \[page 273\]](#)

[Term Mappings \[page 371\]](#)

3.3.2 Annotation @EnterpriseSearch (XS Classic)

You use the annotation `EnterpriseSearch` to define response attributes in your model.

Syntax

```
annotation EnterpriseSearch {
  /* annotation at view level */
  enabled : Boolean;
  /* annotations at element level */
  usageMode : array of String(20) enum {
    AUTO_FACET='AUTO_FACET';
    SUGGESTION='SUGGESTION';
  };
}
```

```

key :      Boolean;
snippets {
  enabled: Boolean;
};
highlighted {
  enabled: Boolean;
};
presentationMode : array of String(20) enum {
  DETAIL='DETAIL';
  HIDDEN='HIDDEN';
  IMAGE='IMAGE';
  SUMMARY='SUMMARY';
  THUMBNAIL=' THUMBNAIL';
  TITLE='TITLE';
  NONE='NONE';
};
};

```

Annotations on View Level

Annotation	Possible Values	Description
@EnterpriseSearch.enabled	true, false	Has to be true. The view has to be defined as @Search.searchable and needs a valid anchor key definition.

Annotations on Element Level

Annotation	Possible Values	Description
@EnterpriseSearch.key	true, false	<p>Defines a column that is part of the anchor key.</p> <p>All anchor key columns have to be part of the same database table and this has to be the first table that is used in the view definition.</p>

i Note

At least one column of the view has to be marked as the anchor key. Search in views without an anchor key is not supported.

Annotation	Possible Values	Description
@EnterpriseSearch.usageMode	#AUTO_FACET #SUGGESTION	AUTO_FACET: defines a column as a facet column. SUGGESTION: defines a column that is used to calculate suggestions.
@EnterpriseSearch.presentationMode	#DETAIL #HIDDEN, #IMAGE #SUMMARY #THUMBNAIL #TITLE #NONE	Only columns with a presentation mode other than 'NONE' will be returned in the search result. If presentation modes are not defined, all columns of the view will be returned.
		<p>i Note</p> <p>Only the following types of columns are allowed as response columns:</p> <ul style="list-style-type: none"> • columns from the anchor table • columns from other tables that are joined as a 1:1 join • columns from other tables that are joined as a 1:n join and that are either marked as a multi-value column or that belong to a subobject. <p>Setting a presentation mode for other columns of a table that is joined as a 1:n join results in wrong search results.</p>
@EnterpriseSearch.snippets.enabled	true, false	Enables snippet calculation for a column. The column has to support text search. This means it needs a fulltext index or has to be of SQL type TEXT, BINTEXT or SHORTTEXT.
		<p>i Note</p> <p>This annotation must not be used for columns that are part of a 1:n join.</p> <p>Setting this annotation for other columns results in wrong search results.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.highlighted.enabled	true, false	<p>Enables highlighting for a column.</p> <p>The column has to support text search. This means it needs a fulltext index or has to be of SQL type TEXT, BINTEXT or SHORTEXT.</p> <div style="border: 1px solid #0070c0; padding: 5px; background-color: #e6e6e6;"> <p>i Note</p> <p>This annotation must not be used for columns that are part of a 1:n join.</p> <p>Setting this annotation for other columns results in wrong search results.</p> </div>

3.3.3 Example: Defining Search Configurations (XS Classic)

See the example code, which contains tables, view definitions, and models.

In this example, we define the indexing and views and models, which are required for the search.

```
entity test
{
  key id: String(10);
  col1: String(100);
  col2: String(100);
  col3: String(100);
}
technical configuration
{
  fulltext index fti_col2    on (col2);
  fulltext index fti_col3    on (col3);
}
;

@Search.searchable: true
@EnterpriseSearch.enabled: true
define view test_view as select from test
{
  @EnterpriseSearch.key: true
  @EnterpriseSearch.presentationMode: [ #TITLE ]
  id as vid,
  @Search.defaultSearchElement: true
  @EnterpriseSearch.presentationMode: [ #TITLE ]
  col1,
  @Search.defaultSearchElement : true
  col2;
  @EnterpriseSearch.usageMode: [ #AUTO_FACET ]
  col3;
};
```

3.4 Modeling with Built-In Procedure `sys.esh_config()`

Overview

The built-in procedure `sys.esh_config()` can be used to write search configurations to the database if an application is developed without using SAP HANA CDS. In this case, the search views are created using `CREATE VIEW` statements. Afterwards, the search configurations can be written to the database server by calling `sys.esh_config()`.

The search runtime `sys.esh_search()` uses the search configurations to run a search.

A metadata call is available for `sys.esh_search()`. This call returns a definition of the columns of the search views and the related search annotations to the client. The metadata is used, for example, by generic search UIs that create the UI layout out of the annotations.

i Note

`sys.esh_config()` analyzes the search view when the configuration is written to the database.

It is important that `sys.esh_config()` is called again when the search view or any of the underlying tables are changed. Such a change may, for example, be the addition or deletion of a full-text index. If the configuration is not rewritten to the database, unexpected errors may be returned by `sys.esh_search()`.

Supported Database Objects

Search configurations can be created for database objects of the following types:

Database Object Type	Description
SQL Views	<p>SQL views are views created using the <code>CREATE VIEW</code> statement. Only views that can be transformed internally to a join view are supported for search. Other, more complex views cannot be used.</p> <p>The source are:</p> <ul style="list-style-type: none">• SQL views created with <code>CREATE VIEW</code> statements• SAP HANA CDS views• ABAP OpenCDS views without parameters

Database Object Type	Description
Table Functions	<p>Table functions are functions that are created using the <code>CREATE FUNCTION</code> statement, that return a table object, and that contain a single <code>SELECT</code> statement only.</p> <p>Function parameters can be used in where conditions or in join conditions as 'search constraints' to exclude certain rows from the tables before the search is performed. This is similar to join views with constraints that are used by Enterprise Search.</p> <p>Restrictions for table functions are the same as for SQL views.</p> <p>The source are:</p> <ul style="list-style-type: none"> • SQL functions created with <code>CREATE FUNCTION</code> statements • ABAP Open CDS views with parameters
Join Views	<p>Join views are views created using the <code>CREATE COLUMN VIEW <v> TYPE JOIN</code> statement.</p> <p>Constraints can be used to exclude certain rows of the view from the search.</p> <p>The source are:</p> <ul style="list-style-type: none"> • Attribute views created in SAP HANA Studio • Search models created using the Enterprise Search modeler of the Application Platform

3.4.1 Interface of `sys.esh_config()`

The configuration API is not based on http, but uses the builtin procedure `sys.esh_config()` instead.

A NCLOB container is used to pass the URI, the http method and the payload to the builtin procedure. Parameters of the http header cannot be defined, so the builtin procedure uses meaningful default values.

The interface of `sys.esh_config()` looks as follows:

Source Code

```
CREATE PROCEDURE sys.esh_config
(
  IN request NCLOB,
  OUT response TABLE ( response NCLOB )
)
AS BUILTIN;
```

3.4.1.1 Bulk Requests and Transaction Handling

The input parameter allows bulk requests to make a large number of configuration changes in a single call.

For each element of the bulk request, one row in the response table is returned.

JSON Format for Bulk Requests

Source Code

```
CALL sys.esh_config('
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "POST",
    "content": {
      ...
    }
  },
  {
    "uri": "~/metadata/EntitySets",
    "method": "POST",
    "content": {
      ...
    }
  },
  ...
  {
    ...
  }
]
')
```

Each configuration change of the bulk request is processed independently of other changes. So some elements might fail while others finish successfully.

Each change is processed in a single transaction. So it either fails completely and leaves the existing configuration table untouched, or all changes are visible after the function call ends.

The call to `sys.esh_config()` is not embedded in the transaction of the caller, similar to a http service that is independent of the caller's database transactions.

3.4.1.2 Error Handling

If the request object does not contain a valid JSON array, a SQL exception is returned.

Examples of errors that can occur include a malformed JSON or missing `uri`, `method`, or `content` elements.

If a part of the bulk request cannot be processed for any reason, the corresponding row in the response parameter contains a JSON error response. Examples of errors that can occur include an invalid `uri`, an invalid `method`, `content` not following the format described below, or validation errors because of an invalid configuration.

Format of an Error Message

Source Code

```
{
  "error":{
    "code":"8103101",
    "message":"Configuration failed",
    "details":[
      {
        "code":"8103005",
        "message":"\"TXT1\": parameter \"@EnterpriseSearch.kei\" must not be
used for view column"
      }
    ]
  }
}
```

Error responses can also contain more than one error. In this case, an array of error messages is returned, as shown in the following example:

Example: Error message containing two errors

Source Code

```
{
  "error":{
    "code":"8103101",
    "message":"Configuration failed",
    "details":[
      {
        "code":"8103005",
        "message":"\"ID1\": parameter \"@EnterpriseSearch.clnt\" must not be
used for view column"
      },
      {
        "code":"8103005",
        "message":"\"TXT1\": parameter \"@EnterpriseSearch.kei\" must not be
used for view column"
      }
    ]
  }
}
```

3.4.2 Creating a Configuration with Method 'POST'

To create a new configuration, the configuration API accepts a metadata document that contains the columns of the join view, SQL view, or table function that are relevant for search. For these columns, the search annotations have to be defined in the metadata document. Columns without search annotations that are not relevant to the search model can be omitted in the configuration.

The example below shows a call that creates two search configurations. The URI "`~/metadata/EntitySets`" and the `POST` method are used to create the new configurations. "`Fullname`" references the schema and the name of the database object to be used for the search.

For details about annotations, see the description of the metadata annotations available for `sys.esh_config()`. If the configuration is created without errors, an empty row in the response table is returned. If errors occur, an error message is returned in the corresponding row of the response table.

Source Code

```
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "POST",
    "content": {
      "Fullname": "DEVELOP/Customer",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          {
            "Name": "CustomerNumber",
            "@Search.defaultSearchElement": true
          },
          {
            "Name": "FirstName",
            "@Search.defaultSearchElement": true,
            "@Search.fuzzinessThreshold": 0.7,
            "@Search.ranking": "HIGH"
          },
          {
            "Name": "LastName",
            "@Search.defaultSearchElement": true,
            "@Search.fuzzinessThreshold": 0.7
          },
          {
            "Name": "YearofBirth",
            "@Search.defaultSearchElement": true,
            "@EnterpriseSearch.usageMode": [
              "AUTO_FACET"
            ]
          }
        ]
      }
    }
  },
  {
    "uri": "~/metadata/EntitySets",
    "method": "POST",
    "content": {
      "Fullname": "DEVELOP/Wine",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          {
            "Name": "WineNumber",
            "@Search.defaultSearchElement": true
          },
          {
            "Name": "Vintner",
            "@Search.defaultSearchElement": true,
            "@Search.fuzzinessThreshold": 0.7
          },
          {

```

3.4.3 Updating or Creating a Configuration with Method 'PUT'

To update existing configurations, the same call is used as when creating a configuration with method `PUT`.

The existing configuration is then deleted, and the complete configuration has to be specified again. It is not possible to overwrite parts of the configuration. If the configuration to be updated does not exist, it is created ("upsert").

If the configuration is created without errors, an empty row in the response table is returned. If errors occur, an error message is returned in the corresponding row of the response table.

3.4.4 Deleting a Configuration with Method 'DELETE'

The example below shows how to delete an existing configuration. Method `DELETE` is used, and the only other information given in the URI is the schema name and the name of the database object to be deleted.

Only the configuration is deleted. The database object (view or table function) is not deleted or changed.

If the configuration can be deleted without errors, an empty response is returned.

i Note

Search configurations are not deleted when the database object or the database schema are deleted. Make sure that configurations are deleted by calling `sys.esh_config()`.

Example: OData metadata document that deletes a search configuration

Sample Code

```
[
  {
    "uri": "~/metadata/EntitySets(DEVELOP%2FCustomer)",
    "method": "DELETE",
    "content": {
    }
  }
]
```

3.4.5 Privileges

To call `sys.esh_config()`, write or delete configurations, you need certain privileges.

For all calls to `sys.esh_config()`, the database user needs the `EXECUTE` privilege on the built-in procedure `sys.esh_config`.

When `sys.esh_config()` is called with method `POST`, `PUT`, or `DELETE`, the caller of `sys.esh_config()` has to be the owner of the database schema or needs the `CREATE ANY` privilege on the database schema.

A `DELETE` call is also possible if the database schema does not exist, so it is possible to delete configurations after the schema has been deleted.

Sample Code

Privileges needed for calls to `sys.esh_config()`

```
GRANT EXECUTE ON sys.esh_config TO <databaseUser>;  
-- additional object privileges as described above
```

In all other cases, the call to `sys.esh_config()` fails because of missing privileges.

3.4.6 Annotations for `sys.esh_config()`

The built-in procedure `sys.esh_config()` supports various annotations. These are described in the chapters below.

3.4.6.1 Entity Type Annotations

The tables show all annotations that are available for an entity type.

Entity Type Annotations for `@Search`

Annotation	Allowed Values	Description
<code>@Search.searchable</code>	true, false	The annotation has to be true to enable <code>@Search</code> annotations. At least one column has to be defined as <code>defaultSearchElement</code> .
<code>@Search.configurationID</code>	<= 5000 characters	Can be set to an application-specific value that is returned in the metadata document. This annotation is used to set a time-stamp, a version number or a git commit hash, for example, that identifies the version of the configuration. When getting the metadata document, this value can be used to verify if the configuration stored in the database is the same as the version expected by the application.

Entity Type Annotations for @EnterpriseSearch

Annotation	Allowed Values	Description
<code>@EnterpriseSearch.enabled</code>	true, false	The annotation has to be true . The view has to be defined as <code>@Search.searchable</code> and needs a valid anchor key definition.
<code>@EnterpriseSearch.hidden</code>	true, false	If set to <code>true</code> , the view is not part of the default search scope of a federated search that is used if no <code>SCOPE</code> parameter is given in a search call. The view is not searched if the view name is not explicitly given in the <code>SCOPE</code> parameter. If this annotation is not given, the default value is <code>false</code> and the view is part of the default search scope.
<code>@EnterpriseSearch.fieldGroupForSearchQuery</code>	-	A field group defines a set of view columns that belong together. The field group is used in the query language to restrict the search for a search term to the columns of the field group. An example is the field group 'name' that contains the columns 'firstName', 'lastName', 'companyName'.
<code>@EnterpriseSearch.fieldGroupForSearchQuery.Elements</code>	array of strings	Contains a list of column names. This defines the view columns that belong to the field group.
<code>@EnterpriseSearch.fieldGroupForSearchQuery.Name</code>	string	Defines the name of a field group. The name is used in the query language as a reference to the field group.

Entity Type Annotations for @EnterpriseSearchHana

Annotation	Allowed Values	Description
<code>@EnterpriseSearchHana.processing.ignoreInvalidSearchOptions</code>	true, false	<p>If set to <code>true</code>, search options given with <code>@EnterpriseSearch.searchOptions</code> are ignored if they are not allowed for the SQL type of the given column.</p> <p>If set to <code>false</code>, an error will be returned by <code>sys.esh_config()</code> in this case. This is the default behavior.</p> <p>This annotation may be useful for applications that always set the same search options and that do not check if, for example, a column has an additional full-text index or not.</p>

Annotation	Allowed Values	Description
<code>@EnterpriseSearchHana.passThroughAllAnnotations</code>	<code>true, false</code>	<p>If set to <code>true</code>, annotations that are not known by <code>sys.esh_config()</code> are accepted and are returned as part of the <code>\$metadata</code> call.</p> <p>If set to <code>false</code>, unknown annotations that are given in the search configuration lead to an error. This is the default behavior.</p> <p>Setting this annotation to <code>true</code> is recommended if annotations in the <code>\$metadata</code> call shall be used to define, for example, the layout of the frontend UI.</p> <div data-bbox="1007 882 1394 1608" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note</p> <p>When setting this annotation to <code>true</code>, application developers have to be aware that this reduces the number of consistency checks for annotations that do not belong to <code>@Search</code>, <code>@EnterpriseSearch</code>, and <code>@EnterpriseSearchHana</code>. If there are, for example, spelling errors in an annotation name used by search (like <code>@Semantics.businessDate.at</code> instead of <code>@Semantics.businessDate.at</code>), the annotation is simply passed through to the metadata as an unknown annotation instead of returning an error.</p> </div>
<code>@EnterpriseSearchHana.identifier</code>	<code>string</code>	<p>Defines the OData identifier of the view. The value has to be a valid OData identifier.</p> <p>If this annotation is not given, the OData identifier is calculated based on the view name.</p>

Annotation	Allowed Values	Description
<code>@EnterpriseSearchHana.uiResource.label.bundle</code>	string	<p>Defines the name of a resource bundle.</p> <p>Can be used by the search UI to load a view label.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p>Note</p> <p><code>uiResource</code> annotations do not change the behavior of <code>sys.esh_search()</code>.</p> <p>They are only returned in the metadata of the search configuration, so a UI may use these values to get texts in the end user's language.</p> <p>To get the annotation, version 5 or higher of the metadata call has to be used ('/v5/\$metadata').</p> </div>
<code>@EnterpriseSearchHana.uiResource.label.key</code>	string	<p>Defines the name of a key in a resource bundle.</p> <p>Can be used by the search UI to load a view label.</p>
<code>@EnterpriseSearchHana.translation</code>	structure	<p>Defines multilingual UI text directly in the search configuration as an alternative to resource bundles. The texts are returned in the output of a metadata call.</p>

Entity Type Annotations for @Aggregation

Annotation	Allowed Values	Description
<code>@Aggregation.LeveledHierarchy</code>	-	<p>Defines a leveled hierarchy that is used to define leveled facets.</p> <p>Examples of leveled hierarchies:</p> <ul style="list-style-type: none"> • year, month, date • country, region, city

Annotation	Allowed Values	Description
<code>@Aggregation.LeveledHierarchy.Value</code>	array of strings	<p>Contains the names of the properties that define the specific hierarchy levels.</p> <p>The sequence in which the properties are specified also defines which level the properties appear on in the hierarchy.</p> <div data-bbox="1007 607 1394 1272" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note</p> <p>If facets are requested with query option <code>facets=all</code>, the result contains only elements of the leveled hierarchy that are annotated with <code>@EnterpriseSearch.filteringFacet.default: true</code>.</p> <p>If the name of the leveled hierarchy is explicitly requested in the query option <code>facets</code>, all levels of the leveled hierarchy are processed as facet columns, independent of the value of the <code>@EnterpriseSearch.filteringFacet.default</code> annotation.</p> </div>
<code>@Aggregation.LeveledHierarchy.Qualifier</code>	string	Defines the name of the hierarchy.

Entity Type Annotations for @Semantics

Annotation	Allowed Values	Description
<code>@Semantics.interval</code>	array of interval definitions	<p>If the view data contains intervals, these intervals are defined using this annotation.</p> <p>The annotation is used by classification search.</p> <p>The interval annotation allows to define one or more intervals, distinguished by a qualifier.</p> <p>The type of the interval can either be expressed statically by specifying the <code>lowerBoundaryIncluded</code> and <code>upperBoundaryIncluded</code> indicators and/or by omitting one of the boundaries for unbounded intervals, or it can be expressed dynamically by specifying the <code>boundaryCodeElement</code>. If the type of the interval is not defined by using one of these annotations, intervals are closed at the specified boundaries by default.</p> <p>Each interval is defined using the attributes below.</p>
<code>...qualifier</code>	string	<p>The qualifier is used to distinguish intervals if more than one interval is defined.</p> <p>If only one interval is defined, the qualifier is optional.</p>
<code>...lowerBoundaryElement</code>	string	<p>Defines the name of the column that contains the lower boundary of an interval.</p> <p>If the interval is used for classification search, the lower boundary column is also given in the <code>@GenericPersistence.propertyValue</code> annotation.</p>
<code>...upperBoundaryElement</code>	string	<p>Defines the name of the column that contains the upper boundary of an interval.</p>

Annotation	Allowed Values	Description
...lowerBoundaryIncluded	true, false	<p>Indicator that defines if the lower boundary value is included in the interval or not. This is a static definition that is valid for all intervals stored in the view.</p> <p>This annotation cannot be used in combination with the <code>boundaryCodeElement</code> annotation.</p>
...upperBoundaryIncluded	true, false	<p>Indicator that defines if the upper boundary value is included in the interval or not. This is a static definition that is valid for all intervals stored in the view.</p> <p>This annotation cannot be used in combination with the <code>boundaryCodeElement</code> annotation.</p>

Annotation	Allowed Values	Description
<code>...boundaryCodeElement</code>	string	<p>Defines the name of the column that contains an indicator for the type of an interval. This is a dynamic definition that can be different for each interval stored in the view.</p> <p>The boundary code column contains a character between 1 and 9 that defines the type of the interval.</p> <p>1 degenerated interval containing a single value (closed-closed, lower boundary equals upper boundary)</p> <p>2 closed-open interval (lower boundary included, upper boundary excluded)</p> <p>3 closed-closed interval</p> <p>4 open-open interval</p> <p>5 open-closed interval</p> <p>6 unbounded-open interval (no lower boundary, upper boundary excluded)</p> <p>7 unbounded-closed interval (no lower boundary, upper boundary included)</p> <p>8 open-unbounded interval (no upper boundary, lower boundary excluded)</p> <p>9 closed-unbounded interval (no upper boundary, lower boundary included)</p>

Example

Sample Code

```
[
  {
    "uri":      "~/metadata/EntitySets",
    "method":  "POST",
    "content":
    {
      "Fullname": "AWARDSSQL/awardssql",
      "EntityType": {
        "@EnterpriseSearch.fieldGroupForSearchQuery": [
          { "Name": "award", "Elements": [ "id", "title", "abstract" ] },
          { "Name": "investigator", "Elements": [ "invFirstName",
"invLastName", "invEmail" ] }
        ],
        "@Aggregation.LeveledHierarchy": [
          { "Qualifier": "instLocation", "Value": [ "instCountry",
"instState", "instCity" ] },
          { "Qualifier": "organization", "Value": [ "orgDirectorate",
"orgDivision" ] }
        ]
      }
    }
  }
]
```

```

],
"@Search.searchable": true,
"@EnterpriseSearch.enabled": true,
"Properties": [
  ...
]
}
}
]

```

3.4.6.2 Property Annotations

The tables below show the annotations that are available for properties (columns) of the entity set.

Property Annotations for @Search

Annotation	Possible Values	Description
@Search.defaultSearchElement	true, false	Defines a column as a freestyle search column. At least one column has to be defined as a default freestyle search column. Searching in views without default freestyle search elements is not supported.
@Search.fuzzinessThreshold	0..1	Defines the threshold for a fuzzy search. The default value is 1. This means that an exact search is performed.
@Search.ranking	string possible values: HIGH, MEDIUM, LOW	Defines the ranking weight for a column: HIGH = 1.0, MEDIUM = 0.7, LOW = 0.5 Only one of the annotations @EnterpriseSearchHana.weight or @Search.ranking can be used for a column.

i Note

Beginning with metadata calls to API version 5 ('/v5/\$metadata'), the annotation @EnterpriseSearchHana.weight is always returned instead of @Search.ranking. HIGH, MEDIUM, and LOW are returned as their numeric values.

Annotation	Possible Values	Description
<code>@Search.termMappingDictionary</code>	string	<p>Defines the name of the term mapping table (format: <code>schemaname.tablename</code>). Passed to the search option <code>termMappingTable</code> of the <code>CONTAINS ()</code> predicate.</p> <div data-bbox="1007 600 1390 936" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>This annotation cannot be used if the <code>@EnterpriseSearch.searchOptions</code> annotation is used. In this case the term mapping definition has to be added to the search options string.</p> </div>
<code>@Search.termMappingListID</code>	array of strings	<p>Defines the names of the term mapping <code>list ids</code>, passed to the search option <code>termMappingListId</code> of the <code>CONTAINS ()</code> predicate.</p> <div data-bbox="1007 1128 1390 1464" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>This annotation cannot be used if the <code>@EnterpriseSearch.searchOptions</code> annotation is used. In this case the term mapping definition has to be added to the search options string.</p> </div>
<code>@Search.mode</code>	'ALPHANUM'	<p>Enables alphanumeric searches on (N)VARCHAR columns.</p> <div data-bbox="1007 1585 1390 1921" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>This annotation cannot be used if the <code>@EnterpriseSearch.searchOptions</code> annotation is used. In this case the term mapping definition has to be added to the search options string.</p> </div>

Annotation	Possible Values	Description
<code>@Search.fulltextIndex.required</code>	true, false	If set to true, a configuration fails if there is no full-text index defined for the column.

i Note

This annotation is checked during the validation of a search configuration only. This means that a search call does not fail if the full-text index has been removed from the column after writing the configuration to the database.

Property Annotations for @Enterprise Search

Annotation	Possible Values	Description
<code>@EnterpriseSearch.client</code>	true, false	Defines the client column and is used by ABAP applications only. <code>sys.esh_search()</code> takes the current client from the session context and adds it to any read access to the database object as an additional "where" condition. The ABAP application server automatically copies the current client to the session context for the primary database connection and for all secondary database connections.
<code>@EnterpriseSearch.defaultValueSuggestElement</code>	true, false	Defines a column that is used to calculate suggestions, if set to <code>true</code> .

i Note

Beginning with API version 20301 the session variable 'CDS_CLIENT' is preferred to get the client number. For older versions or if this variable is not defined, the session variable 'CLIENT' is used.

These session variables are automatically set by the ABAP database client.

Annotation	Possible Values	Description
(Deprecated) <code>@EnterpriseSearch.displayOrder</code>	integer >= 0	<p>i Note</p> <p>Beginning with API version 20407, the annotation <code>@UI.identification.position</code> shall be used instead.</p>
<code>@EnterpriseSearch.filteringAttribute.caseInsensitiveAggregation</code>	true, false	<p>If set to <code>true</code>, a case-insensitive aggregation of facet values is done.</p> <p>If not given or set to <code>false</code>, the default aggregation is case-sensitive.</p> <p>Only if the column is explicitly requested as a facet column.</p>
<code>@EnterpriseSearch.filteringAttribute.countNullValues</code>	true, false	<p>If set to <code>true</code>, facets also return an anchor object count for NULL values.</p> <p>If not given or set to <code>false</code>, NULL values are not returned.</p> <p>Only if the column is explicitly requested as a facet column.</p> <p>i Note</p> <p>NULL values for facets are only returned for search calls to version 6 or higher ('/v6/\$all/...').</p> <p>With older versions ('/v5/\$all/...') NULL values for facets are never returned in the search response.</p> <p>This annotation cannot be used for classification properties.</p>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filteringAttribute.default</code>	true, false	<p><code>filteringAttribute</code> annotations can be used by search UIs to identify columns that are suitable for filter conditions but that shall usually not be displayed as facets.</p> <p>If needed by the UI, columns with <code>filteringAttribute</code> annotations can be explicitly requested as facets. To get the facet values, the column name has to be explicitly added to the facets option of the search call.</p> <p>If facets are requested with <code>facets=all</code> or <code>facets=n</code> (with $n > 0$), columns with <code>filteringAttribute</code> annotations are never returned.</p> <p><code>filteringAttribute</code> and <code>filteringFacet</code> annotations cannot be used at the same time for a column.</p>
<code>@EnterpriseSearch.filteringAttribute.displayPosition</code>	true, false	<p>defines the sequence of facet columns in the search response.</p> <p>Only if the column is explicitly requested as a facet column.</p> <p>See <code>@EnterpriseSearch.filteringFacet.displayPosition</code> for details.</p>
<code>@EnterpriseSearch.filteringFacet.caseInsensitiveAggregation</code>	true, false	<p>Is set to <code>true</code>, a case-insensitive aggregation of facet values is done.</p> <p>If not given or set to <code>false</code>, the default aggregation is case-sensitive.</p>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filteringFacet.countNullValues</code>	true, false	<p>If set to true, facets also return an anchor object count for NULL values.</p> <p>If not given or set to false, NULL values are not returned.</p> <p>NULL values are returned only for facets that show single values. If intervals are returned (for date, numeric or spatial SQL types), NULL values are not part of the facet.</p> <div data-bbox="1007 734 1390 1093" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>NULL values for facets are only returned for search calls to version 6 or higher ('/v6/\$all/...').</p> <p>With older versions ('/v5/\$all/...') NULL values for facets are never returned in the search response.</p> </div> <div data-bbox="1007 1108 1390 1256" style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>This annotation cannot be used for classification properties.</p> </div>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filteringFacet.default</code>	true, false	<p>Defines a column as a facet column.</p> <p>If set to <code>true</code>, a facet is automatically returned for this column in the search response if facets are enabled (with custom query option <code>facets=all</code>, for example).</p> <p>If set to <code>false</code>, a facet for this column is returned only if the facet is requested explicitly (by adding the column name to custom query option <code>facets as</code>, for example, <code>facets=AMOUNT, INSTITUTIONCOUNTRY</code>).</p> <p>If the annotation <code>@EnterpriseSearch.filteringFacet.default</code> is not given but any of the other <code>filteringFacet</code> annotations is used for a column, this implicitly also sets <code>@EnterpriseSearch.filteringFacet.default</code> to <code>false</code>.</p> <p>Beginning with API version 5, columns of SQL type <code>ST_POINT</code> can also be defined as facet columns.</p>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filterin</code> <code>gFacet.displayPosition</code>	integer > 0	<p>Defines the sequence of facet columns in the search response.</p> <p>If the number of facets returned in the search response is limited to n (by setting the facets option to n as, for example, <code>facets=3</code>), only the first n facets in the order defined by the display position are returned.</p> <div data-bbox="1007 680 1390 1323" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>The usage of this annotation is optional. But as soon as it is used in a view definition, it has to be given for all facet columns.</p> <p>All facet columns of a leveled hierarchy have to be assigned to the same display position. For all other facet columns the display position has to be unique.</p> <p>If the <code>displayPosition</code> annotation is not used, facet columns are returned in a stable order so that consecutive calls to <code>sys.esh_search()</code> return the same sequence of facet columns.</p> </div>
<code>@EnterpriseSearch.filterin</code> <code>gFacet.noIntervals</code>	true, false	<p>If set to true, date facets and numeric facets are returned as single values instead of intervals.</p> <p>If set to false, date facets and numeric facets are returned as intervals. This is the default behavior.</p>
<code>@EnterpriseSearch.filterin</code> <code>gFacet.numberOfValues</code>	integer > 0	<p>Defines the number of values that are returned in the facet.</p> <p>If this parameter is not given, 10 values are returned by default.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.filterin gFacet.order.by	#NUMBER_OF_HITS, #FILTER_ELEMENT_VALUE	<p>Defines the sort criterion for facet columns.</p> <p>If set to <code>NUMBER_OF_HITS</code>, the facet is sorted by the number of distinct anchor objects belonging to each facet value. This is the default behavior.</p> <p>If set to <code>FILTER_ELEMENT_VALUE</code>, the facet is sorted by the value of the facet column.</p> <div data-bbox="1007 734 1398 965" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>The annotation cannot be used for spatial datatypes (<code>ST_POINT</code>, <code>ST_GEOMETRY</code>), as these cannot be sorted.</p> </div>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.filteringFacet.order.byReference</code>	string	<p>Defines the name of a column that is used as a sort criterion for a facet column.</p> <p>The facet is sorted by the contents of the column that is referenced by this annotation.</p> <p>For example, a facet that counts documents for month names can be sorted by the month number so that the UI displays the month names in the right sequence. In this case, the month name is defined as a facet column and this annotation references the view column that contains the number of the month.</p> <p>The referenced column cannot be defined as a language-dependent column.</p> <div data-bbox="1007 981 1402 1637" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note</p> <p>Interval facets (numeric columns and date columns) cannot be sorted by a reference to another column.</p> <p>Only one of the annotations <code>@EnterpriseSearch.filteringFacet.order.byReference</code> or <code>@EnterpriseSearch.filteringFacet.order.by</code> can be used.</p> <p>For correct results, there has to be a 1-to-1 relationship between the facet value and the value of the referenced column.</p> </div>
<code>@EnterpriseSearch.filteringFacet.order.direction</code>	#ASC, #DESC	<p>Defines whether the facet is sorted in ascending or descending order.</p> <p>The default is descending order for a facet that is sorted by <code>NUMBER_OF_HITS</code>.</p> <p>In all other cases, the default is to sort in ascending order.</p>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.highlighted.enabled</code>	true, false	<p data-bbox="1007 371 1337 394">Enables highlighting for a column.</p> <p data-bbox="1007 423 1402 689">Only highlighting for columns with a presentation mode other than 'NONE' will be returned in the search result. The original column content is not returned if highlighting is enabled. In other words, either a highlighted text or a column value are returned in the search results.</p> <p data-bbox="1007 719 1382 808">It is possible to get both snippets and highlighted text in the search result by setting both annotations.</p> <p data-bbox="1007 837 1393 969">The column has to support text search. This means it needs a fulltext index or has to be of SQL type <code>TEXT</code>, <code>BINTEXT</code> or <code>SHORTTEXT</code>.</p> <p data-bbox="1007 999 1393 1160">Beginning with Enterprise Search version 4, this annotation is also allowed for columns that are part of a 1:n join if these columns are defined as multi-values or subobjects.</p> <p data-bbox="1007 1189 1393 1525">For <code>sys.esh_search()</code> calls up to API version 20302 (<code>/v20303/\$all?...</code>), highlighted text is always returned for all columns that have a highlighted annotation, independent of presentation mode annotations. If a column has a presentation mode annotation, both the original column value and the highlighted text are returned in the search response.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.key	true, false 	<p>Defines a column that is part of the anchor key.</p> <p>All anchor key columns have to be part of the same database table and this has to be the first table that is used in the view definition.</p> <p>The anchor key columns have to define a unique key of the anchor table. Usually the anchor key columns are identical to the primary key columns of the anchor table. In this case, a client column, annotated with @EnterpriseSearch.client set to true, can be omitted from the anchor key definition.</p> <div data-bbox="1007 898 1398 1167" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>Like primary keys, anchor key columns must not contain NULL values. Therefore they should always be defined as NOT NULL to avoid unexpected search results.</p> </div> <div data-bbox="1007 1182 1398 1406" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>At least one column of the view has to be marked as an anchor key. Searching in views without an anchor key is not supported.</p> </div>

Annotation	Possible Values	Description
(Deprecated) <code>@EnterpriseSearch.presentationMode</code>	array of strings possible values: DETAIL, HIDDEN, IMAGE, SUMMARY, THUMBNAIL, TITLE, LONGTEXT, NONE	<p>i Note</p> <p>Deprecated</p> <p>Beginning with Enterprise Search API version 20405, this annotation is replaced by annotation <code>@UI</code> and others to define the UI behavior. Columns with <code>@UI</code> annotations are returned by default if the query option <code>\$select</code> is not used to define the response columns of a search.</p> <p>In a single view either the presentation mode annotation or the <code>@UI</code> annotations can be used.</p>
<code>@EnterpriseSearch.searchOptions</code>	string	<p>Defines the search options string that is passed to the <code>CONTAINS()</code> predicate when searching in the column.</p> <p>Search options <code>emptyScore</code>, <code>emptyMatchesNull</code>, and <code>returnAll</code> are not allowed.</p>

Annotation	Possible Values	Description
@EnterpriseSearch.snippets.enabled	true, false	<p data-bbox="1007 371 1366 434">Enables snippet calculation for a column.</p> <p data-bbox="1007 456 1390 689">Only snippets for columns with a presentation mode other than 'NONE' will be returned in the search result. The original column content is not returned if snippets are enabled. In other words, either a snippet or a column value are returned in the search result.</p> <p data-bbox="1007 712 1390 846">The column has to support text search. This means it needs a fulltext index or has to be of SQL type TEXT, BINTEXT or SHORTTEXT.</p> <div data-bbox="1007 875 1390 1538" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p data-bbox="1031 887 1110 909">i Note</p> <p data-bbox="1031 943 1358 1106">Beginning with API version 4, this annotation is also allowed for columns that are part of a 1:n join if these columns are defined as multi-values or subobjects.</p> <p data-bbox="1031 1128 1382 1503">For <code>sys.esh_search()</code> calls up to API version 20302 (/v20303/\$all?...), snippets are always returned for all columns that have a snippets annotation, independent of presentation mode annotations. If a column has a presentation mode annotation, both the original column value and the snippet are returned in the search response.</p> </div>

Annotation	Possible Values	Description
<code>@EnterpriseSearch.snippets</code> <code>.maxLength</code>	integer > 0 and <= 5000	<p>Defines the maximum length of a snippet in characters.</p> <p>For columns with annotation <code>@EnterpriseSearch.snippets.enabled</code> set to <code>true</code> this annotation defines the maximum length of a snippet that is returned in the search response.</p> <p>The annotation also defines the maximum length of a snippet that is returned as part of the whyfound information. If the whyfound information contains a highlighted text, the maximum length parameter is ignored.</p> <p>The snippet returned will be as long as possible but it will never be longer than the given maximum length.</p> <p>Without this annotation a snippet has a maximum length of 5000 characters but the length of the snippet depends on the number of different tokens that are found in the column.</p>

(Deprecated) <code>@EnterpriseSearch.usageMode</code>	array of strings possible values: <code>AUTO_FACET</code> , <code>SUGGESTION</code>
--	---

Note

Deprecated

Beginning with Enterprise Search API version 5, this annotation is replaced by annotations `@EnterpriseSearch.filteringFacet` and `@EnterpriseSearch.defaultValueSuggestElement`.

In a view, the annotations `@EnterpriseSearch.filteringFacet` and `@EnterpriseSearch.usageMode` `AUTO_FACET` cannot be used at the same time.

Example

☰ Sample Code

```
[
  {
    "uri":      "~/metadata/EntitySets",
    "method":  "POST",
    "content":
    {
      "Fullname": "AWARDSSQL/awardssql",

          "Name": "instrument"
        },
        ...
      ]
    }
  }
]
```

Annotation	Possible Values	Description
@EnterpriseSearchHana.identifier	string	<p>Defines the OData identifier of a column. The value has to be a valid OData identifier.</p> <p>If an identifier is defined, the identifier is used instead of the original column name in all interfaces of <code>sys.esh_search()</code> including the metadata call. In other words, the internal column name is not visible to the users of <code>sys.esh_search()</code>.</p> <p>If this annotation is not given, the column name is used as an identifier.</p> <div data-bbox="1027 860 1114 891" data-label="Section-Header">i Note</div> <div data-bbox="1027 920 1377 981" data-label="Text"> <p>An identifier cannot be equal to the name of a subobject.</p> </div> <div data-bbox="1027 1032 1114 1064" data-label="Section-Header">i Note</div> <div data-bbox="1027 1093 1353 1153" data-label="Text"> <p>Version-dependent Implementation</p> </div> <div data-bbox="1027 1176 1377 1272" data-label="Text"> <p>Identifiers are returned by the metadata call if the call is done with an api version of '/v20411' or higher.</p> </div> <div data-bbox="1027 1294 1361 1570" data-label="Text"> <p>For older versions ('/v20410' or lower) the column names are returned. The column names can also be used in calls to <code>sys.esh_search()</code> even if identifiers are defined to avoid inconsistencies between the metadata call and the search call.</p> </div> <div data-bbox="1027 1621 1114 1653" data-label="Section-Header">i Note</div> <div data-bbox="1027 1682 1225 1704" data-label="Text"> <p>Non-unique Names</p> </div> <div data-bbox="1027 1727 1377 1890" data-label="Text"> <p>When using identifiers, columns of different subobjects can share the same column name. Client applications have to be aware of this feature and have to use subobject</p> </div>

Annotation	Possible Values	Description
@EnterpriseSearchHana.numc	true, false	<p>names as prefixes to make references to columns unique.</p> <p>Example: Both subobjects 'customer' and 'supplier' can contain a column with the same identifier 'name'. To make names unique, the columns can be referenced as 'customer/name' and 'supplier/name' in the interface to <code>sys.esh_search()</code>.</p> <hr/> <p>defines a column as an ABAP NUMC column (a numeric value padded with leading zeros).</p> <p>API version 20402 and higher: If a score function (linear, gaussian, logarithmic) is defined for this column, search in this column is done like in an integer column.</p> <p>API version 20404 and higher: Without score functions, a search in a NUMC column is done similar to an alphanumeric search limited to numeric characters.</p> <p>Interval facets are returned, if a facet is requested for a NUMC column.</p> <div data-bbox="1007 1346 1402 1543" style="border: 1px solid #ccc; padding: 5px;"> <p>i Note</p> <p>This annotation is allowed for (N) VARCHAR columns with a length of up to 18 characters only.</p> </div>

Annotation	Possible Values	Description
<code>@EnterpriseSearchHana.uiResource.label.bundle</code>	string	<p>Defines the name of a resource bundle.</p> <p>Can be used by the search UI to load labels for view elements.</p> <div data-bbox="1007 504 1396 967" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>uiResource annotations do not change the behavior of <code>sys.esh_search()</code>.</p> <p>They are only returned in the metadata of the search configuration, so a UI may use these values to get texts in the end user's language.</p> <p>To get the annotation, version 5 or higher of the metadata call has to be used (<code>'/v5/\$metadata'</code>).</p> </div>
<code>@EnterpriseSearchHana.uiResource.label.key</code>	string	<p>Defines the name of a key in a resource bundle.</p> <p>Can be used by the search UI to load labels for view elements.</p>
<code>@EnterpriseSearchHana.weight</code>	DECIMAL(4,3) > 0	<p>Defines the ranking weight of a column that is used to calculate the overall score.</p> <p>Only one of the annotations <code>@EnterpriseSearchHana.weight</code> or <code>@Search.ranking</code> can be used for a column.</p> <div data-bbox="1007 1462 1396 1839" style="background-color: #f0f0f0; padding: 10px;"> <p>i Note</p> <p>For metadata calls up to api version 4 (<code>'/\$metadata'</code> or <code>'/v4/\$metadata'</code>), the annotation <code>@Search.ranking</code> is returned and the value given with <code>@EnterpriseSearchHana.weight</code> is rounded to 'HIGH', 'MEDIUM', or 'LOW'.</p> </div>

Property Annotations for @Semantics

Annotation	Possible Values	Description
<code>@Semantics.amount.currencyCode</code>	string	Defines the name of a column that contains the currency code for the monetary amount that is stored in the annotated column. This annotation is used by classification search.
<code>@Semantics.currencyCode</code>	true, false	The column contains a currency code and is referenced at another column by annotation <code>@Semantics.amount.currencyCode</code> .

Annotation	Possible Values	Description
<code>@Semantics.businessDate.at</code>	true, false	Defines a column that contains a date or timestamp.
<code>@Semantics.businessDate.from</code>		The annotations are valid for some SQL types only.
<code>@Semantics.businessDate.to</code>		
<code>@Semantics.systemDate.createdAt</code>		<ul style="list-style-type: none"> DATE, SECONDDATE, TIMESTAMP: These types are always treated as a date or timestamp. The annotation is allowed, but does not change the behavior.
<code>@Semantics.systemDate.lastChangedAt</code>		<ul style="list-style-type: none"> DATE, SECONDDATE, TIMESTAMP: These types are always treated as a date or timestamp. The annotation is allowed, but does not change the behavior.
<code>@Semantics.contact.birthDate</code>		<ul style="list-style-type: none"> VARCHAR (8) , NVARCHAR (8) : The column is treated as a date column. Dates stored in the column have to be of format 'YYYYMMDD'.
(Deprecated) <code>@Semantics.businessDate.createdAt</code>		<ul style="list-style-type: none"> DECIMAL (15) : The column is treated as a timestamp (similar to SQL type SECONDDATE). Timestamps stored in the column have to be of format 'YYYYMMDDHHMMSS'.
(Deprecated) <code>@Semantics.businessDate.lastChangedAt</code>		<ul style="list-style-type: none"> DECIMAL (15) : The column is treated as a timestamp (similar to SQL type SECONDDATE). Timestamps stored in the column have to be of format 'YYYYMMDDHHMMSS'. Only years between 1000 and 9999 are supported.
		<ul style="list-style-type: none"> DECIMAL (21, 7) : The column is treated as a timestamp (similar to SQL type TIMESTAMP). Timestamps stored in the column have to be of format 'YYYYMMDDHHMMSS.NNNNNNN'. Only years between 1000 and 9999 are supported.
		<p>The annotation changes the behavior of (N) VARCHAR and DECIMAL columns so that <code>sys.esh_search()</code> treats them like other date or timestamp columns:</p> <ul style="list-style-type: none"> Facets are returned as date intervals. Only valid dates or date patterns are searched in these columns (except for SQL type DECIMAL that also accepts decimal numbers as search terms).

Annotation	Possible Values	Description
		<ul style="list-style-type: none"> • VARCHAR (8) and NVARCHAR (8) columns accept the initial value of ABAP DATS columns ('00000000') as a search term. DECIMAL columns accept the initial value 0 as a search term. <div data-bbox="1007 600 1398 1106" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>Deprecated Annotations</p> <p>The annotations <code>@Semantics.businessDate.createdAt</code> and <code>@Semantics.businessDate.lastChangedAt</code> are deprecated. Use <code>@Semantics.systemDate.createdAt</code> and <code>@Semantics.systemDate.lastChangedAt</code> instead.</p> </div>

Annotation	Possible Values	Description
<code>@Semantics.languageReference</code>	string	<p>Defines the name of a column that contains the language code of the annotated column's content.</p> <p>If a column contains text in multiple languages, this annotation can be used to define the name of the column that contains the corresponding language code.</p> <p>The language code column may contain language codes in any format as, for example, 1-character SAP language codes or 2-character ISO 639-1 language codes. The language codes given in the language vector have to match the language codes stored in the language code column.</p> <p>The language code column has to be defined as SQL type (N)VARCHAR.</p> <div data-bbox="1007 1055 1394 1682" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>The language code column cannot be part of the search result. In other words, <code>@EnterpriseSearch.presentationMode</code> annotations with a value other than <code>#NONE</code> cannot be used for language code columns. The value of the language code column is instead returned in the search result with the annotation <code>@com.sap.vocabularies.Search.v1.Language</code>.</p> <p>Key and client columns cannot be defined as language dependent columns.</p> </div>
<code>@Semantics.quantity.unitOfMeasure</code>	string	<p>Defines the name of a column that contains the unit of measure for the measured quantity that is stored in the annotated column.</p> <p>This annotation is used by classification search.</p>

Annotation	Possible Values	Description
<code>@Semantics.unitOfMeasure</code>	true, false	The column contains a unit of measure and is referenced at another column by annotation <code>@Semantics.quantity.unitOfMeasure</code> .

Property Annotations for @Consumption

Annotation	Possible Values	Description
<code>@Consumption.labelElement</code>	string	<p>Defines the name of a column that contains a label belonging to a facet column.</p> <p>The label column may either be language-independent or language-dependent (with annotation <code>@Semantics.languageReference</code>).</p> <p>For each facet value, the label is additionally returned in the search response with the annotation <code>@com.sap.vocabularies.Common.v1.Text</code>.</p>

i Note

If a label is defined for a facet column that is of a SQL type that usually returns intervals (as, for example, a numeric column), the facet will never be returned as intervals. It will always return single values and the corresponding labels.

i Note

To get correct search results, there has to be a 1:1 relationship between every value in the facet column and the corresponding value in the label column.

For language-dependent labels, there has to be at most one label text in each language for every value in the facet column.

Property Annotations for @GenericPersistency

Annotation	Possible Values	Description
<code>@GenericPersistency.property</code>	true, false	<p>true, if the column contains the key column of a key-value-pair used for classification search.</p> <p>If this annotation is set to true, at least one value column has to be defined using the <code>@GenericPersistency.propertyValue</code> annotation.</p>
<code>@GenericPersistency.propertyValue</code>	array of strings	<p>Array of column names that defines one or more value columns of a key-value-pair used for classification search.</p> <p>The value columns of a key-value-pair may be of different SQL data types. In this case, it is possible to define more than one column as value column (one for each SQL type).</p> <p>If the value of the key-value-pair is an interval, this annotation contains the name of the lower boundary column only. The remaining columns of the interval are defined using the <code>@Semantics.interval</code> annotation.</p> <p>If a unit of measure column or a currency code column belongs to the value column, the annotations <code>@Semantics.quantity.unitOfMeasure</code> and <code>@Semantics.amount.currencyCode</code> are used on the value column to define these additional columns.</p> <p>This annotation may only be used if <code>@GenericPersistency.property</code> is set to true.</p>

Example

Sample Code

```
[
  {
    "uri":    "~/metadata/EntitySets",
    "method": "POST",
```

```

"content":
{
  "Fullname": "AWARDSSQL/awardssql",
  "@Search.searchable": true,
  "@EnterpriseSearch.enabled": true,
  "Properties": [
    {
      "@EnterpriseSearch.key": true,
      "@EnterpriseSearch.presentationMode": [ "TITLE" ],
      "Name": "id"
    },
    {
      "@EnterpriseSearch.presentationMode": [ "TITLE" ],
      "@Search.defaultSearchElement": true,
      "@Search.fuzzinessThreshold": 0.8,
      "Name": "title"
    },
    {
      "@EnterpriseSearch.presentationMode": [ "TITLE" ],
      "@Search.defaultSearchElement": true,
      "@Search.fuzzinessThreshold": 0.8,
      "Name": "abstract"
    },
    {
      "@EnterpriseSearch.presentationMode": [ "DETAIL" ],
      "@EnterpriseSearch.usageMode": [ "AUTO_FACET" ],
      "@Search.defaultSearchElement": true,
      "Name": "instrument"
    },
    ...
  ]
}
]

```

Sample Code

Example: Definition of Language-Dependent Columns

Sample Code

```

[
{
  "uri": "~/metadata/EntitySets",
  "method": "PUT",
  "content":
  {
    "Fullname": "AWARDSSQL/awardssql",
    "EntityType": {
      "@Search.searchable": true,
      "@EnterpriseSearch.enabled": true,
      "Properties": [
        {
          "@EnterpriseSearch.key": true,
          "@EnterpriseSearch.presentationMode": [ "TITLE" ],
          "Name": "id"
        },
        ...
        {
          "Name": "instCountryLanguage"
        },
        {
          "@EnterpriseSearch.presentationMode": [ "DETAIL" ],
          "@Semantics.languageReference": "instCountryLanguage",
          "Name": "instCountry"
        }
      ]
    }
  }
}
]

```

```

    },
    ...
  ]
}
}
]

```

3.4.6.3 Definition of Multi-Value Properties

A property (or column) that comes from a 1:n join cannot be returned as a single value in the search response because the column usually contains multiple distinct values for each anchor object.

To get all values in the search response, the property has to be defined as a collection. As a result, it will be returned as an array in the search response.

Metadata Parameter	Possible Values	Description
IsCollection	true, false	<p>Defines a column as a multi-value column.</p> <p>This means that the column comes from an 1:n join and that it is returned in the search result as an array.</p>

i Note

This multi-value configuration is only allowed for columns that are of a SQL type that can be used in a group by clause.

Sample Code

Multi-Value Example

```

[
  {
    "uri":    "~/metadata/EntitySets",
    "method": "PUT",
    "content":
    {
      "Fullname": "AWARDSSQL/awardssql",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          {
            "@EnterpriseSearch.key": true,
            "@EnterpriseSearch.presentationMode": [ "TITLE" ],
            "Name": "id"
          },
          ...
        ]
      }
    }
  }
]

```

```

    {
      "@EnterpriseSearch.presentationMode": [ "DETAIL" ],
      "IsCollection": true,
      "Name": "programReferenceText"
    },
    ...
  ]
}
}
]

```

3.4.6.4 Definition of Subobjects

To get back the columns of a complex object that comes from a 1:n join, these columns have to be configured as a subobject.

To define the subobject, all properties of the subobject have to be added to the `sys.esh_config()` call as a collection of a complex type.

Annotation/Metadata Parameter	Possible Values	Description
<code>@EnterpriseSearchHana.layoutStructuredObject.defaultExpand</code>	string possible values: ALL, WHY_FOUND	<p>Defines which subobjects are returned in the search result.</p> <p>ALL: all subobjects of an anchor object are returned.</p> <p>WHY_FOUND: only the subobject of the anchor object are returned that contain at least one of the search terms.</p> <p>If this annotation is not made, the default value is 'ALL'.</p>
<code>@EnterpriseSearchHana.layoutStructuredObject.key</code>	true, false	<p>Defines if a column is part of the subobject's key. Used to identify the distinct subobjects of an anchor object.</p> <p>If there are no key columns defined for a subobject, all columns are used to identify the distinct subobjects.</p>
		<div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>i Note</p> <p>All key columns have to be of a SQL type that can be used in a group by clause.</p> </div>
Name	string	Defines the name of the subobject.

Annotation/Metadata Parameter	Possible Values	Description
IsCollection	true	Defines that the subobject comes from a 1:n join and that there can be multiple subobject instances for a given anchor object.

Sample Code

Subobject Example

```
[
  {
    "uri":      "~/metadata/EntitySets",
    "method":  "PUT",
    "content":
    {
      "Fullname": "AWARDSSQL/awardssql",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          {
            "@EnterpriseSearch.key": true,
            "@EnterpriseSearch.presentationMode": [ "TITLE" ],
            "Name": "id"
          },
          {
            "Name": "programElement",
            "IsCollection": true,
            "@EnterpriseSearchHana.layoutStructuredObject.defaultExpand":
"ALL",
            "Type": {
              "@odata.type": "Meta.ComplexType",
              "Name": "programElementType",
              "Properties": [
                {
                  "@EnterpriseSearch.presentationMode": [ "DETAIL" ],
                  "Name": "programElementCode"
                },
                {
                  "@EnterpriseSearch.presentationMode": [ "DETAIL" ],
                  "@EnterpriseSearch.usageMode": [ "AUTO_FACET" ],
                  "@Search.defaultSearchElement": true,
                  "Name": "programElementText"
                }
              ]
            }
          }
        ]
      }
    }
  }
]
```

3.4.6.4.1 Subobjects Within Other Subobjects

It is also possible to define subobjects within other subobjects. This is done by embedding a subobject definition in the surrounding subobject.

Example

The following example shows the definition of a subobject 'institution' that contains another subobject 'investigator'.

The annotation `@EnterpriseSearchHana.identifier` is used to get rid of the column name prefixes 'inv' and 'inst' in the subobjects. The name columns of the institution and the investigator show that identifiers can be the same for both columns while the real column names have to be different.

Sample Code

Subobject Within Other Subobject

```
[
  {
    "uri":    "~/metadata/EntitySets",
    "method": "PUT",
    "content":
    {
      "Fullname": "AWARDSSQL/awardssql",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "@EnterpriseSearchHana.identifier": "awards",
        "Properties": [
          ...
          {
            "@UI.identification": [ { "position": 13 } ],
            "@EnterpriseSearch.filteringFacet.default": true,
            "Name": "amount"
          },
          {
            "Name": "institution",
            "IsCollection": true,
            "@EnterpriseSearchHana.layoutStructuredObject.defaultExpand":
"ALL",
            "Type": {
              "@odata.type": "Meta.ComplexType",

3.4.6.6 Example: Using Annotations not Related to Search

The following example shows a search view configuration for products.

The configuration contains annotations that are not used by the Enterprise Search runtime in SAP HANA. Examples are the annotations `@UI.identification` and `@Semantics.quantity.unitOfMeasure`. These annotations are returned by a metadata call only and have no impact on the search results.

To enable the processing of annotations that are not related to search, the annotation `@EnterpriseSearchHana.passThroughAllAnnotations` is set to `true`.

i Note

It is important that annotations are defined using the data structure and data type that is expected by the client application. As `sys.esh_config()` does not know anything about the syntax of the annotations that are given, all annotations are simply returned in the metadata as they are given in the search configuration.

An example is the UI annotation

```
"@UI.identification": [ { "position": 1 } ]
```

that leads to different metadata than the wrong annotation

```
"@UI.identification.position": 1
```

☰ Sample Code

Using Other Annotations

```
call esh_config('
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "PUT",
    "content": {
      "Fullname": "SAMPLE/Products",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "@EnterpriseSearchHana.passThroughAllAnnotations": true,
        "@EnterpriseSearchHana.uiResource.label.bundle": "/sap/
search_resourcebundle/resources.properties",
        "@EnterpriseSearchHana.uiResource.label.key": "products",
        "@UI.headerInfo.title.value": "Product",
        "@UI.headerInfo.description.value": "ProductUUID",
        "Properties": [
          {
            "@EnterpriseSearch.key": true,
            "Name": "ProductUUID"
          },
          {
            "@Search.defaultSearchElement": true,
            "@EnterpriseSearch.defaultValueSuggestElement": true,
            "@EnterpriseSearch.filteringFacet.default": true,
            "Name": "Product"
          },
          {
            "@Search.defaultSearchElement": true,
            "@UI.identification": [ { "position": 1 } ],
            "@EnterpriseSearchHana.uiResource.label.key":
"productdescription",
            "@EnterpriseSearch.defaultValueSuggestElement": true,
            "Name": "ShortText"
          },
          {
            "@Search.defaultSearchElement": true,
            "@UI.identification": [ { "position": 3 } ],
            "@EnterpriseSearchHana.uiResource.label.key": "productcategory",
            "@EnterpriseSearch.defaultValueSuggestElement": true,
            "Name": "ProductCategory"
          },
          {
            "@Search.defaultSearchElement": true,
            "@UI.identification": [ { "position": 9 } ],
            "@EnterpriseSearchHana.uiResource.label.key":
"lastchangeddatetime",
            "@EnterpriseSearch.filteringFacet.default": true,
            "Name": "LastChangedDateTime"
          },
          {
            "@Search.defaultSearchElement": false,
            "@UI.identification": [ { "position": 55 } ],
            "@Semantics.imageUrl": true,
            "Name": "ProductPictureURL"
          }
        ]
      }
    }
  ]
)
```

```

    {
      "@Search.defaultSearchElement": true,
      "@UI.identification": [ { "position": 12 } ],

      "@EnterpriseSearchHana.uiResource.label.key": "price",
      "@EnterpriseSearch.filteringFacet.default": true,
      "@Semantics.quantity.unitOfMeasure": "Currency",
      "Name": "Price"
    },
    {
      "@Search.defaultSearchElement": true,
      "@EnterpriseSearchHana.uiResource.label.key": "currency",
      "@EnterpriseSearch.filteringFacet.default": true,
      "@UI.hidden": false,
      "Name": "Currency"
    }
  ]
}
}
]
', ?);

```

3.4.6.7 Defining Multilingual Text

UIs need to show text like, for example, view names and labels in the language of the end-user. With `sys.esh_config()` there are multiple ways how multilingual texts can be defined.

Defining Texts in the Search Application

For applications that work with a defined set of search configurations only it makes sense to store all UI related texts in the application layer itself.

This means that standard translation mechanisms of the application's runtime environment are used and all text definitions can be stored in a single place.

Resource Bundles

Generic search applications do not know in advance in which views the search is done. In this case, the search application needs to get the UI texts based on information stored in the metadata of the search model.

To link the search model to multilingual text, it is possible to define resource bundles and resource keys for the view and for all view elements. This allows to put all texts of a given language in a separate file. The search application can access the files containing the translations to get the texts in the language of the user.

When using resource bundles, the application sitting on top of `sys.esh_config()` and `sys.esh_search()` needs to implement functions to access the resource bundles to get the texts in the required language.

Sample Code

Using Resource Bundles

```
call esh_config('
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "PUT",
    "content": {
      "Fullname": "SAMPLE/Products",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "@EnterpriseSearchHana.uiResource.label.bundle": "/sap/
search_resourcebundle/resources.properties",
        "@EnterpriseSearchHana.uiResource.label.key": "products",
        "Properties": [
          {
            "@EnterpriseSearch.key": true,
            "Name": "ProductUUID"
          },
          {
            "@Search.defaultSearchElement": true,
            "@EnterpriseSearchHana.uiResource.label.key":
"productdescription",
            "Name": "ShortText"
          },
          {
            "@Search.defaultSearchElement": true,
            "@EnterpriseSearchHana.uiResource.label.key": "productcategory",
            "Name": "ProductCategory"
          },
          ...
        ]
      }
    }
  }
]
```

```
]
', ?);
```

Storing Multilingual Texts in the Search Configuration

As an alternative to resource bundles, multilingual text for generic search applications can also be stored directly in the search configuration. This means that the search configuration and all available translations are maintained in a single place.

The search application gets back the text in the end-user's language as part of the output of the metadata call.

As a drawback, this approach does not allow to collect translations for separate languages in separate files.

The following example shows how to define text in the search configuration.

At the beginning of the configuration, there is the annotation `@EnterpriseSearchHana.translation` that defines all required text elements in multiple languages. The texts are assigned to placeholders ("id") that are later used in the search configuration to reference the translated texts. For each placeholder there is also a default text defined (the text that is given without a language).

All UI related annotations that are not processed by `sys.esh_search()` can use the placeholders to reference to translated text. During the metadata call the placeholders are replaced by the translated text in the best available language based on the language settings of the user.

Sample Code

Multilingual Text in the Search Configuration

```
call esh_config('
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "PUT",
    "content": {
      "Fullname": "SAMPLE/Products",
      "EntityType": {
        "@EnterpriseSearchHana.translation": [
          { "id": "$PRODUCT",
            "value": [
              { "text": "Product" },
              { "language": "en_US", "text": "Product" },
              { "language": "de_DE", "text": "Produkt" }
            ]
          },
          { "id": "$PRODUCTS",
            "value": [
              { "text": "Products" },
              { "language": "en_US", "text": "Products" },
              { "language": "de_DE", "text": "Produkte" }
            ]
          },
          { "id": "$SHORTTEXT",
            "value": [
              { "text": "Product Description" },
              { "language": "en_US", "text": "Description" },
              { "language": "de_DE", "text": "Beschreibung" }
            ]
          }
        ],
      },
      { "id": "$PRODUCT_CATEGORY",
```

```

        "value": [
            { "text": "Product Category" },
            { "language": "en_US", "text": "Category" },
            { "language": "de_DE", "text": "Kategorie" }
        ]
    },
],
"@Search.searchable": true,
"@EnterpriseSearch.enabled": true,
"@EnterpriseSearchHana.passThroughAllAnnotations": true,
"@UI.headerInfo.typeName": "$PRODUCT",
"@UI.headerInfo.typeNamePlural": "$PRODUCTS",
"Properties": [
    {
        "@EnterpriseSearch.key": true,
        "Name": "ProductUUID"
    },
    {
        "@Search.defaultSearchElement": true,
        "@SAP.Common.Label": "$SHORTTEXT",
        "Name": "ShortText"
    },
    {
        "@Search.defaultSearchElement": true,
        "@SAP.Common.Label": "$PRODUCT_CATEGORY",
        "Name": "ProductCategory"
    },
    ...
]
}
}
]
', ?);

```

3.4.6.8 Entity Type Annotations for Table Functions and SQL Views with Parameters

When defining a search configuration for a table functions or for a SQL view with parameters, all of the parameters have to be defined in the search configuration using the following annotations.

Annotation	Allowed Values	Description
@Search.constraints.Name	name of view or function parameter	References the name of an existing table function or SQL view parameter. Names are case-sensitive, so the exact name from the SQL definition of the view or function has to be used.

Annotation	Allowed Values	Description
@Search.constraints.Alias	valid identifier	Optional: defines an alternative name of the parameter that has then to be used in the call to <code>sys.esh_search()</code> . The name is case-sensitive.
@Search.constraints.DefaultValue	see below	Optional: defines the default value of the parameter that is used if the parameter is not given in the call to <code>sys.esh_search()</code> . If no default value is given, the parameter always has to be given in the call to <code>sys.esh_search()</code> .

All parameters of a table function or a SQL view with parameters have to be defined in the search configuration.

i Note

If a join view is used instead of a SQL view, the parameters reference the constraints of the join view. In this case, the definition of parameters is optional.

3.4.6.8.1 Definition of Default Parameter Values

The default value of a parameter can be defined as one of the following values:

- a constant string
- the value of the `CURRENT_DATE` function
- the two-character language code of the user's default language
- the value of a session variable

The possible values of the `@Search.constraints.DefaultValue` annotation are described in the table below.

Default Value	Description
'a string'	The default value of the parameter is 'a string'. The string has to be enclosed in single quotes because otherwise it is interpreted as the name of a session variable.
ANYVARIABLE	The value of the session variable <code>ANYVARIABLE</code> . <code>ANYVARIABLE</code> can be replaced with the name of any existing session variable that is defined in the session context.

Default Value	Description
APPLICATIONUSER	The name of the end user, for example a SAP user name or operating system user.
CURRENT_DATE	The current date (server time zone, format YYYYMMDD).
LOCALE_ISO2	The two-character language code (as defined by ISO 639-1), taken from the session variable 'LOCALE'. Default value is en if 'LOCALE' is not set.
LOCALE_SAP	The value of the session variable LOCALE_SAP. This variable contains the single byte language code (SAP language code).

3.4.6.8.2 Definition of Alias Names for Parameters

It is possible to define an alias name for a parameter using the annotation `@Search.constraints.Alias`. The client then always uses the alias name that is defined in the search configuration and does not need to know the real name of the function parameter.

One possible use case of alias names is to search in multiple SQL views where the same parameter is defined with different names in the different views. For example, one view may have a parameter called 'country' and a second view may have a parameter called 'countrycode' with both parameters meaning the same (a 2-character language code).

In this case an alias can be defined to pass the parameter only once to `sys.esh_search()` and then to forward it internally to the different parameters of the views.

3.4.6.8.3 Passing Parameters to `sys.esh_search()`

Parameters are defined in a call to `sys.esh_search()` by calling `$all` with function parameters. The pairs of parameter names and parameter values are added, as shown below.

Additional parameters, that are not used in a view definition, can be given in the call to `sys.esh_search()`. For each view only the parameters that are needed are used and all other parameters are ignored.

☰ Sample Code

```
-- call without parameters
[ { "URI": [ "/v20401/$all?$top=10&..." ] } ]

-- call with parameters
[ { "URI": [ "/v20401/$all(parameter1='value1',parameter2='value2')?
$top=10&..." ] } ]
```

3.4.6.8.4 Examples

The following example shows how parameters are defined in the metadata document that describes a search configuration. It is based on the SQL view with parameters.

Sample Code

Definition of the SQL View with Parameters (Repeated)

```
create view vp_customer
(
  in country nvarchar(2),
  in valid   nvarchar(8)
)
as
select c.cust_id, addr_id, name, street, city, country, valid_from, valid_to
from customer c left outer join address a
  on c.cust_id = a.cust_id
  and country = :country
  and valid_from <= to_date(:valid, 'YYYYMMDD') and valid_to >=
to_date(:valid, 'YYYYMMDD');
```

Sample Code

Configuration Example for SQL View with Parameters

```
[
  {
    "uri": "~/metadata/EntitySets",
    "method": "PUT",
    "content": {
      "@Search.constraints": [
        {
          "Name": "COUNTRY",
          "Alias": "country_code",
          "DefaultValue": "'DE'"
        },
        {
          "Name": "VALID",
          "Alias": "valid_at",
          "DefaultValue": "CURRENT_DATE"
        }
      ],
      "Fullname": "SAMPLE/VP_CUSTOMER",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          {
            "@EnterpriseSearch.key": true,
            "@EnterpriseSearch.presentationMode": [
              "TITLE"
            ],
            "Name": "CUST_ID"
          },
          {
            "@Search.defaultSearchElement": true,
            "@EnterpriseSearch.presentationMode": [
              "TITLE"
            ],
            "Name": "NAME"
          }
        ]
      }
    }
  }
]
```

```

        "@Search.defaultSearchElement": true,
        "Name": "STREET"
    },
    {
        "@Search.defaultSearchElement": true,
        "@EnterpriseSearch.filteringFacet.default": true,
        "Name": "CITY"
    }
]
}
}
]

```

Sample Code

Example Call to sys.esh_search()

```

-- use default values of parameters
call esh_search('[ { "URI": [ "/v20401/SAMPLE/$all?$top=10&
$filter=Search.search(query='SCOPE:vp_customer abc')" ] } ]', ?);

-- define parameter values in call to esh_search()
call esh_search('[ { "URI": [ "/v20401/SAMPLE/
$all(country_code='US',valid_at='20180506')?$top=10&
$filter=Search.search(query='SCOPE:vp_customer abc')" ] } ]', ?);

```

Sample Code

3.5 Modeling With Attribute Views

To create search models with attribute views, use search-specific properties in the SAP HANA modeler.

Context

In the SAP HANA modeler, create an attribute view of type standard using the tables that you want to enable for the search. Create joins and add the attributes you want to use for searching and displaying. You can also join additional attributes derived from the text analysis.

⚠ Caution

If your business object contains attributes with a 1:n relationship, for example, customer with more than one address joined in from an address table, note the following: If you are using such an attribute as a response attribute for your UI, the same customer might show up several times in the result list and thus, the result count might deviate from the actual number of results.

When activating the view, do not enable or apply any analytic privilege. The user access to search views must be restricted using object privileges instead. For more information, see section *Authorizations for SAP HANA Info Access Users*.

To configure the search methods for certain attributes, proceed as follows:

Procedure

1. In the *Output* pane, select the attributes.
2. In the *Properties* view, choose *Search Properties*.
3. For text attributes, set the *Freestyle Search* property to true (default for text attributes).

The values of these attributes are searched using a special method for natural text. You get hits based on single words or parts of words.

Note

This setting is only relevant for search queries. Queries to retrieve suggestions while the user is typing always use all full-text indices. If you set this property to false, the user might select a suggested search term but does not get a result.

4. Set the *Weights for Ranking* to a value between 0.0 and 1.0 (default 0.5).
This property influences the ranking of items in the results list. The higher the weight of the attribute compared to others in the view, the higher up the list an item with a hit in this attribute is positioned.
5. Decide if you want to enable an error-tolerant search (*Fuzziness* true) or use exact search only (false).
If you are using the fuzzy search, the *Fuzziness Threshold* property defines the grade of error tolerance for a search on this attribute. The higher the threshold, the more exactly the search terms must match the text to produce a result. Set the threshold to one of the predefined values (default 0.8).

4 Accessing Data Using Full-Text Search

You can access your data using either ODATA services or SQL statements.

Context

There are several ways to access your data using full-text search:

- Full-text search with ODATA
Use this option if your search models are based on CDS annotations (XS Classic).
- Federated full-text search with built-in procedure `sys.esh_search()`
Use this option if your search models are defined with the built-in procedure `sys.esh_config()` or if they are based on CDS annotations (XS Advanced).
- Full-text search with SQL
Use this option if you modeled your search models with attribute views.

Related Information

[Full-Text Search with OData \[page 156\]](#)

[Federated Full-Text Search with Built-In Procedure `sys.esh_search\(\)` \[page 161\]](#)

[Full-Text Search with SQL \[page 262\]](#)

4.1 Full-Text Search with OData

You define OData services to your views to execute search requests on the data.

i Note

This chapter is only valid for developments with XS Classic.

As a prerequisite for exposing information via OData to applications using SAP HANA XS Classic, you have to define database views that provide the data you want to search for with the required granularity.

Having defined the views, you can now create an OData service definition. This is a file that you use to specify which database views or tables are exposed as OData collections.

An OData search service for SAP HANA XS is defined in a text file with the file suffix `.xsodata`, for example, `OdataSearch.xsodata`.

The file must contain the entry `service {}`. You use the service definition to expose objects (views) in the database catalog. You have to define the key columns of the view.

Examples for OData service definitions: `OdataSearch.xsodata`

```
service
{
  "develop.mypackage::mypackage.mysqlview" as "mysqlview_search"
  key ("BP_NUMBER", "ADDRESS_NUMBER")
  "develop.bporg::mypackage.mysqlview" as "mysqlview_search_genkey"
  key generate local "GeneratedLocalKey"
}
```

This example file includes two service definitions: `mysearchdef` and `mysearchdef_genkey`.

After you have defined the search services, you can call the services by their OData service URL. As soon as one of the custom query options for search (`search` or `facets`) is part of the URL, the OData service calls the search runtime to create the expected search result.

Examples for OData service calls:

```
http://my-company.com:8000/develop/bporg/bporg.xsodata/bporg?search=electronics&
$format=json&facets=all
```

```
http://my-company.com:8000/develop/bporg/bporg.xsodata/bporg?search=electronics&
$top=10&$format=json&$select=NAME_LAST,NAME_FIRST,SEARCH_TERM
```

```
http://my-company.com:8000/develop/bporg/bporg.xsodata/bporg?search=federal%20OR
%20delta&$top=10&$format=json&$inlinecount=allpages
```

[Custom Query Option 'search' \[page 157\]](#)

[Custom Query Option 'facets' \[page 158\]](#)

[Custom Query Option 'facetlimit' \[page 158\]](#)

[Custom Query Option 'estimate' \[page 159\]](#)

[Custom Query Option 'wherefound' \[page 159\]](#)

4.1.1 Custom Query Option 'search'

The search term that is given with the `search` option is passed to the `CONTAINS ()` predicate.

The syntax of the search term is the syntax that is defined for the `CONTAINS ()` predicate and not the syntax that is defined for the OData version 4 system query option `$search`.

When using the `search` option on a CDS view with `@Search` annotations, the search properties defined with these annotations are used.

When using the `@EnterpriseSearch.key` annotation, freestyle search is done with query parts, so all rows belonging to the same anchor object are treated as one large object that is searched.

4.1.2 Custom Query Option 'facets'

The `facets` option defines how many facets are calculated.

With the option you can specify the number of facets:

Value	Description
<code>facets=0</code>	No facets are returned. Default, when the option is not given.
<code>facets=n(n>0)</code>	<code>n</code> facets are returned. This always is a subset of the columns marked with the <code>#AUTO_FACET</code> annotation.
<code>facets=all</code>	Facets for all columns marked with the <code>#AUTO_FACET</code> annotation are returned.
<code>facets = column1,column2,...,columnn</code>	Facets for the columns given are returned. All columns have to be marked with the <code>#AUTO_FACET</code> annotation.

For each facet, the top 10 values are returned if the custom query option `facetlimit` is not used.

When using the `@EnterpriseSearch.key` annotation to define the keys of the anchor table, facets count distinct anchor keys instead of counting rows.

i Note

When using facets, you have to specify `$format=json` in the search URI. There is only preliminary support for `$format=atom`.

Related Information

[Custom Query Option 'facetlimit' \[page 158\]](#)

4.1.3 Custom Query Option 'facetlimit'

Defines how many values for each facet are returned.

Value	Description
<code>facetlimit=n</code>	Defines the number of values for each facet to be returned. Default: 10

4.1.4 Custom Query Option 'estimate'

When using this option in combination with `$inlinecount=allpages`, an estimated result count is returned in some cases to reduce response times.

i Note

The option is without effect if facets are requested.

Using `estimate` without `$inlinecount=allpages` returns an error.

Value	Description
<code>estimate=true</code>	The search may return an estimated result count instead of an exact count. This could help to reduce response times.
<code>estimate=false</code>	The search will return an exact result count. Switched off by default.

4.1.5 Custom Query Option 'wherefound'

This option returns the output of the SQL function `WHY_FOUND()` for each row in the response.

The "where found" information is returned as annotation `@com.sap.vocabularies.Search.v1.WhereFound`.

i Note

`wherefound` can only be used if a search term is given using the custom query option `search`.

Value	Description
<code>wherefound=true</code>	Returns the "where found" information.
<code>wherefound=false</code>	Switched off by default.

4.1.6 OData Features and Limitations

System query options can be used in combination with custom query options defined for search, as well as features offered by SAP HANA XS. Certain limitations apply however.

OData Features Supported by Search

The search runtime and the custom query options `search` and `facets` work for OData resource paths that access a collection. In other words, a valid URI is, for example, `.../<service>.xsodata/<collection>?search=<search term>`.

Optionally, `$count` can be used to count the number of search results (`.../<service>.xsodata/<collection>/<count>?search=<search term>`).

The following OData v2 system query options can be used in combination with the custom query options defined for search:

- `$top`
- `$skip`
- `$format` (facets are supported for `$format=json` only)
- `$select`
- `$filter`
- `$inlinecount`
- `$orderby`

The following XS OData features are supported by the search runtime (see the SAP HANA Developer Guide for a description of these features):

- OData namespace definition
OData key specification (existing key properties and generated local keys).
- OData property projection (when using property projection, all freestyle columns of the database object will be searched, including columns that are not part of the projection).

OData Limitations

The following OData v2 system query options cannot be used in combination with the custom query options defined for search:

- `$expand XS`

The following OData features are not supported by the search runtime (see the SAP HANA Developer Guide for a description of these features):

- OData associations and navigation properties (these can be defined for the XS OData service, but navigation properties cannot be used as part of a search URI)
- OData aggregation

- OData parameter entity sets

The following OData features are not supported:

- `$metadata` does not return metadata for search configuration and facets

4.2 Federated Full-Text Search with Built-In Procedure `sys.esh_search()`

With the built-in procedure `sys.esh_search()`, it is possible to use an existing SQL connection instead of an XS OData service, such as an existing ABAP SQL connection. This means that the customer does not have to configure the http connection, and that any configured search view does not have to be exposed as an OData service, which would make it necessary to create SAP HANA repository objects like `.xsodata`, `.xsapp` and `.xsaccess`. Instead, SQL privileges are used to grant access to the search runtime.

`sys.esh_search()` provides an interface similar to the OData interface available with an XS OData service.

The following example shows the syntax of a search request:

```
call esh_search(' [ "$all?$filter=Search.search(query='mysearchterm')" ]', ?);
```

Note

When calling `esh_search()` in the SQL console of SAP HANA Studio, all single quotes inside the request have to be doubled because they are used inside a SQL string.

4.2.1 Interface of `sys.esh_search()`

With the builtin procedure `sys.esh_search()` all search features are available over a SQL connection. SQL privileges are used to grant access to the search runtime.

The interface of `sys.esh_search()` uses the message format defined in the OData version 4 standard. Therefore it is similar to the previous OData interface available with the XS Classic OData service to get a similar 'look-and-feel' for both interfaces. Differences between `sys.esh_search()` and the XS Classic OData service are that there is no OData service exposed, and that http is not used as transport protocol.

A `NCLOB` container is used to pass one or many search request(s) to the procedure. The response is a table of `NCLOB`s.

The interface of `sys.esh_search()` looks as follows:

Source Code

```
CREATE PROCEDURE sys.esh_search
(
  IN request NCLOB,
  OUT response TABLE ( response NCLOB )
)
```

```
AS BUILTIN;
```

4.2.1.1 Error Handling

If the request object does not contain a valid JSON array, a SQL exception is returned.

Examples of errors that can occur are a malformed JSON or missing "uri", "method", or "content" elements.

For a federated search request, the following types of errors can occur:

Search Request cannot be processed

If the search request is malformed and cannot be processed, an error message similar to the following will be returned:

Source Code

```
{
  "error":{
    "code": "9620044",
    "message": "exception 9620044: Function call all() not allowed in
federation"
  }
}
```

Search Request cannot be processed for one or a few Views

If a federated search can be processed for most but not all views, the `@com.sap.vocabularies.Search.v1.SearchStatistics` annotation of the search response will contain information for each individual view in which an error occurred:

Source Code

```
{
  "value": [...],
  "@com.sap.vocabularies.Search.v1.SearchStatistics":{
    "ConnectorStatistics":[
      {
        "Name":"CUSTOMER",
        "Schema":"VIEW1",
        "StatusCode":200
      },
      {
        "Name":"COMPANY",
        "Schema":"VIEW1",
        "StatusCode":500,
        "error":{
          "code":"9620042",
          "message":"exception 9620042: attribute 'firstname' does not exist
in view 'COMPANY'"
        }
      }
    ]
  }
}
```

4.2.1.2 API Version Information

You can get the current API version of the Enterprise Search API by calling `sys.esh_search()`.

Sample Code

Get API Version with `sys.esh_search()`

```
call esh_search('[ { "URI": [ "$apiversion" ] } ]', ?);
```

The api version is returned in the output of `esh_search()` as an integer number, as shown in the following example.

Sample Code

API Version Returned by `sys.esh_search()`

```
{
  "apiversion": 20410
}
```

4.2.2 Method 'GET' - `/$metadata` Call

Similar to OData it is possible to get the metadata of all views that are 'visible' to the user. As a result of a metadata call the caller gets back the metadata for all views the current user is allowed to search. This includes all views that fulfill all of the following conditions:

1. The user has the `SELECT` privilege on the view.
2. The view is marked as `@EnterpriseSearch.searchable: true` in the configuration.

The metadata call is done by passing the URI `/$metadata` to `sys.esh_search()` as shown in the following example:

Sample Code

```
call esh_search('[ { "URI": [ "$metadata" ] } ]', ?);
```

4.2.2.1 Reading Metadata for one Schema Only

It is also possible to get the metadata for a single schema by only using the URI `/<SCHEMA_NAME>/$metadata`, as shown below for schema 'AWARDS'.

Sample Code

```
sys.esh_search()

call esh_search('[ { "URI": [ "/AWARDS/$metadata" ] } ]', ?);
-- with version number
call esh_search('[ { "URI": [ "/v5/AWARDS/$metadata" ] } ]', ?);
```

4.2.2.2 Version-Dependent Features of Metadata and Handling of Incompatible Changes

With newer versions of SAP HANA, the metadata information may be changed in a way that is incompatible with previous versions. To avoid existing applications failing, the new metadata information is available only if an application explicitly calls the new version of the `sys.esh_search()` API.

Sample Code

Metadata Call in the SQL Console

```
call esh_search('[ "$metadata" ]', ?);
```

The following table shows incompatible metadata features added with newer esh API versions:

ESH Version	Feature	Description
5	Spatial data types	Metadata for columns of SQL type <code>ST_POINT</code> and <code>ST_GEOMETRY</code> is returned.

ESH Version	Feature	Description
5	Annotation changes	<p>Annotations <code>@EnterpriseSearch.filteringFacet</code> and <code>@EnterpriseSearch.defaultValueSuggestElement</code> are returned instead of the deprecated annotation <code>@EnterpriseSearch.usageMode</code>.</p> <p>Annotation <code>@EnterpriseSearchHana.weight</code> is returned even if the ranking weight is given with the annotation <code>@Search.ranking</code>.</p> <p>Annotation <code>@EnterpriseSearchHana.uiResource.label</code> is returned if defined in the search configuration.</p>
5	New annotation	<p>Annotation <code>@EnterpriseSearchHana.supportsTextSearch</code> is returned for all columns that support a full-text search.</p>
6	New annotation	<p>Annotation <code>@EnterpriseSearchHana.isSortable</code> is returned for all columns that have a SQL type that is sortable.</p>
20401	Boolean data type	<p>Metadata for columns of SQL type <code>BOOLEAN</code> is returned.</p>

The following example shows a metadata call to `sys.esh_search()` that uses all new features of API version 6.

Sample Code

Metadata Call in the SQL Console

```
call esh_search('[ { "URI": [ "/v6/$metadata" ] } ]', ?);
```

The example below shows how to call `sys.esh_search()` with features of API version 3 (plus additional compatible changes introduced by later versions).

4.2.2.3 OData Identifiers

Each searchable view is returned as an entity set and an entity type in the \$metadata document.

The name of the entity set equals the odata identifier for the view. The name of the entity type is derived from the odata identifier (by adding the suffix `Type`).

By default, the odata identifier is calculated using the name of the "real" database object based on the following rules:

1. Schema names are ignored.
2. Package name and context are removed from CDS view names.
Example: the OData identifier of CDS view "p1.p2.p3::ctxt.myView" is "myView"
3. All characters that are not allowed in an OData identifier are removed.
Example: the OData identifier of ESH view "S_ARTICLE_H~~ARTICLE" is "S_ARTICLE_HARTICLE"

For a definition of valid characters for OData identifiers, see "odataidentifier" in the OData v4 ABNF construction rules.

Alternatively, the Odata identifier can be defined in the search configuration by using the annotation `@EnterpriseSearchHana.identifier`.

4.2.2.4 Anchor Key Definition and Data Type Information

The metadata call returns the EDM types of all columns. The mapping of SQL types to EDM types is shown in the metadata example below.

- A property, named `C_DATATYPE` in this example, is defined using SQL type `DATATYPE`.
 - `C_ST_POINT_XXXX` and `C_ST_GEOMETRY_XXXX` use SQL type `ST_POINT` and `ST_GEOMETRY` with the spatial reference identifier `XXXX`.
- The data type mapping includes properties for `type`, `maxLength`, `precision`, `scale`, and `spatial reference identifier (SRID)`.
- Columns that are defined as `NOT NULL` get the property `Nullable="false"`.
- Columns that define a default value get the property `DefaultValue`.

The section `<Key>` contains the columns of the anchor key.

Sample Code

Mapping of SQL Types

```
<?xml version="1.0" encoding="UTF-8"?>
<edmx:Edmx xmlns:edmx="http://docs.oasis-open.org/odata/ns/edmx"
Version="4.0">
  <edmx:DataServices>
    <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
      <EntityType Name="myviewType">
        <Key>
          <PropertyRef Name="ID_INTEGER" />
        </Key>
        <Property Name="ID_INTEGER" Type="Edm.Int32" Nullable="false" />
      </EntityType>
    </Schema>
  </edmx:DataServices>
</edmx:Edmx>
```

```

    <Property Name="C_VARCHAR" Type="Edm.String" DefaultValue="abc"
MaxLength="100" />
    <Property Name="C_NVARCHAR" Type="Edm.String" Nullable="false"
MaxLength="100" />
    <Property Name="C_ALPHANUM" Type="Edm.String" MaxLength="10" />
    <Property Name="C_SHORTTEXT" Type="Edm.String" MaxLength="100" />
    <Property Name="C_VARBINARY" Type="Edm.Binary" />
    <Property Name="C_TINYINT" Type="Edm.Byte" />
    <Property Name="C_SMALLINT" Type="Edm.Int16" />
    <Property Name="C_INTEGER" Type="Edm.Int32" />
    <Property Name="C_BIGINT" Type="Edm.Int64" />
    <Property Name="C_SMALLDECIMAL" Type="Edm.Decimal" Precision="16" />
    <Property Name="C_DECIMAL" Type="Edm.Decimal" Precision="34" />
    <Property Name="C_DECIMAL_5_4" Type="Edm.Decimal" Precision="5"
Scale="4" />
    <Property Name="C_DECIMAL_34_0" Type="Edm.Decimal" Precision="34"
Scale="0" />
    <Property Name="C_DECIMAL_34_33" Type="Edm.Decimal" Precision="34"
Scale="33" />
    <Property Name="C_REAL" Type="Edm.Single" />
    <Property Name="C_DOUBLE" Type="Edm.Double" />
    <Property Name="C_DATE" Type="Edm.DateTime" />
    <Property Name="C_TIME" Type="Edm.Time" />
    <Property Name="C_SECONDDATE" Type="Edm.DateTime" />
    <Property Name="C_TIMESTAMP" Type="Edm.DateTime" />
    <Property Name="C_BLOB" Type="Edm.Binary" />
    <Property Name="C_CLOB" Type="Edm.String" MaxLength="2147483647" />
    <Property Name="C_NCLOB" Type="Edm.String" MaxLength="2147483647" />
    <Property Name="C_TEXT" Type="Edm.String" MaxLength="2147483647" />
    <Property Name="C_BINTEXT" Type="Edm.String" MaxLength="2147483647" />
    <Property Name="C_BOOLEAN" Type="Edm.Boolean" />
    <Property Name="C_ST_POINT_4326" Type="Edm.GeographyPoint"
SRID="4326" />
    <Property Name="C_ST_POINT_1000004326" Type="Edm.GeometryPoint"
SRID="1000004326" />
    <Property Name="C_ST_GEOMETRY_4326" Type="Edm.GeographyPoint"
SRID="4326" />
    <Property Name="C_ST_GEOMETRY_1000004326" Type="Edm.GeometryPoint"
SRID="1000004326" />
  </EntityType>
  <EntityContainer Name="esh">
    <EntitySet Name="myview" EntityType="esh.myviewType" />
  </EntityContainer>
</Schema>
</edmx:DataServices>
</edmx:Edmx>

```

i Note

From request version v20409 and above, the output types are aligned to the OData specification. So the following call would create a different output:

Sample Code

```
call esh_search(['v20409/$metadata' ], ?);
```

Sample Code

```

<?xml version="1.0" encoding="UTF-8"?>
<edmx:Edmx xmlns:edmx="http://docs.oasis-open.org/odata/ns/edmx"
Version="4.0">
  <edmx:DataServices>

```

```

<Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
  <EntityType Name="myviewType">
    <Key>
      <PropertyRef Name="ID_INTEGER" />
    </Key>
    ...
    <Property Name="C_DATE" Type="Edm.Date" />
    <Property Name="C_TIME" Type="Edm.TimeOfDay" />
    <Property Name="C_SECONDDATE" Type="Edm.DateTimeOffset" />
    <Property Name="C_TIMESTAMP" Type="Edm.DateTimeOffset" />
    ...
  </EntityType>
  <EntityContainer Name="esh">
    <EntitySet Name="myview" EntityType="esh.myviewType" />
  </EntityContainer>
</Schema>
</edm:DataServices>
</edm:Edmx>

```

4.2.2.5 Search Annotations

For each property of an entity type, the values of the search annotations are returned as defined in the search model.

In addition to the annotations described for `sys.esh_config()` and CDS, the following annotations are returned by the metadata service. These annotations cannot be used with `sys.esh_config()` or CDS:

Annotation	Values	Description
(Deprecated) <code>EnterpriseSearch.displayOrder</code>	integer ≥ 0	<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>Deprecated Annotation</p> <p>Beginning with API version 20407, the annotation <code>@UI.identification.position</code> shall be used instead.</p> </div> <p>The display order defines the order of the columns the UI will use to display a search result.</p> <p>For configurations defined with <code>sys.esh_config()</code>, the value of the corresponding annotation used in the <code>sys.esh_config()</code> call is returned.</p> <p>For configurations defined using CDS, the display order is defined by the sequence of the columns in the view definition.</p>
<code>EnterpriseSearchHana.isSortable</code>	true, false	true, if a column has a SQL type that is sortable
<code>EnterpriseSearchHana.supportsTextSearch</code>	true, false	true, if a column supports full-text search.
<code>SAP.Common.Label</code>	string	<p>Label for a column name.</p> <p>This annotation is always returned for all columns of the view. By default it contains the column name.</p> <p>If translations are stored in the configuration using the <code>@EnterpriseSearchHana.translation</code> annotation, the <code>@SAP.Common.Label</code> annotation may contain a translated text. Translated texts are available beginning with API version 20411.</p>

The following example shows a metadata document that contains annotations:

Sample Code

Metadata Document with Search Annotations

```
<?xml version="1.0" encoding="UTF-8"?>
<edm:Edmx xmlns:edm="http://docs.oasis-open.org/odata/ns/edm"
Version="4.0">
  <edm:Reference Uri="http://vecocomst.dhcp.wdf.sap.corp:1080/coco/
vocabularies/Common.xml">
    <edm:Include Alias="SAP.Common"
Namespace="com.sap.vocabularies.Common.v1"/>
  </edm:Reference>
  <edm:Reference Uri="http://xyz.dhcp.wdf.sap.corp:1080/coco/vocabularies/
Search.xml">
    <edm:Include Alias="Search" Namespace="com.sap.vocabularies.Search.v1"/>
  </edm:Reference>
  <edm:Reference Uri="http://xyz.dhcp.wdf.sap.corp:1080/coco/vocabularies/
EnterpriseSearch.xml">
    <edm:Include Alias="EnterpriseSearch"
Namespace="com.sap.vocabularies.EnterpriseSearch.v1"/>
  </edm:Reference>
  <edm:DataServices>
    <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
      <EntityType Name="awardsType">
        <Annotation Term="Search.searchable" Bool="true" />
        <Annotation Term="EnterpriseSearch.enabled" Bool="true" />
        <Key>
          <PropertyRef Name="id" />
        </Key>
        <Property Name="id" Type="Edm.Int32" Nullable="false">
          <Annotation Term="SAP.Common.Label" String="id" />
          <Annotation Term="EnterpriseSearch.displayOrder" Int="0" />
          <Annotation Term="EnterpriseSearch.key" Bool="true" />
          <Annotation Term="EnterpriseSearch.presentationMode">
            <Collection>
              <String>TITLE</String>
            </Collection>
          </Annotation>
          <Annotation Term="EnterpriseSearchHana.isSortable" Bool="true" />
        </Property>
        <Property Name="abstract" Type="Edm.String" MaxLength="2147483647">
          <Annotation Term="SAP.Common.Label" String="abstract" />
          <Annotation Term="EnterpriseSearch.displayOrder" Int="2" />
          <Annotation Term="EnterpriseSearch.presentationMode">
            <Collection>
              <String>TITLE</String>
            </Collection>
          </Annotation>
          <Annotation Term="Search.defaultSearchElement" Bool="true" />
          <Annotation Term="Search.fuzzinessThreshold" Decimal="0.8" />
          <Annotation Term="EnterpriseSearchHana.supportsTextSearch"
Bool="true" />
        </Property>
        <Property Name="title" Type="Edm.String" MaxLength="500">
          <Annotation Term="SAP.Common.Label" String="title" />
          <Annotation Term="EnterpriseSearch.displayOrder" Int="1" />
          <Annotation Term="EnterpriseSearch.presentationMode">
            <Collection>
              <String>TITLE</String>
            </Collection>
          </Annotation>
          <Annotation Term="Search.defaultSearchElement" Bool="true" />
          <Annotation Term="Search.fuzzinessThreshold" Decimal="0.8" />
          <Annotation Term="EnterpriseSearchHana.supportsTextSearch"
Bool="true" />
        </Property>
      </EntityType>
    </Schema>
  </edm:DataServices>
</Edmx>
```

```

    </Property>
  </EntityType>
  <EntityContainer Name="esh">
    <EntitySet Name="awards" EntityType="esh.awardsType">
      <Annotation String="awards" Term="SAP.Common.Label" />
    </EntitySet>
  </EntityContainer>
</Schema>
</edmx:DataServices>
</edmx:Edmx>

```

4.2.2.6 Multi-Values and Subobjects

The following example shows the metadata for multi-values and subobjects:

Sample Code

Metadata for Multi-Values and Subobjects

```

...
  <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
    <EntityType Name="awardsType">
      <Annotation Term="Search.searchable" Bool="true" />
      <Annotation Term="EnterpriseSearch.enabled" Bool="true" />
      <Key>
        <PropertyRef Name="id" />
      </Key>
      <Property Name="id" Type="Edm.Int32" Nullable="false">
        <Annotation Term="SAP.Common.Label" String="id" />
        <Annotation Term="EnterpriseSearch.displayOrder" Int="0" />
        <Annotation Term="EnterpriseSearch.key" Bool="true" />
        <Annotation Term="EnterpriseSearch.presentationMode">
          <Collection>
            <String>TITLE</String>
          </Collection>
        </Annotation>
      </Property>
      ...
      <Property Name="programReferenceText" Type="Collection(Edm.String)"
        MaxLength="100">
        <Annotation Term="SAP.Common.Label" String="programReferenceText" />
        <Annotation Term="EnterpriseSearch.displayOrder" Int="17" />
        <Annotation Term="EnterpriseSearch.presentationMode">
          <Collection>
            <String>DETAIL</String>
          </Collection>
        </Annotation>
      </Property>
      ...
      <Property Name="programElement"
        Type="Collection(esh.programElementType)">
        <Annotation
          Term="EnterpriseSearchHana.layoutStructuredObject.defaultExpand"
          String="ALL" />
      </Property>
      ...
    </EntityType>
    <ComplexType Type="programElementType">
      <Property Name="programElementCode" Type="Edm.String" MaxLength="4"
        Nullable="false">
        <Annotation Term="EnterpriseSearch.displayOrder" Int="15" />

```

```

        <Annotation Term="EnterpriseSearch.presentationMode">
            <Collection>
                <String>DETAIL</String>
            </Collection>
        </Annotation>
        <Annotation Term="EnterpriseSearchHana.layoutStructuredObject.key"
Bool="true" />
    </Property>
    <Property Name="programElementText" Type="Edm.String" MaxLength="100"
Nullable="false">
        <Annotation Term="EnterpriseSearch.displayOrder" Int="16" />
        <Annotation Term="EnterpriseSearch.presentationMode">
            <Collection>
                <String>DETAIL</String>
            </Collection>
        </Annotation>
        <Annotation Term="Search.defaultSearchElement" Bool="true" />
        <Annotation Term="EnterpriseSearchHana.layoutStructuredObject.key"
Bool="true" />
    </Property>
</ComplexType>
<EntityContainer Name="esh">
    <EntitySet Name="awards" EntityType="esh.awardsType">
        <Annotation String="awards" Term="SAP.Common.Label" />
    </EntitySet>
</EntityContainer>
</Schema>
...

```

4.2.2.7 Leveled Hierarchies

The following example shows the metadata for leveled hierarchies.

Sample Code

Metadata for Leveled Hierarchies

```

...
<Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
    <EntityType Name="awardsType">
        <Annotation Term="Search.searchable" Bool="true" />
        <Annotation Term="EnterpriseSearch.enabled" Bool="true" />
        <Key>
            <PropertyRef Name="id" />
        </Key>
        <Annotation Term="Aggregation.LeveledHierarchy"
Qualifier="instLocation">
            <Collection>
                <PropertyPath>instCountry</PropertyPath>
                <PropertyPath>instState</PropertyPath>
                <PropertyPath>instCity</PropertyPath>
            </Collection>
        </Annotation>
        <Annotation Term="Aggregation.LeveledHierarchy"
Qualifier="organization">
            <Collection>
                <PropertyPath>orgDirectorate</PropertyPath>
                <PropertyPath>orgDivision</PropertyPath>
            </Collection>
        </Annotation>
        <Property Name="id" Type="Edm.Int32" Nullable="false">

```

```

    ...
  </Property>
  ...
</EntityType>
...
</Schema>
...

```

4.2.2.8 Field Groups

The following example shows the metadata for field groups.

Sample Code

Metadata for Field Groups

```

...
<Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
  <EntityType Name="awardsType">
    <Annotation Term="Search.searchable" Bool="true" />
    <Annotation Term="EnterpriseSearch.enabled" Bool="true" />
    <Key>
      <PropertyRef Name="id" />
    </Key>
    <Annotation Term="EnterpriseSearch.fieldGroupForSearchQuery">
      <Collection>
        <Record>
          <PropertyValue Property="Name">award</PropertyValue>
          <PropertyValue Property="Elements">
            <Collection>
              <String>abstract</String>
              <String>id</String>
              <String>title</String>
            </Collection>
          </PropertyValue>
        </Record>
        <Record>
          <PropertyValue Property="Name">investigator</PropertyValue>
          <PropertyValue Property="Elements">
            <Collection>
              <String>invEmail</String>
              <String>invFirstName</String>
              <String>invLastName</String>
            </Collection>
          </PropertyValue>
        </Record>
      </Collection>
    </Annotation>
    <Property Name="id" Type="Edm.Int32" Nullable="false">
      ...
    </Property>
    ...
  </EntityType>
  ...
</Schema>
...

```

4.2.2.9 Returning Metadata for more than one View

If the metadata of more than one searchable view is returned, the result contains one '<EntityType>' element and one '<EntitySet>' element for each view. The views may be created in different database schemas, but they are returned from a single call to the \$metadata service.

All views of all database schemas are returned in a single '<Schema>' element. The name given in the '<Schema>' element is not related to the name of the database schema.

Sample Code

Metadata for more than one view

```
<?xml version="1.0" encoding="UTF-8"?>
<edmx:Edmx xmlns:edmx="http://docs.oasis-open.org/odata/ns/edmx"
Version="4.0">
  <edmx:DataServices>
    <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
      <EntityType Name="firstViewType">
        <Key>
          <PropertyRef Name="ID_INTEGER" />
        </Key>
        <Property Name="ID_INTEGER" Type="Edm.Int32" Nullable="false" />
        <Property Name="C_VARCHAR" Type="Edm.String" DefaultValue="abc"
MaxLength="100" />
      </EntityType>
      <EntityType Name="secondViewType">
        <Key>
          <PropertyRef Name="ID_INTEGER" />
        </Key>
        <Property Name="ID_INTEGER" Type="Edm.Int32" Nullable="false" />
        <Property Name="C_VARCHAR" Type="Edm.String" DefaultValue="abc"
MaxLength="100" />
      </EntityType>
      <EntityType Name="anotherViewType">
        <Key>
          <PropertyRef Name="ID_INTEGER" />
        </Key>
        <Property Name="ID_INTEGER" Type="Edm.Int32" Nullable="false" />
        <Property Name="C_VARCHAR" Type="Edm.String" DefaultValue="abc"
MaxLength="100" />
      </EntityType>
    </Schema>
  </edmx:DataServices>
</edmx:Edmx>
```

4.2.2.10 Metadata for Annotations not Related to Search

If the search configuration contains additional annotations that are not used by search, these annotations are copied to the metadata document, as shown in the example below.

The following metadata document shows a search view configuration for products.

Sample Code

```
<?xml version="1.0" encoding="UTF-8"?>
<edmx:Edmx xmlns:edmx="http://docs.oasis-open.org/odata/ns/edmx"
Version="4.0">
  <edmx:DataServices>
    <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">
      <EntityType Name="ProductsType">
        <Annotation Term="Search.searchable" Bool="true" />
        <Annotation Term="EnterpriseSearch.enabled" Bool="true" />
        <Annotation Term="EnterpriseSearchHana.defaultScope"
Bool="true" />
        <Key>
          <PropertyRef Name="ProductUUID" />
        </Key>
        <Annotation Term="EnterpriseSearchHana.uiResource.label.bundle"
String="/sap/search_resourcebundle/resources.properties" />
        <Annotation Term="EnterpriseSearchHana.uiResource.label.key"
String="products" />
        <Annotation Term="UI.headerInfo.description.value"
String="ProductUUID" />
        <Annotation Term="UI.headerInfo.title.value" String="Product" />
        <Property Name="Currency" Type="Edm.String" MaxLength="3">
          <Annotation Term="EnterpriseSearch.filteringFacet.default"
Bool="true" />

</Schema>
</edmx:DataServices>
</edmx:Edmx>

```

4.2.2.11 Multilingual UI Texts

If a search configuration includes multilingual UI text definitions that are created using the `@EnterpriseSearchHana.translation` annotation, the language vector can be passed to the metadata call to define a sequence of preferred languages. In this case, the defined UI texts are returned in the best available language according to the language vector, or in the default language if no text in a suitable language exists.

The metadata call below requests texts in French first. If no French text exists, a German or an English text shall be returned.

Note

The language codes given in the metadata call have to be identical to the language codes stored in the configuration. Otherwise, the text in the default language will be returned.

As a recommendation, applications should follow a naming convention like, for example, two-character language codes (ISO 639-1) followed by two-character country codes (ISO 3166-1).

Sample Code

Metadata Call with Language Vector

```
call esh_search('[ { "URI": [ "/v20411/$metadata" ], "Language": [ "fr_FR",  
"de_DE", "en_US" ] } ]', ?);
```

The metadata output below shows German text (assuming that there are no French translations available).

Sample Code

Metadata Containing Translated Texts

```
<?xml version="1.0" encoding="UTF-8"?>  
<edm:Edmx xmlns:edm="http://docs.oasis-open.org/odata/ns/edm"  
Version="4.0">  
  <edm:DataServices>  
    <Schema xmlns="http://docs.oasis-open.org/odata/ns/edm" Namespace="esh">  
      <EntityType Name="ProductsType">  
        <Annotation Term="Search.searchable" Bool="true" />  
        <Annotation Term="EnterpriseSearch.enabled" Bool="true" />  
        <Key>  
          <PropertyRef Name="ProductUUID" />  
        </Key>  
        <Annotation Term="UI.headerInfo.typeName" String="Produkt" />  
        <Annotation Term="UI.headerInfo.typeNamePlural"  
String="Produkte" />  
        <Property Name="ProductCategory" Type="Edm.String" MaxLength="50">  
          <Annotation Term="SAP.Common.Label" String="Kategorie" />  
          <Annotation Term="Search.defaultSearchElement" Bool="true" />  
        </Property>  
        <Property Name="ShortText" Type="Edm.String" MaxLength="200">  
          <Annotation Term="SAP.Common.Label" String="Beschreibung" />  
          <Annotation Term="Search.defaultSearchElement" Bool="true" />  
        </Property>  
      </EntityType>  
    <EntityContainer Name="esh">  
      <EntitySet Name="Products" EntityType="esh.ProductsType">  
    </EntitySet>  
  </EntityContainer>
```

```
</Schema>
</edm:DataServices>
</edm:Edmx>
```

i Note

If the metadata call is done without a language vector, all texts are returned as default texts. These are the texts that are defined without a language in the `@EnterpriseSearchHana.translation` annotation.

4.2.3 Input Parameter 'request'

The input parameter of the `sys.esh_search` procedure contains a JSON array of JSON objects. Each object in the array defines a search. By adding more than one object to the array it is possible to run many searches in parallel ('bulk request').

Each object in the array contains a URI that defines a search and that is described in the following sections. Optionally, the objects may contain search configurations or a reference to a result table.

i Note

`sys.esh_search()` Interface up to Version 4

The new interface that uses a JSON array of JSON objects has been introduced with API version 5.

Up to API version 4, the input parameter of the `sys.esh_search()` procedure contained a JSON array of strings only. By adding more than one search URL to the array it was possible to run many searches in parallel ('bulk request').

Each string of the array contained a search request in URI format as it is described in the following sections.

Newer versions of `sys.esh_search()` API still support this interface, so there is no need to change existing applications. Nevertheless, it is recommended that new applications use the new interface syntax.

4.2.3.1 Search in a Single View

With `sys.esh_search()`, it is possible to search in a single view.

This is done by searching in the object `'/$all'` with an additional scope parameter that defines the view that is searched.

The example shows how to search for the term 'carbon' in a view called 'awards'.

Sample Code

Call of `sys.esh_search()` in the SQL Console

```
-- Enterprise Search api version 5 and higher
call esh_search('[ { "URI": [ "/v5/$all?&estimate=true&
$top=10&facets=all&$filter=Search.search(query='SCOPE:awards
carbon')" ] } ]', ?);
```

```
-- Enterprise Search api up to version 4
call esh_search('[ "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='SCOPE:awards carbon')" ]', ?);
```

The view is searched if the user has the `SELECT` privilege for this view and if the view is defined with annotation `@EnterpriseSearch.enabled:true`.

4.2.3.2 Federated Search Request over Multiple Views

With `sys.esh_search()`, it is possible to run a federated search over multiple views in a single call.

To search in all available search views, the object `/$all` is used without an additional scope definition.

Example of a federated search request with `esh_search()` in the SQL console:

Sample Code

Federated Search Call in the SQL Console

```
-- Enterprise Search api version 5 and higher
call esh_search('[ { "URI": [ "/v5/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query='carbon')" ] } ]', ?);
-- Enterprise Search api up to version 4
call esh_search('[ "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='carbon')" ]', ?);
```

As no search scope is given, the search is done over all views that the user is allowed to search in.

- Views on which the user has the `SELECT` privilege.
- Views with annotation `@EnterpriseSearch.enabled:true`.
- Views that are not hidden with annotation `@EnterpriseSearchHana.defaultScope:false`.

It is also possible to limit the search scope to a subset of the views that the user is allowed to search in. In this case, the scope parameter contains a list of view names, as shown in the following example, that searches in views `'awards'` and `'documents'`.

Sample Code

Federated Search Call with Scope Definition in the SQL Console

```
-- Enterprise Search api version 5 and higher
call esh_search('[ { "URI": [ "/v5/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query='SCOPE:(awards OR documents)
carbon')" ] } ]', ?);
-- Enterprise Search api up to version 4
call esh_search('[ "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='SCOPE:(awards OR documents) carbon')" ]', ?);
```

If views are hidden with annotation `@EnterpriseSearchHana.defaultScope:false`, it is possible to search in these views by explicitly giving their names in the scope parameter.

4.2.3.3 Bulk Requests

As shown in the examples above, `sys.esh_search()` accepts an array as input parameter. This means that it is possible to execute multiple searches in a single call to the `sys.esh_search()` procedure. This reduces the number of database calls if many searches need to be executed, and it also enables the parallel execution of the search calls.

Sample Code

Bulk Request Call of `sys.esh_search()` in the SQL Console

```
-- Enterprise Search API version 5 and higher
call esh_search(' [ { "URI": [ "/v5/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query='SCOPE:awards
carbon')" ] },
                { "URI": [ "/v5/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query='SCOPE:awards
ocean')" ] },
                { "URI": [ "/v5/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query='SCOPE:documents
carbon')" ] }
                ], ? );

-- Enterprise Search API up to version 4
call esh_search(' [ "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='SCOPE:awards carbon')",
                  "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='SCOPE:awards ocean')",
                  "/v4/$all?$count=true&estimate=true&$stop=10&facets=all&
$filter=Search.search(query='SCOPE:documents carbon')"
                  ], ? );
```

4.2.3.4 Parallel Execution Limits

It is possible to limit the degree of parallelization within the `sys.esh_search()` procedure as it is possible with any other search call. Options to limit the number of parallel threads are database configuration parameters like `max_concurrency`, `max_concurrency_hint`, or `default_statement_concurrency_limit`. Another option is to define a workload class that limits the degree of parallelization.

In case of a federated search or a bulk request, `sys.esh_search()` executes many searches. There is one search for every view in the search scope for each element of a bulk request. These searches are executed in parallel, but the number of parallel search jobs is limited as defined by the database configuration.

Within each search job, there is again a number of threads started to execute several parts of the search in parallel. The number of these threads is again limited by the same parameters.

If, for example, the number of parallel jobs is limited to n , there are at most n searches in different views running in parallel. Each of these searches will again start at most n threads that run in parallel. As a result, the call to `sys.esh_search()` uses at most $n*n$ threads to execute a search.

4.2.3.5 Limit Search to one Schema

You can limit the search call to a single schema.

If a user has `SELECT` privileges for search views of multiple applications that are installed in multiple schemas, the user may want to limit the search to a single schema to only search in views that belong to a specific application. Or there may be conflicts because views in different schemas use the same name, and as a result the search call fails with an error.

In these cases, it is possible to limit the search call to a single schema only. The object `'/<SCHEMA_NAME>/$all'` is used to specify the schema, as shown in the example below that searches in schema 'AWARDS' only.

Sample Code

Search in one Schema Only

```
call esh_search('[ { "URI": [ "/v5/AWARDS/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query=''carbon'')" ] } ]', ?);
call esh_search('[ { "URI": [ "/v5/AWARDS/$all?$count=true&estimate=true&
$stop=10&facets=all&$filter=Search.search(query=''SCOPE:(awards OR documents)
carbon'')" ] } ]', ?);
```

4.2.3.6 Escaping

When building the search request, some special characters have to be escaped to get a valid function call to `sys.esh_search()`.

Query Language Escaping

The search expression entered by the user may contain characters that have a special meaning in the query language specification (like, for example, an asterisk). Make sure that users know about these characters and use the appropriate escape characters defined in the query language specification, if needed.

URL Encoding

The search requests passed to `esh_search()` use the URL format. Therefore a URL encoding is needed to pass special characters to the request.

The most important characters that need an URL encoding are " (%22), % (%25), + (%2B), ? (%3F), and & (%26). Optional encodings are ' (%27), \ (%5C) and space (%20).

JSON Escaping

The JSON escaping only has to be done if you did not URL encode the relevant characters.

The URL encoded search URLs are added to a JSON array of strings to do the call. To get a valid JSON array of strings all backslashes and double quotes within the search URL have to be escaped according to the JSON specification.

This means that a backslash (\) have to be replaced by two backslashes (\\) if you did not URL encode it as %5C.

Double quotes have to be URL encoded as %22, so there should be no double quotes (") remaining that have to be replaced by a backslash followed by a double quote (\").

SQL Escaping

It is recommended to pass the 'request' parameter to `sys.esh_search()` as a bind parameter to avoid SQL injection errors.

If the input parameter is directly written to the procedure call (to do a call in HANA Studio, for example), all single quotes within the 'request' parameter have to be escaped according to the SQL specification.

Therefore all single quotes (') have to be replaced by two single quotes (").

Example

The end user wants to search for

abcd?

Query language encoding: As '?' is a wildcard character, the question mark has to be escaped. This means that the user enters the search term **abcd\?**

URL encoding: The UI creates the URL format of the search request. The question mark has to be URL encoded as %3F. The resulting URL is

```
/v4/$all?$top=10&$filter=Search.search(query='SCOPE:awards "abcd\%3F"')
```

JSON escaping: The URL is added to a JSON array that is used as an input to `sys.esh_search()`. Inside the JSON string the backslash has to be written as '\\ ' and double quotes have to be written as '\"'. The resulting JSON object is

```
[ "/v4/$all?$top=10&$filter=Search.search(query='SCOPE:awards \"abcd\\%3F\"') " ]
```

SQL escaping: If the call to `sys.esh_search()` is done using a bind parameter, SQL escaping is not needed. If the JSON array is copied to the SQL statement, the single quotes inside the SQL string have to be written as two single quotes. The resulting SQL statement is

```
call esh_search(' [ { "URI": [ "/v4/$all?$top=10&$filter=Search.search(query='\'SCOPE:awards \"abcd\\%3F\\\'') \" ] } ]', ?);
```

4.2.4 Output Parameter 'response'

The built-in procedure returns the search results in OData version 4 JSON format.

The response is returned as a table that contains one line for each URI that has been given in the request parameter. The order of the rows in the response is the same as the order of the URIs in the request.

Each row in the response contains either the search results in OData JSON format or an error message in JSON format.

Only metadata needed by search applications is returned. So a minimal set of OData metadata annotations is created.

Related Information

[Response of a Federated Search \[page 184\]](#)

4.2.5 Response of a Federated Search

The search response of a federated search is returned in OData format. It contains the search results from all views in a single result list.

Example of a federated search response:

Source Code

        ],
        "StatusCode": 200
    }
}

```

4.2.5.1 Annotations in the Search Response

The following annotations are returned in the search response.

i Note

Version-dependent Implementation: Column Names

Most of the following annotations reference column names. The behavior of these annotations changes if the search call is done for API version '/v20411' or higher.

If a column is used as an identifier (see annotation `@EnterpriseSearchHana.identifier`), then the identifier is returned instead of the real column name.

If a column is part of a subobject, then the subobject path is added as a prefix to the column name or column identifier.

Example:

```
"@com.sap.vocabularies.Search.v1.WhereFound": "<TERM>colorado</
TERM><FOUND>institution/Name</FOUND>"
```

instead of

```
"@com.sap.vocabularies.Search.v1.WhereFound": "<TERM>colorado</
TERM><FOUND>instName</FOUND>"
```

Annotation	Description	Example
CPUTime	<p>The active CPU time of a search in a single view in seconds, returned as part of the connector statistics.</p> <div data-bbox="603 477 986 1025" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>The active CPU time is accounted from user space. This is less precise, especially on systems with # active threads > # cpu cores, but doesn't add overhead.</p> <p>Currently, the CPU time returned in the search response can be less than the CPU time that is actually needed to complete a search. The difference between the measured CPU time and the real CPU time depends on the query that is executed.</p> </div>	<pre>@com.sap.vocabularies.Search.v1.CPUTime": 3.4567</pre>
Facet	<p>Defines the properties of a facet.</p> <p>URI: Currently always empty.</p> <p>PropertyName: The name of the facet column.</p> <p>PropertyType: The edm data type of the facet column.</p> <p>FilterProperty: The name of the facet column.</p>	<div data-bbox="1007 1066 1385 1527" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p>Sample Code</p> <pre>@com.sap.vocabularies.Search.v1.Facet": { "URI": "", "Dimensions": [{ "PropertyName": "aColumn", "PropertyType": "Edm.String", "FilterProperty": "aColumn" }] }</pre> </div>

Annotation	Description	Example
Facets	Contains the result lists of a facet column.	<div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p>☰ Sample Code</p> <pre> "@com.sap.vocabularies.Search.v1.Facets": [{ "@com.sap.vocabularies.Common.v1.Label": "Count by aColumn", "@odata.context": "\$metadata#Collection(Edm.EntityType)", "@com.sap.vocabularies.Search.v1.Facet": { ... (see below) }, "Items": [{ "@odata.id": null, "aColumn": "abc", "_Count": 98 }, { "@odata.id": null, "aColumn": "xyz", "_Count": 35 }, ...] }, ...] </pre> </div>
Label	<p>The text to be displayed. The example returns:</p> <ol style="list-style-type: none"> A heading for the facet list The display value of a single item in the facet list 	<ol style="list-style-type: none"> <pre> "@com.sap.vocabularies.Common.v1.Label": "XYZ" </pre> <pre> "Column1@com.sap.vocabularies.Common.v1.Label": "YYY" </pre>
Language	For a language-dependent column, this annotation returns the language code as it is stored in the corresponding language code column.	<pre> "Column1@com.sap.vocabularies.Search.v1.Language": "en" </pre>

Annotation	Description	Example
<code>odata.context</code>	In a federated search request over multiple views, each item in the search result may belong to a different view. For each of the search results, this annotation contains the OData identifier of the corresponding view.	<code>"@odata.context": "\$metadata#AWARDS"</code>
<code>odata.count</code>	Contains the overall number of anchor objects in the search result.	<code>"@odata.count": 485</code>
Ranking	The ranking value, output of the <code>SCORE ()</code> function, returned for each item in the result.	<code>"@com.sap.vocabularies.Search.v1.Ranking": 0.75</code>
ResponseTime	The response time of a search in seconds, returned for each element of a bulk request.	<code>"@com.sap.vocabularies.Search.v1.ResponseTime": 0.0143</code>
SearchStatistics	<p>Contains information regarding the status of the search.</p> <p>ConnectorStatistics: For each view that has been searched, the name of the database object, the runtime, the active CPU time, error and warning messages, and a status code are returned.</p> <p>Messages: Error and warning messages not related to a single view are returned.</p> <p>StatusCode: The overall status code of the search.</p>	<p>☰ Sample Code</p> <pre>"@com.sap.vocabularies.Search.v1.SearchStatistics": { "ConnectorStatistics": [...], "Messages": [...], "StatusCode": 200 }</pre>
WhereFound	<p>The output of the <code>WHY_FOUND ()</code> function, returned for each item in the result, if a freestyle search had been called and if <code>wherefound=true</code> had been given.</p> <p>The <code>wherefound</code> information shows which search term was found in which column of the search view.</p>	<p>☰ Sample Code</p> <pre>"@com.sap.vocabularies.Search.v1.WhereFound": "<TERM>2016/< TERM><FOUND>abstract< /FOUND><TERM>carbon</ TERM><FOUND>abstract< /FOUND><FOUND>title</ FOUND>"</pre>

Annotation	Description	Example
WhyFound	For each object in the search results, the whyfound annotation contains a snippet for each of the columns that are mentioned in the wherefound information.	<pre> @com.sap.vocabularies.Search.v1.WhyFound : { "abstract": ["... a detailed history of atmospheric elemental carbon (EC) concentrations for a site ... Whiteface Mt., NY between 2011 and 2016. These filters along with archived ..."], "title": ["... Sediments as Records of Atmospheric Elemental Carbon"] } </pre>

4.2.5.1.1 @com.sap.vocabularies.Search.v1.Ranking

The SCORE () is returned in the result list if a search is performed using Search.search(query=<searchterm>) with a non-empty search term.

4.2.5.2 Snippets and Highlighted Text

Snippets and highlighted text are returned using the annotations <columnname>@com.sap.vocabularies.Search.v1.Snippets and <columnname>@com.sap.vocabularies.Search.v1.Highlighted.

A snippet contains either short text fragments that include any of the search terms or, if no search term has been found in the column, a text fragment showing the first few words of the text.

The highlighted text always contains the complete text of the column, with highlighted search terms that have been found in the column.

☰ Sample Code

Search Response Containing Snippets and Highlighted Text

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9246466,
      "id": 1535764,
      "abstract@com.sap.vocabularies.Search.v1.Snippets": "The dissolved
organic <b>carbon</b> (DOC) in the world ocean ... system through its
connection with atmospheric <b>carbon</b> dioxide. Keeping track of this ...",
      "title@com.sap.vocabularies.Search.v1.Highlighted": "Preparation and
Distribution of Dissolved Organic <b>Carbon</b> Consensus Reference
Materials",
      ...
    },
    ...
  ]
}

```

4.2.5.3 Multi-Value Columns

Multi-value columns are columns that contain more than one value for each anchor object and that come from a 1:n join.

The following example shows a search response, where the 'programReferenceText' for object 1234567 contains four different values. These are returned as a JSON array.

NULL values within a multi-value column are not returned.

Sample Code

Example of a search response containing a multi-value column

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.990905,
      "id": 1234567,
      "title": "Postdoctoral Fellowship in Biology",
      "programReferenceText": [
        "ARCTIC RESEARCH",
        "INTERDISCIPLINARY PROPOSALS",
        "ENVIRONMENTAL CHEMISTRY",
        "WATER RESOURCES/COASTAL & MARINE ENVIRON"
      ],
      ...
    },
    ...
  ]
}

```

If snippets or highlighting are enabled for a multi-value column, the snippets or highlighted text are also returned as a JSON array.

Sample Code

Search Response Containing Snippets for a Multi-Value Column

```

{
  "value": [

```

```

    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.990905,
      "id": 1234567,
      "title": "Postdoctoral Fellowship in Biology",
      "programReferenceText@com.sap.vocabularies.Search.v1.Snippets": [
        "ARCTIC RESEARCH",
        "INTERDISCIPLINARY PROPOSALS",
        "<b>ENVIRONMENTAL</b> CHEMISTRY",
        "WATER RESOURCES/COASTAL & MARINE <b>ENVIRON</b>"
      ],
      ...
    },
    ...
  ]
}

```

4.2.5.4 Subobjects

Subobjects are defined as a group of columns that define an object, for example the first name and last name of a person or the address of a company.

The object can occur more than once for each anchor object, so subobjects are similar to multi-values and are also joined as a 1:n join. Subobjects are returned as a JSON array that contains a complex type, as shown in the example below.

Subobjects that contain NULL in all columns are not returned.

The example shows a search response containing subobjects for investigators that are defined as first name, last name, email address, and role of a person.

Sample Code

Example of a search result containing subobjects

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9957994,
      "id": 1523821,
      "title": "Postdoctoral Fellowship in Biology",
      "investigator": [
        {
          "invFirstName": "Julie",
          "invLastName": "Armstrong",
          "invEmail": "jarmstrong@...",
          "invRole": "Co-Principal Investigator"
        },
        {
          "invFirstName": "Richard",
          "invLastName": "Wilson",
          "invEmail": "rwilson@...",
          "invRole": "Co-Principal Investigator"
        },
        {
          "invFirstName": "Michel",
          "invLastName": "Leclercq",
          "invEmail": "michel.l@...",
          "invRole": "Principal Investigator"
        }
      ]
    },
    ...
  ]
}

```

```

    ...
  },
  ...
]
}

```

If a subobject definition uses option 'defaultExpand' set to 'ALL', the search response contains all subobjects of each anchor object.

If a subobject definition uses option 'defaultExpand' set to 'WHY_FOUND', the search response contains only the subobjects of the anchor object that contain at least one of the search terms.

If snippets or highlighting are enabled for a column of a subobject, the snippet or highlighted text is returned for each sub-object as part of the JSON array.

☰ Sample Code

Search Result Containing Highlighting for a Subobject Column

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9957994,
      "id": 1523821,
      "title": "Postdoctoral Fellowship in Biology",
      "investigator": [
        {
          "invFirstName": "Julie",
          "invLastName": "Armstrong",
          "invEmail": "jarmstrong@...",
          "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal
<b>Investigator</b>"
        },
        {
          "invFirstName": "Richard",
          "invLastName": "Wilson",
          "invEmail": "rwilson@...",
          "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal
<b>Investigator</b>"
        },
        {
          "invFirstName": "Michel",
          "invLastName": "Leclerq",
          "invEmail": "michel.l@...",
          "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Principal
<b>Investigator</b>"
        }
      ],
      ...
    },
    ...
  ] f
}

```

If the configuration of a subobject contains other subobjects, these subobjects are returned within the surrounding subobject. The following example assumes that a subobject 'institution' is defined that embeds another subobject called 'investigator'.

Sample Code

Search Result for a Subobject that Contains Another Subobject

```
{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9957994,
      "id": 1523821,
      "title": "Postdoctoral Fellowship in Biology",
      "institution": [
        {
          "instName": "A University",
          "instCountry": "United States",
          "investigator": [
            {
              "invFirstName": "Julie",
              "invLastName": "Armstrong",
              "invEmail": "jarmstrong@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
            },
            {
              "invFirstName": "Richard",
              "invLastName": "Wilson",
              "invEmail": "rwilson@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
            },
            {
              "invFirstName": "Michel",
              "invLastName": "Leclerq",
              "invEmail": "michel.l@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Principal <b>Investigator</b>"
            }
          ]
        },
        ...
      ],
      ...
    }
  ]
}
```

If the search is done for API version '/v20411' or higher and if the columns of the subobjects are defined with identifiers (see annotation `@EnterpriseSearchHana.identifier`), the column identifiers will be returned instead of the real column names, as shown in the following example.

Sample Code

Search Result for Nested Subobjects with Column Identifiers

```
{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9957994,
      "id": 1523821,
      "title": "Postdoctoral Fellowship in Biology",
      "institution": [
        {
          "Name": "A University",
          "Country": "United States",
          "investigator": [
            {
              "invFirstName": "Julie",
              "invLastName": "Armstrong",
              "invEmail": "jarmstrong@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
            },
            {
              "invFirstName": "Richard",
              "invLastName": "Wilson",
              "invEmail": "rwilson@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
            },
            {
              "invFirstName": "Michel",
              "invLastName": "Leclerq",
              "invEmail": "michel.l@...",
              "invRole@com.sap.vocabularies.Search.v1.Highlighted": "Principal <b>Investigator</b>"
            }
          ]
        },
        ...
      ],
      ...
    }
  ]
}
```

```

    {
      "FirstName": "Julie",
      "Name": "Armstrong",
      "Email": "jarmstrong@...",
      "Role@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
    },
    {
      "FirstName": "Richard",
      "Name": "Wilson",
      "Email": "rwilson@...",
      "Role@com.sap.vocabularies.Search.v1.Highlighted": "Co-Principal <b>Investigator</b>"
    },
    {
      "FirstName": "Michel",
      "Name": "Leclerq",
      "Email": "michel.l@...",
      "Role@com.sap.vocabularies.Search.v1.Highlighted": "Principal <b>Investigator</b>"
    }
  ],
  ...
},
...
]
}

```

4.2.5.5 Spatial Data

`sys.esh_search()` returns spatial data (coordinates) in GeoJSON format.

Columns of SQL type `ST_POINT` and `ST_GEOMETRY` are returned in GeoJSON format. GeoJSON is a geospatial data interchange format based on JavaScript Object Notation (JSON).

Coordinates are returned in the spatial reference system of the database column. The spatial reference identifier is returned in the metadata and is not included in the search response.

The example below shows a search response for a view containing two spatial columns:

1. a column called `LOCATION` with SQL type `ST_POINT`
2. a column called `ENVELOPE` with SQL type `ST_GEOMETRY` that contains objects of spatial type `ST_POLYGON`

The additional column `ID` is the key column of the view. All columns are returned in the search response.

Sample Code

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 1,
      "ENVELOPE": {
        "type": "Polygon",
        "coordinates": [ [ [ 13.404953821, 52.520006821 ],
                          [ 13.40495418, 52.520006821 ],
                          [ 13.40495418, 52.52000718 ],
                          [ 13.404953821, 52.52000718 ],
                          [ 13.404953821, 52.520006821 ] ] ] ]
    }
  ]
}

```

```

    ] ]
  },
  "ID": 1,
  "LOCATION": {
    "type": "Point", "coordinates": [ 13.404954, 52.520007 ]
  }
},
{
  "@com.sap.vocabularies.Search.v1.Ranking": 0.965,
  "ENVELOPE": {
    "type": "Polygon",
    "coordinates": [ [ [ 9.99368182, 53.55108482 ],
                      [ 9.99368218, 53.55108482 ],
                      [ 9.99368218, 53.55108518 ],
                      [ 9.99368182, 53.55108518 ],
                      [ 9.99368182, 53.55108482 ]
                    ] ]
  }
},
  "ID": 2,
  "LOCATION": {
    "type": "Point", "coordinates": [ 9.993682, 53.551085 ]
  }
},
...
]
}

```

4.2.5.6 Facets

If facets are requested in a search call, the search response contains more than just the objects that are found, as it also includes additional result sets for the columns that are marked as facet columns.

For each facet, a list of the most frequent values in the search response is returned. For each value, the number of anchor objects that contain this value is also returned.

Beginning with Enterprise Search version 6 (`sys.esh_search()` call with `'/v6/$all/...'`), facets also include empty strings. Optionally NULL values are also returned, if annotation `@EnterpriseSearch.filteringFacet.countNullValues` is set to true. Up to Enterprise Search version 5 (`'/v5/$all'`), empty strings and NULL values are never returned in a facet.

The example below shows a search response that includes the output of a facet calculation, as it might be returned by a search call such as

```
/ $all? $top=10 & facets=all & $filter=Search.search(query='carbon').
```

Sample Code

Example of a search response containing facet counts

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9915987,
      "id": 1523821,
      ...
    },
    ...
  ],
  "@com.sap.vocabularies.Search.v1.Facets": [

```

```

{
  "@com.sap.vocabularies.Common.v1.Label": "Count by instrument",
  "@odata.context": "$metadata#Collection(Edm.EntityType)",
  "@com.sap.vocabularies.Search.v1.Facet": {
    "URI": "",
    "Dimensions": [
      {
        "PropertyName": "instrument",
        "PropertyType": "Edm.String",
        "FilterProperty": "instrument"
      }
    ]
  },
  "Items": [
    {
      "@odata.id": null,
      "instrument": "Standard Grant",
      "_Count": 548
    },
    {
      "@odata.id": null,
      "instrument": null,
      "_Count": 412
    },
    {
      "@odata.id": null,
      "instrument": "Continuing grant",
      "_Count": 126
    },
    {
      "@odata.id": null,
      "instrument": "",
      "_Count": 54
    },
    {
      "@odata.id": null,
      "instrument": "Fellowship",
      "_Count": 21
    },
    ...
  ]
},
{
  "@com.sap.vocabularies.Common.v1.Label": "Count by programElementText",
  "@odata.context": "$metadata#Collection(Edm.EntityType)",
  "@com.sap.vocabularies.Search.v1.Facet": {
    "URI": "",
    "Dimensions": [
      {
        "PropertyName": "programElementText",
        "PropertyType": "Edm.String",
        "FilterProperty": "programElementText"
      }
    ]
  },
  "Items": [
    {
      "@odata.id": null,
      "programElementText": "CHEMICAL OCEANOGRAPHY",
      "_Count": 29
    },
    {
      "@odata.id": null,
      "programElementText": "BIOLOGICAL OCEANOGRAPHY",
      "_Count": 22
    },
    ...
  ]
}

```

```
},  
...  
]  
}
```

4.2.5.7 Facet with Label Column

If facets are defined with an additional label column, for each facet value the search response contains the value of the facet column and additionally the value of the label column.

The following example shows a facet for a column containing color codes with an additional label column that contains color names. The label is returned with annotation `@com.sap.vocabularies.Common.v1.Text`.

Sample Code

Facet for Color Codes with Additional Label for Color Names

```
{  
  ...  
  "@com.sap.vocabularies.Search.v1.Facets": [  
    {  
      "@com.sap.vocabularies.Common.v1.Label": "Count by color",  
      "@odata.context": "$metadata#Collection(Edm.EntityType)",  
      "@com.sap.vocabularies.Search.v1.Facet": {  
        "URI": "",  
        "Dimensions": [  
          {  
            "PropertyName": "color",  
            "PropertyType": "Edm.String",  
            "FilterProperty": "color"  
          }  
        ]  
      },  
      "Items": [  
        {  
          "@odata.id": null,  
          "color": "0000FF",  
          "color@com.sap.vocabularies.Common.v1.Text": "blue",  
          "_Count": 23  
        },  
        {  
          "@odata.id": null,  
          "color": "808080",  
          "color@com.sap.vocabularies.Common.v1.Text": "grey",  
          "_Count": 17  
        },  
        {  
          "@odata.id": null,  
          "color": "FFD700",  
          "color@com.sap.vocabularies.Common.v1.Text": "gold",  
          "_Count": 15  
        },  
        {  
          "@odata.id": null,  
          "color": "80C4DE",  
          "color@com.sap.vocabularies.Common.v1.Text": "light steel blue",  
          "_Count": 3  
        }  
      ]  
    }  
  ]  
}
```

```
],
...
}
```

Labels may also be defined as language-dependent columns using annotation `@Semantics.languageReference`. In this case the language code is returned in addition to the label, because each label can be returned in a different language following the language priorities given in the language vector.

The example below shows a facet response with language-dependent labels and with language codes that are returned with annotation `@com.sap.vocabularies.Common.v1.Language`.

Sample Code

Facet for Color Codes with Language-Dependent Label for Color Names

```
{
  ...
  "@com.sap.vocabularies.Search.v1.Facets": [
    {
      "@com.sap.vocabularies.Common.v1.Label": "Count by color",
      "@odata.context": "$metadata#Collection(Edm.EntityType)",
      "@com.sap.vocabularies.Search.v1.Facet": {
        "URI": "",
        "Dimensions": [
          {
            "PropertyName": "color",
            "PropertyType": "Edm.String",
            "FilterProperty": "color"
          }
        ]
      }
    },
    "Items": [
      {
        "@odata.id": null,
        "color": "0000FF",
        "color@com.sap.vocabularies.Common.v1.Text": "Blau",
        "color@com.sap.vocabularies.Search.v1.Language": "de",
        "_Count": 23
      },
      {
        "@odata.id": null,
        "color": "808080",
        "color@com.sap.vocabularies.Common.v1.Text": "gris",
        "color@com.sap.vocabularies.Search.v1.Language": "fr",
        "_Count": 17
      },
      {
        "@odata.id": null,
        "color": "FFD700",
        "color@com.sap.vocabularies.Common.v1.Text": "Gold",
        "color@com.sap.vocabularies.Search.v1.Language": "de",
        "_Count": 15
      },
      {
        "@odata.id": null,
        "color": "80C4DE",
        "color@com.sap.vocabularies.Common.v1.Text": "light steel blue",
        "color@com.sap.vocabularies.Search.v1.Language": "en",
        "_Count": 3
      }
    ]
  }
},
],
```

```
} ...
```

4.2.5.8 Facets for Numeric and NUMC Columns

i Note

Version Dependent Implementation

Intervals for numeric facets are returned beginning with API version 5 if `sys.esh_search()` uses `"/v5/$all"` instead of `"/$all"`.

Up to API version 4, facets for numeric columns are returned as a list of the most frequent numbers like facets for other SQL types, as it is shown in the previous section.

Beginning with API version 20404, interval facets for NUMC columns are supported.

Facets for numeric and NUMC columns are returned as intervals. The borders of the intervals are calculated based on the search results:

1. The first interval contains the minimum value of the numeric column in the current search result.
2. The last interval contains the maximum value of the numeric column in the current search results.
3. Interval borders and sizes are optimized to get 'nice' borders (like, for example, '100-200', '200-300', '300-400' instead of '153.57-230.27', '230.27-306.97', '306.97-383.67').

The number of intervals returned varies. The optimal number of intervals returned is defined by the value of the custom query option `facetlimit` or the value of the `@EnterpriseSearch.filteringFacet.numberOfValues` annotation. If possible, the number of intervals returned equals this optimal number of intervals. The maximum number of intervals created is the optimal number of intervals plus three.

i Note

If there are only a few distinct values in the search response (up to the optimal number of intervals), the facet returned contains the distinct values instead of intervals.

If the annotation `@EnterpriseSearch.filteringFacet.noIntervals` is set to `true`, the facet always returns distinct values instead of intervals.

Numeric SQL types that are returned as the intervals:

1. TINYINT, SMALLINT, INTEGER, BIGINT
2. DECIMAL, SMALLDECIMAL
3. REAL, DOUBLE, FLOAT

Intervals are not returned ordered by count. Instead, they are ordered by value.

i Note

Empty intervals are not returned in the search response.

All intervals with a count greater than 0 are always returned in the search response.

Interval borders are returned in the format of the SQL type of the numeric column. The facet's property type equals the name of the EDM type followed by 'Range', as, for example, 'DecimalRange' for 'Edm.Decimal'.

The following example shows a search response with intervals:

Sample Code

Interval Facet for a Numeric Column Called 'amount'

```
...
"@com.sap.vocabularies.Search.v1.Facets": [
  {
    "@com.sap.vocabularies.Common.v1.Label": "Count by amount",
    "@odata.context": "$metadata#Collection(Edm.EntityType)",
    "@com.sap.vocabularies.Search.v1.Facet": {
      "URI": "",
      "Dimensions": [
        {
          "PropertyName": "amount",
          "PropertyType": "Edm.Int32",
          "FilterProperty": "amount"
        }
      ]
    }
  },
  "Items": [
    {
      "@odata.id": null,
      "amount": {
        "From": null,
        "To": 500000
      },
      "_Count": 729
    },
    {
      "@odata.id": null,
      "amount": {
        "From": 500000,
        "To": 1000000
      },
      "_Count": 101
    },
    {
      "@odata.id": null,
      "amount": {
        "From": 1000000,
        "To": 1500000
      },
      "_Count": 8
    },
    {
      "@odata.id": null,
      "amount": {
        "From": 2000000,
        "To": 2500000
      },
      "_Count": 3
    },
    {
      "@odata.id": null,
      "amount": {
        "From": 3000000,
        "To": null
      },
      "_Count": 1
    }
  ]
}
```

```

    }
  ],
  ...
}

```

The example below shows a search response with few distinct values. Therefore, the facet returned contains distinct values instead of intervals.

Sample Code

Numeric Facet with Discrete Values

```

...
"@com.sap.vocabularies.Search.v1.Facets": [
  {
    "@com.sap.vocabularies.Common.v1.Label": "Count by amount",
    "@odata.context": "$metadata#Collection(Edm.EntityType)",
    "@com.sap.vocabularies.Search.v1.Facet": {
      "URI": "",
      "Dimensions": [
        {
          "PropertyName": "amount",
          "PropertyType": "Edm.Int32",
          "FilterProperty": "amount"
        }
      ]
    }
  },
  "Items": [
    {
      "@odata.id": null,
      "amount": 500000,
      "_Count": 5
    },
    {
      "@odata.id": null,
      "amount": 661501,
      "_Count": 2
    },
    {
      "@odata.id": null,
      "amount": 515901,
      "_Count": 1
    },
    {
      "@odata.id": null,
      "amount": 560971,
      "_Count": 1
    },
    {
      "@odata.id": null,
      "amount": 689502,
      "_Count": 1
    }
  ]
},
...

```

Interval borders for NUMC columns are also returned in the format of the SQL type of the NUMC column. This means that NUMC values are returned as character strings padded with leading zeros.

The following example shows a NUMC facet for a column called CODE with SQL type NVARCHAR (8).

☰ Sample Code

Interval Facet Example for a NUMC Column

```
...
"@com.sap.vocabularies.Search.v1.Facets": [
  {
    "@com.sap.vocabularies.Common.v1.Label": "Count by CODE",
    "@odata.context": "$metadata#Collection(Edm.EntityType)",
    "@com.sap.vocabularies.Search.v1.Facet": {
      "URI": "",
      "Dimensions": [
        {
          "PropertyName": "CODE",
          "PropertyType": "Edm.String",
          "FilterProperty": "CODE"
        }
      ]
    },
    "Items": [
      {
        "@odata.id": null,
        "CODE": {
          "From": null,
          "To": "00000020"
        },
        "_Count": 23
      },
      {
        "@odata.id": null,
        "CODE": {
          "From": "00000040",
          "To": "00000060"
        },
        "_Count": 7
      },
      {
        "@odata.id": null,
        "CODE": {
          "From": "00000180",
          "To": "00000200"
        },
        "_Count": 19
      },
      {
        "@odata.id": null,
        "CODE": {
          "From": "00000200",
          "To": null
        },
        "_Count": 15
      }
    ]
  }
],
...
```

4.2.5.9 Facets for Date and Timestamp Columns

Facets for date and timestamp columns are returned using a set of predefined date intervals. All rows of the search result that lie within an interval are added to the corresponding document count.

The predefined date intervals contain some overlapping intervals. As a consequence, some documents are counted in more than one interval.

Note

If the annotation `@EnterpriseSearch.filteringFacet.noIntervals` is set to true, the facet always returns distinct date values instead of intervals.

SQL types that are returned as date intervals are:

1. DATE
2. TIMESTAMP
3. SECONDDATE
4. (N) VARCHAR with any of the `@Semantics` annotations for dates
5. DECIMAL with any of the `@Semantics` annotations for dates

The table below shows the predefined intervals and an example for a search done on 2016-09-14.

Interval Label	From	To	Example Start	Example End
Future	<tomorrow>	<no end date>	2016-09-15	
Last 3 years	<today> - 3 years	<today>	2013-09-14	2016-09-14
Last 5 years	<today> - 5 years	<today>	2011-09-14	2016-09-14
Last seven days	<today> - 7	<yesterday>	2016-09-07	2016-09-13
Last two weeks	<today> - 14	<yesterday>	2016-08-31	2016-09-13
Next seven days	<tomorrow>	<today> + 7	2016-09-15	2016-09-21
Next two weeks	<tomorrow>	<today> + 14	2016-09-15	2016-09-28
Next year	<next year>-01-01	<next year>-12-31	2017-01-01	2017-12-31
Older	0001-01-01	<today> - 5 years - 1	0001-01-01	2011-09-13
This month	<this month>-01	<last day of month>	2016-09-01	2016-09-30
This year	<this year>-01-01	<this year>-12-31	2016-01-01	2016-12-31
Today	<today>	<today>	2016-09-14	2016-09-14

Intervals are not returned ordered by count. Instead, they are ordered by date, so they are returned in the order given in the table above.

i Note

Empty intervals are not returned in the search response.

All intervals with a count greater than 0 are always returned in the search response. The query option 'facetlimit' does not change the number of intervals returned for a date or timestamp facet.

Interval borders are returned in the format of the SQL type of the date column, as for example '2016-08-11' for a DATE column and '20160811' for a VARCHAR column. The facet's property type equals the name of the EDM type followed by 'Range', as, for example, 'DateTimeRange' for 'Edm.DateTime'.

≡ Sample Code

Date Facet

```
...
"@com.sap.vocabularies.Search.v1.Facets": [
  {
    "@com.sap.vocabularies.Common.v1.Label": "Count by effectiveDate",
    "@odata.context": "$metadata#Collection(Edm.EntityType)",
    "@com.sap.vocabularies.Search.v1.Facet": {
      "URI": "",
      "Dimensions": [
        {
          "PropertyName": "effectiveDate",
          "PropertyType": "DateTimeRange",
          "FilterProperty": "effectiveDate"
        }
      ]
    },
    "Items": [
      {
        "@odata.id": null,
        "effectiveDate": {
          "From": "2016-08-11",
          "To": null,
          "@com.sap.vocabularies.Common.v1.Label": "Future"
        },
        "_Count": 4
      },
      {
        "@odata.id": null,
        "effectiveDate": {
          "From": "2016-08-11",
          "To": "2016-08-24",
          "@com.sap.vocabularies.Common.v1.Label": "Next two weeks"
        },
        "_Count": 1
      },
      {
        "@odata.id": null,
        "effectiveDate": {
          "From": "2016-08-01",
          "To": "2016-08-31",
          "@com.sap.vocabularies.Common.v1.Label": "This month"
        },
        "_Count": 1
      },
      {
        "@odata.id": null,
        "effectiveDate": {
          "From": "2016-01-01",
          "To": "2016-12-31",
          "@com.sap.vocabularies.Common.v1.Label": "This year"
        }
      }
    ]
  }
]
```

```

    },
    "_Count": 177
  },
  {
    "@odata.id": null,
    "effectiveDate": {
      "From": "2013-08-10",
      "To": "2016-08-10",
      "@com.sap.vocabularies.Common.v1.Label": "Last 3 years"
    },
    "_Count": 832
  },
  {
    "@odata.id": null,
    "effectiveDate": {
      "From": "2011-08-10",
      "To": "2016-08-10",
      "@com.sap.vocabularies.Common.v1.Label": "Last 5 years"
    },
    "_Count": 832
  }
]
},
],
...

```

4.2.5.10 Spatial Facets for ST_POINT Columns

Facets for ST_POINT columns are calculated using the grid-based aggregation functions of HANA.

Each facet value consists of three elements:

1. The **'Envelope'** defines the border of a grid cell and is returned as a polygon in GeoJSON format.
2. The **'Centroid'** defines the centroid of the grid cell and is returned as a point in GeoJSON format.
3. The **'_Count'** defines the number of anchor objects that lie within a grid cell.

Note

The `facetlimit` parameter defines the width and height of the grid. If the parameter is not given, a 10x10 grid is created.

Empty grid elements are not returned in the search response.

All elements with a count greater than 0 are always returned in the search response. The query option `facetlimit` does not change the number of grid elements returned for a spatial facet.

The example shows a spatial facet for a column called 'LOCATION' with SQL type ST_POINT.

Sample Code

Spatial Facet

```

{
  "value": [
    ...
  ],
  "@com.sap.vocabularies.Search.v1.Facets": [
    {

```

```

"@com.sap.vocabularies.Common.v1.Label": "Count by LOCATION",
"@odata.context": "$metadata#Collection(Edm.EntityType)",
"@com.sap.vocabularies.Search.v1.Facet": {
  "URI": "",
  "Dimensions": [
    {
      "PropertyName": "LOCATION",
      "PropertyType": "GeometryPolygonFacet",
      "FilterProperty": "LOCATION"
    }
  ]
},
"Items": [
  {
    "@odata.id": null,
    "LOCATION": {
      "Envelope": {
        "type": "Polygon",
        "coordinates": [ [ [ 8.466039, 49.218317 ],
                          [ 8.9931613, 49.218317 ],
                          [ 8.9931613, 49.759913 ],
                          [ 8.466039, 49.759913 ],
                          [ 8.466039, 49.218317 ]
                        ] ]
      },
      "Centroid": {
        "type": "Point",
        "coordinates": [ 8.72960015, 49.489115001 ]
      }
    },
    "_Count": 23
  },
  {
    "@odata.id": null,
    "LOCATION": {
      "Envelope": {
        "type": "Polygon",
        "coordinates": [ [ [ 13.210139701, 52.467893001 ],
                          [ 13.737262, 52.467893001 ],
                          [ 13.737262, 53.009489001 ],
                          [ 13.210139701, 53.009489001 ],
                          [ 13.210139701, 52.467893001 ]
                        ] ]
      },
      "Centroid": {
        "type": "Point",
        "coordinates": [ 13.47370085, 52.738691 ]
      }
    },
    "_Count": 11
  },
  ...
]
},
"@odata.count": 241,
...
}

```

4.2.5.11 Leveled Hierarchy Facets

A leveled hierarchy facet counts the number of distinct anchor objects on the first column of the hierarchy that returns more than one distinct value.

The following examples show a search on a view with a leveled hierarchy called 'instLocation' with levels 'instCountry', 'instState', 'instCity'.

Sample Code

Definition of a leveled hierarchy

```
@Hierarchy.leveled: [ {
  name: 'instLocation',
  levels: [ { element: 'instCountry' },
            { element: 'instState' },
            { element: 'instCity' } ]
}
]
```

A search such as `/sall?$stop=10&facets=all&$filter=Search.search(query='carbon')` might return the object count for column 'instCountry'.

Sample Code

Leveled facet for column 'instCountry'

```
{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9915987,
      "id": 1523821,
      ...
    },
    ...
  ],
  "@com.sap.vocabularies.Search.v1.Facets": [
    {
      "@com.sap.vocabularies.Common.v1.Label": "Count by instCountry",
      "@odata.context": "$metadata#Collection(Edm.EntityType)",
      "@com.sap.vocabularies.Search.v1.Facet": {
        "Dimensions": [
          {
            "HierarchyName": "instLocation",
            "PropertyName": "instCountry",
            "PropertyType": "Edm.String",
            "FilterProperty": "instCountry"
          }
        ]
      }
    }
  ],
  "Items": [
    {
      "@odata.id": null,
      "instCountry": "United States",
      "_Count": "695"
    },
    {
      "@odata.id": null,
      "instCountry": "Bermuda",
      "_Count": 4
    },
    {

```

```

        "@odata.id": null,
        "instCountry": "Germany",
        "_Count": 1
      }
    ]
  },
  ...
]
}

```

A follow-up search with an additional filter for country such as `/$all?$top=10&facets=all&$filter=Search.search(query='carbon instcountry:'United States')` might return the object count for column 'instState'.

Sample Code

Leveled facet for column 'instState'

```

{
  "value": [
    {
      "@com.sap.vocabularies.Search.v1.Ranking": 0.9957994,
      "id": 1523821,
      ...
    },
    ...
  ],
  "@com.sap.vocabularies.Search.v1.Facets": [
    {
      "@com.sap.vocabularies.Common.v1.Label": "Count by instState",
      "@odata.context": "$metadata#Collection(Edm.EntityType)",
      "@com.sap.vocabularies.Search.v1.Facet": {
        "URI": "",
        "Dimensions": [
          {
            "HierarchyName": "instLocation",
            "PropertyName": "instState",
            "PropertyType": "Edm.String",
            "FilterProperty": "instState"
          }
        ]
      }
    },
    ...
  ],
  "Items": [
    {
      "@odata.id": null,
      "instState": "California",
      "_Count": "88"
    },
    {
      "@odata.id": null,
      "instState": "New York",
      "_Count": 56
    },
    {
      "@odata.id": null,
      "instState": "Massachusetts",
      "_Count": 47
    },
    {
      "@odata.id": null,
      "instState": "Texas",
      "_Count": 42
    },
    ...
  ]
}

```

```

    },
    ...
  ],
  ...
}

```

4.2.5.12 \$apply with groupby

If \$apply with a groupby option is used, the distinct values of the columns given in the groupby option are returned only.

For example, the query `/sall?$top=3&$orderby=instCity&$apply=filter(Search.search(query='SCOPE:awards carbon'))/groupby((instCity))` returns the following result:

Sample Code

Groupby over a Single Column

```

{
  "value": [
    {
      "@odata.context": "$metadata#awards",
      "instCity": "ALBUQUERQUE"
    },
    {
      "@odata.context": "$metadata#awards",
      "instCity": "AMES"
    },
    {
      "@odata.context": "$metadata#awards",
      "instCity": "AMHERST"
    }
  ]
}

```

A groupby operation over two columns, as for example `/sall?$top=3&$orderby=instCity, instName desc&$apply=filter(Search.search(query='SCOPE:awards carbon'))/groupby((instCity,instName))`, returns the following result:

Sample Code

Groupby over Multiple Columns

```

{
  "value": [
    {
      "@odata.context": "$metadata#awards",
      "instCity": "ALBUQUERQUE",
      "instName": "University of New Mexico"
    },
    {
      "@odata.context": "$metadata#awards",
      "instCity": "AMES",
      "instName": "Iowa State University"
    }
  ],
}

```

```

    {
      "@odata.context": "$metadata#awards",
      "instCity": "AMHERST",
      "instName": "University of Massachusetts Amherst"
    }
  ]
}

```

4.2.5.13 \$apply with groupby and Aggregation

By default, a `groupby` operation with aggregation by count returns the results ordered by count in a descending order.

The following example shows the results of a query like `/ $all?$top=3&$apply=filter(Search.search(query='SCOPE:awards carbon'))/groupby((instCity,instName),aggregate($count as Count)):`

Sample Code

Groupby over Multiple Columns with Aggregation by Count

```

{
  "@com.sap.vocabularies.Common.v1.Label": "Count by (instCity,instName)",
  "@odata.context": "$metadata#awards(instCity,instName,Count)",
  "value": [
    {
      "instCity": "NEW YORK",
      "instName": "Columbia University",
      "Count": 16
    },
    {
      "instCity": "Seattle",
      "instName": "University of Washington",
      "Count": 15
    },
    {
      "instCity": "UNIVERSITY PARK",
      "instName": "Pennsylvania State Univ University Park",
      "Count": 13
    }
  ]
}

```

4.2.6 Database Privileges Needed for Search

Privileges Needed to Call `sys.esh_search()` with Dynamic Search Configurations

When using dynamic search configurations, the database user needs the following permissions:

- 'Read' privileges for all database objects that will be searched:
 - select privilege for views
 - execute privilege for table functions
- Select privileges on all term mapping and stopwords tables that are used in the search configuration.

Sample Code

Privileges Needed for Calls to `sys.esh_search()` with Dynamic Search Configurations

```
GRANT SELECT ON <SearchView> TO <databaseUser>;
GRANT EXECUTE ON <SearchTableFunction> TO <databaseUser>;
GRANT SELECT ON <TermMappingTable> TO <databaseUser>;
GRANT SELECT ON <StopwordTable> TO <databaseUser>;
```

Privileges Needed to Call `sys.esh_search()` with Static Search Configurations

When using search configurations created by CDS annotations or by `sys.esh_config()`, the user needs the following database privileges to call `sys.esh_search()`:

- 'Read' privileges for all database objects that will be searched:
 - select privilege for views
 - execute privilege for table functions
- Select privileges on all term mapping and stopwords tables that are used in the search configuration.

Sample Code

Privileges Needed for Calls to `sys.esh_search()` with Static Search Configurations

```
GRANT SELECT ON <SearchView> TO <databaseUser>;
GRANT EXECUTE ON <SearchTableFunction> TO <databaseUser>;
GRANT SELECT ON <TermMappingTable> TO <databaseUser>;
GRANT SELECT ON <StopwordTable> TO <databaseUser>;
```

Note

Beginning with SAP HANA 2.0 SPS02, execute privileges on `sys.esh_search()` are not needed any longer, because this privilege is part of the `PUBLIC` role.

When using restricted database users, the following privileges are still needed.

Sample Code

```
GRANT EXECUTE ON sys.esh_search TO <databaseUser>;
```

Beginning with SAP HANA 2.0 SPS03, select privileges on views `_SYS_RT.ESH_MODEL` and `_SYS_RT.ESH_MODEL_PROPERTY` are not needed any longer, because these privileges are part of the `PUBLIC` role.

Sample Code

```
GRANT SELECT ON _sys_rt.esh_model TO <databaseUser>;  
GRANT SELECT ON _sys_rt.esh_model_property TO <databaseUser>;
```

Privileges Needed to Call `sys.esh_config()`

For calls to `sys.esh_config()` the database user needs the 'EXECUTE' privilege on the builtin procedure `sys.esh_config()`.

When `sys.esh_config()` is called with method 'POST', 'PUT', or 'DELETE', the caller of `sys.esh_config()` has to be the owner of the database schema or needs the 'CREATE ANY' privilege on the database schema.

A 'DELETE' call is also possible if the database schema does not exist, so it is possible to delete configurations after the schema has been deleted.

Sample Code

Privileges Needed for Calls to `sys.esh_config()`

```
GRANT EXECUTE ON sys.esh_config TO <databaseUser>;  
-- additional object privileges as described above
```

Privileges Needed to Create Search Annotations in CDS

Any user that is allowed to create tables and views with `.hdbdd` files (Repository, XS Classic) or with `.hdbcds` files in (HANA DI, XS Advanced) can add `@Search`, `@EnterpriseSearch`, `@EnterpriseSearchHana`, and other search related annotations to these views.

Privileges Needed to Call Search in OData

To use the search feature on a database object (table or view) in an XS Classic OData service, the user needs the following permissions:

- Read access to the XS Classic OData service that exposes the searchable database object.
- Select privilege for the database object.

No other privileges are needed to enable the search feature using the XS Classic OData service.

Privileges in HANA DI

i Note

Privileges needed for the search feature are assigned automatically with SAP HANA 2.0 SPS01 Rev. 11 and higher.

In environments that use SAP HANA DI (as, for example, XS Advanced), the object owner and the application user role automatically get the privileges needed for `sys.esh_search()`, `sys.esh_config()`, `_sys_rt.esh_model` and `_sys_rt.esh_model_property` assigned to them. This means that the search feature is available without granting any additional privileges.

Related Information

[Dynamic Search Configurations \[page 244\]](#)

4.2.7 OData Query Options Supported by Federated Search

Federated search supports the following OData query options.

System Query Options:

- `$orderby`

i Note

`$orderby` can only be used if the search is limited to a single view - either because only one view with search configuration exists or because the scope operator of the current query limits the scope to a single view. As soon as search is done in two or more views, the use of `$orderby` will result in an error.

- `$select`

i Note

`$select` reduces the search scope to views that contain all of the columns that are given in the `$select` parameter. If no view contains all of the given columns, search fails with an error.

- `$filter`
- `$top`
- `$skip`
- `$count`
- `$apply`

Custom Query Options:

- `facets`
- `facetlimit`
- `estimate`
- `wherefound`
- `whyfound`
- `filteredgroupby`

i Note

Many of the query options accept column names as parameters. Calls with API version '/v20411' and higher can use column identifiers instead of the real column names. If columns belong to subobjects, the subobject paths should be added to the parameters to avoid ambiguous names.

⇌ Sample Code

```
-- old api version -> column names are used
/v20306/$all?$select=id,instName,invLastName&facets=instCountry&
$orderby=instCity&$filter=...

-- new api version -> column identifiers and subobject paths are used
/v20411/$all?$select=id,institution/Name,institution/investigator/
Name&facets=institution/Country&$orderby=institution/City&$filter=...
```

Related Information

[System Query Options \[page 215\]](#)

[Custom Query Options \[page 220\]](#)

4.2.7.1 System Query Options

The built-in procedure `sys.esh_search()` supports the following system query options:

System Query Option	Description
<code>\$orderby</code>	<p>Sort the response by any column in an ascending or descending order. Results can be sorted by the output of the SQL function <code>SCORE()</code> using <code>Search.score()</code> as a function.</p> <p>Example: <code>\$orderby=Search.score() desc</code></p> <p><code>\$orderby=CityName</code></p> <p><code>\$orderby=CityName asc,Name1 desc</code></p> <p><code>\$orderby=CityName,Search.score() desc</code></p>

i Note

`$orderby=Search.score()` can only be used if the request contains a call to `Search.search()`, and if the search term is not empty.

i Note

`$orderby` can only be used if the search is limited to a single view - either because only one view with the search configuration exists or because the scope operator of the current query limits the scope to a single view. As soon as the search is completed in two or more views, the use of `$orderby` will result in an error.

System Query Option	Description
---------------------	-------------

<code>\$select</code>	
-----------------------	--

	Defines the columns that are returned in the JSON response.
--	---

	If the <code>\$select</code> option is not given, search still returns a result set. This result set does not contain any column values, but scores, whyfound information, and so on are still returned.
--	--

	If the search configuration contains columns with <code>@UI</code> annotations, all of these columns are returned as default response columns if a search is called without the <code>\$select</code> option.
--	---

i Note

Only the following types of columns are allowed in the `$select` option to define the response columns:

- columns from the anchor table
- columns from other tables that are joined as a 1:1 join
- columns from other tables that are joined as a 1:n join and that are either marked as a multi-value column or that belong to a subobject.
- columns from other tables that are joined as a 1:n join and that are language-dependent. The language-dependency makes these columns behave like columns from a 1:1 join.

Search will return wrong result when the `$select` option contains other columns of a table that is joined as a 1:n join.

i Note

`$select` restricts the search scope to views that contain all the columns specified in the `$select` parameter. If none of the views contain all the specified columns, the search fails with an error.

Example: `$select=ID, Name1, Name2`

System Query Option	Description
---------------------	-------------

<code>\$filter</code>	<p>Note</p> <p>A subset of the OData <code>\$filter</code> expressions is supported by <code>sys.esh_search()</code>. Nevertheless, it is recommended to use the <code>Search.search()</code> function as the only parameter to the <code>\$filter</code> option. Instead of using a <code>\$filter</code> expression, all filter conditions should be passed to <code>sys.esh_search()</code> as part of the query language expression.</p> <p>Filter condition supports only a subset of the Boolean expressions defined in the OData v4 standard:</p> <ul style="list-style-type: none">• logical operators (eq, ne, gt, ge, lt, le, and, or, not)• primitive literals as operands: property names (column names), numeric and string constants, null value• search specific functions: <code>Search.search()</code> <p>Arithmetic operators, canonical functions, path expressions and so on are not allowed.</p> <p>Example:</p> <p>Preferred to have everything in a query language expression: <code>\$filter=Search.search(query='carbon ROW: (inststate:EQ:colorado instcity:EQ:boulder)')</code></p> <p>Not recommended, but also working:<code>\$filter=Search.search(query='carbon') and instState eq 'Colorado' and instCity eq 'Boulder'</code></p>
-----------------------	--

<code>\$top</code>	Defines the number of items returned in the response. Example: <code>\$top=10</code>
--------------------	--

<code>\$skip</code>	Defines how many items are skipped in the response. Example: <code>\$skip=20</code>
---------------------	---

<code>\$count</code>	If <code>\$count=true</code> , the total number of matching items is returned in the response. This is the number of items that would be returned if <code>\$top</code> and <code>\$skip</code> were not used. See also the custom query option <code>estimate</code> . When the <code>@EnterpriseSearch.key</code> annotation is used to define the keys of the anchor table, distinct anchor keys are counted instead of counting the rows in the database view. Example: <code>\$count=true&estimate=true</code>
----------------------	---

System Query Option	Description
---------------------	-------------

\$apply

\$apply can be used instead of \$filter to define a search filter.

It allows to define a `groupby` operation to group the search result by one or more columns and to get the distinct values of these columns only. If needed, an aggregation by count is also possible to get the number of distinct anchor keys for each of the distinct values, too.

The query options \$top and \$skip are applied to the list of aggregated values. \$count counts the number of distinct aggregated values.

Examples:

☰, Sample Code

```
/* $apply with a filter only */
/$all?$top=3&$apply=filter(Search.search(query='SCOPE:awards
carbon'))
```

☰, Sample Code

```
/* this gives the same results as the following query */
/$all?$top=3&$filter=Search.search(query='SCOPE:awards
carbon')
```

☰, Sample Code

```
/* $apply with groupby */
/$all?$top=3&$apply=filter(Search.search(query='SCOPE:awards
carbon'))/groupby((instCity))
/$all?$top=3&$apply=filter(Search.search(query='SCOPE:awards
carbon'))/groupby((instCity,instName))
```

☰, Sample Code

```
/* groupby with orderby */
/$all?$top=3&$orderby=instCity desc&
$apply=filter(Search.search(query='SCOPE:awards carbon'))/
groupby((instCity))
```

☰, Sample Code

```
/* $apply with groupby and aggregation by count */
/$all?$top=3&$apply=filter(Search.search(query='SCOPE:awards
carbon'))/groupby((instCity),aggregate($count as Count))
/$all?$top=3&$apply=filter(Search.search(query='SCOPE:awards
carbon'))/groupby((instCity,instName),aggregate($count as
Count))
```

i Note

Limitations of `$apply`

`$apply` with `groupby` can only be used if the search is limited to a single view (either because there is one search configuration only or by setting the `SCOPE` parameter defined in the query language to a single view). A federated search over more than one view is not supported by `groupby`.

When `$apply` is used, the following query options cannot be used:

- `$select`. The columns returned are defined by the `groupby()` clause.
- `$filter`. The filter is already given in `$apply`.
- `facets`
- `facetlimit`
- `wherefound`
- `whyfound`

It is also not possible to order the result set by score (`$orderby=Search.score()`). `$orderby` can still be used with the column names given in the `groupby()` clause.

i Note

The following OData v4 system query options are not supported:

- `$expand`: Associations to other entity sets are not available, so there is nothing to be expanded.
- `$format`: The JSON format is always returned.
- `$search`: The `Search.search()` function is used instead.

4.2.7.2 Custom Query Options

The following OData custom query options are supported:

OData Custom Query Option	Description
facets	<p>The <code>facets</code> option defines how many facets are calculated:</p> <ul style="list-style-type: none">• <code>facets = 0</code>: No facets are returned (default if the option is not given).• <code>facets = n</code> ($n > 0$): Maximum n facets are returned. This is always a subset of the columns tagged with the <code>@EnterpriseSearch.filteringFacet.default:true</code> annotation.• <code>facets = all</code>: Facets for all columns tagged with the <code>@EnterpriseSearch.filteringFacet.default:true</code> annotation are returned.• <code>facets = column1,column2,...,columnn</code>: Facets for the specified columns are returned. All columns have to be tagged with the <code>@EnterpriseSearch.filteringFacet.default</code> annotation (set to true or false). <p>For each facet, the top 10 values are returned if the <code>facetlimit</code> option is not selected.</p> <p>Facets always count distinct anchor keys instead of counting rows.</p> <div data-bbox="804 1364 1402 1608"><p>≡, Sample Code</p><p>Examples</p><pre>facets=all facets=CountryCode,AddressType facets=3,facetlimit=5</pre></div>
facetlimit	<p>By default, the top 10 values for each facet are returned. Using the 'facetlimit' option, it is possible to define how many values are returned for each facet.</p> <p><code>facetlimit=10</code> is the default value.</p>

OData Custom Query Option	Description
estimate	<p>When using <code>estimate=true</code> with <code>\$count=true</code>, an estimated result count is returned in some cases in order to reduce response times.</p> <p>The option has no effect if facets are requested. In this case, the exact result count is always returned.</p> <p>Using <code>estimate</code> without <code>\$count=true</code> returns an error:</p> <ul style="list-style-type: none"> • <code>estimate=true</code>: Search might return an estimated result count instead of an exact count. • <code>estimate=false</code>: This is the default setting.
wherefound	<p>If <code>wherefound=true</code> is specified, the search response returns the names of the attributes where the search term has been found.</p> <p>The where found information is returned as the annotation <code>@com.sap.vocabularies.Search.v1.WhereFound</code>.</p> <p>Wherefound can only be used if a search term is entered using the search option:</p> <ul style="list-style-type: none"> • <code>wherefound=true</code>: The where found information is returned. • <code>wherefound=false</code>: This is the default setting.

OData Custom Query Option

Description

whyfound

If `whyfound=true` is specified, search returns highlighted text or snippets for all columns that contain a part of the search expression. The why found information is returned as the annotation

```
@com.sap.vocabularies.Search.v1.WhyFound.
```

Whyfound can only be used if a search term is entered using the search option:

- `whyfound=true`: The why found information is returned.
- `whyfound=false`: This is the default setting.

For calls to API version 20301 or lower (as, for example, `/v6/$all?...`), the whyfound information always contains a snippet.

Beginning with calls to API version 20302 (`/v20302/$all?...`), the whyfound information contains either a highlighted string or a snippet.

- The full content of the column with highlighting is returned for all columns that do not have an `@EnterpriseSearch.snippets.enabled` annotation set to `true`. This makes sure that the application always gets back the complete column to display in the UI. Otherwise, only a snippet would be returned and, for example, one half of a longer document title could be missing.
- A snippet of the column content is returned for all columns with `@EnterpriseSearch.snippets.enabled` set to `true`.

i Note

Applications that use API calls to version 20302 or higher have to make sure that long text columns, that contain description texts, pdf documents, and so on, are defined with annotation

```
@EnterpriseSearch.snippets.enabled
```

 set to `true`, if these columns are used for search. Otherwise the whyfound information would contain the full column content and would therefore be very large.

i Note

Wherefound and Whyfound

OData Custom Query Option

Description

wherefound and whyfound return information for columns used in a search only. For freestyle search terms (example: 'searchTerm') this includes all columns with defaultSearchElement set to true. For searches in a single column (example: 'aColumn:searchTerm') this includes the given column.

Columns that are only used in attribute conditions (example: 'aColumn:eq:term' or 'aColumn:[1 5]') are not added to the whyfound and wherefound information.

filteredgroupby

If filteredgroupby=false is given, groupby filters are not applied.

filteredgroupby=true: groupby filters are applied. This is the default behavior for groupby () operations.

filteredgroupby=false: groupby filters are not applied.

i Note

Applications that use API calls to version 20302 or higher have to make sure that long text columns, that contain description texts, pdf documents, and so on, are defined with annotation @EnterpriseSearch.snippets.enabled set to true, if these columns are used for search. Otherwise the whyfound information would contain the full column content and would therefore be very large.

i Note

wherefound and whyfound return information for columns used in a search only. For freestyle search terms (example: 'searchTerm'), this includes all columns with defaultSearchElement set to true. For searches in a single column (example: 'aColumn:searchTerm'), this includes the given column.

Columns that are only used in attribute conditions (example: 'aColumn:eq:term' or 'aColumn:[1 5]') are not added to the whyfound and wherefound information.

4.2.7.3 OData Custom Functions

Search.score()

Search.score () can be used with \$orderby in order to arrange the search results by SCORE () in an ascending or descending order.

The results can only be sorted by `Search.score()` if the output of the `SCORE()` function is available in the search response.

Search.search()

`Search.search()` is used to define the search term. It accepts the following parameter:

Parameter	Possible Values	Description
<code>query</code>	<search term>	Defines the search term. The syntax of the search query language is used.

Sample Code

Examples

```
$filter=Search.search(query='sap walld*')
$filter=Search.search(query='SCOPE:employees miller')
$apply=filter(Search.search(query='sap walld*'))
```

Note

Escaping of single quotes: The string parameters that are passed to `search.search()` cannot contain unquoted single quotes. Each single quote in a string has to be replaced by two single quotes, as specified by the OData standard.

Related Information

[Enterprise Search Query Language \[page 224\]](#)

4.2.8 Enterprise Search Query Language

You use the search query language to define a search query, which is handled by the built-in procedure `sys.esh_search()`. The search query language offers a range of operators, wildcards and escaping rules while specifying a search request.

Basic Search Terms

The most simple search query consists of a single term, for example `car`.

This search returns all items where the term **car** is found in any relevant column of the search model.

The relevant columns are predefined in the search configuration. See the documentation for `sys.esh_config()`.

Note

The search is case-insensitive. Searching with **car**, **Car**, **CAR**, or **cAr** returns the same result.

Searching with several terms returns all items where all of the search terms are found in one or more fields, regardless of the order of the terms or the field.

A search for **my car** returns all items where both the term **my** and the term **car** occur in any field. Tokenization during query parsing is done exclusively at the space " " character.

Wildcards

The ***** wildcard can be used at any place inside a search token and stands for zero or more characters.

A search for **car*** returns all items where any relevant column contains a term starting with **car**, e.g. **car**, **cars**, **care**, **carry**, **carbon**, **careful**.

A search for ***car** returns all items where any relevant column contains a term ending with **car**, e.g. **car**, **streetcar**, **autocar**, **flatcar**.

A search for ***car*** returns all items where any relevant column contains a term containing the subterm **car** like **car**, **cars**, **care**, **carry**, **carbon**, **careful**, **streetcar**, **autocar**, **flatcar**, **flatcars**.

The **?** wildcard can be used at any place in the search token and stands for any one character.

A search for **ca?**, for example, matches **car**, **cat**, **can**, but not **cars**, **caterpillar**, **case**.

You can also use wildcards within tokens, for example **c*ar** or **c?ar**.

Phrases

You can also use phrases in your search query. A phrase is a group of words written in double quotes. Phrase searches are used to find an exact phrase, for example **"my car"**.

The search for **"my car"** returns all items where the complete phrase is found as it is in any relevant column.

Phrase searches can be combined with wildcards. The search for **"my ca?"** matches the phrases **"my cat"**, **"my car"**, **"my can"**.

Operators

You can use the operators **AND** and **NOT** in your search queries.

The **AND** operator is the default operator.

The following search queries

`my car`

`my AND car`

`my and car`

return the same result.

i Note

Unlike phrase search, it does not matter in which order or in which field or fields the terms match.

The **NOT** operator is used to find items where one term is included but another is not.

A search for `my NOT car` returns all items where the term "my" is found in any freestyle field, but the term **car** is found is not found in any of the freestyle fields.

i Note

The query `my NOT car` could also be written as `my AND -car`.

A shortcut for the **NOT** operator is the -. The following variants of the search query return the same result:

`my NOT car`

`my AND NOT car`

`my and not car`

`my -car`

The **NOT** operator can also be used with one term. A search for `-car` returns all items that do not have the term "car", same as `* AND NOT car`.

The **OR** operator is used to express that either search term should lead to a search result: `my OR car` returns all items where any of the search terms are found in any relevant column.

The **NOT** operator could also be used in conjunction with **OR**: `my OR NOT car` or `my OR -car` returns all items that have the term **my** in any field or **car** in no field. To help you understand mor easily, imagine a search execution as a set-based operation. Take the whole set of items and remove all items with the term **car** in any field. Now calculate the union with the set of items having the term **my** in any field. The same result would be returned with `-(car -my)`.

Boosting

A term can be boosted with the ^ operator.

The query `my car^2` gives the term **car** a double weight compared to the term **my**.

The default value is 1. The weight must be a value >=0.

Grouping

Grouping can be used to build more complex search expressions using brackets, for example `(my AND car) OR (her AND dog)`.

Searching in Fields

The search field can be specified using the field name followed by a colon `title:car`. This returns all items where the term `car` is found in the `title` field.

Field identifiers shall be case insensitive. `Title`, `TITLE`, `TiTIE`, `title` would address the same field `title`.

Field identifiers must be single words. There should be a configuration to declare the field identifier, which can differ from the technical name of the column. Also, it should be possible to define a list of fields as search scope.

Any search term from above could be used as the second part of the search. If there is more than one term and you want to search for all terms in only one field, then a grouping with brackets is necessary:

```
title:(my car)
```

```
title:"my car"
```

```
title:((my AND car) OR (her AND dog))
```

```
title:car~0.9
```

The search queries `title:my car` and `car title:my` would get the same results as the term `car` is searched for in all relevant columns.

You can extend the search scope using multiple fields. The default operator for scope is `OR`.

The following queries return all items where the term `car` is found in the `title`, `author` or `abstract` field:

```
(title OR author OR abstract):car
```

```
(title author abstract):car
```

You can also use the `AND` and `NOT` operators:

The query `(title AND author AND abstract):car` returns all items where the term `car` is found in the `title` and `author` and `abstract` field.

IN-Lists

You specify an IN-list as follows:

```
id:OR(K1 K2 K3 K4 K5 K6 K7)
```

This is a shorter and more convenient way from of the following statement:

```
id:K1 OR id:K2 OR id:K3 OR id:K4 OR id:K5 OR id:K6 OR id:K7
```

Fuzzy Search

Fuzzy search can be used to find similar terms.

The search query `car~` matches with `car`, `cars`, `can`, `cat`.

If no value for fuzziness is provided, the default value of 0.8 is used. Use can specify a higher fuzziness value if you want to receive more precise results, or you can specify a lower fuzziness value if you want to match more tokens.

The fuzziness value needs to be a floating point number between 0.0 and 1.0 (e.g. `car~0.9`).

Note

Fuzzy search does not work in combination with a wildcard search.

Escaping

The escaping of the special characters `^ # : ~ () [] NOT_ AND_ OR_ NOT AND OR` is done with double quotes `""`.

Escaping of the special characters `* ? " \` is done with `\` within a quoted token. `"***"` searches for the token `***`.

A search for `"(3:3^2~#)-1"` searches for the token `(3:3^2~#)-1`. The special character "-" must be escaped if it is the first character of a token.

A search with a token having a - inside is supported.

A search for `check-in` searches for `check-in`, whereas `check -in` searches for `check` and excludes `in`.

A search for `check "-in"` searches for `check` and `-in`.

Precedence of Phrases and Operators

The following precedence is forged by the system handling a search:

1. Special characters: `?*\^`
2. Phrases `""` and special characters: `()`:
3. Special characters: `[]`
4. Special character: `~`
5. The `NOT_` operator
6. The `AND_` operator
7. The `OR_` operator
8. The `NOT` operators: `- NOT`
9. The `AND` operator
10. The `OR` operator

Search on Single or Multiple Views

All examples above show searches on a single view. This is the case if only one searchable view exists in a system, or the UI restricts the search to one view. If more than one search view is available, a federated search is performed where the user needs the option to select a search scope. The search scope identifier is derived from the view name. Characters which are not allowed for OData identifiers are removed, such as `./\ $`. Package prefixes and context of SAP HANA CDS annotations are also removed.

Examples

Perform a search in all relevant columns of all connectors by just providing the token: `car`

Perform a search specifically in the document view: `scope:document car`

Perform a search in a list of views: `scope:(document OR customer) car`.

Perform a complex search query: `scope:document car title:my` This query searches in all `document` fields with the term `car` and additionally in the `title` field with the term `my`.

Example

Example of a call with `sys.esh_search()`:

```
call esh_search(' [ "$all?$filter=Search.search(query=' 'scope:(document OR customer) car')&$top=10" ]', ?);
```

4.2.8.1 Supported Features of the Query Language

The query language supports the following features:

- Operators: AND, OR, NOT, -, (), ~, ^
- Wildcards (*, ?) and escaped wildcards (*, \?)
- Phrases ("...") and escaped double quotes (\")
- Escaping of backslash (\\)
- Escaping of other reserved query language characters (\-, \ (, \), \~ and \^)
- Definition of fuzzy search options ((~))
 - Example: `car~0.9` matches words similar to `car`. The given fuzziness threshold needs to be a floating point number between 0 and 1.
 - Example: `car~` uses the default fuzziness threshold of 0.8 because no other value is provided.
 - Use a higher fuzziness threshold value if search results shall be more precise or a lower value if more different tokens shall match.
 - A fuzzy search cannot be combined with a wildcard search. If wildcards are given the fuzziness threshold is ignored and an 'exact' wildcard match is done.
- Scope definitions, as for example `query='SCOPE:view1 abc*'` or `query='SCOPE:(view1 OR view2) abc*'`

- View names are case-insensitive.
- Instead of the real view names, OData compatible identifiers are used in the scope definition. Valid OData identifiers are shown in the output of the metadata call and construction rules for identifiers are described in [Method 'GET' - \\$metadata Call \[page 163\]](#).
- Attribute filters, as for example `query='country:de sap'`, `query='country:de name:sap'`, or `query='country:(de OR at OR ch) sap*'`
 - Column names are case-insensitive.
 - A federated search over multiple views skips all views that do not contain the column given in the attribute filter.
- Attribute filters for multiple columns, for example `query='(title author abstract):adams'`.
 - The above expression is equal to `query='title:adams OR author:adams OR abstract:adams'`. This means that 'adams' is searched in any of the given columns.
 - Complex expressions are allowed, for example `query='((title OR author) AND NOT abstract):adams'`
- In-lists for attribute filters, for example `query='country:OR(de at ch)'`.
 - This is short for `query='country:de OR country:at OR country:ch'` and means that 'country' has to be one of the values given.
 - Alternatively a search for all values given is possible: `query='country:AND(de at ch)'`. This is short for `query='country:de AND country:at AND country:ch'`.
- Near-search, for example `query='NEAR(5):(sap germany)'` to search in all default search columns or `query='content:NEAR(2):(sap palo alto)'` to search in the given column only.
 - Unordered near (default): `query='NEAR(2):(sap germany)'` or `query='NEAR(2,U):(sap germany)'`
 - Ordered near: `query='NEAR(2,O):(sap germany)'`
- Attribute conditions, for example `query='price:LE:100'`
 - Case-insensitive operators (default): `:EQ:`, `:NE:`, `:LT:`, `:LE:`, `:GT:`, `:GE:`
 - Case-sensitive operators: `:EQ(S):`, `:NE(S):`, `:LT(S):`, `:LE(S):`, `:GT(S):`, `:GE(S):`
 - The `:EQ:` operator accepts wildcards, similar to SQL operator `LIKE`, as for example `'query=name:EQ:sa*'`, `'query=name:EQ(S):SA*'`
 - Other operators do not accept wildcards.
 - When using operators, the values have to be given as they are stored in the column. For example, an alphanumeric value stored in a `VARCHAR` column has to be given with leading zeros (`'query=id:EQ:00000012'`).
- Attribute condition to search for NULL values
 - Search for NULL value scan be done with the `:IS:null` operator, as for example `'query=name:IS:null'`
 - Search for non-NULL values can be done using the `*` wildcard, as for example `'query=name:*'`
- Search for boolean values: `'query=invalid:EQ:true'`, `'query=inactive:NE:false'`
- Attribute conditions for boolean datatype
 - Search for boolean values: `'query=invalid:EQ:true'`, `'query=inactive:NE:false'`
- Attribute conditions for spatial datatypes
 - Operators `:WITHIN:`, `:COVERED_BY:`, `:INTERSECTS:`
 - Left side of the operator is a column of SQL type `ST_POINT` or `ST_GEOMETRY`
 - Right side of the operator is a spatial object in well-known text (WKT) format

- Example: `location:COVERED_BY:POLYGON((13.4 52.5, 13.5 52.5, 13.5 52.6, 13.4 52.6, 13.4 52.5))`
- Between operator (range search), for example `query='price:[100 200]`
 - This is equal to `query='ROW: (price:GE:100 AND price:LE:200) '`
 - Open and closed intervals to include or exclude end points: `price:[100 199]`, `price:[100 200[`, `price:]99 199]`, `price:]99 200[`
 - Case-insensitive operator (default), `:BT: keyword` is optional: `title:[car rocket] OR title:BT:[car rocket]`
 - Case-sensitive operator, `:BT(S): keyword` is mandatory: `title:BT(S):[Car Rocket]`
- Search with partial dates in date and timestamp columns, `query='abstract:rocket createdat:2016-08'`
See [Search with Partial Dates \[page 237\]](#)
- Empty search term, `*-search:` A search without a search term returns all rows of a view
 - Example: `query=' '` and `query='*'` both return all rows.
 - As a consequence, `query='NOT *'` returns an empty result.
- Row operator, for example `query='ROW: (type:EQ:short abstract:rocket) '`
 - See [Row Operator \[page 239\]](#)
- Separation of search conditions entered by the user and automatically added filter conditions
 - Example: `carbon 2016 FILTER: (instcountry:"United States" inststate:EQ:Colorado)`
 - See [Separation of User Input and Other Filter Conditions \[page 240\]](#)
- Definition of access privileges using the AUTH: operator
 - Example: `carbon AUTH: (instcountry:EQ(S):"United States" inststate:EQ(S):Colorado)`
 - See [Row-Based Privileges \[page 259\]](#)

4.2.8.2 Subsubjects and Column Identifiers in the Query Language

Beginning with API version '/v20411' the query language allows the usage of subobject paths and column identifiers instead of real column names to reference the columns of a search model.

Column identifiers can be used and subobject hierarchies can be added as prefixes to column names, as shown in the following example.

If column identifiers or column names are used without subobject path prefixes and these names are not unique, all columns sharing the same column name or column identifier are searched.

Sample Code

Subsubject Path Prefixes and Column Identifiers in the Query Language

```
-- old api version -> column names are used
/v20309/$all?...&$filter=Search.search(query='carbon (instname
invname):adams')

-- new api version -> column identifiers and subobject paths are used
/v20411/$all?...&$filter=Search.search(query='carbon (institution/name
institution/investigator/name):adams')
```

```
-- new api version -> use a non-unique column identifier without subobject
path to search in all columns sharing this identifier
/v20411/$all?...&$filter=Search.search(query='carbon name:adams')
```

4.2.8.3 Search with Multiple Tokens and Generation of Phrases

Some search features that are available with `sys.esh_search()` process more than one query language token at once to get the expected results.

For example, when searching for 'SAP HANA database' in a search view that contains columns with full-text indexes only, it is sufficient to do three independent searches for 'SAP', 'HANA', and 'database'. Because of the full-text indexes, a value is found if it contains all three tokens.

When the same search is done in an `NVARCHAR` column without a full-text index, a column value of 'SAP HANA database' is not found if the search is done with single tokens only (because, for example, the token 'SAP' does not match 'SAP HANA database' without a full-text index). To get the expected results, phrases and subphrases of the search term have to be searched for in the `NVARCHAR` column, too. This means that besides a search for 'SAP', 'HANA', and 'database' the following phrases will also be searched for: "SAP HANA", "HANA database", and "SAP HANA database". Using these additional search terms, a value of 'SAP HANA database' will also be returned without a full-text index.

`sys.esh_search()` does not create phrases over all tokens that the user entered in the query language expression. Instead, phrases are only added to the search if tokens are side by side, if there are no other query language elements between the tokens (like, for example, an `AND` operator), and if the tokens are not modified by adding, for example, a fuzzy search operator or a column name. This is called a **'tight AND'** in `sys.esh_search()`.

When searching for a phrase, the phrase is not combined with other tokens by a **'tight AND'**. For example, the search for `query="sap hana" database` searches for the phrase "sap hana" and for the single token 'database', but not for the combined phrase "sap hana database".

An exception are phrases that contain a single token only, because the phrase may have been used to escape a special character. For example, `query='sap "-hana" database` searches not only for 'sap', '-hana', 'database', but also for "sap -hana", "-hana database", and "sap -hana database". This is done, because in this case the phrase is used to search for a '-' character instead of interpreting it as a `NOT` operator.

The following query language expressions show examples of a **'tight AND'**. This means that all examples search for 'sap', 'hana', and also for the phrase "sap hana":

Sample Code

Examples for 'tight AND'

```
query='sap hana'
query='column1:(sap hana) '
query='(column1 column2):(sap hana) '
query='SCOPE:view1 sap hana'
query='sap "hana"'
```

The following examples show a search for SAP HANA without a **'tight AND'** between the tokens. This means that search is done for single tokens 'sap' and 'hana' only. The phrase "sap hana" is not searched for.

Sample Code

Examples Without a **'tight AND'**

```
query='sap AND hana'  
query='sap hana~0.7'  
query='column1:sap column1:hana'  
query='column1:sap hana'
```

Columns Without a Fulltext Index

If a column without a full-text index contains a value that comprises multiple tokens, this value can only be found if `sys.esh_search()` creates the phrase that contains all of the tokens, as described in the previous section. This means that the query language expression has to contain either all of the tokens combined with a **'tight AND'** or an explicit phrase with all of the tokens.

Composition of Words

If the search option `'composeWords=n'` is given for a column, this means that `n` tokens will be combined to a single token as an additional and alternative search term. To enable this feature, `sys.esh_search()` has to additionally check phrases containing up to `n` tokens for matching word compositions. This is automatically done for all tokens that are combined with a **'tight AND'**.

Term Mappings

If term mappings are enabled for a column, multi-token term mappings defined in the term mapping table are also supported. If there is a term mapping that replaces, for example, two tokens by one or more other tokens, it can only be applied to search phrases of two or more tokens. Therefore, `sys.esh_search()` automatically checks additional phrases of all tokens that are combined with a **'tight AND'** for matching term mappings.

Stopwords

To get better response times with `sys.esh_search()` and to avoid very long running queries, stopwords can be added to a search configuration. To enable stopwords, the fuzzy search options for stopwords (`stopwordTable` and `stopwordListId`) have to be given for all columns that will use stopwords.

The implementation of stopwords in `sys.esh_search()` is different from a stopwords search with the SQL `CONTAINS()` predicate in a single column only. `sys.esh_search()` processes stopwords as described below.

1. When running searches on the columns of the search view, `sys.esh_search()` considers all searches that consist of a single stopwords only as non-matching. As a result, some subsearches are removed from the overall search because they cannot return any results. In some cases this significantly reduces response times of a search.
2. As a consequence of `sys.esh_search()` ignoring all single-token stopwords searches, a query language expression that contains a single stopwords, that is not side by side to another token (with a **'tight AND'** between tokens), does not find any search results.
3. Stopwords are only searched for in combination with at least one other token from the search term that is side by side to the stopwords with a **'tight AND'** between tokens. The second token may either be a non-stopwords token or a stopwords token.
4. Stopwords are optional search terms. Results are returned even if they do not contain the stopwords given in the search term.

i Note

Currently only single-token stopwords in the stopwords table are used. Multi-token stopwords can be defined in the stopwords table, but are ignored by `sys.esh_search()`.

i Note

To get better search results we recommend to use the same stopwords definition for all columns.

Limitations

Maximum length of a generated phrase

During a search, all possible phrases with a length of up to 6 tokens are generated. This means, that multi-token term mappings cannot replace a sequence of 7 or more tokens. In addition, setting the parameter `composeWords` to a value of 7 or higher has the same effect as setting the parameter to a value of 6. It is also not possible to find a value with more than 6 tokens in a column without full-text index.

As a work around, longer search terms with more than 6 tokens have to be enclosed by double quotes to make sure that the whole search term is processed as a single phrase. Then even term mappings and the composition of words can be used with 7 or more tokens.

4.2.8.4 Field Groups

Attributes of a view can be combined in a field group. The name of the field group can then be used to search a search term in all columns of the field group.

For example, the field group 'award' can be defined as a group over columns 'id', 'title', and 'abstract'. 'award' can then be used as a identifier in the query language expression.

As a second group, 'investigator' can be defined as a group over columns 'invFirstName', 'invLastName', and 'invEmail'.

Sample Code

Example: Query Language Expression

```
SCOPE:awards investigator:adams award:carbon
// this is equivalent to the following search
SCOPE:awards (invFirstName invLastName invEmail):adams (id title
abstract):carbon
```

4.2.8.5 Supported SQL Types

The query language supports all SQL types that can be used in a call to the `CONTAINS ()` predicate.

(N)VARCHAR and Text Types

Usually each token of the search input is searched for individually in the different columns, as the query language defines all `AND`, `OR`, and `NOT` operations as set based operations by default. This means that results would be missing when searching in string type columns (`VARCHAR` and `NVARCHAR`) or when searching in a text column with an active term mapping configuration.

To receive the search results as expected by the user, additional searches with combined adjacent search terms have to be implemented.

For example, the query `SAP SE` defines two searches for `'SAP'` and for `'SE'` in a company name column of type `NVARCHAR` (without a full-text index). As this does not find a company named `'SAP SE'`, an additional search is done that combines both terms and searches for `'SAP SE'` in the `NVARCHAR` column.

Search terms given in the query language expression are combined if they are adjacent, if there are no other operators given between the search terms, and if there are no modifiers like fuzzy threshold, ranking weight, or column selectors.

Examples:

- `'hana database'` searches for `'hana'` and `'database'` or for `'hana database'`.
- `'hana AND database'` searches for `'hana'` and `'database'` only. Because of the `AND` operator the search terms are not considered to be adjacent anymore.
- `'hana database~0.7'` searches for `'hana'` and `'database~0.7'` only because of the fuzzy threshold given for `'database'`.

Date Types

When searching in columns with date types (SQL types `DATE`, `SECONDDATE`, `TIMESTAMP`) or in columns that contain dates (SQL types `NVARCHAR` and `DECIMAL` with `@Semantics` annotation for dates), the following date formats are supported by the query language:

- `YYYYMMDD` (ISO)
- `YYYY-MM-DD` (W3C)
- `MM/DD/YYYY` (US)
- `DD.MM.YYYY` (German)

Spatial Data

It is possible to define filters on the spatial data types `ST_POINT` and `ST_GEOMETRY`.

The attribute conditions `:WITHIN:`, `:COVERED_BY:` and `:INTERSECTS:` are available and are internally mapped to the SQL functions `ST_Within`, `ST_CoveredBy`, and `ST_Intersects`.

The operators accept the name of a column of type `ST_POINT` or `ST_GEOMETRY` on the left side and a spatial object in well-known text format (WKT) on the right side. Accepted object types are; Point, MultiPoint, LineString, MultiLineString, Polygon, MultiPolygon, CircularString, and GeometryCollection.

The coordinates in the WKT representation have to be given in the spatial reference system of the database column.

Sample Code

Spatial Filter Examples

```
location:COVERED_BY:POLYGON((13.4 52.5, 13.5 52.5, 13.5 52.6, 13.4 52.6, 13.4
52.5))
envelope:INTERSECTS:LINESTRING(13.123 52.543, 13.899 52.789)
```

It is also possible to do a fuzzy search on columns of data type `ST_POINT`. In this case a fuzzy score function for `ST_POINT` has to be defined in the search configuration to get meaningful fuzzy scores.

The following example shows how to define a score function on a column called "LOCATION" with data type `ST_POINT` and how to run a search in this column. The coordinates given in the query language expression are used as the reference point for the score function, so entries nearer to this location get higher fuzzy scores.

Sample Code

Sample Configuration for Score Function on `ST_POINT` Column

```
...
{
  "@Search.fuzzinessThreshold": 0.5,
  "@EnterpriseSearch.searchOptions":
  "scoreFunction=linear,scoreFunctionScale=10000,scoreFunctionDecay=0.8",
  "Name": "LOCATION"
}
...
```

Sample Code

Example Queries: Fuzzy Search in `ST_POINT` Column

```
SCOPE:customers location:POINT(8.375620 49.983617)
SCOPE:customers adams location:POINT(8.375620 49.983617)
```

Binary Data

Columns of SQL type `VARBINARY` that contain binary data can be used for filter conditions.

It is possible to search for binary values that are given as hexadecimal values in a query language expression. This means that it is, for example, possible to search for BUID values.

Sample Code

Binary Values in Filter Conditions

```
SCOPE:customers id:EQ:FA163E38C6481EE8AADE50EE79D086E4
SCOPE:products id:NE:fa163e38c6481EE8aade50ee79d086e4
```

Note

Binary values in the search result are returned using a base64 encoding, as defined in the OData standard version 4.

Related Information

[Search with Partial Dates \[page 237\]](#)

4.2.8.5.1 Search with Partial Dates

It is possible to search with incomplete dates, either with a freestyle search over all columns or with a search in a single column.

Sample Code

Search with an Incomplete Date

```
// search for all awards related to 'Adams' with any date in 2015
SCOPE:awards adams 2015
// search for all awards related to 'Adams' ending in April 2016
SCOPE:awards adams expirationDate:2016-04
```

Searching with an incomplete date is supported for all date and timestamp columns (see below). When searching with a valid date pattern in any of these columns, all dates or timestamps that match the given pattern are returned.

Columns are treated as date columns if they are of SQL type `DATE`, or `(N) VARCHAR` with any of the `@Semantics` annotations for dates.

Columns are treated as timestamp columns if they are of SQL type `TIMESTAMP`, `SECONDDATE`, or `DECIMAL` with any of the `@Semantics` annotations for dates.

Supported date formats are:

- ISO: `YYYYMMDD`, `YYYYMM`, `YYYYMM*`
- W3C: `YYYY-MM-DD`, `YYYY-MM`, `YYYY-MM-*`
- US: `MM/DD/YYYY`, `MM/*/YYYY`
- German: `DD.MM.YYYY`, `MM.YYYY`, `*.MM.YYYY`

To search for all dates within a given year, the year has to be given only:

- `YYYY`, `YYYY*`

Note

For all of the above date patterns, leading zeros in the year (`YYYY`) are not supported. This means that with a date pattern, it is possible to search for dates between 1000-01-01 and 9999-12-31 only.

Sample Code

Search for all Dates Within a Given Year

```
// search for all dates in 2015
SCOPE:awards 2015

// search for all dates in 2015 using a wildcard
SCOPE:awards 2015*
```

To search for all dates within a given month, year and month have to be given in any of the supported date formats.

Sample Code

Search for all Dates Within a Given Year and Month

```
// search for all dates in April 2015
SCOPE:awards 201504
SCOPE:awards 2015-04
SCOPE:awards 04.2015
// search for all dates in April 2015 using a wildcard
SCOPE:awards 201504*
SCOPE:awards 2015-04*
SCOPE:awards 2015-04-*
SCOPE:awards *04.2015
SCOPE:awards *.04.2015
SCOPE:awards 04/*/2015
```

4.2.8.6 Row Operator

Usually all terms and attribute conditions given in the query language expression are treated as individual query parts. In some cases, when using 1:n joins, more than one search term or attribute condition will be valid for the same row of the view. The `ROW:` operator is used to combine these conditions.

Within the row operator, the `AND` operator, the `NOT/-` operator, and the fuzzy operator (`~`) can be used.

Sample Code

Row Operator Examples

```
ROW:(invlastname:wilson instcountry:"united states")
ROW:(programreferencetext:(chemistry environmental) is equal to
ROW(programreferencetext:chemistry programreferencetext:environmental)
// error, freestyle search not supported
ROW:(organic carbon)
// error, OR operator, attribute lists and attribute groups not supported
ROW:(invfirstname:richard OR instcountry:"united states")
ROW:((invfirstname invlastname):wilson)
ROW:(investigator:wilson)
```

Because of limitations in the search engine, only one condition or search term within the `ROW:` operator can be assigned a ranking weight greater than 0. All other conditions and terms have to be set to a ranking weight of 0.

Sample Code

Row Operator and Ranking Weight

```
// weight given in query language
ROW:(invlastname:wilson instcountry:bermuda^0.8) is equal to
ROW(invlastname:wilson^0 instcountry:bermuda^0.8)
// weight given for row operator
ROW:(invlastname:wilson instcountry:bermuda)^0.8 is equal to
ROW(invlastname:wilson^0.8 instcountry:bermuda^0)
// assumption: search configuration contains default weight=0.7 for column
CityName
ROW:(invlastname:wilson instcountry:bermuda) is equal to
ROW(invlastname:wilson^0.7 instcountry:bermuda^0)

// search configuration does not contain a default weight for column CityName
ROW:(invlastname:wilson instcountry:bermuda) is equal to
ROW(invlastname:wilson^1 instcountry:bermuda^0)

// complex expression
ROW(invlastname:wilson~0.7^0.8 AND NOT abstract:carbon~0.9 AND
instcountry:EQ:bermuda)

// error
ROW:(invlastname:wilson^1 instcountry:bermuda^0.8)
```

4.2.8.7 Separation of User Input and Other Filter Conditions

In the query language expression, it is possible to separate the search terms given by the user from other filter conditions that are automatically generated by the search application, for example, selected facet values and authorization checks.

i Note

The separation of search terms and filter conditions is currently used by `sys.esh_search()` to implement some performance optimizations. While it does not change the search results, it is recommended to use this feature to improve response times.

For example, a user may enter a search term like 'carbon 2016', may have the authorization to see documents for the 'United States' only and may have selected the facet value 'Colorado' in the UI.

The resulting search without the separation of search terms (`carbon 2016`) and filter conditions (`instcountry:"United States" inststate:EQ:Colorado`) then displays as follows:

Sample Code

Query Language Expression Without Separation of Search Terms and Filter Conditions

```
SCOPE:awards carbon 2016 instcountry:"United States" inststate:EQ:Colorado
```

The following example shows the same query with filter conditions separated from the search term:

Sample Code

Query Language Expression with Separation of Search Terms and Filter Conditions

```
SCOPE:awards carbon 2016 FILTER:(instcountry:"United States"  
inststate:EQ:Colorado)
```

Filter Conditions and Wherefound/Whyfound Information

In the example above, it does not make sense to display the authorization condition ('United States') and the selected facet value ('Colorado') in the whyfound information. Users expect to get back the whyfound information for their search terms only and do not want to see the additional filters as highlighted information in the UI.

Therefore search conditions that are given in the `FILTER:` part of a search expression are not added to the wherefound and whyfound information that is returned by `sys.esh_search()`.

If an application needs wherefound or whyfound information for filters, it is possible to get this information using the `FILTERWF:` operator instead of the `FILTER:` operator, as shown in the example below.

☰ Sample Code

Get Wherefound and Whyfound Information for Filter Conditions

```
SCOPE:awards carbon 2016 FILTERWF:(instcountry:"United States"  
inststate:EQ:Colorado)
```

4.2.9 Method 'GetSuggestion' - Suggestion Call

The suggestion call returns a list of automatically completed terms of the request term that are calculated from the content of a column.

Overview

If you type a search term the beginning of the word is automatically completed and suggestions are returned. If the search term contains more than one word, then only for the word snippet entered last suggestions will be returned. The other words in front will be used as freestyle terms.

To use suggestions you must enable `@EnterpriseSearch.defaultValueSuggestElement` for all columns. This property is part of the annotation `EnterpriseSearch`.

Multiple occurrences of the same term are reduced to a unique term.

The response of a suggestion request returns the following information for a hit:

- the scope, i.e. the name of the view where the hit is found
- the suggestion term itself
- the highlighted term, i.e. the suggestion term including the search highlighted term
- the rank of the hit
- the count number of objects with this suggestion term

i Note

The suggestion term and the highlighted term are returned lowercase.

The suggestion service supports only freestyle search. Therefore, the input terms are always interpreted as freestyle search terms and never as query language. The output is a summary of attribute values that do not contain any specific query language syntax.

The Request

The suggestion call is invoked by the `GetSuggestion` function, which offers the following parameters:

- `term`

This mandatory argument contains the text, for which suggestions are requested.

- `fuzzinessThreshold`

With this optional numeric parameter the user can control the fuzziness of the suggestion terms. The default fuzziness is 0.85. The value range of the parameter is (0, 1].

We recommend values greater than 0.5 else the process time might increase overproportional.

- `type`

This optional numeric parameter determinates where the `getSuggestion` function searches for suggestions.

- `content`: search inside the data of connectors (default)
- `scope`: returns suggestions for connector names

- `count`

Set to `true` the optional boolean parameter calculates the number of objects. It is shown in the response as `count`. The default is `false`.

Features

The suggestion terms do not have to match the suggestion term exactly as fuzzy search (a fault tolerant search) is supported.

Supported query options (URL parameters) are `$filter`, `$apply`, `$top`, `$skip`

The following query options are not supported and usage will result in an error:

- `$orderby` (the response is ordered by score in descending order by default)
- `$select`, `$count`
- `facets`, `facetlimit`
- `estimate`
- `wherefound`, `whyfound`

Federated search over multiple views is supported:

- Suggestions from multiple views are returned ordered by score.
- To limit suggestions to a single view, the `SCOPE` parameter can be given in the query parameter of the `Search.search()` function.

Suggestion columns that are no freestyle columns are accepted as a valid configuration. There are scenarios where a suggestion column is not a freestyle column. For example, suggestions use a column that contains noun groups that have been found in a `longtext` column, while the search uses the `longtext` column to find all related documents.

Blob columns are not supported for suggestions.

Examples

In the example we assume a table containing a column with company names. While entering the search term the company names are being completed automatically.

Request: /\$all/GetSuggestion (term='deut')? \$filter=Search.search(query=<additional restrictions>)

Sample Code

```
{
  "scope": "COMPLETE_VIEW",
  "term": "sap deutschland",
  "highlighted": "sap <b>deut</b>schland",
  "rank": 0.9
},
{
  "scope": "COMPLETE_VIEW",
  "term": "sap ag deutschland",
  "highlighted": "sap ag <b>deut</b>schland",
  "rank": 0.8
},
...]
```

Request: /\$all/GetSuggestion (term='sap deut')? \$filter=Search.search(query==<additional restrictions>)

Sample Code

```
"value": [
{
  "scope": "COMPLETE_VIEW",
  "term": "sap deutschland",
  "highlighted": "<b>sap</b> <b>deut</b>schland",
  "rank": 0.9
},
{
  "scope": "COMPLETE_VIEW",
  "term": "sap ag deutschland",
  "highlighted": "<b>sap</b> ag <b>deut</b>schland",
  "rank": 0.8
},
...]
```

Intrinsic Fuzzy Weight and Search Options

The suggestion call uses a fuzziness weight of 0.85 and the following search options by default during execution:

- for character like columns: `similarCalculationMode=substringsearch`
- for full-index columns: `similarCalculationMode=typeAhead`, `ts=compare`, `etw=0.02`
Nevertheless, via the annotation `@EnterpriseSearch.searchOptions` the mode `similarCalculationMode=substringsearch` can be set. As a result, `GetSuggestion()` with full-text indexes and with columns with `scm=substringsearch` behave similar (not identical) to character like columns.
- for numeric columns: none, default `CONTAINS` statement

4.2.10 Dynamic Search Configurations

Overview

i Note

Some applications define their own persistence to store search configurations. With `sys.esh_config()` and static configurations, the configurations have to be copied from the application's persistence to the SAP HANA search models by calling `sys.esh_config()` after every configuration change. In some cases, this may lead to inconsistencies between the search model stored in the SAP HANA configuration and the model stored in the application's persistence layer. To avoid the synchronization effort and possible inconsistencies, such applications want to pass the configuration to SAP HANA dynamically with each call to `sys.esh_config()`.

Other applications define varying configurations that depend on, for example, the user settings or other parameters. In this case, each call to `sys.esh_config()` needs a new configuration and it is not possible to write these configurations to SAP HANA with `sys.esh_config()`, as multiple searches with different configurations may run in parallel.

For the above use cases, `sys.esh_search()` allows the definition of dynamic search configurations at runtime. If a search configuration is passed to `sys.esh_search()`, all search configurations already stored in the SAP HANA configuration tables are ignored. This means that only the given search configurations are visible to this search call.

The format of the search configurations for `sys.esh_config()` is identical to the configurations for `sys.esh_config()`. For details, see the `sys.esh_config()` documentation. At runtime, the search configurations that are passed to `sys.esh_config()` have to be validated and the search views have to be analyzed. As this is time-consuming, dynamic search configurations lead to slightly higher response times of `sys.esh_config()` compared to calls with static search configurations that had been created before with `sys.esh_config()` and SAP HANA CDS.

Basic Example

i Note

The configurations given in the examples below have been shortened to keep the sample code clear.

The following example shows how to add a dynamic search configuration to a call to `sys.esh_search()`.

Sample Code

Dynamic Search Configuration

```
[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            {
              "@EnterpriseSearch.key": true,
              "@EnterpriseSearch.presentationMode": [
                "TITLE"
              ],
              "Name": "id"
            },
            {
              "@EnterpriseSearch.presentationMode": [
                "TITLE"
              ],
              "@Search.defaultSearchElement": true,
              "Name": "title"
            }
          ]
        }
      }
    ],
    "URI": [
      "/v5/$all?$count=true&$top=10&$filter=Search.search(query='SCOPE:awards carbon')"
    ]
  }
]
```

Bulk Request

It is possible to run many searches in parallel by specifying multiple pairs of configurations and search URIs. The following example shows a bulk request with two configurations and two search URIs. Both searches are executed in parallel.

Sample Code

Bulk Request with two Configurations and two Search URIs

```
[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            {
              "@EnterpriseSearch.key": true,
              "@EnterpriseSearch.presentationMode": [
```

```

        "TITLE"
      ],
      "Name": "id"
    },
    {
      "@EnterpriseSearch.presentationMode": [
        "TITLE"
      ],
      "@Search.defaultSearchElement": true,
      "Name": "title"
    }
  ]
}
],
"URI": [
  "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
]
},
{
  "Configuration": [
    {
      "Fullname": "AWARDSDB/documents",
      "EntityType": {
        "@Search.searchable": true,
        "@EnterpriseSearch.enabled": true,
        "Properties": [
          ...
        ]
      }
    }
  ]
},
"URI": [
  "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
]
}
]

```

Federated Search

As with static configurations, it is possible to run a federated search over multiple dynamic configurations. In this case, multiple configurations are given together with a single search URI.

The example below shows a federated search over two dynamic search configurations.

Sample Code

Federated Search Using two Dynamic Search Configurations

```

[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            {
              "@EnterpriseSearch.key": true,
              "@EnterpriseSearch.presentationMode": [

```

```

        "TITLE"
    ],
    "Name": "id"
  },
  {
    "@EnterpriseSearch.presentationMode": [
      "TITLE"
    ],
    "@Search.defaultSearchElement": true,
    "Name": "title"
  }
]
},
{
  "Fullname": "AWARDSDB/documents",
  "EntityType": {
    "@Search.searchable": true,
    "@EnterpriseSearch.enabled": true,
    "Properties": [
      ]
    }
  }
],
"URI": [
  "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
]
}
]

```

Sharing a Configuration

In some cases, an application wants to run more than one search with a single configuration. To avoid that the configuration has to be repeated and evaluated for each URI, it is possible to define multiple URIs that share the same configuration.

The example shows how to define two URIs that share the same configuration.

Sample Code

Two Search URIs Sharing a Single Configuration

```

[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            {
              "@EnterpriseSearch.key": true,
              "@EnterpriseSearch.presentationMode": [
                "TITLE"
              ],
              "Name": "id"
            },
            {
              "@EnterpriseSearch.presentationMode": [

```

```

        "TITLE"
      ],
      "@Search.defaultSearchElement": true,
      "Name": "title"
    }
  ]
}
],
"URI": [
  "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon')",
  "/v5/$all?$count=true&$top=10&$filter=Search.search(query='fiber')"
]
}
]

```

Privileges Needed for Dynamic Search Configurations

When using dynamic search configurations, the database user needs the following permissions:

- **Execute permission** on the built-in procedure `sys.esh_search()`
- **Read** privileges for all database objects that will be searched (select privilege for views or execute privilege for table functions)
- **Select** privileges on all term mapping tables that are used in the search configuration

Select privileges on `_SYS_RT.ESH_MODEL` and `_SYS_RT.ESH_MODEL_PROPERTY` are not needed when using dynamic search configurations.

4.2.11 The Language Vector

By using the language vector it is possible to define a prioritized list of language codes.

Definition of the Language Vector

In a call to `sys.esh_search()` it is possible to define a sorted list of language codes that defines the language priorities for the contents of language-dependent columns. The list of language codes is called the language vector.

For example, a user that is an English native speaker, that is fluent in Italian and that has a basic knowledge of Spanish can define the language vector `['en', 'it', 'es']`. In this case, English texts will be returned for language-dependent columns whenever they are available. Otherwise, texts will be returned in Italian or Spanish, or, if none of these languages is available, the contents of the column will be empty.

The following example shows how to pass the language vector to `sys.esh_search()` using the `Language` parameter.

Sample Code

```
[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            ...
          ]
        }
      }
    ],
    "URI": [
      "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
    ],
    "Language": [
      "en", "it", "es"
    ]
  }
]
```

Note

Because of the large number of existing language code formats, there are no conversions between language code formats available within `esh_search()`. This means that the language codes given in the call have to be of the same format as the language codes stored in the language columns of the view. If varied language code formats are used in the different language columns, all of these language code formats have to be given in the call to `sys.esh_search()`.

Language codes are case-sensitive. So, for example, when using ISO 639-1 codes, lowercase country codes have to be given, whereas ABAP 2-character codes have to be given in uppercase.

The example above shows ISO 639-1 language codes. If the application uses ISO 639-2 to store 3-character language codes, the vector has to be `['eng', 'ita', 'spa']` instead.

If the calling application uses both 1-character ABAP language codes (as defined by column `SPRAS` in table `T002`) and 2-character ABAP language codes (as defined by column `LAISO` in tables `T002` or `T002X`), both codes have to be given and the language vector for the previous example has to be either `['E', 'I', 'S', 'EN', 'IT', 'ES']` or `['E', 'EN', 'I', 'IT', 'S', 'ES']`.

If no language vector is given in the call to `sys.esh_search()`, a default language vector is created out of the database session context variables `LOCALE` and `LOCALE_SAP`. These variables usually contain the ABAP 1-character language code and the ISO 639-1 language code of the logon language. These codes are used to build the default language vector. For example, for English as a logon language the default language vector is `['E', 'en']`.

If the session variables are not defined, English is used as default language and the language vector is set to `['E', 'en']`.

4.2.11.1 Search in Language-Dependent Columns

If a column is defined as a language-dependent column by using the annotation `@Semantics.languageReference`, the language vector is used and the behavior of search in this column changes as follows:

1. In the language-dependent column, values are searched in all of the languages that are given in the language vector. Values in other languages that are not given in the language vector are not searched.
2. WSnippets in the whyfound information are returned in any of the languages given in the language-vector that contains a search term. The value that matched the search term best is returned, independent of the order of languages in the language vector.
3. Column values in the search results are returned in the best available language as defined by the language vector.
4. Snippets and highlighted text in the search result are returned in the best available language only.

If a text does not exist in any of the languages defined in the language vector, an empty value (NULL) is returned instead. Instead of returning NULL values for snippets or highlighting annotations, the annotations may be removed from the search response.

If a text does not exist in any of the languages defined in the language vector, an empty value (NULL) is returned instead. Instead of returning NULL values for snippets or highlighting annotations, the annotations may be removed from the search response.

For language-dependent columns, the language of the value that is returned in the search response is returned with the annotation `@com.sap.vocabularies.Search.v1.Language`.

i Note

Version Dependent Implementation: With API version 6 (SAP HANA 2.0 SPS02) search was done in all languages that were available for a language-dependent column. As this gave unexpected search results, search is now done in the languages given in the language vector only.

i Note

While language dependent columns are usually modeled as 1-to-many joins to a text table, using the `@Semantics.languageReference` annotation makes the language-dependent text column behave like a 1:1 column because search will always return one value only. Therefore language-dependent columns can be defined as response columns by using the query option `$select` or the `@EnterpriseSearch.presentationMode` annotation.

The language code column is not allowed as a response column, so the `@EnterpriseSearch.presentationMode` annotation cannot be used. Instead, the language code is always returned with annotation `@com.sap.vocabularies.Search.v1.Language`.

i Note

Best Available Language

Languages in the language vector are ordered by priority.

In the example above (`"Language": ["en", "it", "es"]`) this means that the preferred language is English. If there is no English text available, the text shall be returned in Italian. And if there is also no Italian text available, a Spanish text shall be returned.

This decision is made for each column and also for each row of the language-dependent columns individually, so one column value may be returned in English, while another value is returned in Spanish because there is no English or Italian text available.

The behavior described here is called 'best available' language.

Combining Language-Dependent Columns with Other Search Features

For language-dependent columns, that are defined as a multi-value or a facet column or that are part of a subobject, the behavior changes as described below:

1. Facet columns (without a label column) are always returned in the first language given in the language vector. If a value in this language does not exist, the facet value is set to NULL. Therefore it is only included in the facet if NULL values for facets are enabled.
2. Facets with label column: label texts for facets are returned in the best available language only.
 - For each value of the facet, a text in a different language may be returned if not all texts are available in all languages.
 - The label column for a facet column is defined using the annotation `@Consumption.labelElement`.
3. Each language-dependent subobject column is returned in the best available language only. The key of the subobject is used to identify texts in different languages that belong to the same subobject. Therefore the definition of a subobject key is mandatory if a subobject contains a language-dependent column and the language-dependent column must not be part of the subobject key definition.
4. Multi-value columns are always returned in the first language that is given in the language vector. If a value in this language does not exist, an empty value (NULL) is returned.

4.2.12 Suggestions, Groupby, and Groupby-Filter

The groupby operation of `sys.esh_search()` can be used to get the distinct values of a column.

It can also be used to create suggestions in a search application. The suggestion feature is also called typeahead or autocomplete, and it suggests possible search terms for a partial user input.

Getting the Distinct Values of a Column

The following example shows how to get the names of institutions working on a topic that contains the search term 'carbon'.

Sample Code

Example: Get Distinct Last Names

```
/* get all institution names (unordered) */
```

```

call esh_search('[ "/AWARDSSQL/$all?
$apply=filter(Search.search(query='SCOPE:awards carbon'))/
groupby((instName))" ], ?);

/* get first three institution names (ordered by lastname) */
call esh_search('[ "/AWARDSSQL/$all?$top=3&$orderby=instName&
$apply=filter(Search.search(query='SCOPE:awards carbon'))/
groupby((instName))" ], ?);

```

The response of the second call:

Sample Code

Response of a Groupby Query

```

{
  "value": [
    {
      "@odata.context": "$metadata#awards",
      "instName": "ABC University"
    },
    {
      "@odata.context": "$metadata#awards",
      "instName": "Another University"
    },
    {
      "@odata.context": "$metadata#awards",
      "instName": "BBB Company Inc"
    }
  ]
}

```

It is also possible to count the number of anchor keys for each institution name and to return the results ordered by this count in descending order, as it is shown in the following example.

Sample Code

```

/* get most frequent institution names (ordered by descending count of anchor
documents) */
call esh_search('[ "/AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards carbon'))/
groupby((instName),aggregate($count as Count))" ], ?);

```

The response of this call:

Sample Code

Example: Response of a Groupby Query with Aggregation

```

{
  "@com.sap.vocabularies.Common.v1.Label": "Count by instName",
  "@odata.context": "$metadata#awards(instName,Count)",
  "value": [
    {
      "instName": "A Company LLC",
      "Count": 16
    },
    {
      "instName": "University of XXX",
      "Count": 15
    }
  ],
}

```

```

    {
      "instName": "ABC University",
      "Count": 13
    }
  ]
}

```

Suggestions

If an application wants to display suggestions for possible search terms to an user, it may send a search request after the user entered a partial search term.

In the following example, the user entered 'ferr' and the application shall display three suggestions for possible last names beginning with 'ferr', like 'Ferreira', 'Ferraro', or 'Ferris'. To get the most frequent last names (this is the last names with the largest count of anchor objects), an aggregation by count is added to the query. The resulting search query is shown below.

Sample Code

Example: Suggestion Call for Last Names

```

/* get three most-frequent last names beginning with 'ferr' */
call esh_search([' /AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards invLastName:ferr*'))/
groupby((invLastName),aggregate($count as Count))" ], ?);

```

The search result:

Sample Code

Search Response for Suggested Last Names

```

{
  "@com.sap.vocabularies.Common.v1.Label": "Count by invLastName",
  "@odata.context": "$metadata#awards(invLastName,Count)",
  "value": [
    {
      "invLastName": "Ferreira",
      "Count": 9
    },
    {
      "invLastName": "Ferraro",
      "Count": 8
    },
    {
      "invLastName": "Ferris",
      "Count": 4
    }
  ]
}

```

Groupby Filter for Suggestions

In the data model that is used for the example above, the `invLastName` column is coming from a one-to-many join. This means that there may be more than one last name assigned to a single anchor object.

Because of the two-step search approach (see `search-read-breakup`), the search result as output of the first step is defined as all anchor objects that fulfill the search condition (`invLastName:ferr*`). In the second step, the groupby operator reads all last names assigned to these anchor objects and creates a list of distinct last names. Because of the one-to-many join, it is expected that the groupby operator returns last names beginning with `ferr` and also last names that do not begin with `ferr` (if, for example, last names 'Ferreira' and 'Moore' are assigned to the same anchor object).

Users expect to get back suggestions beginning with their input only. So, for example, 'Moore' is not expected as a suggestion when 'ferr' has been entered by the user. Therefore the groupby operator implicitly takes the filter conditions that are defined on the groupby column and adds this filter condition to the second search step when reading the distinct values of the groupby column.

Only filter conditions that explicitly contain the column name of the groupby column are added to the groupby filter. In the example above, the filter condition `invLastName:ferr*` is added to the groupby operation on column `invLastName` because the column name is part of the filter condition.

All kinds of attribute filter conditions are supported. The filter conditions have to be explicitly defined on the groupby column or on one of the groupby columns, if the groupby operator uses more than one column. Examples for supported attribute conditions are shown below.

- `invLastName:ferr*`
- `invLastName:EQ:Ferraro`
- `invLastName:LT:Bauer`
- `invLastName:BT:[Armstrong,Bertolini]`
- fuzzy search with `invLastName:ferris~0.8`

i Note

`FILTER()` and Groupby Filter

Search conditions that are given in the `FILTER()` operator of the query language are not added as groupby filters.

The `FILTER()` operator is used to add authorization checks and boosting conditions to the query and to separate these from the search conditions. The filter conditions are extracted from the search conditions only.

Groupby filters can be disabled by setting the query option `filteredgroupby=false` in the call to `sys.esh_search()`. In this case all distinct values of the groupby column are returned.

More Examples for Suggestion Calls

It is possible to get suggestions for more than one column by adding more than one query to the search call. The following example shows how to get suggestions for last names and first names in a single call to `sys.esh_search()`.

☰ Sample Code

Example: Getting Suggestions for Multiple Columns in a Single Call

```
/* get most frequent last names and first names */
call esh_search('[ "/AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards invLastName:ferr*'))/
groupby((invLastName),aggregate($count as Count))",
"/AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards invFirstName:ferr*'))/
groupby((invFirstName),aggregate($count as Count))" ]', ?);
```

Suggestion calls are also possible if the user enters more than one search term. If the application wants to display suggestions for the last token that the user entered, the search call looks as shown below. The example shows a query for user input 'carbon ferr'. A search for carbon shall be done and all last names beginning with ferr shall be returned.

☰ Sample Code

Example: Getting Suggestions Combined with Other Search Terms

```
/* get most frequent last names beginning with 'ferr' for user input 'carbon
ferr' */
/* -> suggestion for last term that the user currently
types */
call esh_search('[ "/AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards carbon invLastName:ferr*'))/
groupby((invLastName),aggregate($count as Count))" ]', ?);
```

In the previous example, 'carbon' is searched in all default search columns using the search settings defined in the configuration (fuzziness threshold, search options, and so on).

The suggestion term 'ferr' is searched as an exact search with a wildcard. Alternatively a fuzzy search can be done with similar calculation mode typeahead. This gives similar results to the search with a wildcard, but also accepts spelling errors in the user input.

The following example shows a user input of 'carbon ferre' that also returns 'ferraro' and 'ferrier' as suggestions. With the wildcard search these names would not be suggested because they do not match the search condition ferre*.

☰ Sample Code

Example: Getting Suggestions with Fuzzy Search

```
/* get most frequent last names beginning with 'ferre' for user input 'carbon
ferre' */
/* fuzzy search that accepts spelling errors */
call esh_search('[ "/AWARDSSQL/$all?$top=3&
$apply=filter(Search.search(query='SCOPE:awards carbon
invLastName:ferre~0.7[similarCalculationMode=typeahead]'))
/groupby((invLastName),aggregate($count as Count))" ]', ?);
```

In this example, the search mode 'typeahead' is only used for the suggestion term and replaces the wildcard search. For all other search terms the settings from the search configuration are used.

4.2.13 Definition of the User Language

By default, `sys.esh_search()` uses the language that is defined in the database session context to get language-dependent texts for response columns.

Alternatively, it is possible to define the language as a parameter to `sys.esh_search()`.

The language may be given as a 2-character iso language code or as a 1-character ABAP language code. If needed, `sys.esh_search()` internally converts a given language code to the other format (for example, an ABAP application gives a 1-character ABAP language code, while the search view is defined with 2-character iso language codes).

Sample Code

Language Code Example

```
[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            ...
          ]
        }
      }
    ],
    "URI": [
      "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
    ],
    "Language": [
      "en"
    ]
  }
]
```

4.2.14 Writing the Search Response to a Table

Applications may want to call `sys.esh_search()` and to process the result set in a single SQL Script procedure (without first passing the search response to the application, parsing the JSON response, and then passing the search result back to the database).

It is possible to optionally specify the name of a result table in the call to `sys.esh_search()`. In this case, instead of copying the search response to the JSON response object, the keys and optionally the score of the search results are copied to the result table.

The lifecycle of the data in the result table has to be handled by the application. This means that the application has to make sure that the result table is empty before `sys.esh_search()` is called. Otherwise the new search results will be appended to the existing table contents. The application also has to make sure that the results are removed from the result table if they are no longer needed. To simplify this, a temporary table may be used as a result table.

The result table has to be defined as follows:

- For each anchor key column (column with `@EnterpriseSearch.key` annotation), the result table has to define a column with the same name and with an identical or compatible SQL data type.
- Optionally, a column called 'SCORE' or '_SCORE' can be added. The SQL type of this column has to be compatible with the `SCORE()` function. `DECIMAL` or `DECIMAL(4, 3)`, for example, can be used.

The columns are identified by their name and it is not possible to define another mapping of columns.

If a result table is specified, the search result is only copied to the result table. In other words, the JSON response object returned by `sys.esh_search()` only contains status information and error messages, but no search results (the 'value' array is empty), no result count, and no facets.

Most of the search parameters (for example, 'facets', 'facetlimit' or '\$count') are ignored. '\$top', '\$skip', and '\$orderby' are used to define which columns are copied to the result table.

A result table can only be specified, if the search URI references a single view. In other words, the scope of the search has to be limited to one view only.

Both static search configurations and dynamic search configurations can be used in combination with a result table.

Sample Code

Definition of a Result Table

```
[
  {
    "URI": [
      "/v5/$all?$count=true&$top=10&$filter=Search.search(query='SCOPE:awards
carbon')"
    ],
    "ResultTable": {
      "SchemaName": "AWARDSDB",
      "TableName": "TEMP_RESULT_TABLE"
    }
  }
]
```

4.2.15 Defining a Search Timeout

The timeout parameter can be used to define a timeout in seconds for each element of a bulk request or a federated search.

Context

If a search in a view takes longer than the defined timeout, the search will be canceled and a timeout error will be returned for this search. Only the long-running search is canceled. This means that the results of all other search requests that finished earlier will be returned in the search response.

i Note

The timeout is checked at several points while executing a search. As a result, it is not a hard limit for the runtime of a search. The search may run longer than specified in the timeout parameter until the next check for a timeout is reached.

i Note

Instead of using the timeout parameter, a database client may also specify a query timeout. If this timeout is reached, all running searches are stopped, all search results collected so far are discarded, and the call to `sys.esh_search()` fails with a SQL timeout error. For example, to set the query timeout in Java, the JDBC function `setQueryTimeout` in class `java.sql.Statement` can be used.

Procedure

Use the Timeout parameter to define a timeout in seconds.

Sample Code

Example Timeout set to 5 seconds

```
[
  {
    "Configuration": [
      {
        "Fullname": "AWARDSDB/awards",
        "EntityType": {
          "@Search.searchable": true,
          "@EnterpriseSearch.enabled": true,
          "Properties": [
            ...
          ]
        }
      }
    ],
    "URI": [
      "/v5/$all?$count=true&$top=10&$filter=Search.search(query='carbon') "
    ],
    "Timeout": 5
  }
]
```

4.2.16 Row-Based Privileges

Introduction

In some search use cases the users shall not be able to see all lines of a search view. Instead, they shall only see a limited set of lines of the search view based on their current access privileges.

One option to define these access privileges is using database features like SQL-based privileges.

As an alternative, the privileges may also be managed by the application layer that runs the search application on top of the SAP HANA database. An example is Enterprise Search where the access privileges are defined in the ABAP CDS layer and have to be passed to the search runtime running in the SAP HANA database. In this scenario, the `AUTH: operator` described in this section can be used by the search application to define the access privileges of the user that executes a search.

Example

Let's assume there is a search view that is built on top of a customer table that contains, for example, the customer name. The second table used in the search view is a details view that contains a country code, an amount column and some other values. The details table is joined to the customer table using a one-to-many join.

A search user that wants to search for a customer called 'Adams' may now be authorized to see only those lines of the search view where the country code equals 'US' as well as the amount is lesser than 100.000.

The search application has to create a search call that contains the search term entered by the user ('adams') and also the condition that defines the access privileges (`countrycode:EQ(S):US AND amount:LT(S):100000`).

Unwanted Results When Defining Privileges as Search Conditions

The access privileges given in this example can be added to the search call in various ways. But if the `AUTH: operator` described in the following section is not used, the privileges are given in the wrong way and, as a result, the user may see some information he is not allowed to see. This section explains how the access privileges shall not be defined and the following section shows how they can be defined using the `AUTH: operator` of the query language.

Privileges as Search Conditions (Leads to Unwanted Results)

The simplest way for an application to define access privileges is to give the conditions as part of the search conditions, as shown below.

Sample Code

```
query=SCOPE:searchview adams countrycode:EQ(S):US amount:LT(S):100000
```

In this case, the anchor table logic of `sys.esh_search()` leads to search results that are not expected. The search defined above executes three different searches that are run in parallel:

1. a search for 'adams' in all default search columns
2. a search for 'countrycode=US'
3. a search for 'amount<100000'

The search result contains all anchor objects where all of these conditions are fulfilled.

The intention of the access privilege is to see only customers where a single line in the search view contains `countrycode=US` as well as an `amount<100000`. Because both columns come from a one-to-many join and the checks for these conditions are run in parallel and independent of each other, the search result also contains customers where, for example, one line in the search view contains `countrycode=US` and `amount=200000` and another line contains `countrycode=FR` and `amount=1000`. This means that no line in the search view fulfills the condition defined in the privilege but it is anyways returned, or, in other words, the search returns more anchor objects in the search result than expected.

Privileges Using the ROW: Operator (Leads to Unwanted Results)

A more advanced way to define access privileges uses the `ROW:` operator to define the privilege condition, as shown below.

Sample Code

```
query=SCOPE:searchview adams ROW:(countrycode:EQ(S):US amount:LT(S):100000)
```

In this case, the search result contains only those anchor objects where a single line in the search view fulfills both conditions at the same time. But nevertheless, users may still get back too many anchor objects. In this example, one line coming from a one-to-many join may fulfill the privilege condition while another line from a one-to-many join may contain the search term 'adams'.

And the user also gets back too many information in the search result because the access privilege defined in the `ROW:` operator is only used in the initial search step to identify the anchor objects. All other steps that follow the search step to create the final search result do not use the privilege condition. For example, the generation of snippets or the calculation of facets is not aware of the privilege and all rows belonging to the anchor objects are returned.

As a result, a country code facet, that should only contain 'US' as its only value because of the defined privilege, also contains all other countrycodes that are defined in other lines of the search view belonging to the same anchor objects. So the search result may disclose information the user shall not be able to see.

Using the AUTH: Operator to get the Expected Results

The correct way for an application to define access privileges is by using the `AUTH:` operator.

The `AUTH:` operator has been added to the query language to define the access privileges and to make sure that they are considered in all steps of the `sys.esh_search()` processing to get the final search results. This means that the privileges are applied to the search step in the correct way and they are also applied to all other calculations that follow to create the final search result.

Sample Code

```
query=SCOPE:searchview adams AUTH:(countrycode:EQ(S):US amount:LT(S):100000)
```

The AUTH: Operator

The `AUTH:` operator can be used to define access privileges for a search view on a row level. The condition defined within the `AUTH:` operator has to be fulfilled by a single line in the search view. All lines in the view that do not fulfill the condition are not visible to the user.

In other words, `sys.esh_search()` behaves as if only those lines were part of the search view that fulfill the condition defined in the `AUTH:` operator.

The `AUTH: operator` can be given at any position in the query language expression. But it has to be defined on 'top-level' and it has to be combined with the surrounding expressions using an `AND` operator. This is identical to other operators like the `ROW:` and `FILTER:` operators.

Within the `AUTH: operator` complex conditions can be defined and multiple conditions can be combined using the `AND`, `OR`, `NOT` operators and parentheses. Allowed operators within each condition are case-sensitive attribute conditions like `:EQ(S):`, `:LT(S):`, or `:BT(S):`, a search for `NULL` using the `IS:NULL:` operator and a search for non-empty (not null) values using the `:EQ:*` operator.

Limitations of the AUTH: Operator

The following limitations apply to the `AUTH:` operator:

- Case-insensitive comparisons like `:EQ:` or `:LT:` are not supported.
- Attribute conditions are supported only. Search conditions using the `:` operator are not supported
- With API version 20501, columns used in a classification model are not allowed

Note on Search Performance

Because of the anchor table logic, the access privileges have to be checked for every search in every column. This means that the search gets much more complex than without privilege conditions, especially if the conditions are complex and contain many attribute conditions.

As a result, a search using access privileges runs slower than a search without privileges. Therefore applications shall define privileges only for those search views where confidential information has to be concealed from the users and where this level of security is critical for the application.

4.3 Full-Text Search with SQL

In column-oriented tables, you can perform searches using the SQL `SELECT` statement.

Prerequisites

Before building SQL search queries, the following prerequisites must be met:

- The tables you want to search are column-oriented.
- You have created the required views for the tables you want to search.
- You have created the required full-text indexes for the columns you want to search.

Context

SAP HANA supports the standard SQL search syntax and functions for search queries on nearly all visible data types. You build SQL queries using the `SELECT` statement, as in the following example:

```
SELECT * FROM Contacts WHERE ID=1
```

However, in SAP HANA, columns of large object types and text have additional requirements. To enable search on columns of these types, you must ensure the following requirements are met:

- Full-text indexes have been created for the search-relevant columns. For columns of type `TEXT` and `SHORTTEXT`, this is done automatically.
- Search queries on the columns use the `CONTAINS` predicate.

For large object types and text, you build SQL queries using the `SELECT` statement and `CONTAINS` predicate, as in the following example:

```
SELECT * FROM Documents WHERE CONTAINS (*, 'Comment')
```

To build a search query, proceed as follows:

Procedure

1. Use the SQL `SELECT` statement and specify the table or view and column you want to search. If required, include the `CONTAINS` predicate.
2. If required, specify scalar functions for the search.
3. Specify the search terms and the search type (`EXACT`, `LINGUISTIC`, or `FUZZY`). The search type is optional.

i Note

If you do not specify a search type, the search query is performed as an exact search by default.

Example

For further examples of the syntax used with the `SELECT` statement, see *SAP HANA SQL and System Views Reference*.

Related Information

[SAP HANA SQL and System Views Reference](#)

4.3.1 Search Queries with CONTAINS

In SAP HANA, you can search one or multiple columns by creating a query that includes the `CONTAINS` predicate. In SAP HANA, a search query with `CONTAINS` has a look and feel similar to common Internet search engines.

The `CONTAINS` predicate is optional for search queries on columns of most data types; however, for large object types and text, this predicate is mandatory. You can build a search query with the `CONTAINS` predicate as follows:

```
SELECT * FROM <tablename>
WHERE CONTAINS ((<column1>, <column2>, <column3>), <search_string>)
```

When you specify the `CONTAINS` predicate, SAP HANA runs the following internal checks:

- SAP HANA checks if the query contains one or more terms. If the query contains multiple terms, the terms are tokenized and concatenated.
- SAP HANA checks whether the query is to be run on one or more columns. If you only specify one column, to optimize the search, additional processes are skipped and the query is run on the single column. If you specify a wildcard, and therefore possibly numerous columns, SAP HANA automatically determines which columns are relevant for the search query.

After the checks are performed, SAP HANA builds and runs an internal query on the relevant columns only.

i Note

If a column has a full-text index assigned, SAP HANA will automatically search on the index rather than on the original column.

Determination of Search-Relevant Columns

You can specify the search-relevant columns either at the creation of the view or directly for the query. SAP HANA determines which relevant columns to search based on the following hierarchy:

1. You specify a list of columns within the `CONTAINS` predicate. Even if a list of columns has been defined for the view, it is overridden by the columns stated in the query.

2. If you enter an asterisk (*) instead of a column list but you specified a list of relevant columns when creating the view, this list is used for the query.
3. If you enter an asterisk (*) and no list was provided when the view was created, all visible columns of the view or table are considered as search-relevant.

For information about creating views, see *Creating Views* in the *SAP HANA Administration Guide*.

Search Operators and Syntax

With the `CONTAINS` predicate, SAP HANA supports the following search operators:

- `OR`
Matches are returned that contain at least one of the terms joined by the `OR` operator.
- `-` (minus)
With a minus sign, SAP HANA searches in columns for matches that do not contain the term immediately following the minus sign.
- `" "` (quotation marks)
Terms within the quotation marks are not tokenized and are handled as a string. Therefore, all search matches must be exact.
- `*`
The asterisk sign replaces 0 or more characters in a search term (e.g., `cat*` would match **cats** and **catalogues**).
- `?`
The question mark replaces a single character in a search term (e.g., `cat?` would match **cats**).

Note

If you enter multiple search terms, the `AND` operator is automatically interpreted. Therefore, you do not need to specify it.

For more information about the unique syntax requirements of the `CONTAINS` predicate, see the *SAP HANA SQL and System Views Reference*.

Scalar Functions

For search queries using the `CONTAINS` predicate, you can use different scalar functions to either return additional information about the results of your search queries or enhance how the results are displayed. These functions include `SNIPPETS`, `HIGHLIGHTED`, and `SCORE`.

Limitations

The following limitations apply to search queries using the `CONTAINS` predicate:

- You cannot search on more than one column table or attribute view at a time. If more than one table is joined in the `SELECT` statement, then all columns mentioned in the `CONTAINS` predicate must come from only one of the tables.
- When using the `SCORE ()` function, all columns mentioned in all `CONTAINS` predicates must come from only one table (or attribute view).
- You cannot enter a minus (-) search operator directly after `OR`.
- Brackets are not supported as search operators.
- Searches using the `CONTAINS` predicate do not consider non-physical columns, such as calculated columns, as search-relevant because these columns are created during the search and, therefore, are not available when SAP HANA internally checks the `CONTAINS` search query.
- The `CONTAINS` predicate only works on column-oriented tables.
- The `CONTAINS` predicate only works in the column engine. If there is a blocker to the column engine, `CONTAINS` is not supported.
- If you specify multiple `CONTAINS` predicates in the `WHERE` clause of the `SELECT` statement, only one of the predicates is allowed to consist of more than one column in the list of `<contains_columns>`.

Related Information

[SAP HANA SQL Reference Guide for SAP HANA Platform Administration Information Map](#)

4.3.1.1 SNIPPETS Function

For search queries using the `CONTAINS` predicate, you can use the function `SNIPPETS` to return search results with an excerpt of the text with your search term highlighted in bold. This short text excerpt provides some context for you to see where and how the term is used in the document.

This function uses the following syntax:

```
SELECT *, SNIPPETS (<text_column>) FROM <tablename>
WHERE CONTAINS (<search_term>)
```

Limitations

The `SNIPPETS` function only works on columns of the data type `TEXT` or columns with a full-text index.

i Note

When processing HTML documents, the results of the `SNIPPETS` function depend on the column type. For columns of type `TEXT`, `[N] VARCHAR`, or `[N] CLOB`, HTML markup from the original input will appear in the

SNIPPETS results. For columns of type `BINTEXT` and `BLOB`, HTML markup from the original input will not appear in the `SNIPPETS` results.

4.3.1.2 HIGHLIGHTED Function

For search queries using the `CONTAINS` predicate, you can use the function `HIGHLIGHTED` to return the content of the found document with your search term highlighted in bold.

Search queries using the `HIGHLIGHTED` function return the data type `NCLOB`.

This function uses the following syntax:

```
SELECT *, HIGHLIGHTED (<text_column>) FROM <tablename>
WHERE CONTAINS (<search_term>)
```

Limitations

The `HIGHLIGHTED` function only works on columns of the data type `TEXT` or columns with a full-text index.

i Note

When processing HTML documents, the results of the `HIGHLIGHTED` function depend on the column type. For columns of type `TEXT`, `[N] VARCHAR`, or `[N] CLOB`, HTML markup from the original input will appear in the `HIGHLIGHTED` results. For columns of type `BINTEXT` and `BLOB`, HTML markup from the original input will not appear in the `HIGHLIGHTED` results.

4.3.1.3 SCORE Function

For search queries using the `CONTAINS` predicate, you can use the function `SCORE` to get the score, that means the relevance, of a record found.

SAP HANA calculates a score based on the following information:

- The relevance or weighting of attributes in a search using the `CONTAINS` predicate. The relevance of a hit depends on the weight of the column that caused the hit. You can specify weights when you create the view or in the `CONTAINS` predicate.
- Fuzziness in fuzzy search. The more exact a hit is, the higher the score is.
- Text ranking (TF-IDF).

This function uses the following syntax:

```
SELECT SCORE (), * FROM <tablename>
WHERE CONTAINS (<search_term>)
```

4.3.2 EXACT Search

An exact search returns records only if the search term or search phrase is contained in the table column exactly as specified. In the `SELECT` statement of the search query, you can specify the `EXACT` search type.

In an exact search, the search engine uses the word dictionary and the phrase index to detect the possible matches. The search engine then checks whether the words appear and use exactly the same spelling.

- For text columns, the search term must match at least one of the tokenized terms to return a column entry as a match.
- For string columns, the search term must match the entire string to return a column entry as a match.

Note

For more flexibility in a search query, you can use the supported wildcards `%` and `*`. Wildcards are supported for both text and string columns.

You can perform an exact search by using the `CONTAINS` predicate with the `EXACT` option in the `WHERE` clause of a `SELECT` statement. The exact search is the default search type. If you do not specify any search type in the search query, an exact search will be executed automatically.

Example

```
SELECT * FROM <tablename>
WHERE CONTAINS (<column_name>, <search_string>, EXACT)
```

```
SELECT * FROM <tablename>
WHERE CONTAINS (<column_name>, <search_string>)
--- Exact search will be executed implicitly.
```

```
SELECT * FROM <tablename>
WHERE CONTAINS (<column_name>, '"cats and dogs"')
--- Phrase search.
```

4.3.3 LINGUISTIC Search

A linguistic search finds all words that have the same word stem as the search term. It also finds all words for which the search term is the word stem. In the `SELECT` statement of the full-text search query, you can specify the `LINGUISTIC` search type.

When you execute a linguistic search, the system has to determine the stems of the searched terms. It will look up the stems in the stem dictionary. The hits in the stem dictionary point to all words in the word dictionary that have this stem

You can call the linguistic search by using the `CONTAINS` predicate with the `LINGUISTIC` option in the `WHERE` clause of a `SELECT` statement.

A linguistic search for *produced* will also find *producing* and *produce*.

Example

```
SELECT * FROM <tablename>
WHERE CONTAINS (<column_name, 'produced' , LINGUISTIC)
```

Limitations

You can only perform linguistic searches on columns that meet the following conditions:

- The columns contain text.
- For the columns, the `FAST_PREPROCESS` parameter is specified as `OFF`.

4.3.3.1 Term Mappings for Linguistic Search

A linguistic search finds all words that have the same word stem as the search term. By using term mappings the search term is expanded by synonyms, hypernyms, and hyponyms, which you specified in a term mapping table. The combination of linguistic search and term mappings could bring more records to the search result that could be useful to the users.

How do term mappings get into a linguistic search?

After entering a search term the preprocessor tokenizes the search term and creates stems. The stem dictionary of the fulltext index is checked on these stems and corresponding terms are returned. On the new and the initial search terms a term mapping is executed and synonyms are looked up for in the term mapping table. For all found synonyms, hypernyms, or hyponyms the stem dictionary is checked again. Finally a new search request, where all found terms, synonyms and the initial search term are connected with OR, is executed and the result is returned to the user.

Example

The term mapping table contains the entry *shipping addresses* which is linked to *delivery address*.

A search for *ship addresses* results in the following technical actions:

1. The initial search term is split by the preprocessor into the stems *ship* and *address*.
2. The stem dictionary returns the corresponding phrases *shipping* and *address* and builds the search queries *shipping address*, *shipping addresses* and *ship address*
3. The term mapping table is checked and provides for *shipping address* the term mapping *delivery address*.
4. For a last time the stemming dictionary is asked for the new input. For the new word *delivery* the entry *deliveries* is found and the additional search input *deliveries address* is generated.

In the end we have 6 search inputs which are connected with OR in the final search request:

- *ship addresses*
- *shipping address*
- *shipping addresses*
- *ship address*
- *delivery address*
- *deliveries address*

The Required Term Mapping Table

For the linguistic search the same term mapping table as for fuzzy search is used. If you did not use fuzzy search with term mappings before, you have to create a new term mapping table.

The Select Statement

You can call the linguistic search by using the `CONTAINS` predicate with the `LINGUISTIC` option in the `WHERE` clause of a `SELECT` statement.

```
Example: SELECT * FROM example WHERE CONTAINS(destination, 'ship addresses',
LINGUISTIC('termMappingTable=termmappings,termMappingListId=01')) ORDER BY score
DESC, id;
```

i Note

If the term mapping table is neither a column store table nor a column store join view but a calc view, SQL view or row store table, you have to specify the names of both fulltext indexes via the search options `termMappingTableFulltextIndexTerm1` and `termMappingTableFulltextIndexTerm2`.

```
For example LINGUISTIC('termMappingTable=termmappings, termMappingListId=01,
termMappingTableFulltextIndexTerm1= $TA_IDX_MYTM_TERM1,
termMappingTableFulltextIndexTerm2= $TA_IDX_MYTM_TERM2')
```

[Creating the Term Mapping Table \[page 270\]](#)

[Creating the Full-Text Index for the Stems \[page 271\]](#)

[Example SQL Statements \[page 271\]](#)

4.3.3.1.1 Creating the Term Mapping Table

The term mappings for the linguistic as well for the fuzzy search are stored in a designated table in the SAP HANA database.

Context

The term mapping table uses the following format:

Column Name	Type	Primary Key	Description	Comment
MAPPING_ID	VARCHAR(32)	x	Primary key	For example, a GUID
LIST_ID	VARCHAR(32)		Term mapping list ID	Used to group term mappings
LANGUAGE_CODE	VARCHAR(2)		Language code (ISO2)	NULL: term mapping is valid for all languages
TERM_1	NVARCHAR(200)		Term 1, the term to be replaced	
TERM_2	NVARCHAR(200)		Term 2, the term that replaces term 1	
WEIGHT	DECIMAL, DECIMAL(n,m)		Weight, 0.0 <= Weight <= 1.0	

Procedure

1. If you don't use a term mapping table yet, create a new term mapping table.

Example code for creating a term mapping table:

```
CREATE COLUMN TABLE termmappings
(
  mapping_id    VARCHAR(32)    PRIMARY KEY,
  list_id       VARCHAR(32)    NOT NULL,
  language_code VARCHAR(2),
  term_1        NVARCHAR(200) NOT NULL,
  term_2        NVARCHAR(200) NOT NULL,
  weight        DECIMAL        NOT NULL
);
```

2. Fill the term mapping table with terms and their corresponding synonyms, hypernyms and hyponyms.

Example: `INSERT INTO termmappings VALUES ('1','01','de','shipping address','delivery address','0.9');` `INSERT INTO termmappings VALUES ('2','01','de','delivery address','shipping address','0.9');`

4.3.3.1.2 Creating the Full-Text Index for the Stems

In order to automatically calculate the stems for the term mapping definitions, two full-text indexes must be created.

Procedure

Create one full-text index on the `<TERM_1>` and one full-text index on the `<TERM_2>` column of the term mapping table. Use the option `TEXT ANALYSIS ON`. Specify the language column and the text analysis configuration of type `LINGANALYSIS_STEMS`.

```
CREATE FULLTEXT INDEX <idx_mytm_term1> ON <mytm>(term_1)
LANGUAGE COLUMN language_code
TEXT ANALYSIS ON
CONFIGURATION 'LINGANALYSIS_STEMS';
CREATE FULLTEXT INDEX <idx_mytm_term2> ON <mytm>(term_2)
LANGUAGE COLUMN <language_code>
TEXT ANALYSIS ON
CONFIGURATION 'LINGANALYSIS_STEMS';
```

Results

The stems are visible in the `$TA` tables `$TA_IDX_MYTM_TERM1` and `$TA_IDX_MYTM_TERM2` in the example above.

The first `$TA` table (`$TA_IDX_MYTM_TERM1`) defines the stems of the left side of the term mapping definitions. The second `$TA` table (`$TA_IDX_MYTM_TERM2`) defines the stems of the right side of the term mapping definitions.

Both tables are used to read the stems of the term mappings during runtime.

4.3.3.1.3 Example SQL Statements

The following SQL statements show an complete example how to prepare all tables and indexes in order to use term mappings in linguistic search.

Create the term mapping table `termmappings` if it is not yet available:

```
CREATE COLUMN TABLE termmappings
(
  mapping_id    VARCHAR(32)    PRIMARY KEY,
  list_id      VARCHAR(32)    NOT NULL,
  language_code VARCHAR(2),
  term_1       NVARCHAR(200) NOT NULL,
  term_2       NVARCHAR(200) NOT NULL,
  weight       DECIMAL       NOT NULL
);
```

Create the a new table named *example* to store your variants and synonyms for *shipping address* in the column *destination*:

```
CREATE COLUMN TABLE example
(
  id          INTEGER          PRIMARY KEY,
  destination SHORTTEXT(200),
  language   VARCHAR(2)
);
```

Fill the table *example* and enter values into the column *destination*:

```
INSERT INTO example VALUES ('1','ship addresses', 'en');
INSERT INTO example VALUES ('2','ship address', 'en');
INSERT INTO example VALUES ('3','shipping addresses', 'en');
INSERT INTO example VALUES ('4','shipping address', 'en');
INSERT INTO example VALUES ('5','delivery address', 'en');
INSERT INTO example VALUES ('6','deliveries address', 'en');
```

Fill the term mapping table with synonyms:

```
INSERT INTO termmappings VALUES ('1','01','de','ship addresses','delivery
address','0.9');
INSERT INTO termmappings VALUES ('2','01','de','delivery address','ship
addresses','0.9');
```

Create two full-text indexes for the stems:

```
CREATE FULLTEXT INDEX idx_mytm_term1 ON termmappings(term_1)
LANGUAGE COLUMN language_code
TEXT ANALYSIS ON
CONFIGURATION 'LINGANALYSIS_STEMS';
CREATE FULLTEXT INDEX idx_mytm_term2 ON termmappings(term_2)
LANGUAGE COLUMN language_code
TEXT ANALYSIS ON
CONFIGURATION 'LINGANALYSIS_STEMS';
```

Create an `SELECT` statement executing a linguistic search:

```
SELECT * FROM example WHERE CONTAINS(destination, 'ship addresses',
LINGUISTIC('termMappingTable=termmappings,termMappingListId=01')) ORDER BY score
DESC, id;
```

SCORE	ID	DESTINATION
1.0	1	ship addresses
0.9	2	ship address
0.9	3	shipping addresses
0.9	4	shipping address
0.9	5	delivery address
0.9	6	deliveries address

4.3.4 FUZZY Search

Fuzzy Search is a fast and fault-tolerant search feature for SAP HANA. A fuzzy search returns records even if the search term contains additional or missing characters or other types of spelling errors.

Note

We advise you to read through the Enabling Search section in the *SAP HANA Developer Guide* before working with this reference. This provides you with information about how to create a full-text index, which is a prerequisite for fuzzy search in SAP HANA.

About this Reference

In this complete reference, you can find all the documentation that you need to use the SAP HANA fuzzy search function in your development projects.

You can learn about the basic concepts of the `CONTAINS ()` predicate and the `SCORE ()` function. In data type-specific chapters, you can find information about the parameters specific for a certain data type, for the data types string or text for example. Further chapters deal with language specifics, for Chinese for example, and offer support information, such as monitoring, tracing and sizing.

The reference also contains lots of information about using search rules. These are used to separate search queries from the code for easier modification or replacement. A tutorial is provided so that you can practice directly on the search rule feature.

Fuzzy Search in a Nutshell

The term "fault-tolerant search" means that a database query returns records even if the search term (the user input) contains additional or missing characters, or other types of spelling error.

Fuzzy search can be used in various applications, for example:

- *Fault-tolerant search in text columns (html or pdf for example)*: Search for documents on 'Driethanolamyn' and find all documents that contain the term 'Triethanolamine'.
- *Fault-tolerant search in structured database content*: Search for a product called 'coffe krisp biscuit' and find 'Toffee Crisp Biscuits'.
- *Fault-tolerant check for duplicate records*: Before creating a new customer record in a CRM system, search for similar customer records and verify that no duplicates are already stored in the system. When creating a new record called 'SAB Aktiengesellschaft & Co KG Deutschl.' in 'Wahldorf' for example, the system would bring up 'SAP Deutschland AG & Co. KG' in 'Walldorf' as a possible duplicate.

You can call the fuzzy search by using the `CONTAINS` predicate with the `FUZZY` option in the `WHERE` clause of a `SELECT` statement.

Example

```
SELECT * FROM <tablename>
```

```
WHERE CONTAINS (<column_name>, <search_string>, FUZZY (0.8))
```

4.3.4.1 Supported Database Objects and SQL Types

Fuzzy search and the CONTAINS() predicate are supported for column tables and attribute views only. Analytic views and calculation views are not supported.

In some cases, CONTAINS() and fuzzy search work for 'SQL views', too, but there are limitations. A search is possible only if the SQL view can be transformed into an attribute view by the SQL interpreter. This transformation is not possible if, for example, the view uses rowstore tables, UNION or INTERSECT or EXCEPT (some 'toplevel unions' may work), nested select statements, cross joins, non-equi-joins, or joins over calculated columns.

Fuzzy Search supports the following SQL types:

SQL Type	Supported Fuzzy Search Features
<i>Character String Types</i>	
VARCHAR	string features
NVARCHAR	string features
SHORTTEXT	text features
<i>Large Object (LOB) Types</i>	
TEXT	text features
BINTEXT	text features
<i>Datetime Types</i>	
DATE	date features, score functions
TIMESTAMP, SECONDDATE	score functions
<i>Numeric Types</i>	
TINYINT, SMALLINT, INTEGER, BIGINT	score functions
SMALLDECIMAL, DECIMAL, REAL, DOUBLE	score functions
<i>Other</i>	

SQL Type	Supported Fuzzy Search Features
Column with FULLTEXT INDEX	text features

No other SQL types are supported by fuzzy search.

String Types

String types support a basic fuzzy string search. The values of a column are compared with the user input, using the fault-tolerant fuzzy string comparison.

When working with string types, the fuzzy string comparison always compares the full strings. If searching with 'SAP', for example, a record such as 'SAP Deutschland AG & Co. KG' gets a very low score, because only a very small part of the string (3 of 27 characters) matches.

Text Types

Text types support a more sophisticated kind of fuzzy search. Texts are tokenized (split into terms) and the fuzzy comparison is done term by term.

For example, when searching with 'SAP', a record such as 'SAP Deutschland AG & Co. KG' gets a high score, because the term 'SAP' exists in both texts. A record such as 'SAPPHIRE NOW Orlando' gets a lower score, because 'SAP' is only a part of the longer term 'SAPPHIRE' (3 of 8 characters match).

Date Types

Fuzzy search on date values checks for date-specific errors like dates that lie within a given range of days or dates that have month and day exchanged (for example, American versus British date format).

[Fuzzy Search on Text Columns \[page 349\]](#)

[Fuzzy Search on DATE Columns \[page 385\]](#)

4.3.4.2 Syntax

You can call the fuzzy search by using the `CONTAINS()` function with the `FUZZY()` option in the `WHERE` clause of a `SELECT` statement.

Basic example without additional search options

```
SELECT SCORE() AS score, *
FROM documents
WHERE CONTAINS(doc_content, 'Driethanolamyn', FUZZY(0.8))
ORDER BY score DESC;
```

Example with additional search options

Additional search options that change the default behavior of the fuzzy search can be specified as additional string parameters in the `FUZZY()` function.

The search options are specified as a comma-separated list of key-value pairs.

```
SELECT SCORE() AS score, *
FROM documents
WHERE CONTAINS(doc_content, 'Driethanolamyn', FUZZY(0.8, 'option1=value1,
option2=value2'))
ORDER BY score DESC;
```

Related Information

[The CONTAINS\(\) Predicate \[page 276\]](#)

[Available Fuzzy Search Options \[page 302\]](#)

4.3.4.3 The CONTAINS() Predicate

To enable fuzzy search, the `FUZZY()` predicate is used inside the `CONTAINS()` predicate. The `FUZZY()` predicate takes a fuzzy threshold as an argument. The fuzzy threshold defines the level of error tolerance for the search.

Supported Database Objects

Fuzzy search and the `CONTAINS()` predicate are available for the `SELECT` statements on the following database objects:

- One column table
- One attribute view
- In some cases, also on SQL views (created with the `CREATE VIEW` statement), and on joins of multiple tables and views

i Note

The following database objects are not supported:

- Row tables
- Calculation views
- Analytic views
- Temporary tables
- SQL Script table variables

Usage Examples

A statement like `...WHERE CONTAINS(col, 'search term', FUZZY(0.7))...` on a VARCHAR column returns all values with a fuzzy score greater than or equal to 0.7.

A search with `FUZZY(x)` returns all values that have a fuzzy score greater than or equal to x. In case of a full-text search, this search returns all values where each token matches with a fuzzy score greater than or equal to x. The score returned may be lesser than x because it is influenced by other factors (like the calculation of a TF/IDF score).

Search with FUZZY(0.0)

It is not possible to search for all values that have a fuzzy score greater than or equal to 0. This would return all values of a column and would result in large result sets. A search with `FUZZY(0.0)` therefore returns all values that have a fuzzy score greater than 0.

Use Cases of CONTAINS()

The `CONTAINS()` predicate can be used in the `WHERE` clause of a `SELECT` statement. The type of search it performs depends on its arguments:

1. A freestyle search on multiple columns
2. A full-text search on one column containing large documents
3. A search on one database column containing structured data

All searches can be performed either as an exact search or as a fuzzy search with additional tolerance for writing errors.

Freestyle Search on Multiple Columns

```
-- exact search
SELECT ... WHERE CONTAINS((col1, col2, col3), 'term1 term2 term3') ...;
-- or
SELECT ... WHERE CONTAINS((col1, col2, col3), 'term1 term2 term3', EXACT) ...;
-- fuzzy search
```

```
SELECT ... WHERE CONTAINS((col1, col2, col3), 'term1 term2 term3',  
FUZZY(0.7)) ...;
```

Full-Text Search on One Column Containing Large Documents

To perform a full-text search, the column to be searched must be a text column. A text column is a column that either has a full-text index or that is of SQL type `SHORTTEXT` or `TEXT`.

```
-- exact search  
SELECT ... WHERE CONTAINS(col1, 'term1 term2 term3') ...;  
-- fuzzy search  
SELECT ... WHERE CONTAINS(col1, 'term1 term2 term3', FUZZY(0.7)) ...;
```

Search on One Database Column Containing Structured Data

```
-- exact search  
SELECT ... WHERE CONTAINS(col1, 'term1 term2 term3') ...;  
-- fuzzy search  
SELECT ... WHERE CONTAINS(col1, 'term1 term2 term3', FUZZY(0.7)) ...;
```

Multiple CONTAINS() Predicates in one SELECT

It is possible to use the `CONTAINS()` predicate more than once in a `WHERE` clause. In this case, only one `CONTAINS()` can be used for a freestyle search on multiple columns. All other calls to `CONTAINS()` can only access a single column.

```
SELECT ...  
WHERE CONTAINS((col1, col2, col3), 'a b c', FUZZY(0.8))  
  AND CONTAINS(col4, 'x y z', FUZZY(0.7))  
  AND CONTAINS(col5, 'u v w', FUZZY(0.7))  
  AND ...
```

4.3.4.3.1 CONTAINS() Query Syntax and Fuzzy Search Options

Reserved Words and Special Characters in the Search String

When searching with `CONTAINS()`, some terms and characters have a special meaning, as described below. For more information, see the text search documentation.

Reserved Word/Special Character	Description
OR	<p>A search such as CONTAINS(col, 'sap OR hana') searches for all records that contain 'sap' or 'hana' in the column 'col'. The OR keyword is case-sensitive, so CONTAINS(col, 'sap or hana') searches for records that contain 'sap' and 'or' and 'hana'.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>If your search input contains an 'or', make sure that it is not in uppercase characters in order to avoid the OR semantics.</p> </div>
Minus Sign (-)	<p>A search such as CONTAINS(col, 'sap -hana') searches for all records that contain 'sap' but not 'hana'. If the second term is given as a phrase, as in CONTAINS(col, 'sap "-hana"'), the database searches for records that contain 'sap' and '-hana'. In text columns, the '-' is removed from the second search term, since it is a delimiter symbol.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>If your search input contains terms starting with a minus sign, make sure that these terms are enclosed in double quotes in order to avoid the NOT semantics.</p> </div>
Double Quotes (")	<p>A search that is enclosed in double quotes is searched as a phrase. For example, CONTAINS(col, "sap hana") searches for all records that contain 'sap hana' as a phrase without any additional terms in between.</p>
Asterisk (*) and Question Mark (?)	<p>Asterisks and question marks activate a wildcard search. In this case, no fuzzy search is performed. An exact match with wildcards is called instead.</p> <p>The asterisk is defined as a wildcard for any number of characters (including zero characters).</p> <p>The question mark is a wildcard for exactly one character.</p>
Percent Sign (%)	<p>The percentage sign is replaced with an asterisk (*), and a wildcard search is called.</p>

Combining CONTAINS() Query Syntax and Fuzzy Search Options

Fuzzy search options have initially been designed for use cases, for example, to detect duplicate records that need very specific configuration options to get the expected results. This means, that the search options support queries with CONTAINS() clauses that search in a single column only and that search for a list of tokens.

Sample Code

CONTAINS() with Fuzzy Search Options

```
SELECT ... WHERE CONTAINS(col1, 'this is a search term', FUZZY(0.7, 'opt1=val1, opt2=val2')) ...;
```

As soon as the search term is combined with CONTAINS() query syntax like an OR operator, a NOT operator (-), or a phrase search, the search is internally split into multiple subqueries that are processed individually. In this case the search options are passed to each of the subqueries and are processed there locally. So to understand why a specific result is returned, you have to look at each of the subqueries and the effect of the search options on these queries.

Sample Code

CONTAINS() Query Syntax and Fuzzy Search Options

```
SELECT ... WHERE CONTAINS(col1, 'terma OR termb', FUZZY(0.7, 'opt1=val1, opt2=val2')) ...;

/* this is internally processed as two subqueries, similar to the following statement */
SELECT ... WHERE (CONTAINS(col1, 'terma', FUZZY(0.7, 'opt1=val1, opt2=val2'))
OR CONTAINS(col1, 'termb', FUZZY(0.7, 'opt1=val1, opt2=val2'))) ...;

SELECT ... WHERE CONTAINS(col1, 'this is a "search term"', FUZZY(0.7, 'opt1=val1, opt2=val2')) ...;

/* this is internally processed as two subqueries, similar to the following statement */
SELECT ... WHERE (CONTAINS(col1, 'this is a', FUZZY(0.7, 'opt1=val1, opt2=val2'))
AND CONTAINS(col1, '"search term"', FUZZY(0.7, 'opt1=val1, opt2=val2'))) ...;
```

4.3.4.3.2 Freestyle Search and Fuzzy Search Options

A freestyle search distributes the search terms on the given columns and searches for any possible combination of search terms and columns. The fuzzy search options that are given for a freestyle column are used for each query on this column.

When using fuzzy search options with a freestyle search, you have to look at all the generated queries to explain why a result is returned. Some search options may also lead to unexpected behavior when used for a freestyle search. This is the reason why some search options are not available for freestyle search.

Sample Code

Freestyle Search and Fuzzy Search Options

```
SELECT ... WHERE CONTAINS((col1, col2), 'terma termb', FUZZY((0.7, 'opt1=val1, opt2=val2'), (0.9, 'opt3=val3'))) ...;
```

```

/* this is internally processed as many subqueries, similar to the following
statement */
SELECT ... WHERE
  ( CONTAINS(col1, 'terma', FUZZY(0.7, 'opt1=val1, opt2=val2')) AND
    CONTAINS(col1, 'termb', FUZZY(0.7, 'opt1=val1, opt2=val2')) )
OR
  ( CONTAINS(col1, 'terma', FUZZY(0.7, 'opt1=val1, opt2=val2')) AND
    CONTAINS(col2, 'termb', FUZZY((0.9, 'opt3=val3')) )
OR
  ( CONTAINS(col2, 'terma', FUZZY((0.9, 'opt3=val3'))           AND
    CONTAINS(col1, 'termb', FUZZY(0.7, 'opt1=val1, opt2=val2')) )
OR
  ( CONTAINS(col2, 'terma', FUZZY((0.9, 'opt3=val3'))           AND
    CONTAINS(col2, 'termb', FUZZY((0.9, 'opt3=val3')) )
OR
  CONTAINS(col1, '"terma termb"', FUZZY(0.7, 'opt1=val1, opt2=val2'))
OR
  CONTAINS(col2, '"terma termb"', FUZZY((0.9, 'opt3=val3'))
...;

```

4.3.4.3.3 The SCORE() Function

When using CONTAINS() in the WHERE clause of a SELECT statement, the SCORE() function can be used to retrieve the score. This is a numeric value between 0.0 and 1.0.

The score defines the similarity between the user input and the records returned by the search. A score of 0.0 means that there is no similarity. The higher the score, the more similar a record is to the search input.

When more than one CONTAINS() is given in the WHERE clause, the score is calculated as a weighted average of the scores of all columns.

```

SELECT SCORE(), col1, col2, ... FROM tab
WHERE CONTAINS(col1, 'x y z')
      AND CONTAINS(col2, 'a b c')
      AND ...
ORDER BY SCORE() DESC;

```

It is possible to assign a weight to each column. When a weight is not given, the default weight is 1.0.

```

SELECT SCORE(), ... FROM tab
WHERE CONTAINS((col1, col2, col3), 'a b c', FUZZY(0.8), WEIGHT(1.0, 0.5, 0.5))
      AND CONTAINS(col4, 'x y z', FUZZY(0.7), WEIGHT(0.7))
      AND CONTAINS(col5, 'u v w', FUZZY(0.7))
      AND ...
ORDER BY SCORE() DESC;

```

WHERE conditions other than CONTAINS() are not part of the score calculation. The condition `col5 = 'u v w'` is not used to calculate the score for example.

```

SELECT SCORE(), ... FROM tab
WHERE CONTAINS((col1, col2, col3), 'a b c', FUZZY(0.8))
      AND CONTAINS(col4, 'x y z', FUZZY(0.7))
      AND col5 = 'u v w'
      AND ...
ORDER BY SCORE() DESC;

```

4.3.4.3.4 Examples

This section contains examples showing how to use the CONTAINS() predicate and the SCORE() function.

4.3.4.3.4.1 Fuzzy Search on One Column

Procedure

1. Create the data.

```
CREATE COLUMN TABLE companies
(
  id          INTEGER          PRIMARY KEY,
  companyname SHORTTEXT(200) FUZZY SEARCH INDEX ON
);
INSERT INTO companies VALUES (1, 'SAP Corp');
INSERT INTO companies VALUES (2, 'SAP in Walldorf Corp');
INSERT INTO companies VALUES (3, 'ASAP');
INSERT INTO companies VALUES (4, 'ASAP Corp');
INSERT INTO companies VALUES (5, 'BSAP orp');
INSERT INTO companies VALUES (6, 'IBM Corp');
```

2. Perform the search on one column.

```
SELECT SCORE() AS score, * FROM companies
WHERE CONTAINS(companyname,'xSAP Corp Walldorf',
FUZZY(0.7,'textSearch=compare,bestMatchingTokenWeight=0.7'))
ORDER BY score DESC;
```

SCORE	ID	COMPANYNAME
0.94	2	SAP in Walldorf Corp

4.3.4.3.4.2 Fuzzy Search on Two Columns

Procedure

1. Create the data.

```
CREATE COLUMN TABLE companies2
(
  id          INTEGER          PRIMARY KEY,
  companyname SHORTTEXT(200) FUZZY SEARCH INDEX ON,
  contact     SHORTTEXT(100) FUZZY SEARCH INDEX ON
);
INSERT INTO companies2 VALUES (1, 'SAP Corp', 'Mister Master');
INSERT INTO companies2 VALUES (2, 'SAP in Walldorf Corp', 'Master Mister');
INSERT INTO companies2 VALUES (3, 'ASAP', 'Nister Naster');
INSERT INTO companies2 VALUES (4, 'ASAP Corp', 'Mixer Maxter');
```

```
INSERT INTO companies2 VALUES (5, 'BSAP orp', 'Imster Marter');
INSERT INTO companies2 VALUES (6, 'IBM Corp', 'M. Master');
```

2. Perform the search on two columns.

```
SELECT SCORE() AS score, * FROM companies2
WHERE CONTAINS(companyname, 'IBM',
FUZZY(0.7, 'textSearch=compare, bestMatchingTokenWeight=0.7'))
AND CONTAINS(contact, 'Master',
FUZZY(0.7, 'textSearch=compare, bestMatchingTokenWeight=0.7'))
ORDER BY score DESC;
```

SCORE	ID	COMPANYNAME	CONTACT
0.91	6	IBM Corp	M. Master

3. Perform a freestyle search.

```
SELECT SCORE() AS score, * FROM companies2
WHERE CONTAINS((companyname, contact), 'IBM Master', FUZZY(0.7))
ORDER BY score DESC;
```

SCORE	ID	COMPANYNAME	CONTACT
0.8	6	IBM Corp	M. Master

Note

Freestyle searches always use TF/IDF to calculate the score and do not support parameters like 'textSearch=compare' or 'bestMatchingTokenWeight=0.7' which influence score calculation. This therefore results in a different score for the same record.

4.3.4.3.4.3 Perform a Freestyle Search on Two Columns

Procedure

1. Create the data.

```
CREATE COLUMN TABLE companies2
(
  id          INTEGER          PRIMARY KEY,
  companyname SHORTTEXT(200) FUZZY SEARCH INDEX ON,
  contact     SHORTTEXT(100) FUZZY SEARCH INDEX ON
);
INSERT INTO companies2 VALUES (1, 'SAP Corp', 'Mister Master');
INSERT INTO companies2 VALUES (2, 'SAP in Walldorf Corp', 'Master Mister');
INSERT INTO companies2 VALUES (3, 'ASAP', 'Nister Naster');
INSERT INTO companies2 VALUES (4, 'ASAP Corp', 'Mixer Maxter');
INSERT INTO companies2 VALUES (5, 'BSAP orp', 'Imster Marter');
INSERT INTO companies2 VALUES (6, 'IBM Corp', 'M. Master');
```

2. Perform a freestyle search on two columns.

```
SELECT SCORE() AS score, * FROM companies2
WHERE CONTAINS((companyname,contact), 'IBM Master', FUZZY(0.7))
ORDER BY score DESC;
```

SCORE	ID	COMPANYNAME	CONTACT
0.83	6	IBM Corp	M. Master

Note

Freestyle search always uses TF/IDF to calculate the score and does not support parameters that influence score calculation, such as `textSearch=compare` or `bestMatchingTokenWeight=0.7`. This therefore results in a different score for the same record.

4.3.4.4 Fuzzy Score

This topic describes how fuzzy scores are calculated when comparing two strings or two terms.

The fuzzy search algorithm calculates a fuzzy score for each string comparison. The higher the score, the more similar the strings are. A score of 1.0 means the strings are identical. A score of 0.0 means the strings have nothing in common.

You can request the score in the SELECT statement by using the SCORE() function. You can sort the results of a query by score in descending order to get the best records first (the best record is the record that is most similar to the user input). If a fuzzy search of multiple columns is used in a SELECT statement, the score is returned as an average of the scores of all columns used.

When searching text columns, a TF/IDF (term frequency/inverse document frequency) score is returned by default instead of the fuzzy score. The fuzzy score influences the TF/IDF calculation, but it is important to keep in mind that, with TF/IDF, the range of the score values returned is normed to the interval between 0.0 and 1.0, and the best record always gets a score of 1.0, regardless of its fuzzy score.

The TF/IDF calculation can be disabled so that you get the fuzzy score instead. In particular, this makes sense for short-text columns containing data such as product names or company names. On the other hand, you should use TF/IDF for long-text columns containing data such as product descriptions, HTML data, or Microsoft Word and PDF documents.

4.3.4.4.1 Option similarCalculationMode

Option `similarCalculationMode` controls how the similarity of two strings (or, for TEXT attributes, terms) is calculated.

Score Calculation Modes

Basically, the similarity of two strings is defined by the number of common characters, wrong characters, additional characters in the search string, and additional characters in the reference string.

The following calculation modes exist:

Modes

Mode	Impact on wrong characters	Impact on additional characters in search	Impact on additional characters in table
compare (default)	moderate	high	high
search	high	high	low
searchCompare	moderate/high	high	low
symmetricsearch	high	moderate	moderate
substringsearch	high	high	low
typeAhead	high	very high	low
flexible	controlled by parameter <code>errorDevaluate</code>	very high	controlled by parameter <code>lengthTolerance</code>

Note that a high impact results in a lower score.

Examples with score

Request	Reference	search					
		Compare	typeAhead	hCompare	Search	Symmetric-search	substringSearch
search	searching	0.76	1.0	1.0	0.96	0.86	0.9
search	seerch	0.85	0.85	0.85	0.75	0.75	0.8
search	searchingforex-traterrestriallife	0.0	0.91	0.91	0.91	0.87	0.88
searchingforex-traterrestriallife	searching	0.0	0	0	0.35	0.84	0
searchingforex-traterrestriallife	seerch	0.0	0	0	0.24	0.79	0
searchingforex-traterrestriallife	searchingforthe-meaningoflife	0.6	0.6	0.6	0.57	0.6	0

SQL Examples: Preparations

```
DROP TABLE test_similar_calculation_mode;
CREATE COLUMN TABLE test_similar_calculation_mode
(
    id INTEGER PRIMARY KEY,
    s NVARCHAR(255)
);
INSERT INTO test_similar_calculation_mode VALUES ('1','stringg');
INSERT INTO test_similar_calculation_mode VALUES ('2','string theory');
INSERT INTO test_similar_calculation_mode VALUES ('3','this is a very very very
long string');
INSERT INTO test_similar_calculation_mode VALUES ('4','this is another very long
string');
```

similarCalculationMode compare

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strongtheory', FUZZY(0.5, 'similarCalculationMode=compare'))
ORDER BY score DESC;
```

Score	ID	S
0.84	2	string theory

similarCalculationMode searchCompare

similarCalculationMode searchCompare

The mode `searchCompare` combines the strength of modes `compare` and `search` while eliminating some of the shortcomings of `search mode search`. It is used when the user searches for similar words or for words starting with the user's input. For words with a similar length to the user's input, the tolerance for spelling errors is higher than for words that start with the user's input. The longer the user's input, the more spelling errors are allowed. In contrast to `search mode search`, the search term has to be found as a sequence within the database entry when using `search mode searchCompare`.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'stri', FUZZY(0.6, 'similarCalculationMode=searchCompare'))
ORDER BY score DESC
```

Score	ID	S
0.95	1	stringg

Score	ID	S
0.93	2	string theory
0.91	3	this is a very very very long string
0.91	4	this is another very long string

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strong', FÜZZY(0.6,
'similarCalculationMode=searchCompare'))
ORDER BY score DESC;
```

Score	ID	S
0.8	4	this is another very long string
0.79	3	this is a very very very long string
0.74	2	string theory
0.7	1	stringg

The parameter 'spellCheckFactor' defines the influence of spelling errors on the score, as shown in the following example that uses 0.8 instead of the default value 0.9.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strong', FÜZZY(0.6,
'similarCalculationMode=searchCompare,spellCheckFactor=0.8'))
ORDER BY score DESC;
```

Score	ID	S
0.75	3	this is another very long string
0.75	4	this is a very very very long string
0.7	2	string theory
0.66	1	stringg

Note

similarCalculationMode=searchCompare cannot be used in combination with interScriptMatching=true.

minSearchLength

There is an additional option for `similarCalculationMode=searchCompare` and `similarCalculationMode=flexible` that allows to set a threshold for the minimal length of a string (or token for text) for searching. Shorter strings will only be compared and the search feature is disabled.

This will avoid large result sets and reduce the processing time. Otherwise searching with 'a' would find all words containing an a.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'no', FUZZY(0.6, 'similarCalculationMode=searchCompare'))
ORDER BY score DESC
```

Score	ID	S
0.67	4	this is a very very very long string

Using `minSearchLength` will avoid those unwanted results:

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'no', FUZZY(0.6,
'similarCalculationMode=searchCompare,minSearchLength=3'))
ORDER BY score DESC
```

Score	ID	S
-------	----	---

similarCalculationMode typeAhead

The mode `typeAhead` is used when the user enters the beginning of a string and all strings starting with the user input will be returned. The tolerance for spelling errors at the beginning of the string is lower than with mode `compare`, but there may even be spelling errors in the first character of the string.

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'stri', FUZZY(0.6, 'similarCalculationMode=typeAhead'))
ORDER BY score DESC
```

Score	ID	S
0.95	1	stringg

Score	ID	S
0.93	2	string theory

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strong', FUZZY(0.6, 'similarCalculationMode=typeAhead'))
ORDER BY score DESC;
```

Score	ID	S
0.74	2	string theory
0.7	1	stringg

The parameter `spellCheckFactor` defines the influence of spelling errors on the score, as shown in the following example that uses 0.8 instead of the default value 0.9.

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strong', FUZZY(0.6,
'similarCalculationMode=typeAhead,spellCheckFactor=0.8'))
ORDER BY score DESC;
```

Score	ID	S
0.7	2	string theory
0.66	1	stringg

Note

`similarCalculationMode=typeAhead` cannot be used in combination with `interScriptMatching=true`.

similarCalculationMode search

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strongtheory', FUZZY(0.5, 'similarCalculationMode=search'))
ORDER BY score DESC;
```

Score	ID	S
0.82	2	string theory
0.78	4	this is another very long string
0.70	3	this is a very very very long string

similarCalculationMode symmetricsearch

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strongtheory', FUZZY(0.5,
'similarCalculationMode=symmetricsearch'))
ORDER BY score DESC;
```

Score	ID	S
0.80	2	string theory
0.69	4	this is another very long string
0.62	3	this is a very very very long string
0.54	1	stringg

similarCalculationMode substringsearch

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'strongtheory', FUZZY(0.5,
'similarCalculationMode=substringsearch'))
ORDER BY score DESC;
```

Score	ID	S
0.78	2	string theory

Related Information

[Option similarCalculationMode flexible \[page 290\]](#)

4.3.4.4.1.1 Option similarCalculationMode flexible

The option `similarCalculationMode flexible` allows to parametrize how wrong or additional characters are influencing the score.

Parameter	Description
lengthTolerance	<p>Sets the tolerance for matching longer reference records. The higher its value the longer the hit can be.</p> <p>Range 0..1, default is 0.5. (similarCalculationMode=compare equals 0.0, search equals 0.5).</p> <p>With higher values of lengthTolerance it is a good idea to set fuzzySubstringMatch=on.</p>
errorDevaluate	<p>Defines the devaluation on wrong characters. A higher number gives more devaluation for each typo.</p> <p>Range 0..1, default is 0.9 (similarCaluclationMode=compare equals 0.3, search equals 0.9).</p>
minSearchLength	<p>The parameter allows to set a threshold for the minimal length of a string (or token for text) for searching. Shorter strings will only be compared and the search feature is disabled.</p> <p>This will avoid large result sets and reduce the processing time. Otherwise searching with 'a' would find all words containing an a.</p> <p>Default is 0. A reasonable value is 3 or 4.</p>

SQL Example Preparation

Sample Code

```

DROP TABLE test_similar_calculation_mode;
CREATE COLUMN TABLE test_similar_calculation_mode
(
    id INTEGER          PRIMARY KEY,
    s NVARCHAR(255)    -- no fulltext index
);
INSERT INTO test_similar_calculation_mode VALUES ('1','This is Peter''s
string');
INSERT INTO test_similar_calculation_mode VALUES ('2','Peter''s string');
INSERT INTO test_similar_calculation_mode VALUES ('3','This is Peter''s
longer string');
INSERT INTO test_similar_calculation_mode VALUES ('4','This is Peter''s much
longer string');
INSERT INTO test_similar_calculation_mode VALUES ('5','This is Frank''s
string');
INSERT INTO test_similar_calculation_mode VALUES ('6','This is not Frank''s
string');
INSERT INTO test_similar_calculation_mode VALUES ('7','string Peter''s');

```

Example: Default Settings

Score	ID	S
1	1	This is Peter's string
0.89	3	This is Peter's longer string

The default settings (`lengthTolerance=0.5`, `errorDevaluate=0.9`, `fuzzySubstringMatch=off`) will not find strings that are much longer or shorter than the search term. The devaluation for spelling errors is high.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'This is Peter's string', FUZZY(0.85,
'similarCalculationMode=flexible, lengthTolerance=0.5, errorDevaluate=0.9,
fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

Example Settings for Searching

Score	ID	S
1	1	This is Peter's string
0.98	2	This is Peter's longer string
0.93	3	This is Peter's much longer string

These settings will find strings that are much longer search term.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'This is Peter's string', FUZZY(0.85,
'similarCalculationMode=flexible, lengthTolerance=0.85, errorDevaluate=0.9,
fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

Example Settings for Comparing

Here we won't find any strings with significant length difference. But the tolerance for spelling changes is much higher.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'This is Peter''s string', FUZZY(0.85,
'similarCalculationMode=flexible, lengthTolerance=0.0, errorDevaluate=0.1,
fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

Score	ID	S
1	1	This is Peter's string
0.85	2	This is Frank's string

Related Information

[Option similarCalculationMode \[page 285\]](#)

4.3.4.4.2 Option spellCheckFactor

Option `spellCheckFactor` defines the score for strings that are not identical but get a fuzzy score of 1.0.

There are two use cases for option `spellCheckFactor`:

- A) This option allows you to set the score for terms that are not fully equal but that would be a 100% match because of the internal character standardization used by the fuzzy search.
For example, the terms 'Café' and 'cafe' give a score of 1.0 although the terms are not equal. For some users it might be necessary to distinguish between the terms.
The decision whether two terms are equal is based on the term representation stored in the column dictionary. Option `spellCheckFactor` therefore works differently on string and text columns, as described in the following sections.
- B) The fuzzy search can return a 100% match for terms that are not identical but cannot be differentiated by the fuzzy-string-compare algorithm.
For example, the fuzzy search cannot differentiate between the terms 'abaca' and 'acaba'. In this case, the `spellCheckFactor` can be used to avoid a score of 1.0.

If A) and B) are not needed by an application, you can set the `spellCheckFactor` to 1.0 to disable the feature.

4.3.4.4.2.1 Standardization of Letters and Terms

All characters are replaced by lowercase characters without any diacritics before the fuzzy comparison takes place. This is called standardization. It is therefore possible to get a 100% match when comparing two unequal terms, because the standardization process returned two identical terms.

Standardization Examples

Original Letter	Standardized Letter
E	e
e	e
É	e
é	e
Ë	e
ë	e

The letter i is treated differently, since it is not standardized to an i as would be the 'standard' rule.

Original Letter	Standardized Letter
I	i
İ	i
i	i
ı	i

German umlauts are replaced by two characters.

Original Letter	Standardized Letter
Ä	ae
ä	ae
Ö	oe
ö	oe
Ü	ue
ü	ue
ß	ss

Due to this standardization we get high fuzzy scores for common differences in the spelling of words.

Original term	Standardized term
müller	mueller
Mueller	mueller
Cafe	cafe
Café	cafe

4.3.4.4.2 Search on a String Column (VARCHAR, NVARCHAR)

The decision as to whether two strings are the same is based on the string representation stored in the dictionary for the column in question. The contents of a string column are converted to lowercase characters before being stored in the dictionary. No other standardizations are carried out.

It is therefore not possible to use option `spellCheckFactor` distinguish between 'café' and 'cafe' for example.

Example

```
CREATE COLUMN TABLE test_spell_check_factor
(
  id INTEGER          PRIMARY KEY,
  s  NVARCHAR(255)
);
INSERT INTO test_spell_check_factor VALUES ('1','Muller');
INSERT INTO test_spell_check_factor VALUES ('2','Mueller');
INSERT INTO test_spell_check_factor VALUES ('3','Müller');
INSERT INTO test_spell_check_factor VALUES ('4','Möller');
SELECT SCORE() AS score, id, s
FROM test_spell_check_factor
WHERE CONTAINS(s, 'Müller', FUZZY(0.5, 'spellCheckFactor=0.9'))
ORDER BY score DESC;
DROP TABLE test_spell_check_factor;
```

SCORE	ID	T	Description
1.0	3	Müller	
0.9	2	Mueller	<< spellCheckFactor got used
0.88	1	Muller	
0.88	4	Möller	

4.3.4.4.2.3 Search on a Text Column (SHORTTEXT, TEXT or FULLTEXT INDEX)

Terms in text columns are standardized to lowercase characters without diacritics before being stored in the dictionary. In text columns it is therefore not possible to distinguish for example between 'café' and 'cafe' or 'Müller' and 'mueller'. In this case, the search always returns a score of 1.0.

The main use case of `spellCheckFactor` on text columns is therefore to avoid a score of 1.0 for terms like 'abaca' and 'acaba'.

Example

```
CREATE COLUMN TABLE test_spell_check_factor
(
  id INTEGER          PRIMARY KEY,
  t  SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
INSERT INTO test_spell_check_factor VALUES ('1','Muller');
INSERT INTO test_spell_check_factor VALUES ('2','Mueller');
INSERT INTO test_spell_check_factor VALUES ('3','Müller');
INSERT INTO test_spell_check_factor VALUES ('4','Möller');
SELECT SCORE() AS score, id, t
FROM test_spell_check_factor
WHERE CONTAINS(t, 'Müller', FUZZY(0.5,
'spellCheckFactor=0.9,textSearch=compare'))
ORDER BY score DESC;
DROP TABLE test_spell_check_factor;
```

SCORE	ID	T
1.0	2	Mueller
1.0	3	Müller
0.88	1	Muller
0.88	4	Möller

4.3.4.4.3 Option interScriptMatching

The option `interScriptMatching=on` is used to find Latin transliterations of non-Latin search terms, and vice versa.

Introduction to Inter-Script Matching

Fuzzy search supports all characters that are defined in the Unicode standard. When calculating a score, the characters of the search term and a database entry are compared, and each differing character is a spelling error that results in a reduced score value.

Often, users cannot enter data using the 'original' characters of a foreign language. As a result, a transliteration to the Latin alphabet is used to enter this data. A German user who wants to create a new Chinese business partner for example, types in the city name as 'Shanghai' instead of using the Chinese characters ('上海'). Later, a Chinese user who searches for the business partner in '上海' does not find the data because the search term '上海' and the city name 'Shanghai' stored in the database do not have any characters in common.

To support search requirements as in the example above, you can use the search option `interScriptMatching`. When `interScriptMatching=on` is used, it is possible to find Latin transliterations of non-Latin search terms, and vice versa. The behavior of the fuzzy search changes as follows:

1. Search with Latin characters

- Latin alphabet database entries are searched as usual
 - Non-Latin alphabet database entries are searched using a Latin transliteration of the original data
2. Search with non-Latin characters
- Latin alphabet database entries are searched using a Latin transliteration of the search term
 - Non-Latin alphabet database entries are searched using the original search term

Supported Character Sets

At present, only Chinese characters are supported for inter-script matching.

When comparing Chinese and Latin characters with `interScriptMatching=on`, a pinyin transcription is used to transcribe the sound of Chinese characters into Latin script.

Example

Preparations

```
CREATE COLUMN TABLE interscript
(
  str NVARCHAR(100) PRIMARY KEY
);
INSERT INTO interscript VALUES ('Shanghai');
INSERT INTO interscript VALUES ('上海');
INSERT INTO interscript VALUES ('Beijing');
INSERT INTO interscript VALUES ('北京');
-- without inter-script matching
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str,
'shanghai', FUZZY(0.7)) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str, '上海',
FUZZY(0.7)) ORDER BY SCORE() DESC;
-- with inter-script matching
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str,
'shanghai', FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str, '上海',
FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str,
'beijing', FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str,
'Béijīng', FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str, '北京',
FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
-- with spelling error
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str, 'beijin',
FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM interscript WHERE CONTAINS(str, '被禁',
FUZZY(0.7, 'interScriptMatching=on')) ORDER BY SCORE() DESC;
DROP TABLE interscript;
```

For example, the second to last statement (...WHERE CONTAINS(str, 'beijin', FUZZY(0.7, 'interScriptMatching=on'))...) returns the following results.

Score	Str
0.93	Beijing
0.89	北京

4.3.4.4.4 Option `fuzzySubstringMatch`

The option `fuzzySubstringMatch` offers and controls a post processing of the score calculation.

The option `fuzzySubstringMatch` enables an additional comparison to prevent distributed or wrong positioned features from giving a good score.

<code>fuzzySubstringMatch</code>	Effect	Comment
anywhere	<ul style="list-style-type: none"> demanding non distributed features no preference on the position within the string (or word if using TEXT) 	
beginning	<ul style="list-style-type: none"> demanding non distributed features forces features to be in the beginning of the string (or word if using TEXT) 	
off (default)	no change to score	Default in case of <code>similarCalculationMode=searchCompare</code> is 'on'
(Deprecated) on	enables comparison	Deprecated - use 'anywhere' instead

Note

`fuzzySubstringMatch` cannot be used in combination with `similarCalculationMode=substringSearch` and `similarCalculationMode=typeAhead`.

SQL Example: Comparing 'democracy'

Sample Code

Preparation

```
CREATE COLUMN TABLE test_similar_calculation_mode
(
    id INTEGER PRIMARY KEY,
    s NVARCHAR(255) -- no fulltext index
);
INSERT INTO test_similar_calculation_mode VALUES ('1','democracy');
```

```
INSERT INTO test_similar_calculation_mode VALUES ('2','cracydemo');
```

When fuzzySubstringMatch is set to 'off' string fragments can be widely spread without negative score influence.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'decramocy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

SCORE	ID	S
0.95	1	democracy
0.87	2	cracydemo

When the option is switched to 'on' the additional check prevents the hit we saw above.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'decramocy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=on'))
ORDER BY score DESC;
```

SCORE	ID	S
-------	----	---

The same effect is generated with the value 'anywhere'.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'decramocy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=anywhere'))
ORDER BY score DESC;
```

SCORE	ID	S
-------	----	---

Also with value 'beginning' we don't see hits that have spread fragments.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'decramocy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=beginning'))
ORDER BY score DESC;
```

SCORE	ID	S
-------	----	---

SQL Example: Comparing 'democracy'

When fuzzySubstringMatch is set to 'off' string fragments can be mixed without negative score influence.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'democracy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

SCORE	ID	S
1	1	democracy
0.95	2	cracydemo

When the option is switched to 'on' the additional check prevents the second hit we saw above.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'democracy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=on'))
ORDER BY score DESC;
```

SCORE	ID	S
1	1	democracy

The same effect is generated with the value 'anywhere'.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'democracy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=anywhere'))
ORDER BY score DESC;
```

SCORE	ID	S
1	1	democracy

Also with value 'beginning' we don't see the second hit.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'democracy', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.0, errorDevaluate=0.1, fuzzySubstringMatch=beginning'))
ORDER BY score DESC;
```

SCORE	ID	S
1	1	democracy

SQL Example: Searching 'demo'

When fuzzySubstringMatch is set to 'off' we see the original fuzzy hits.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'demo', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.85, errorDevaluate=0.9, fuzzySubstringMatch=off'))
ORDER BY score DESC;
```

SCORE	ID	S
0.86	1	democracy
0.83	2	cracydemo

When the option is switched to 'on' there is no change because demo is found without going spread.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
WHERE CONTAINS(s, 'demo', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.85, errorDevaluate=0.9, fuzzySubstringMatch=on'))
ORDER BY score DESC;
```

SCORE	ID	S
0.86	1	democracy
0.83	2	cracydemo

The same effect is generated with the value 'anywhere'.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation_mode
```

```
WHERE CONTAINS(s, 'demo', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.85, errorDevaluate=0.9, fuzzySubstringMatch=anywhere'))
ORDER BY score DESC;
```

SCORE	ID	S
0.9	1	democracy
0.88	2	cracydemo

With fuzzySubstringMatch=beginning 'cracydemo' is not found anymore because 'demo' is not in the beginning of it.

Sample Code

```
SELECT TO_INT(SCORE()*100)/100 AS score, id, s
FROM test_similar_calculation mode
WHERE CONTAINS(s, 'demo', FUZZY(0.8, 'similarCalculationMode=flexible,
lengthTolerance=0.85, errorDevaluate=0.9, fuzzySubstringMatch=beginning'))
ORDER BY score DESC;
```

SCORE	ID	S
0.9	1	democracy

4.3.4.5 Available Fuzzy Search Options

Note that some data types in the table below are data type combinations.

- **String:** SQL types VARCHAR and NVARCHAR
- **Text:** SQL types TEXT and SHORTTEXT and any columns that have an additional FULLTEXT INDEX
- **Date:** SQL type DATE

Available Fuzzy Search Options

Name of Option	Short Name	Range	De-fault	Applies to Types	Description
emptyScore	es	0.0..1.0	not set	Text, String, Date	Defines how an empty value and a non-empty value match. For more information, see Option emptyScore and emptyMatchesNull [page 312]
emptyMatchesNull	emn	on,off,true,false	off	Text, String, Date	Returns null values if an empty value is searched. For more information, see Option emptyScore and emptyMatchesNull [page 312]

Name of Option	Short Name	Range	Default	Applies to Types	Description
returnAll	ra	on,off,true,false	off	Text, String, Date	Returns all non-matching values of a column with a score of 0. For more information, see Option returnAll [page 318] .
similarCalculationMode	scm	search,compare,symmetricsearch,substringsearch,searchcompare-see, typeaheadsee	compare	Text, String	<p>Defines how the score is calculated for a comparison of strings (or terms in a text column).</p> <div style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>Note that 'scm=substringsearch' is allowed for string columns only.</p> </div> <div style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>'scm=searchcompare' and 'scm=typeahead' cannot be combined with inter-script-matching ('ism=on').</p> </div> <p>For more information, see Option similarCalculationMode [page 285].</p>
interScriptMatching	ism	on,off,true,false	off	Text, String	<p>Activates fuzzy matching across different scripts (for example, simplified chinese and pinyin).</p> <p>For more information, see Option interScriptMatching [page 296].</p>
spellCheckFactor	scf	0.0..1.0	0.9	Text, String	<p>Sets the score for strings that get a fuzzy score of 1.0 but are not fully equal.</p> <p>For more information, see Option spellCheckFactor [page 293].</p>
abbreviationSimilarity	abs	0.0..1.0	0.0	Text	<p>Activates abbreviation similarity and sets the score.</p> <p>For more information, see Option abbreviationSimilarity [page 359].</p>
andSymmetric	as	on,off,true,false	off	Text	<p>Activates a symmetric AND content search.</p> <p>For more information, see Partially Matching with Parameter andThreshold [page 357].</p>
andThreshold	at	0.0..1.0	1.0	Text	<p>Activates a 'soft AND' and determines the percentage of the tokens that need to match.</p> <p>For more information, see Partially Matching with Parameter andThreshold [page 357].</p>

Name of Option	Short Name	Range	Default	Applies to Types	Description
bestMatchingTokenWeight	bmtw	0.0..1.0	0	Text	<p>Influences the score, shifts total score value between best token score values and root mean square of score values.</p> <p>For more information, see Option bestMatchingTokenWeight [page 352].</p>
composeWords	cw	1..5	1	Text	<p>The maximum number of consecutive words from user input to be composed (default value 1 means composition is disabled by default).</p> <p>For more information, see Option composeWords [page 381].</p>
compoundWordWeight	cww	0.0..1.0	0.9	Text	<p>Term mapping weight for (de)compositions from (de)composeWords.</p> <p>For more information, see Option compoundWordWeight [page 383].</p>
considerNonMatchingTokens	cnmt	max, min, all, input, table	max	Text	<p>Influences the score, defines the number of terms used for score calculation.</p> <p>For more information, see Option considerNonMatchingTokens [page 354].</p>
decomposeWords	dw	1..5	1	Text	<p>The maximum number of words into which a word from the user input is decomposed (default value 1 means composition is disabled by default).</p> <p>For more information, see Option decomposeWords [page 382].</p>
excessTokenWeight	etw	0.0..1.0	1.0	Text	<p>Defines the weight of excess tokens to improve sort order.</p> <p>For more information, see Option excessTokenWeight [page 356].</p>
minTextScore	mts	0.0..1.0	0.0	Text	<p>Minimum score of a TEXT field; if this score is not reached, the record is not part of the result.</p> <p>For more information, see Option minTextScore [page 361].</p>
phraseCheckFactor	pcf	0.1..1.0	1.0	Text	<p>The overall fuzzy score of a text column is multiplied with this value if the search terms do not appear in the correct order.</p> <p>For more information, see Option phraseCheckFactor [page 363].</p>

Name of Option	Short Name	Range	Default	Applies to Types	Description
stopwordListId	sli			Text	Activates the stopwords. For more information, see Usage [page 364] .
stopwordTable	st		not set	Text	Activates the stopwords. For more information, see Usage [page 364]
termMappingListId	tmlid			Text, String	Activates the term mappings. For more information, see Partially Matching with Parameter and Threshold [page 357] .
termMappingTable	tmtle		not set	Text, String	Activates the term mappings. For more information, see Term Mappings [page 371] .
textSearch	ts	fulltext, compare, compareauto	full-text	Text, String, Date, Numeric text-Search=compareauto only is allowed on column types Date and Numeric, it has no function, but does not throw an error.	Switches between full-text search with TF/IDF score and duplicate search with fuzzy score. For more information, see Option textSearch [page 362] .
maxDateDistance	mdd	0..100	0	Date	Specifies the allowed date distance when using fuzzy search on dates. For more information, see Fuzzy Search on DATE Columns [page 385] .
scoreFunction	sf	linear, gaussian, logarithmic	not set	Numeric	Defines the score function.
scoreFunctionDecay	sfd	0 <= decay < 1 (linear), 0 < decay < 1 (gaussian)	0.5	Numeric	Defines the score function parameter 'decay'.
scoreFunctionOffset	sfo	>= 0	0	Numeric	Defines the score function parameter 'offset'.

Name of Option	Short Name	Range	Default	Applies to Types	Description
scoreFunctionScale	sfs	> 0	not set	Numeric	Defines the score function parameter 'scale'.
unmatchedStopwordScore	uss	0.0..1.0	0.98	Text	Defines the score for stopwords in the search term that are not found.

4.3.4.5.1 Permitted Combinations of Fuzzy Search Parameters

Possible combinations of search options are shown in the table below.

Depending on the following conditions, some of the searchOptions parameters might not be permitted, because they do not make sense:

- The data type of a column
- The type of the search (freestyle or attribute search)
- The selected method for score calculation on text columns (fuzzy score or TF/IDF, search option textSearch)

If the user sets an option that is not allowed, an SQL error is thrown, and the SELECT aborts.

The search types used in the table below are:

- Freestyle search: the CONTAINS() predicate uses more than one column.
- Attribute search: the CONTAINS() predicate uses only a single column
- Search on TEXT...: attribute search on a column of type TEXT, SHORTTEXT, or another type with an additional FULLTEXT INDEX.
- Search on types other than TEXT: attribute search that is not performed on a TEXT column as defined above.

	Search on TEXT with Fuzzy Score	Search on TEXT with TD/IDF Score	Freestyle Search	Search on Types Other Than TEXT
	Attribute search and textSearch= compare and datatype= TEXT	Attribute search and textSearch=fulltext and datatype=TEXT	Freestyle search over multiple columns	Attribute search and datatype <>TEXT
textSearch=compare	YES	NO	YES (Only valid for text types. Other types will be ignored.)	NO

	Search on TEXT with Fuzzy Score	Search on TEXT with TD/IDF Score	Freestyle Search	Search on Types Other Than TEXT
textSearch=compareauto	YES	NO	YES (Search option is available for freestyle search beginning with fuzzy search version 20501. The search option has an effect on text and string types with full-text index only. For other column types it will be ignored.)	YES (Search option has an effect on text and string types only. For other column types the option will be ignored.)
textSearch=fulltext	NO	YES	YES (Only valid for text types. Other types will be ignored.)	NO
similarCalculationMode	YES (scm=substring-search is only valid for string types. Other types including text types are not supported.)	YES (scm=substring-search is only valid for string types. Other types including text types are not supported.)	YES (scm=substring-search for freestyle search: text columns use scm=compare instead.)	YES (scm=substring-search is only valid for string types. Other types including text types are not supported.)
interScriptMatching	YES	YES	YES	YES (Only valid for string types. Other types are not supported.)
spellCheckFactor	YES	YES	YES	YES
composeWords	YES	YES	YES (Search option has an effect on text columns only. For other column types the option is ignored.)	NO
decomposeWords	YES	YES	YES (Search option has an effect on text columns only. For other column types the option is ignored.)	NO
compoundWordWeight	YES	YES	YES (Search option has an effect on text columns only. For other column types the option is ignored.)	NO
termMappingTable/ListId	YES	YES	YES (Search option has an effect on text columns only. For other column types the option is ignored.)	YES (Only valid for text and string types.)
returnAll	YES	YES	NO	YES

	Search on TEXT with Fuzzy Score	Search on TEXT with TD/IDF Score	Freestyle Search	Search on Types Other Than TEXT
emptyScore	YES	NO	NO	YES (Only valid for text, string and date types. Numeric types are not supported.)
emptyMatchesNull	YES	NO	NO	YES (Only valid for text, string and date types. Numeric types are not supported.)
abbreviationSimilarity	YES	NO	NO	NO
stopwordTable/ListId	YES	NO	NO (Stopwords are only available for search calls with built-in procedure <code>sys.esh_search()</code> and for freestyle queries starting with API version 20305.)	NO
unmatchedStopwordScore	YES	NO	NO (Stopwords are only available for search calls with built-in procedure <code>sys.esh_search()</code> and for freestyle queries starting with API version 20305.)	NO
andThreshold	YES	NO	NO	NO
andSymmetric	YES	NO	NO	NO
bestMatchingTokenWeight	YES	NO	YES (Only valid for text types with search option <code>textSearch=compare</code> only. Search will fail with an error used on text types with TF/IDF score (<code>textSearch=fulltext</code>). Other types will be ignored.)	NO

	Search on TEXT with Fuzzy Score	Search on TEXT with TD/IDF Score	Freestyle Search	Search on Types Other Than TEXT
considerNonMatchingTokens	YES	NO	YES (Only valid for text types with search option <code>textSearch=compare</code> only. Search will fail with an error used on text types with TF/IDF score (<code>textSearch=fulltext</code>). Other types will be ignored.)	NO
excessTokenWeight	YES	NO	YES (Only valid for text types with search option <code>textSearch=compare</code> only. Search will fail with an error used on text types with TF/IDF score (<code>textSearch=fulltext</code>). Other types will be ignored.)	NO
minTextScore	YES	NO	NO	NO
phraseCheckFactor	YES	NO	NO	NO
searchMode	NO	NO	YES (Only valid for string types. Other will be ignored.)	YES (Only valid for string types. Other types are not supported.)
maxDateDistance	NO	NO	YES (Only valid for date types. Other will be ignored.)	YES (Only valid for date types. Other types are not supported.)
scoreFunction	NO	NO	YES (Only valid for numeric types. Other types are not supported.)	YES (Only valid for numeric types. Other types are not supported.)
scoreFunctionDecay	NO	NO	YES (Only valid for numeric types. Other types are not supported.)	YES (Only valid for numeric types. Other types are not supported.)
scoreFunctionOffset	NO	NO	YES (Only valid for numeric types. Other types are not supported.)	YES (Only valid for numeric types. Other types are not supported.)

	Search on TEXT with Fuzzy Score	Search on TEXT with TD/IDF Score	Freestyle Search	Search on Types Other Than TEXT
scoreFunctionScale	NO	NO	YES (Only valid for numeric types. Other types are not supported.)	YES (Only valid for numeric types. Other types are not supported.)
rank Calculation	fuzzy score	TF/IDF	TF/IDF or fuzzy score (text columns), fuzzy score (other SQL types)	fuzzy score

Legend

YES - The parameter is allowed.

NO - The parameter is not allowed, and an error message is returned if the user sets this option.

	Fuzzy	EXACT	LINGUISTIC
textSearch=compare	YES	YES	YES
textSearch=fulltext	YES	YES	YES
similarCalculationMode	YES	ignored	ignored

rank Calculation			

4.3.4.5.2 Search Options and CONTAINS()

This section gives several examples of using search options and the CONTAINS() statement.

Example without specifying additional search options

```
SELECT SCORE() AS score, *
FROM documents
WHERE CONTAINS(doc_content, 'Driethanolamyn', FUZZY(0.8))
ORDER BY score DESC;
```

Example with additional search options

You can specify additional search options that change the default behavior of the fuzzy search as an additional string parameter for the FUZZY() function.

```
SELECT SCORE() AS score, *
FROM documents
WHERE CONTAINS(doc_content, 'Driethanolamyn', FUZZY(0.8, 'option1=value1,
option2=value2'))
ORDER BY score DESC;
```

Specify the search options as a comma-separated list of key/value pairs.

Example with EXACT search and additional search options

You can also use search options in combination with an exact search. So, for example, you can use search options for term mappings and stopwords for fuzzy search and for exact search.

```
SELECT SCORE() AS score, *
FROM documents
WHERE CONTAINS(doc_content, 'Driethanolamyn', EXACT('option1=value1,
option2=value2'))
ORDER BY score DESC;
```

4.3.4.6 Fuzzy Search - Options for All Column Types

There are search options that are not only valid for a specific column type such as text or string. These options are described in this chapter.

4.3.4.6.1 Option `emptyScore` and `emptyMatchesNull`

These options define the score for empty strings and NULL values when comparing them to non-empty values.

Introduction

Many database tables often contain incomplete data. For example, the first name or the phone number of a customer might be empty, either because the information was not known when the database record was created or because of missing data maintenance.

The search input might therefore contain more information than the database record that the user is looking for. In this case, the user still expects to get the result.

To get the expected behaviour using standard SQL, an application developer writes code as in the following example:

```
SELECT score(), ... FROM ...
WHERE ...
  AND (CONTAINS(firstname, 'Peter', FUZZY(0.8)) OR firstname IS NULL)
  AND ...
```

It is not possible to specify the score for the 'firstname IS NULL' clause, so the overall score() for records with an empty firstname may get an unexpected score() that probably does not match the sort order of other results. SQL statements also become longer and more complex with the additional WHERE clauses.

This is why the 'emptyScore' option has been introduced.

To ensure symmetry, the search works the other way around too. When searching with an empty column, records that contain a value in the column are therefore also returned. This is important for batch processes for

example, where the order of records processed is not known, and results should be the same, regardless of the order of processing.

In the following sections, an empty column value is a column value that is either an empty string ("") or a NULL value. We do not distinguish between these two values.

Supported Data Types

The search option 'emptyScore' supports the following SQL data types:

- VARCHAR
- NVARCHAR
- SHORTTEXT
- TEXT
- DATE
- Columns with a FULLTEXT INDEX

Note

Numeric types like INTEGER, DECIMAL, FLOAT, and so on are currently not supported.

Examples

```
DROP TABLE test_emptyscore;
CREATE COLUMN TABLE test_emptyscore
(
  id INTEGER PRIMARY KEY,
  t TEXT FUZZY SEARCH INDEX ON
);
INSERT INTO test_emptyscore VALUES ('1', 'eins');
INSERT INTO test_emptyscore VALUES ('2', ''); -- empty string
INSERT INTO test_emptyscore VALUES ('3', ' '); -- n blanks
INSERT INTO test_emptyscore VALUES ('4', NULL); -- NULL value
```

Select 'eins' without emptyScore

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, 'eins',
FUZZY(0.5, 'textSearch=compare')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	1	eins

Select 'eins' with emptyScore

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, 'eins',
FUZZY(0.5, 'textSearch=compare, emptyScore=0.5')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	1	eins
0.5	2	
0.5	4	<NULL>

Select empty string without emptyScore

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, '', FUZZY(0.5, 'textSearch=compare')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	2	

Select empty string with emptyScore

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, '', FUZZY(0.5, 'textSearch=compare, emptyScore=0.5')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	2	
1.0	4	<NULL>
0.5	1	eins
0.5	3	

Select empty string with emptyScore and minTextScore

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, '', FUZZY(0.5, 'textSearch=compare, emptyScore=0.5, mintextscore=0.8')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	2	
1.0	4	<NULL>
0.5	1	eins
0.5	3	

Note

When searching with an empty value, for example, records that contain a value in the column are returned and will get the score of the parameter emptyScore. The list will not be shortened, even though the parameter minTextScore is set.

Select 'eins' with emptyMatchesNull

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, 'eins', FUZZY(0.5, 'textSearch=compare, emptyMatchesNull=true')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	1	eins

Select empty string with emptyMatchesNull

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, '', FUZZY(0.5,
'textSearch=compare, emptyMatchesNull=true')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	2	
1.0	4	<NULL>

Related Information

[Finding NULL Values When Searching for an Empty String With emptyMatchesNull \[page 317\]](#)

4.3.4.6.1.1 Getting Records with Empty Column Values

When the search is called with the emptyScore option as in the following example

```
SELECT score(), ... FROM ...
WHERE ...
AND CONTAINS(firstname, 'Peter', FUZZY(0.8, 'textSearch=compare,
emptyScore=0.9, ...<otherOptions>...))
AND ...
```

the records returned by the search are the same as with the following SQL statement (scores differ of course because of the emptyScore parameter)

```
SELECT score(), ... FROM ...
WHERE ...
AND ( CONTAINS(firstname, 'Peter', FUZZY(0.8,
'textSearch=compare, ...<otherOptions>...))
OR firstname IS NULL
OR firstname = ''
)
AND ...
```

For records containing a NULL or an empty string in the firstname column, the value of emptyScore (0.9 in this example) is used as firstname score when calculating the overall score. For records containing a non-empty firstname, the fuzzy score is calculated and used.

For columns that do not allow empty strings as values (date types for example) the result of the search is the same as the query

```
SELECT score(), ... FROM ...
WHERE ...
AND ( CONTAINS(dateofbirth, '2000-01-02', FUZZY(0.8, '...<otherOptions>...))
```

```
        OR dateofbirth IS NULL
    )
    AND ...
```

Note

Numeric types like INTEGER, DECIMAL and FLOAT are currently not supported.

4.3.4.6.1.2 Finding Non-Empty Column Values when Searching with an Empty Column Value

When the search is called with an empty string and with option emptyScore as in the following example:

```
SELECT score(), ... FROM ...
WHERE ...
    AND CONTAINS(firstname, '', FUZZY(0.8, 'textSearch=compare,
emptyScore=0.9, ...<otherOptions>...))
    AND ...
```

the result of the search is the same as with the following SQL statement (scores differ, of course, because of the emptyScore parameter):

```
SELECT score(), ... FROM ...
WHERE ...
    AND (    firstname IS NULL
            OR firstname = ''
            OR firstname LIKE '_%'
        )
    AND ...
```

For records that contain a NULL or an empty string in the firstname column, a score of 1.0 is used, because an empty string is considered a 'perfect' match for a search with an empty string. Records with a non-empty firstname get a firstname score of 0.9, which is the value of the emptyScore parameter in this example.

For columns that do not allow empty strings as a value (for example, date types), the result of the search is the same as the query:

```
SELECT score(), ... FROM ...
WHERE ...
    AND (    dateofbirth IS NULL
            OR dateofbirth IS NOT NULL
        )
    AND ...
```

4.3.4.6.1.3 Finding NULL Values When Searching for an Empty String With emptyMatchesNull

In some cases a search application does not distinguish empty strings from null values. It is expected that a search for an empty string returns all empty strings and all null values, but values that are not empty shall not be returned. This behavior can be enabled by setting `emptyMatchesNull=true`.

This option has an effect on the search result if `emptyScore` is not set, otherwise the `emptyMatchesNull` parameter is ignored. If the search term is not empty, the `emptyMatchesNull` option does not change the search result.

Source Code

```
SELECT score(), ... FROM ...
WHERE ...
  AND CONTAINS(firstname, '', FUZZY(0.8, 'textSearch=compare,
emptyMatchesNull=true, ...<otherOptions>...))
  AND ...
```

The result of the search is the same as with the following SQL statement (scores differ of course because of the `emptyScore` parameter):

Source Code

```
SELECT score(), ... FROM ...
WHERE ...
  AND (   firstname IS NULL
        OR firstname = ''
        )
  AND ...
```

Examples

Select 'eins' with emptyMatchesNull

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, 'eins',
FUZZY(0.5, 'textSearch=compare, emptyMatchesNull=true')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	1	eins

Select empty string with emptyMatchesNull

```
SELECT SCORE() AS score, * FROM test_emptyscore WHERE CONTAINS(T, '', FUZZY(0.5,
'textSearch=compare, emptyMatchesNull=true')) ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	2	
1.0	4	<NULL>

4.3.4.6.2 Option returnAll

Option `returnAll` influences the score by returning all values of a column not matching the defined fuzzy search conditions and giving them the score 0.

The default value of the search option `returnAll` is `returnAll=off`. In this case, the fuzzy search behavior does not change and is as follows:

A `CONTAINS()` predicate using a fuzzy search returns all values of a table column that meet the fuzzy search conditions as defined in the `FUZZY()` predicate. All other values of the column are not returned.

With `returnAll=on` the behavior changes, and all other values of the column are also returned with a score of 0. In other words, a `CONTAINS()` predicate with `returnAll=on` influences the score only and does not behave like a filter condition (it does not remove any rows from the result set).

Note

Option `returnAll` cannot be used for exact searches (example: `'...CONTAINS(col, 'xyz', EXACT('returnAll=on'))...'.`)

The following example shows a use case of option `returnAll`. This option is usually used with search rule sets in order to avoid creating additional rules.

Example without returnAll

The following example shows the behavior of a fuzzy search without the option `returnAll`.

```
CREATE COLUMN TABLE customer
(
  id          INTEGER          PRIMARY KEY,
  firstname   NVARCHAR(50),
  lastname    NVARCHAR(50),
  streetname  NVARCHAR(50),
  housenumber NVARCHAR(20),
  postcode    NVARCHAR(20),
  cityname    NVARCHAR(50)
);
INSERT INTO customer VALUES (1, 'Donna', 'Moore', 'Deer Creek Drive', '3475',
'94304', 'Palo Alto, CA');
INSERT INTO customer VALUES (2, 'Donna', 'More', 'Deer Creek Drive', '1809',
'94304', 'Palo Alto, CA');
INSERT INTO customer VALUES (3, 'Donna', 'Moore', 'Deer Creec Drive', '3477',
'94305', 'Palo Alto CA');
```

The user searches for a customer and expects to find all similar entries in the table.

```
SELECT TO_DECIMAL(SCORE(),3,2) score, * FROM customer
WHERE CONTAINS(firstname, 'Dona', FUZZY(0.7))
AND CONTAINS(lastname, 'Moore', FUZZY(0.7))
AND CONTAINS(streetname, 'Deep Creek Drive', FUZZY(0.7))
AND CONTAINS(housenumber, '3475', FUZZY(0.7))
AND CONTAINS(postcode, '94304', FUZZY(0.7))
AND CONTAINS(cityname, 'Palo Alto CA', FUZZY(0.7));
```

The search returns the following:

SCORE	ID	FIRSTNAME	LASTNAME	STREET-NAME	HOUSENUM-BER	POSTCODE	CITYNAME
0.95	1	Donna	Moore	Deer Creek Drive	3475	94304	Palo Alto, CA
0.91	2	Donna	Moore	Deer Creec Drive	3477	94305	Palo Alto, CA

One row is missing because of the wrong house number, but users expect to find this row. Because of the wrong house number, it is given a lower score than the other rows that contain just a few 'minor' spelling errors.

To get the missing row, there are two options:

- Remove the HOUSENUMBER column from the SELECT statement.
- Add a second SELECT statement that returns all rows with a wrong housenumber.

```
SELECT TO_DECIMAL(SCORE(),3,2) score, * FROM customer
WHERE CONTAINS(firstname, 'Dona', FUZZY(0.7))
AND CONTAINS(lastname, 'Moore', FUZZY(0.7))
AND CONTAINS(streetname, 'Deep Creek Drive', FUZZY(0.7))
AND CONTAINS(housenumber, '3475', FUZZY(0.7))
AND CONTAINS(postcode, '94304', FUZZY(0.7))
AND CONTAINS(cityname, 'Palo Alto CA', FUZZY(0.7));
SELECT TO_DECIMAL(SCORE(),3,2) score, * FROM customer
WHERE CONTAINS(firstname, 'Dona', FUZZY(0.7))
AND CONTAINS(lastname, 'Moore', FUZZY(0.7))
AND CONTAINS(streetname, 'Deep Creek Drive', FUZZY(0.7))
AND CONTAINS(housenumber, '3475', FUZZY(0.7))
AND CONTAINS(postcode, '94304', FUZZY(0.7))
AND CONTAINS(cityname, 'Palo Alto CA', FUZZY(0.7))
UNION
SELECT TO_DECIMAL(0.9 * SCORE(),3,2) score, * FROM customer
WHERE CONTAINS(firstname, 'Dona', FUZZY(0.7))
AND CONTAINS(lastname, 'Moore', FUZZY(0.7))
AND CONTAINS(streetname, 'Deep Creek Drive', FUZZY(0.7))
AND NOT CONTAINS(housenumber, '3475', FUZZY(0.7))
AND CONTAINS(postcode, '94304', FUZZY(0.7))
AND CONTAINS(cityname, 'Palo Alto CA', FUZZY(0.7));
```

The search statements returns:

SCORE	ID	FIRSTNAME	LASTNAME	STREET-NAME	HOUSENUM-BER	POSTCODE	CITYNAME
0.95	1	Donna	Moore	Deer Creek Drive	3475	94304	Palo Alto, CA

SCORE	ID	FIRSTNAME	LASTNAME	STREET-NAME	HOUSENUMBER	POSTCODE	CITYNAME
0.93	2	Donna	More	Deer Creek Drive	1809	94304	Palo Alto, CA
0.91	3	Donna	Moore	Deer Creec Drive	3477	94305	Palo Alto, CA

and

SCORE	ID	FIRSTNAME	LASTNAME	STREET-NAME	HOUSENUMBER	POSTCODE	CITYNAME
0.95	1	Donna	Moore	Deer Creek Drive	3475	94304	Palo Alto, CA
0.91	3	Donna	Moore	Deer Creec Drive	3477	94305	Palo Alto, CA
0.84	2	Donna	More	Deer Creek Drive	1809	94304	Palo Alto, CA

The second statement gives the sort order the user expects. It also runs more slowly than the first statement however, because two searches are executed, and the results are combined to the final result set.

Example with returnAll=on

The following example shows the behavior of a fuzzy search with option `returnAll=on`.

```
CREATE COLUMN TABLE customer
(
  id          INTEGER          PRIMARY KEY,
  firstname   NVARCHAR(50),
  lastname    NVARCHAR(50),
  streetname  NVARCHAR(50),
  housenumber NVARCHAR(20),
  postcode    NVARCHAR(20),
  cityname    NVARCHAR(50)
);
INSERT INTO customer VALUES (1, 'Donna', 'Moore', 'Deer Creek Drive', '3475',
'94304', 'Palo Alto, CA');
INSERT INTO customer VALUES (2, 'Donna', 'More', 'Deer Creek Drive', '1809',
'94304', 'Palo Alto, CA');
INSERT INTO customer VALUES (3, 'Donna', 'Moore', 'Deer Creec Drive', '3477',
'94305', 'Palo Alto CA');
```

To obtain the expected behavior in a single search statement, search option `returnAll` can be used.

Because of the high influence of a column with a score of 0 on the overall score, the weight of the column is reduced to 0.2.

```
SELECT TO_DECIMAL(SCORE(),3,2) score, * FROM customer
WHERE CONTAINS(firstname, 'Dona', FUZZY(0.7))
AND CONTAINS(lastname, 'Moore', FUZZY(0.7))
AND CONTAINS(streetname, 'Deep Creek Drive', FUZZY(0.7))
AND CONTAINS(housenumber, '3475', FUZZY(0.7, 'returnAll=on'),
WEIGHT(0.2))
```

```
AND CONTAINS (postcode, '94304', FUZZY (0.7))
AND CONTAINS (cityname, 'Palo Alto CA', FUZZY (0.7));
```

The search returns all expected rows:

SCORE	ID	FIRSTNAME	LASTNAME	STREET-NAME	HOUSENUM-BER	POSTCODE	CITYNAME
0.95	1	Donna	Moore	Deer Creek Drive	3475	94304	Palo Alto, CA
0.92	3	Donna	Moore	Deer Creec Drive	3477	94305	Palo Alto, CA
0.89	2	Donna	More	Deer Creek Drive	1809	94304	Palo Alto, CA

4.3.4.7 Fuzzy Search on String Columns

This topic describes the fuzzy search features that are available for string columns (such as SQL type NVARCHAR). Fuzzy string search also provides a number of special algorithms for content, such as house numbers or postcodes.

String types support a basic fuzzy string search. The values of a column are compared with the user input using the fault-tolerant fuzzy string comparison.

When working with string types, the fuzzy string compare always compares the full strings. When searching with 'SAP' for example, a record like 'SAP Deutschland AG & Co. KG' gets a very low score, because only a very small part of the string is equal (3 of 27 characters match).

A fuzzy search on string types is a replacement for non-fault tolerant SQL statements like

```
SELECT ... FROM products WHERE product_name = 'coffe krisp biscuit' ...
```

which would not return any results because of the spelling errors.

The following SQL data types are supported:

- VARCHAR
- NVARCHAR

It is possible to speed up the fuzzy search by creating additional data structures called 'fuzzy search indexes'. These are used for faster calculation of the fuzzy score. These indexes exist in the memory only, so no additional disk space is needed.

To achieve the best possible response, you should enable the fuzzy search indexes for all database columns with a high load of fuzzy searches and for all database columns that are used in performance-critical queries.

The following search options influence the score calculation:

- Option `spellCheckFactor`: Defines the score of terms that get a fuzzy score of 1.0 but are not equal.
- Option `similarCalculationMode`: Defines how the score is calculated when comparing terms. Defines options to search with substrings of terms.
- Option `emptyScore`: Defines the score of empty column values when searching with non-empty user input (and vice versa).

4.3.4.7.1 Option `searchMode`

With the `FUZZY SEARCH MODE` clause it is possible to define a content-specific search mode for `VARCHAR` and `NVARCHAR` columns. There are search modes for columns containing house numbers, postcodes or alphanumeric values.

Using the search option `searchMode` it is possible to override the search mode that is defined for a column. For example, it is possible to do a default fuzzy string search on a column that has been defined with `FUZZY SEARCH MODE postcode`.

Sample Code

```
CREATE COLUMN TABLE tab
(
  id INTEGER PRIMARY KEY,
  col1 NVARCHAR(10)
);
INSERT INTO tab VALUES (1, '0000000123');
INSERT INTO tab VALUES (2, '0012300000');
INSERT INTO tab VALUES (3, '123ab');
SELECT SCORE(), col1 FROM tab
WHERE CONTAINS(col1, '123', FUZZY(0.8, 'searchMode=alphanum'));
```

The following search modes are available:

Search Mode	Description
<code>searchMode=default</code>	A default string search is done.
<code>searchMode=null</code>	
<code>searchMode=alphanum</code>	A alphanumeric search is done. Alphanumeric Search [page 323]
<code>searchMode=houzenumber</code>	A house number search is done. Use Case: Fuzzy Search - House Numbers [page 344]
<code>searchMode=postcode</code>	A postcode search is done. Use Case: Fuzzy Search - Postcodes [page 340]

4.3.4.7.2 Alphanumeric Search

The alphanumeric search is a search mode for alphanumeric columns as they are, for example, used by ABAP applications. An alphanumeric column in this case is a column where numeric values (values that contain digits only) are padded with leading zeros and where alphanumeric values (values that contain digits and other characters like letters) are not padded with leading zeros.

i Note

For alphanumeric search to work as expected, applications have to make sure that they follow the rules for alphanumeric columns as described below.

Numeric Values

Numeric values are values that contain digits only. These values have to be padded with leading zeros up to the length of the column.

Given a `NVARCHAR (10)` column, valid entries in this column are for example:

- 0000000123
- 0012300000
- 0000000000

Invalid values are for example

- 123
- 00123
- 12300000

i Note

Search results are undefined for invalid numeric values that do not have the correct number of leading zeros.

Alphanumeric Values

Alphanumeric values are values that contain digits and also other characters like letters. These values do not have to be padded with leading zeros, they are stored in the column as they are given by the user.

Examples for valid entries are:

- abc123
- abc
- 00abc
- 123.0

- 12345a
- 0012345abc

i Note

As these values do not have to be padded with leading zeros, 'abc' and '00abc' are treated as two different values.

Search Mode 'alphanumeric'

For alphanumeric columns that follow the rules given above, using the search mode `alphanumeric` gives better search results. An alphanumeric search is done when either the column is defined with `FUZZY_SEARCH_MODE alphanumeric` or the `CONTAINS ()` predicate contains the search option `searchMode=alphanumeric`.

In case of an alphanumeric search, the behavior of exact and fuzzy search changes as follows:

For numeric search terms:

- For an exact search, leading zeros are automatically added to the search input. For example, a search for '123' internally searches for '0000000123'.
- When the fuzzy score is calculated for a numeric value, leading zeros are ignored. For example, when comparing '0000000123' and '0000000124', the score is calculated based on the comparison of '123' and '124'. Search will also return similar alphanumeric entries like '12a'.

For alphanumeric search terms:

- For an exact search, the search input is not changed. For example, a search for '12345a' internally searches for '12345a'.
- When the fuzzy score is calculated, the search term is also not changed. As leading zeros are ignored, similar numeric values of the same or similar length are also returned. For example, a search for '12345a' will return '12345b' and also '123456', but not '1234560000'.

The fuzzy score is calculated as for 'normal' string columns. The only change to fuzzy search is how leading zeros are treated.

When `FUZZY_SEARCH_INDEX ON` is defined for the column, a fuzzy index for alphanumeric search is created and search results are returned faster.

Search Mode 'alphanumeric' and Wildcards

When searching with wildcards, the behavior of search is similar to an exact search, as described above.

For numeric search terms:

- Leading zeros are ignored when comparing the search input to the table data.

For alphanumeric search terms:

- Leading zeros are not added to the search input and they are not ignored when comparing the search input to the table data.

The following table shows search terms and search results for a column of type NVARCHAR (10) with searchmode alphanum.

Search Term	Finds	Does not Find
12	0000000012	0000120000
12*	0000000012 0000001234 0000120000 12a 12a34	0012a
*12	0000000012 a12 00a12	0000120000
12	0000000012 0000001234 0000120000 0000561234 12a 12a34 00012a	
12a*	12a 12a34	0012a 0012a34
12?	0000000123 12a	0012a
?12?	a12b 0000003124 0000000123	

SQL Syntax

```

Sample Code

CREATE COLUMN TABLE tab
(
  id          INTEGER          PRIMARY KEY,

```

```

    alnum    NVARCHAR(20)  FUZZY SEARCH MODE 'alphanum',
    str      NVARCHAR(255)
);

```

To enable or disable the alphanum search mode at a later point in time, the `ALTER TABLE` statement is used. The fuzzy search mode is not changed if the `FUZZY SEARCH MODE` clause is omitted.

Sample Code

```

-- enable alphanum search
ALTER TABLE tab ALTER
(
    alnum NVARCHAR(20)    FUZZY SEARCH MODE 'alphanum'
);

-- disable alphanum search
ALTER TABLE tab ALTER
(
    alnum NVARCHAR(20)    FUZZY SEARCH MODE NULL
);

-- do not change the status of the search mode
ALTER TABLE tab ALTER
(
    alnum NVARCHAR(20)
);

```

Example

Sample Code

```

CREATE COLUMN TABLE tab
(
    id          INTEGER          PRIMARY KEY,
    alnum       NVARCHAR(10)     FUZZY SEARCH MODE 'alphanum',
    str         NVARCHAR(255)
);

-- numeric values are padded with zeros by the application
INSERT INTO tab VALUES (1, '0000000000', '0');
INSERT INTO tab VALUES (2, '0000000123', '123');

-- alphanumeric values are not padded
INSERT INTO tab VALUES (3, 'x', 'x');
INSERT INTO tab VALUES (4, 'x123', 'x123');
INSERT INTO tab VALUES (5, '123x', '123x');
INSERT INTO tab VALUES (6, '1230000000', '1230000000');
INSERT INTO tab VALUES (7, '123x000000', '123x000000');
INSERT INTO tab VALUES (8, 'x123000000', 'x123000000');
INSERT INTO tab VALUES (9, '000000123x', '000000123x');
INSERT INTO tab VALUES (10, '000000x123', '000000x123');

-- freestyle search

-- when doing a freestyle search, the application cannot pad the search term
because there are other non-alphanum columns or alphanum columns of varying
length
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM tab

```

```

WHERE CONTAINS((alnum, str), '123', FUZZY(0.8))
ORDER BY SCORE() DESC;

-- alphanum search

-- this is the search an application would do because it 'knows' that it
searches an alphanum column
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM tab
WHERE CONTAINS(alnum, '0000000123', FUZZY(0.8))
ORDER BY SCORE() DESC;

-- without padding, search also works
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM tab
WHERE CONTAINS(alnum, '123', FUZZY(0.8))
ORDER BY SCORE() DESC;

-- non alphanum search

-- the application 'knows' that it does search a 'normal' column, so no
padding is done
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM tab
WHERE CONTAINS(str, '123', FUZZY(0.8))
ORDER BY SCORE() DESC;

-- with padding, the expected result is not found
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM tab
WHERE CONTAINS(str, '0000000123', FUZZY(0.8))
ORDER BY SCORE() DESC;

-- exact search on alphanum column
SELECT TO_DECIMAL(SCORE(),3,2), id, alnum
FROM tab
WHERE CONTAINS(alnum, '123')
ORDER BY SCORE() DESC;

SELECT TO_DECIMAL(SCORE(),3,2), id, alnum
FROM tab
WHERE CONTAINS(alnum, '0000000123')
ORDER BY SCORE() DESC;

-- remove alphanum flag from column
ALTER TABLE tab ALTER (alnum NVARCHAR(10) FUZZY SEARCH MODE NULL);

-- exact search on alphanum data does not give expected results
SELECT TO_DECIMAL(SCORE(),3,2), id, alnum
FROM tab
WHERE CONTAINS(alnum, '123')
ORDER BY SCORE() DESC;

-- enable alphanum search using search options
SELECT TO_DECIMAL(SCORE(),3,2), id, alnum
FROM tab
WHERE CONTAINS(alnum, '123', EXACT('searchmode=alphanum'))
ORDER BY SCORE() DESC;

-- enable fuzzy alphanum search using search options
SELECT TO_DECIMAL(SCORE(),3,2), id, alnum
FROM tab
WHERE CONTAINS(alnum, '124', FUZZY(0.8, 'searchmode=alphanum'))
ORDER BY SCORE() DESC;

```

4.3.4.7.3 Identifiers

Often a search is done in columns that contain numerical or alphanumeric identifiers. In many cases, the significant parts of the identifier are the beginning or the end of the identifier, so users want to search with left or right bound substrings of the identifier to find the desired search results.

Without the identifier search described here, users have to use wildcards to get the expected results. For example, a search for '*00123' finds all values that end with '00123' as, for example, '45000000123', and a search for 'A456*' finds all values beginning with 'a456' as, for example, 'A456-123-789'.

4.3.4.7.3.1 Identifier Search for Non-Alphanumeric Values

An identifier search in a column enables the following search features.

1. exact search for the given search term
2. search with wildcards ('*' and '?')
3. search with the beginning or the end of an identifier
4. matching any number of zeros
5. matching any separator character

4.3.4.7.3.1.1 Identifier Search Basics

Identifier Search Basics

The identifier search in a column is enabled by setting the `searchMode` parameter to `identifier`. This changes the behavior of a fuzzy search as follows.

Exact matches are always returned with a score of 1.0. Exact matches are matches where the search term given by the user equals the value found in the column. The comparison between both values is case-insensitive.

All other matches are returned with a score that is defined by the search option `spellCheckFactor`. This includes all matches where the search term given by the user is different from the value found in the column. All matches that are not exact matches get the same score. There is no specific sort order for non-exact matches, like for example a sort order based on a score depending on the number of missing characters in the search term. There is also no matching of values with spelling errors. All characters given in the search term have to be found in the column value, except for separator characters, as described below.

The default value of parameter `spellCheckFactor` is 0.9 but can be changed to any other value between 1.0 and 0.0..

Sample Code

Identifier Search

```
CREATE COLUMN TABLE tab1
(
  i integer primary key,
  id nvarchar(20)
);

INSERT INTO tab1 VALUES (1, '2345');
INSERT INTO tab1 VALUES (2, '12345');
INSERT INTO tab1 VALUES (3, 'abcdefgh12345');
INSERT INTO tab1 VALUES (4, 'abc0000000012345');

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '2345',
EXACT('searchMode=identifier'));
/* returns
  score  id
  1.0    2345          (exact match)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '2345', FUZZY(0.8,
'searchMode=identifier'));
/* returns
  score  id
  1.0    2345          (exact match)
  0.9    12345          (match at the end of the string)
  0.9    abcdefgh12345 (match at the end of the string)
  0.9    abc0000000012345 (match at the end of the string)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '2345', FUZZY(0.8,
'searchMode=identifier,spellCheckFactor=0.8'));
/* returns
  score  id
  1.0    2345          (exact match)
  0.8    12345          (spellCheckFactor=0.8)
  0.8    abcdefgh12345 (spellCheckFactor=0.8)
  0.8    abc0000000012345 (spellCheckFactor=0.8)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, 'abcd', FUZZY(0.8,
'searchMode=identifier'));
/* returns
  score  id
  0.9    abcdefgh12345 (match at the beginning of the string)
*/
```

4.3.4.7.3.1.2 Setting the Minimal Search Length for Identifier Search

Search terms that are at least 4 characters long are searched at the beginning or the end of database entries.

For shorter search terms the identifier search searches values with the same number of characters only. Separator characters are ignored in this case, as they are ignored with longer search terms. This is especially important for freestyle queries over multiple columns where it does not make sense to return all identifiers that start or end with a single character or a two or three character search term. For example, a freestyle search for

'a search term' would return all identifier values that start or end with an 'a' which is usually not expected by the users and which would also make the search much slower.

The parameter 'minSearchLength' can be used to change the minimum length of search terms to be searched at the beginning or the end of an identifier.

i Note

For identifier search, the default value of the search option `minSearchLength` is 4.

Sample Code

Identifier Search

```
SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, 'abc', FUZZY(0.8,
'searchMode=identifier'));
/* returns no result, because search term is only 3 characters long and there
are no matching values stored in the table */

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, 'abc', FUZZY(0.8,
'searchMode=identifier,minSearchLength=3'));
/* returns
  score  id
  0.9    abcdefgh12345      (match at the beginning of the string)
  0.9    abc0000000012345 (match at the beginning of the string)
*/
```

i Note

Limitations of Identifier Search

Other search options that can be used in combination with `searchMode=identifier` are `emptyScore`, `emptyMatchesNull`, `returnAll` and `similarCalculationMode=typeahead`.

`searchMode=identifier` cannot be used when searching in a full-text index.

4.3.4.73.1.3 Matching Many Zeros

Sometimes identifiers contain many zeros in the middle of the identifier. To simplify search, users do not have to specify the exact number of zeros in the search term. It is sufficient to type in three zeros and the identifier search finds all values that contain three or more zeros.

Sample Code

Matching any Number of Zeros

```
CREATE COLUMN TABLE tab1
(
  i integer primary key,
  id nvarchar(20)
);

INSERT INTO tab1 VALUES (1, 'ab000012345');
INSERT INTO tab1 VALUES (2, 'ab0000000012345');
```

```

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, 'ab000012345', FUZZY(0.8,
'searchMode=identifier'));
/* returns
  score  id
  1.0    ab000012345      (exact match)
  0.9    ab0000000012345 (matching many zeros)
*/

```

4.3.4.7.3.1.4 Matching of Separator Characters

In ABAP systems the formatting of values is often changed before the values are displayed in the UI. This means that the UI may show some separator characters to improve the readability of the values while there are no or other separator characters stored in the database. To avoid that users do not find the expected results because of the different representations of the same value, all separator characters are ignored when running an identifier search. This includes separator characters in both the search term and the values stored in the column. Only digits and letters are compared and all other characters are considered to be separator characters.

Sample Code

Matching of Separator Characters

```

CREATE COLUMN TABLE tab1
(
  i integer primary key,
  id nvarchar(20)
);

INSERT INTO tab1 VALUES (1, '9780123456789');
INSERT INTO tab1 VALUES (2, '978/0/12/34567-89');
INSERT INTO tab1 VALUES (3, '978-0-1234-5678-9');

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '9780123456789',
FUZZY(0.8, 'searchMode=identifier'));
/* returns
  score  id
  1.0    9780123456789      (exact match)
  0.9    978/0/12/34567-89 (different separator characters)
  0.9    978-0-1234-5678-9 (different separator characters)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '978-0-1234-5678-9',
FUZZY(0.8, 'searchMode=identifier'));
/* returns
  score  id
  1.0    978-0-1234-5678-9 (exact match)
  0.9    978/0/12/34567-89 (different separator characters)
  0.9    9780123456789     (different separator characters)
*/

```

4.3.4.7.3.1.5 Typeahead Search for Identifiers

The identifier search can be combined with typeahead queries. In this case, only identifiers beginning with the search term are returned. Separator characters are ignored when comparing the search term and the values from the database, as described above.

Sample Code

Typeahead Search for Identifiers

```
CREATE COLUMN TABLE tab1
(
  i integer primary key,
  id nvarchar(20)
);

INSERT INTO tab1 VALUES (1, '2345');
INSERT INTO tab1 VALUES (2, '234567890');
INSERT INTO tab1 VALUES (3, 'abcdefgh12345');

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '2345', FUZZY(0.8,
'searchMode=identifier'));
/* returns
  score  id
  1.0    2345          (exact match)
  0.9    234567890    (match at the beginning of the string)
  0.9    abcdefgh12345 (match at the end of the string)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '234-5', FUZZY(0.8,
'searchMode=identifier'));
/* returns
  score  id
  0.9    2345          (match at the beginning of the string)
  0.9    234567890    (match at the beginning of the string)
  0.9    abcdefgh12345 (match at the end of the string)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '2345', FUZZY(0.8,
'searchMode=identifier,similarCalculationMode=typeahead'));
/* returns
  score  id
  1.0    2345          (exact match)
  0.9    234567890    (typeahead: match at the beginning of the string)
*/

SELECT i, id, SCORE() FROM tab1 WHERE CONTAINS(id, '234-5', FUZZY(0.8,
'searchMode=identifier,similarCalculationMode=typeahead'));
/* returns
  score  id
  0.9    2345          (typeahead: match at the beginning of the string)
  0.9    234567890    (typeahead: match at the beginning of the string)
*/
```

4.3.4.7.3.2 Identifier Search for Alphanumeric Values

The identifier search is also available for columns that contain ABAP alphanumeric columns with leading zeros. The alphanumeric identifier search behaves similar to the non-alphanumeric identifier search described above and adds the alphanum search features to it.

This means that for numeric values all leading zeros are ignored when comparing the search term with the values stored in the table. For values that contain characters other than digits (letters or separator characters), leading zeros are not ignored and are treated as leading characters as with the non-alphanumeric identifier search.

i Note

For alphanumeric identifier search to work as expected, applications have to make sure that they follow the rules for alphanum columns as described in [Alphanumeric Search \[page 323\]](#).

Sample Code

Alphanumeric Identifier Search

```
CREATE COLUMN TABLE tabl
(
  i integer primary key,
  alphanumid nvarchar(20)
);

INSERT INTO tabl VALUES (1, '000000000000000012345');
INSERT INTO tabl VALUES (2, '12-345');

SELECT i, alphanumid, SCORE() FROM tabl WHERE CONTAINS(alphanumid, '12345',
FUZZY(0.8, 'searchMode=alphanum_identifier'));
/* returns
  score  id
  1.0    000000000000000012345  (exact alphanumeric match)
  0.9    12-345                  (non-alphanumeric value)
*/

SELECT i, alphanumid, SCORE() FROM tabl WHERE CONTAINS(alphanumid, '2345',
FUZZY(0.8, 'searchMode=alphanum_identifier'));
/* returns
  score  id
  0.9    000000000000000012345  (match at the end of the string)
  0.9    12-345                  (match at the end of the string with
separator character)
*/

SELECT i, alphanumid, SCORE() FROM tabl WHERE CONTAINS(alphanumid, '23/45',
FUZZY(0.8, 'searchMode=alphanum_identifier'));
/* returns
  score  id
  0.9    000000000000000012345  (match at the end of the string)
  0.9    12-345                  (match at the end of the string)
*/
```

4.3.4.7.3.3 Defining the Default Behavior of a Column

It is possible to set the default behavior of a search in an `NVARCHAR` column to the identifier search. This is done by setting the fuzzy search mode parameter for the column by using either the `CREATE TABLE` or the `ALTER TABLE` statement.

Once the default search mode for a column is set, the `searchMode` parameter does not have to be used anymore to do an identifier search.

Sample Code

Setting the Fuzzy Search Mode Using a `CREATE TABLE` Statement

```
CREATE COLUMN TABLE tab1
(
  i          integer primary key,
  id         nvarchar(20) FUZZY SEARCH MODE 'identifier',
  alphanumid nvarchar(20) FUZZY SEARCH MODE 'alphanum_identifier'
);

INSERT INTO tab1 VALUES (1, '12345', '000000000000000012345');

-- finds 12345
SELECT i, id,          SCORE() FROM tab1 WHERE CONTAINS(id,          '2345',
FUZZY(0.9));

-- finds 000000000000000012345
SELECT i, alphanumid, SCORE() FROM tab1 WHERE CONTAINS(alphanumid, '2345',
FUZZY(0.9));
```

Sample Code

Setting the Fuzzy Search Mode Using an `ALTER TABLE` Statement

```
CREATE COLUMN TABLE tab1
(
  i          integer primary key,
  id         nvarchar(20),
  alphanumid nvarchar(20)
);

INSERT INTO tab1 VALUES (1, '12345', '000000000000000012345');

-- no result
SELECT i, id,          SCORE() FROM tab1 WHERE CONTAINS(id,          '2345',
FUZZY(0.9));

-- finds 12345
SELECT i, id,          SCORE() FROM tab1 WHERE CONTAINS(id,          '2345',
FUZZY(0.9, 'searchMode=identifier'));

-- no result
SELECT i, alphanumid, SCORE() FROM tab1 WHERE CONTAINS(alphanumid, '2345',
FUZZY(0.9));

-- finds 000000000000000012345
SELECT i, alphanumid, SCORE() FROM tab1 WHERE CONTAINS(alphanumid, '2345',
FUZZY(0.9, 'searchMode=alphanum_identifier'));

ALTER TABLE tab1 ALTER
(
  id nvarchar(20)          FUZZY SEARCH MODE 'identifier',
```

```

    alphanumid nvarchar(20) FUZZY SEARCH MODE 'alphanum_identifier'
);

-- finds 12345
SELECT i, id,          SCORE() FROM tab1 WHERE CONTAINS(id,          '2345',
FUZZY(0.9));

-- finds 000000000000000012345
SELECT i, alphanumid, SCORE() FROM tab1 WHERE CONTAINS(alphanumid, '2345',
FUZZY(0.9));

```

4.3.4.7.3.4 Faster Search Using a Fuzzy Search Index

It is possible to speed up an identifier search by adding a fuzzy search index to a database column. This is also done by using either the `CREATE TABLE` or the `ALTER TABLE` statement.

Sample Code

Adding a Fuzzy Search Index for Identifier Search Using a `CREATE TABLE` Statement

```

CREATE COLUMN TABLE tab1
(
    i          integer primary key,
    id        nvarchar(20) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'identifier',
    alphanumid nvarchar(20) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'alphanum_identifier'
);
CREATE COLUMN TABLE tab1
(
    i          integer primary key,
    id        nvarchar(20) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'identifier',
    alphanumid nvarchar(20) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'alphanum_identifier'
);

```

Sample Code

Adding a Fuzzy Search Index for Identifier Search Using an `ALTER TABLE` Statement

```

ALTER TABLE tab1 ALTER
(
    id nvarchar(20)          FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'identifier',
    alphanumid nvarchar(20) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'alphanum_identifier'
);

```

4.3.4.7.4 Speeding Up the Fuzzy Search with the Fuzzy Search Index

You can speed up the fuzzy search on string types by creating a special data structure called a fuzzy search index.

The additional index will increase the total memory footprint of the loaded table. In unfavourable cases the memory footprint of the column can be doubled.

```
CREATE COLUMN TABLE mytable
(
  id      INTEGER      PRIMARY KEY,
  col1    VARCHAR(100)  FUZZY SEARCH INDEX ON,
  col2    NVARCHAR(100) FUZZY SEARCH INDEX ON
);
```

Additional performance improvements are possible when creating database indexes on the columns.

```
CREATE INDEX myindex1 ON mytable(col1);
CREATE INDEX myindex2 ON mytable(col2);
```

The state of the fuzzy search index can be changed at a later point in time by using the ALTER TABLE statement.

```
ALTER TABLE mytable ALTER
(
  col1    VARCHAR(100)  FUZZY SEARCH INDEX OFF,
  col2    NVARCHAR(100)
);
```

The view SYS.TABLE_COLUMNS shows the current state of the fuzzy search index. When working with attribute views, this information is also visible in SYS.VIEW_COLUMNS.

```
SELECT column_name, data_type_name, fuzzy_search_index
FROM table_columns
WHERE table_name = 'MYTABLE';
```

4.3.4.7.5 Substring-Optimized Fuzzy Search on String Columns

String columns (VARCHAR and NVARCHAR) are not suitable for finding small parts of a longer string, for example finding 'test' in 'this is a long test run'. This is more the domain of TEXT fields that have an additional FULLTEXT INDEX. To find a short string in what might be longer values of string columns (VARCHAR and NVARCHAR), a special search mode `scm=substringsearch` has been established. The substring search can be used as a work-around if there is no option to perform the search on a TEXT column. The results will be similar but not identical.

4.3.4.7.5.1 Score Calculation

`search` is a `similarCalculationMode` that is suitable for performing a substring-optimized fuzzy search on string columns. However, it also has the following shortcomings:

- Based on the algorithm, it finds longer texts that are not similar in a human sense with a particularly good score.
- This also impairs the sorting of the result set.

To overcome these issues, a new type of `similarCalculationMode` has been introduced, known as the `subStringSearch`. Search option `scm=substringsearch` returns all rows containing the search input. Very long search strings are truncated after 100 characters. A fault tolerance of up to 8 typographical errors for long search strings limits the result list.

See also the example listed in the topic under Related Links.

Results with `similarCalculationMode=search`

```
SELECT SCORE(), STRING FROM TABLE WHERE CONTAINS (STRING, 'test', FUZZY(0.5, 'similarCalculationMode=search'))
```

SCORE()	STRING
1.0	test
0.93	long test
0.91	this is a long test run
0.68	this is a long text column
0.68	this is not a result
0.62	text
0.58	long text

Results with `similarCalculationMode=subStringSearch`

```
SELECT SCORE(), STRING FROM TABLE WHERE CONTAINS (STRING, 'test', FUZZY(0.7, 'similarCalculationMode=substringsearch'))
```

SCORE()	STRING
1.0	test
0.97	long test
0.95	this is a long test run

SCORE()	STRING
0.8	text
0.77	long text
0.76	this is a long text column

As shown in the example, all results containing the search term 'test' are sorted on top, followed by the results containing the term 'text'. The record 'this is not a result' is sorted out.

4.3.4.7.5.2 Comparison of subStringSearch on String Columns And Text Search on Text Columns

Hits and Score

The hits from a `subStringSearch` on string column are determined in a completely different way to the hits from a text search on a text column. The scoring calculation uses a different algorithm too. The results therefore cannot be the same. They are similar however. The following example shows a comparison of a `subStringSearch` with a very similar text search.

Example:

```
DROP TABLE tab;
CREATE COLUMN TABLE tab (
  id          INTEGER primary key,
  str         NVARCHAR(120) fuzzy search index on,
  txt         TEXT fuzzy search index on);
INSERT INTO tab VALUES (0, 'Albia City', 'Albia City');
INSERT INTO tab VALUES (1, 'Albia', 'Albia');
INSERT INTO tab VALUES (2, 'Albia City Hall', 'Albia City Hall');
INSERT INTO tab VALUES (3, 'City Of Albia', 'City Of Albia');
INSERT INTO tab VALUES (4, 'Albion City Park', 'Albion City Park');
INSERT INTO tab VALUES (5, 'Albiacityhall', 'Albiacityhall');
INSERT INTO tab VALUES (6, 'Albiacity', 'Albiacity');
INSERT INTO tab VALUES (7, 'Cityalbia', 'Cityalbia');
MERGE DELTA OF tab;
SELECT TO_DECIMAL(SCORE(),3,2) score, txt FROM tab WHERE CONTAINS(txt, 'olbia
city',
FUZZY(0.75, 'textsearch=compare, considernonmatchingtokens=input,
composewords=5, decomposewords=5'))
ORDER BY SCORE() DESC;
```

SCORE()	TXT
0.9	Albia City
0.9	Albia City Hall
0.9	City Of Albia
0.81	Albiacity
0.77	Cityalbia

```
SELECT TO_DECIMAL(SCORE(),3,2) score, str FROM tab WHERE CONTAINS(str, 'olbia
city',
FUZZY(0.75,
'similarcalculationmode=substringsearch'))
ORDER BY SCORE() DESC;
```

SCORE()	STR
0.89	Albia City
0.88	City Of Albia
0.88	Albia City Hall
0.82	Albiacity
0.82	Cityalbia
0.78	Albiacityhall

subStringSearch uses a strict AND. Records like "Albia" are therefore not returned, as "City" is missing in the input. As for longer reference entries and additional or missing blanks, it is quite tolerant. Wrong, missing or additional characters result in a moderate deduction.

The main difference to a standard string search is that subStringSearch suppresses reference hits that just contain widely spread fragments of the search string which are not considered similar to the input by the human eye.

Response Time

The response time of a subStringSearch depends on various factors. Internally, it starts with a fuzzy search on the string column. The results are then filtered, and a score is calculated. The time consumed is depends significantly on the number of hits that the fuzzy search returns. In general, the subStringSearch using the fuzzy index can take twice as long as the underlying string search. If the subStringSearch runs without fuzzy index, it might be faster than the string search, but consumes more CPU time. Compared to a text search, the subStringSearch is a few times slower or worse. It should therefore not be used for large amounts of data, and only when text columns are not an option.

Memory Consumption

The memory consumption of a `subStringSearch` is not different to the string search it is based on. It depends of course on whether or not the fuzzy index is used.

4.3.4.7.6 Content-Specific Fuzzy Search on String Columns

4.3.4.7.6.1 Use Case: Fuzzy Search - Postcodes

Postcodes in almost all countries are ordered by region. This means that if the leading characters of the postcodes of two different addresses are the same, the addresses are near to each other. In Germany, for example, addresses within large cities share the first or even the first two digits of their postcode.

The only exception known to the development team is Cambodia, where postcodes are not ordered by region.

When doing a fuzzy search on addresses, it makes sense to return a higher score for postcodes that are 'near' to a given user input than for postcodes that are 'far away' from the user input. It makes sense to give a higher weight to the leading characters and a lower weight to the trailing characters of the postcode.

Valid addresses may contain a country code in front of the postcode (for example, 'D-12345' or 'DE-12345' for a German address). This is also supported by the fuzzy postcode search.

Score Calculation

Before the fuzzy score is calculated, the postcode strings are standardized.

1. Country codes are separated from the postcode strings. Country codes in this case consist of one to three letters (a-z only, no numbers) at the beginning of the postcode, followed by a minus sign. Longer words are not considered a country code because postal standards do not allow country names in front of the postcode.
2. Country codes are standardized to enable a comparison of different codes for the same country, for example, 'D-', 'DE-' and 'DEU-' for German postcodes. All unknown/invalid country codes are standardized to one special 'dummy' country code.
3. Spaces and dashes are removed from the remaining postcode.
4. All letters are standardized to uppercase.

User Input	Country Code	Remaining Postcode
71691		71691
716 91		71691
D-71691	D	71691

User Input	Country Code	Remaining Postcode
DE-71 691	DE	71691
D 71691		D71691
Germany-71691		GERMANY71691
GB-A1H 2ZU	GB	A1H2ZU
A1H-2ZU		A1H2ZU
gb-A1h 2zu	GB	A1H2ZU
XY-12345	XX	12345
zz-12345	XX	12345
AI-2640	AI	2640

The last example is the only known example where the country code is part of the postcode (AI = Anguilla). The algorithm works here as well, since the country code is also compared. The two examples directly above the AI example show invalid country codes. Both are standardized to the same non-existent 'dummy' country code.

Postcode Comparison

The standardized postcodes are compared using a variation of the fuzzy string comparison. This variation gives a higher weight to the first two characters of the postcode.

Country codes are given the same weight as a single character at the end of the postcode.

- Only postcodes with the same country code can get a score of 1.0.
- If one country code is given and the second country code is empty, the score of the postcode comparison is less than 1.0.
- If both country codes are given and are different, the score of the postcode comparison is also less than 1.0.

Parameter similarCalculationMode

The search option 'similarCalculationMode' with options 'search' and 'symmetricsearch' is available for postcode columns.

When using the search option 'similarCalculationMode', a postcode search with a postcode prefix will find all addresses in a given area.

- A search with '71' returns all postcodes beginning with '71'.
- A search with '1234' returns all postcodes starting with a sequence similar to '1234' and, with a lower score, all postcodes that contain a '1234'.

Parameter spellCheckFactor

Two postcodes may be considered identical by the fuzzy string comparison, but may still be different. In this case, the value of the parameter 'spellCheckFactor' is applied and the score is multiplied by the spellCheckFactor.

Examples of non-equal postcodes that get a score of 1.0 are:

- '123456' and '12 34 56'
- '7070717' and '7071707'

The default value of the search option spellCheckFactor is 0.9. To disable this feature, set 'spellCheckFactor=1.0'.

Example

The following example uses a spellCheckFactor of 1.0, which is not the default value.

Postcode 1	Postcode 2	Score	Remarks
71691	71691	1.0	
71691	71 691	1.0	
71691	81691	0.51	Highest weight on the first digit
71691	72691	0.7	High weight on the second digit
71691	71692	0.96	Lower weight on all other digits
71691	D-71691	0.96	Country code missing in one column
D-71691	A-71691	0.96	Country codes are different
71691	D-71692	0.92	
D-71691	A-71692	0.92	
GB-A1H 2ZU	Gb-a1h2zu	1.0	
XX-12345	YY-12345	1.0	Invalid country codes are 'equal'
D-12345	YY-12345	0.96	Valid and invalid country code

SQL Syntax

(N)VARCHAR columns have to be defined as postcode columns to enable the fuzzy postcode search. You do this using the FUZZY SEARCH MODE clause.

You can also improve the performance of the postcode search by activating a fuzzy search index and by creating a database index on the postcode column.

```
CREATE COLUMN TABLE tab
(
  id          INTEGER          PRIMARY KEY,
  postcode    NVARCHAR(20)     FUZZY SEARCH INDEX ON FUZZY SEARCH MODE 'postcode'
);
CREATE INDEX myindex1 ON tab(postcode);
```

You can enable or disable the postcode search at a later point in time with the ALTER TABLE statement. To disable the postcode search, do not specify the FUZZY SEARCH MODE for the postcode column.

```
-- enable postcode search
ALTER TABLE tab ALTER
(
  postcode    NVARCHAR(100)    FUZZY SEARCH MODE 'postcode'
);
-- disable postcode search
ALTER TABLE tab ALTER
(
  postcode    NVARCHAR(100)    FUZZY SEARCH MODE NULL
);
-- do not change the status of the search mode
ALTER TABLE tab ALTER
(
  postcode    NVARCHAR(100)
);
```

You can query the status of the fuzzy search index and the fuzzy search mode from the system view TABLE_COLUMNS.

```
SELECT column_name, data_type_name, fuzzy_search_index, fuzzy_search_mode
FROM table_columns
WHERE table_name = 'TAB';
```

Example

```
CREATE COLUMN TABLE postcodes
(
  postcode NVARCHAR(50) FUZZY SEARCH INDEX ON FUZZY SEARCH MODE 'postcode'
);
INSERT INTO postcodes VALUES ('71691');
INSERT INTO postcodes VALUES ('81691');
INSERT INTO postcodes VALUES ('72691');
INSERT INTO postcodes VALUES ('71692');
INSERT INTO postcodes VALUES ('716 91');
INSERT INTO postcodes VALUES ('A1H 2ZU');
INSERT INTO postcodes VALUES ('A1H2ZU');
INSERT INTO postcodes VALUES ('D-71691');
INSERT INTO postcodes VALUES ('D-71692');
INSERT INTO postcodes VALUES ('A-71691');
INSERT INTO postcodes VALUES ('A-71692');
INSERT INTO postcodes VALUES ('DE-71 691');
INSERT INTO postcodes VALUES ('D 71691');
INSERT INTO postcodes VALUES ('GB-A1H 2ZU');
INSERT INTO postcodes VALUES ('XX-12345');
INSERT INTO postcodes VALUES ('D-12345');
INSERT INTO postcodes VALUES ('71234');
```

```

SELECT TO_DECIMAL(SCORE(),3,2), *
FROM postcodes
WHERE CONTAINS(postcode, '71691', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM postcodes
WHERE CONTAINS(postcode, 'D-71691', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM postcodes
WHERE CONTAINS(postcode, 'Gb-a1h2zu', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM postcodes
WHERE CONTAINS(postcode, 'YY-12345', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *FROM postcodes
WHERE CONTAINS(postcode, '71', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM postcodes
WHERE CONTAINS(postcode, '1234', FUZZY(0.5, 'spellCheckFactor=1.0'))
ORDER BY SCORE() DESC;

```

4.3.4.7.6.2 Use Case: Fuzzy Search - House Numbers

Score Calculation

The house number comparison aims for a 'simple' solution that is easy to understand, gives good results, and works for most countries. The limitations of the algorithm are:

- The algorithm focuses on numeric values - either a single number ('8') or a range of numbers ('8 - 12').
- House number additions (for example, the 'a' in '8a') are either equal or not equal.

When comparing two strings containing house numbers with each other, the score is calculated in accordance with the rules described below.

House number addition. A house number addition in terms of this backlog item is any additional text that is written before or after the numeric value of a house number.

House number ranges. When a string contains at least two numbers and there is a dash between the first and second number, this is treated as a house number range. The first number is the lower bound of the range, the last number is the upper bound.

Multiple numbers. When multiple numbers are part of a house number string that does not define a house number range, the first number is the house number used for the comparison. All remaining information is used as a house number addition.

Whitespace characters. For all rules, whitespace characters are ignored when comparing the house numbers. For the score calculation it does not matter if a house number is given as '8a' or '8 a' or if it is '8-10' or '8 - 10'.

Symmetry. In all examples, the score calculation is symmetric. This means that either string 1 or string 2 can be the user input and the other string is stored in the database table.

Rule 1 - House Numbers or House Number Ranges Are Identical

For identical house numbers, a score of 1.0 is returned. Identical house numbers are house number strings that are equal when whitespace characters are ignored.

Examples:

String 1	String 2	Score
5	5	1.0
5a	5 a	1.0
8-12	8-12	1.0
9 in the backyard	9 in the backyard	1.0

Rule 2 - House Numbers or House Number Ranges Are Very Similar (House Number Additions Are Different)

House numbers or house number ranges are considered very similar when the numerical values are identical but the additional information differs.

Examples:

String 1	String 2	Score
5	5 a	0.9
5a	5 b	0.9
5	Nr. 5	0.9
8-12	8 - 12a	0.9
8-12	Nr. 8-12	0.9
8-12	8 - 12/5	0.9
8 this is a long text -12	8 - 12a	0.9
7	below 7	0.9
9	9 in the backyard	0.9
in the backyard 9	9 in the backyard	0.9

Rule 3 - House Numbers or House Number Ranges Are Less Similar

House numbers and house number ranges are considered less similar in the following cases:

1. A house number is compared to a house number range and the numerical value of the house number equals the lower or upper bound of the range.

- Two house number ranges are compared and the numerical values of either the lower or upper bounds are equal.

String 1	String 2	Score
8	8-12	0.8
12a	8-12	0.8
8-10	8-12	0.8
8-10	8-12	0.8
10-12a	8-12	0.8
8 in the backyard	8-12	0.8

Rule 4 - Overlapping House Number Ranges

House numbers and house number ranges overlap in the following cases:

- A house number is compared to a house number range and the numerical value of the house number lies within the range.
- Two house number ranges are compared and the ranges overlap.

Examples:

String 1	String 2	Score
10	8-12	0.7
10a	8-12	0.7
9	8-12	0.7
8-12	10-14	0.7
8-12a	10b-14	0.7

Last Rule - House Numbers Are Not Equal

Examples:

String 1	String 2	Score
5	6	0.0
8a	9a	0.0
6	8-12	0.0
8-10	12-14	0.0

House Number Columns and Other String Search Options

The following search options available for string column types are not valid for house number columns:

- **SpellCheckFactor:** When comparing house numbers, the search option 'spellCheckFactor' is ignored. So for house numbers, the results are always the same as with 'spellCheckFactor=1.0'.
- **SimilarCalculationMode:** When comparing house numbers, the search option 'similarCalculationMode' is ignored and has no effect on the search result.

Both options are ignored. No error is returned when any of the options is given.

SQL Syntax

To enable the search for house numbers on an (N)VARCHAR column, the FUZZY SEARCH MODE clause is used in a CREATE TABLE statement.

```
CREATE COLUMN TABLE tab
(
  id    INTEGER          PRIMARY KEY,
  coll  NVARCHAR(20)     FUZZY SEARCH MODE 'hounumber'
);
```

To enable or disable the house number search mode at a later point in time, use the ALTER TABLE statement. The fuzzy search mode is not changed if the FUZZY SEARCH MODE clause is omitted.

```
-- enable hounumber search
ALTER TABLE tab ALTER
(
  coll VARCHAR(20)     FUZZY SEARCH MODE 'hounumber'
);
-- disable hounumber search
ALTER TABLE tab ALTER
(
  coll VARCHAR(20)     FUZZY SEARCH MODE NULL
);
-- do not change the status of the search mode
ALTER TABLE tab ALTER
(
  coll VARCHAR(20)
);
```

You can query the state of the fuzzy search mode using the system view TABLE_COLUMNS.

```
SELECT column_name, data_type_name, fuzzy_search_mode
FROM table_columns
WHERE table_name = 'TAB';
```

i Note

You cannot use a fuzzy search index in combination with the house number search mode.

i Note

The use of freestyle search (multiple columns) in combination with a house number search mode may result in problems as non-matching search terms are interpreted as additional house number information and lead to a good match (see example 7 of rule 2).

Example

The following example creates a table that contains only a single house number column and executes some searches on this column.

```
CREATE COLUMN TABLE housenumbers
(
  housenumber NVARCHAR(50) FUZZY SEARCH MODE 'housenumber'
);
INSERT INTO housenumbers VALUES ('5');
INSERT INTO housenumbers VALUES ('5a');
INSERT INTO housenumbers VALUES ('5 a');
INSERT INTO housenumbers VALUES ('Nr. 5');
INSERT INTO housenumbers VALUES ('8-12');
INSERT INTO housenumbers VALUES ('8 - 12');
INSERT INTO housenumbers VALUES ('8 - 12a');
INSERT INTO housenumbers VALUES ('Nr. 8-12');
INSERT INTO housenumbers VALUES ('8 - 12/5');
INSERT INTO housenumbers VALUES ('8');
INSERT INTO housenumbers VALUES ('12a');
INSERT INTO housenumbers VALUES ('8-10');
INSERT INTO housenumbers VALUES ('10-12a');
INSERT INTO housenumbers VALUES ('10a');
INSERT INTO housenumbers VALUES ('10-14');
INSERT INTO housenumbers VALUES ('9');
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM housenumbers
WHERE CONTAINS(housenumber, '5', FUZZY(0.8))
ORDER BY TO_DECIMAL(SCORE(),3,2) DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM housenumbers
WHERE CONTAINS(housenumber, 'Nr. 5', FUZZY(0.8))
ORDER BY TO_DECIMAL(SCORE(),3,2) DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM housenumbers
WHERE CONTAINS(housenumber, '8a-12', FUZZY(0.8))
ORDER BY TO_DECIMAL(SCORE(),3,2) DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM housenumbers
WHERE CONTAINS(housenumber, '10-12', FUZZY(0.8))
ORDER BY TO_DECIMAL(SCORE(),3,2) DESC;
SELECT TO_DECIMAL(SCORE(),3,2), *
FROM housenumbers
WHERE CONTAINS(housenumber, '9 in the BACKYARD', FUZZY(0.8))
ORDER BY TO_DECIMAL(SCORE(),3,2) DESC;
```

4.3.4.7.7 Speeding Up the Fuzzy Search on String Columns

Context

Fuzzy search on string types can be sped up by creating a special data structure called a fuzzy search index. The additional index will increase the total memory footprint of the loaded table. In unfavourable cases the memory footprint of the column can be doubled.

```
CREATE COLUMN TABLE mytable
(
  id      INTEGER      PRIMARY KEY,
  col1    VARCHAR(100) FUZZY SEARCH INDEX ON,
  col2    NVARCHAR(100) FUZZY SEARCH INDEX ON
);
```

Additional performance improvements are possible when creating database indexes on the columns.

```
CREATE INDEX myindex1 ON mytable(col1);
CREATE INDEX myindex2 ON mytable(col2);
```

The state of the fuzzy search index can be changed at a later point in time by using the ALTER TABLE statement.

```
ALTER TABLE mytable ALTER
(
  col1    VARCHAR(100) FUZZY SEARCH INDEX OFF,
  col2    NVARCHAR(100)
);
```

The view SYS.TABLE_COLUMNS shows the current state of the fuzzy search index. When working with attribute views, this information is also visible in SYS.VIEW_COLUMNS.

```
SELECT column_name, data_type_name, fuzzy_search_index
FROM table_columns
WHERE table_name = 'MYTABLE';
```

4.3.4.8 Fuzzy Search on Text Columns

This topic describes the fuzzy search features that are available for text columns (such as SQL type SHORTTEXT) and for columns with an additional FULLTEXT INDEX.

Text types support a more sophisticated kind of fuzzy search. Texts are tokenized (split into terms), and the fuzzy comparison is performed term by term. When searching with 'SAP' for example, a record like 'SAP Deutschland AG & Co. KG' gets a high score, because the term 'SAP' exists in both texts. A record like 'SAPPHIRE NOW Orlando' gets a lower score, because 'SAP' is just a part of the longer term 'SAPPHIRE' (3 of 8 characters match).

Fuzzy search on text columns replaces non-fault tolerant statements like

```
SELECT ... FROM documents WHERE doc_content LIKE '% Driethanolamyn %' ...
```

The following SQL data types are supported:

- TEXT
- SHORTTEXT
- fulltext index

A fulltext index is an additional index structure that can be defined for non-text columns to add text search features. Supported column types include NCLOB and NVARCHAR.

It is possible to speed up the fuzzy search by creating data structures called 'fuzzy search indexes', which are used for faster calculation of the fuzzy score. These indexes exist in the memory only, so no additional disk space is needed.

To achieve the best possible response times, you should enable the fuzzy search indexes for all database columns with a high load of fuzzy searches and for all database columns that are used in performance-critical queries.

Fuzzy Search on SQL Type TEXT

A call to contains that references a TEXT column is automatically processed as a text search. In this case, the mode textsearch=compare and all fuzzy search options are allowed:

```
CREATE COLUMN TABLE mytable
(
  coll TEXT
);
SELECT score() AS score, * FROM mytable WHERE contains(coll, 'a b', fuzzy(0.8,
'textsearch=compare'));
```

Fuzzy Search on SQL Type SHORTTEXT

When a SHORTTEXT column is created, a column of column store type cs_string and a second hidden text column are created. A call to contains that references the SHORTTEXT column is automatically redirected by the freestyler to the additional hidden TEXT column. In this case, the mode textsearch=compare and all fuzzy search options are allowed:

```
CREATE COLUMN TABLE mytable
(
  coll SHORTTEXT(200)
);
SELECT score() AS score, * FROM mytable WHERE contains(coll, 'a b', fuzzy(0.8,
'textsearch=compare'));
```

Fuzzy Search on a FULLTEXT INDEX

When a full-text index is created on a column that is not of type TEXT (e.g. NVARCHAR, NCLOB, ...) a hidden text column is added to the table. A call to contains that references the non-TEXT column is automatically

redirected by the freestyler to the additional text column. In this case, the mode `textsearch=compare` and all fuzzy search options are allowed:

```
CREATE COLUMN TABLE mytable
(
  coll NVARCHAR(2000)
);
CREATE FULLTEXT INDEX myindex ON mytable(coll);
SELECT score() AS score, * FROM mytable WHERE contains(coll, 'a b', fuzzy(0.8,
'textsearch=compare'));
```

Merge Delta for Better Performance

When inserting or loading a large number of rows into a table that has a TEXT or SHORTTEXT column or uses a FULLTEXT INDEX, it is important to merge the delta part of the table in order to ensure satisfactory search performance.

A delta merge can be started manually using the following SQL statement:

```
MERGE DELTA OF mytable;
```

Alternatively, a delta merge can be triggered automatically by the mergedog process.

4.3.4.8.1 Multi-Token Search on Text Columns

When using more than one token in a query, the default content type is AND (for example, ... WHERE CONTAINS (mycolumn, 'software firm', FUZZY(0.5)) ... will return entries that contain a token similar to 'software' and a token similar to 'firm').

Alternatively, you can use OR by adding the key word between the tokens (for example, ... WHERE CONTAINS (mycolumn, 'apple OR 'banana', FUZZY(0.5)) ... will return entries that contain a token similar to 'apple' and entries that contain a token similar to 'banana').

PHRASE is similar to AND, but restricts hits to ones that contain the tokens as a phrase, in other words, in the same order and with nothing between them. A PHRASE is indicated by adding double quotes around the tokens, within the single quotes (for example, ... WHERE CONTAINS (mycolumn, "'day dream'", FUZZY(0.5)) ... will not return an entry containing 'I dream of a day').

The content type AND that is used for full-text searches (default behavior: `textSearch=fulltext`) is implemented as a logical AND to achieve better performance. A search for 'Miller & Miller AG' for example, with content type AND, matches 'Miller AG'.

For duplicate detection, and for comparing company names, product names and so on, use `textSearch=compare`. This produces better search results due to the strict AND comparison that is used. In other words, when searching for 'Miller & Miller' with content type AND, only records that contain the term 'Miller' at least twice will be returned.

A strict AND assigns terms from the user input to terms in the database entry just once (and vice versa). For more information, see [Partially Matching with Parameter andThreshold \[page 357\]](#).

Parameters Influencing the Score

Name of Option	Range	Default	Applies to Types
<code>bestMatchingTokenWeight</code>	0.0..1.0	0	TEXT
<code>considerNonMatchingTokens</code>	max, min, all, input, table	max	TEXT
<code>excessTokenWeight</code>	0.0..1.0	1.0	TEXT

Formula for score calculation:

$$\text{score} = \text{bestMatchingTokenWeight} \times \max(\text{tokenScores}) + (1 - \text{bestMatchingTokenWeight}) \times \sqrt{(\sum(\text{tokenScore}^2) / (\text{matchedTokenCount} + \text{excessTokenCount} \times \text{excessTokenWeight}))}$$

Recommendations for specific search content types

If you are using an "OR" search (searching for "this or that"), you should set `considerNonMatchingTokens` to `table` to get a useful score assessment.

Parameters Influencing the Result Set

Option	Range	Default	Applies to Types
<code>andSymmetric</code>	on,off,true,false	off	TEXT
<code>andThreshold</code>	0.0..1.0	1.0	TEXT

For examples, see [Symmetric Search with Parameter `andSymmetric` \[page 358\]](#) and [Partially Matching with Parameter `andThreshold` \[page 357\]](#).

Related Information

[Option `bestMatchingTokenWeight` \[page 352\]](#)

[Option `considerNonMatchingTokens` \[page 354\]](#)

[Option `excessTokenWeight` \[page 356\]](#)

4.3.4.8.1.1 Option `bestMatchingTokenWeight`

Missing tokens in the search input or tokens with a low score can lower the total score for the field more than desired. The parameter `bestMatchingTokenWeight` allows you to get a better score in such cases. This is done by putting more emphasis on the score of the token that matches best. With this parameter, you can shift the total score value for a field between the root mean square of score values and the best token score value.

The lower boundary (root mean square of score values) is reached by setting `bestMatchingTokenWeight` to 0, which is the default value. The upper boundary is reached by setting `bestMatchingTokenWeight` to 1.

Examples

```
DROP TABLE test_table;
CREATE COLUMN TABLE test_table
(
  id INTEGER          PRIMARY KEY,
  t  SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
INSERT INTO test_table VALUES ('1', 'one');
INSERT INTO test_table VALUES ('2', 'one two');
INSERT INTO test_table VALUES ('3', 'one two three');
INSERT INTO test_table VALUES ('4', 'one two three four');
INSERT INTO test_table VALUES ('5', 'one two three four five');
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5, 'textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	T
0.68	3	one two three
0.59	4	one two three four
0.53	5	one two three four five

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5, 'textSearch=compare,
bestMatchingTokenWeight=0.1'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.7	3	one two three
0.61	4	one two three four
0.56	5	one two three four five

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5, 'textSearch=compare,
bestMatchingTokenWeight=1.0'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.81	3	one two three
0.81	4	one two three four
0.81	5	one two three four five

4.3.4.8.1.2 Option considerNonMatchingTokens

To get the score for the whole field content, we have to compute the mean of the token scores. There are cases in which not every token in the search term has a matching token in the table content, and vice versa. These tokens are called non-matching tokens (or excess tokens).

You can use parameter `considerNonMatchingTokens` to decide how these non-matching tokens affect the calculation of the score for the whole field content.

This is done by specifying what is considered to be the number of tokens relevant for the score calculation (`tokenCount`). The number of matching tokens is subtracted from this number to get the number of non-matching tokens (or excess tokens).

`tokenCount` is determined in accordance with parameter `considerNonMatchingTokens` as follows:

- `input`: use search term token count
- `table`: use column value token count
- `all`: use sum of search term and column value token count divided by 2
- `min`: use smaller value of token counts from search term and column value
- `max`: use larger value of token counts from search term and column value (default)

Examples

```
DROP TABLE test_table;
CREATE COLUMN TABLE test_table
(
  id INTEGER          PRIMARY KEY,
  t  SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
INSERT INTO test_table VALUES ('1', 'one');
INSERT INTO test_table VALUES ('2', 'one two');
INSERT INTO test_table VALUES ('3', 'one two three');
INSERT INTO test_table VALUES ('4', 'one two three four');
INSERT INTO test_table VALUES ('5', 'one two three four five');
```

`considerNonMatchingTokens = input`

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5,'textSearch=compare,
considerNonMatchingTokens=input'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.68	3	one two three
0.68	4	one two three four
0.68	5	one two three four five

`considerNonMatchingTokens = table`

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
```

```
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5,'textSearch=compare,
considerNonMatchingTokens=table'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.68	3	one two three
0.59	4	one two three four
0.53	5	one two three four five

considerNonMatchingTokens = all

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5,'textSearch=compare,
considerNonMatchingTokens=all'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.68	3	one two three
0.61	4	one two three four
0.59	5	one two three four five

considerNonMatchingTokens = min

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5,'textSearch=compare,
considerNonMatchingTokens=min'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.68	3	one two three
0.68	4	one two three four
0.68	5	one two three four five

considerNonMatchingTokens = max

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'won zwo tree', FUZZY(0.5,'textSearch=compare,
considerNonMatchingTokens=max'))
ORDER BY score DESC, id
```

SCORE	ID	T
0.68	3	one two three
0.59	4	one two three four
0.53	5	one two three four five

4.3.4.8.1.3 Option excessTokenWeight

The parameter `excessTokenWeight` defines the weight of excess (that is, unassigned) tokens. It is set to 1.0 by default.

Excess tokens are tokens that do not have a counterpart token on either the input side or the request side. For example, when searching for "Art Garfunkel", the database entry "Art Garfunkel and Paul Simon" has the excess tokens "and", "Paul", "Simon".

This parameter enables a better sorting by score when the lengths (that is, the number of tokens) of the request entry and the reference entry are different.

Examples

```
DROP TABLE test_table;
CREATE COLUMN TABLE test_table
(
  id INTEGER PRIMARY KEY,
  t TEXT FUZZY SEARCH INDEX ON
);
INSERT INTO test_table VALUES (1,'Art Garfunkel');
INSERT INTO test_table VALUES (2,'Art Garfunkel and Paul Simon');
INSERT INTO test_table VALUES (3,'A Heart in New York (Art Garfunkel solo hit)');
INSERT INTO test_table VALUES (4,'Tra Funkelrag');
-- select 1
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'Art Garfunkel',
FUZZY(0.5,'textSearch=compare,excessTokenWeight=1.0'))
ORDER BY score DESC, id;
-- select 2
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test_table
WHERE CONTAINS(t, 'Art Garfunkel',
FUZZY(0.5,'textSearch=compare,excessTokenWeight=0.1'))
ORDER BY score DESC, id;
```

Result for select 1

SCORE	ID	T
1.0	1	Art Garfunkel
0.74	4	Tra Funkelrag
0.63	2	Art Garfunkel and Paul Simon
0.47	3	A Heart in New York (Art Garfunkel solo hit)

Result for select 2

SCORE	ID	T
1.0	1	Art Garfunkel
0.93	2	Art Garfunkel and Paul Simon

SCORE	ID	T
0.86	3	A Heart in New York (Art Garfunkel solo hit)
0.74	4	Tra Funkelrag

4.3.4.8.2 Multi-Token Search with Soft AND

4.3.4.8.2.1 Partially Matching with Parameter andThreshold

It is possible to specify a 'partial AND' that requires a subset of request tokens only to match the reference tokens. You will then get better results when comparing data like company names.

The 'andThreshold' parameter defines the percentage of tokens that have to match when comparing the user input with a row stored in a TEXT column. In other words, the ratio between the number of matching tokens and the number of input tokens has to be greater than or equal to the given andThreshold.

Option Name	Range	Default	Applies to Types	Description
andThreshold	0.0..1.0	1.0	TEXT	Determines the percentage of tokens that need to match

andThreshold = 1.0 -> all tokens have to match, 'strict AND'

0.0 < andThreshold < 1.0 -> some of the tokens have to match, 'soft AND'

andThreshold = 0.0 -> at least one token has to match, 'OR'

Summary

- The andThreshold parameter is available as a searchOption.
- Allowed values are between 0.0 and 1.0. An SQL error is returned for values outside this range.
- The parameter works on TEXT columns only and is ignored for all other SQL types.
- The parameter is used with content type AND only and is ignored for all other content types.
- The parameter influences performance.

Example

```
DROP TABLE test_soft_and;
CREATE COLUMN TABLE test_soft_and
(
  id INTEGER          PRIMARY KEY,
  t  SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
```

```

INSERT INTO test_soft_and VALUES ('1','eins');
INSERT INTO test_soft_and VALUES ('2','eins zwei');
INSERT INTO test_soft_and VALUES ('3','eins zwei drei');
INSERT INTO test_soft_and VALUES ('4','eins zwei drei vier');
INSERT INTO test_soft_and VALUES ('5','eins zwei drei vier funf');

```

Search with andThreshold

```

SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'eins XXX drei vier',
FUZZY(0.5,'andThreshold=0.75,bestMatchingTokenWeight=0.5,textSearch=compare'))
ORDER BY score DESC, id;

```

SCORE	ID	T
0.933012723922729	4	eins zwei drei vier
0.887298345565796	5	eins zwei drei vier funf

4.3.4.8.2.2 Symmetric Search with Parameter andSymmetric

In addition to the parameter andThreshold, it is possible to specify a 'symmetric AND' that also returns a record when all tokens of a database entry are part of the user input. The parameter 'andSymmetric' was added to the fuzzy search and activates the symmetric AND comparison when comparing the user input with a row stored in a TEXT column.

Option Name	Range	Default	Applies to Types	Short Description
andSymmetric	on,off,true,false	off	TEXT	Activates a symmetric AND content search

Example

When using content type AND, a search with 'SAP Deutschland AG' returns 'SAP Deutschland AG & Co KG' but not 'SAP Deutschland' or 'SAP Walldorf'. When using the symmetric and, the search with 'SAP Deutschland AG' returns 'SAP Deutschland AG & Co KG' and 'SAP Deutschland', but not 'SAP Walldorf'.

Summary

- The parameter andSymmetric is available as a searchOption.
- Allowed values are [on,true] and [off, false]. An SQL error is returned for other values.
- The parameter works on TEXT columns only and is ignored for all other SQL types.
- The parameter is used with content type AND only and is ignored for all other content types.
- The parameter works in combination with andThreshold to activate a symmetric 'soft AND'.
- The parameter influence the performance.

Example

```

DROP TABLE test_soft_and;

```

```

CREATE COLUMN TABLE test_soft_and
(
  id INTEGER          PRIMARY KEY,
  t  SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
INSERT INTO test_soft_and VALUES ('1','one');
INSERT INTO test_soft_and VALUES ('2','one two');
INSERT INTO test_soft_and VALUES ('3','one two three');
INSERT INTO test_soft_and VALUES ('4','one two three four');
INSERT INTO test_soft_and VALUES ('5','one two three four five');

```

Search with andSymmetric=off

```

SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'one two three', FUZZY(0.5,
'andSymmetric=off,bestMatchingTokenWeight=0.5,textSearch=compare'))
ORDER BY score DESC, id;

```

SCORE	ID	T
1	3	one two three
0.933012723922729	4	one two three four
0.887298345565796	5	one two three four five

Search with andSymmetric=on

```

SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'one two three',
FUZZY(0.5, 'andSymmetric=on,bestMatchingTokenWeight=0.5,textSearch=compare'))
ORDER BY score DESC, id;

```

SCORE	ID	T
1	3	one two three
0.933012723922729	4	one two three four
0.90824830532074	2	one two
0.887298345565796	5	one two three four five
0.788675129413605	1	one

4.3.4.8.3 Option abbreviationSimilarity

The **abbreviation similarity** option allows you to search for and with initial characters. You can thus find abbreviations when searching with long strings or find long strings when searching with initial characters.

Option Name	Range	Default	Applies to Types	Description
abbreviationSimilarity	0.0..1.0	0.0	TEXT	Defines the similarity that is returned for a matching initial character.

i Note

abbreviationSimilarity = 0.0 disables the abbreviation search.

The abbreviationSimilarity option works for TEXT fields only. It is available for all term actions available in SQL, like EXACT, SIMILAR, LINGUISTIC. It accepts values between 0.0 and 1.0. If the given value for abbreviationSimilarity is out of this range, the system returns a SQL error.

Search for initial characters:

"Peter" finds "P." and "P"

"P." always finds "P" with similarity 1.0

"Hans-Peter" finds "Hans P", "H. Peter" and "H.-P."

Search with initial characters:

"P." and "P" find "Peter"

"P." always finds "P" with similarity 1.

"Hans P" and "H P" find "Hans-Peter"

Example

The abbreviationSimilarity option is used to search for and find a word using its first character and vice versa with a given score. With abbreviationSimilarity = 0.9, a SELECT retrieves "word" with SCORE = 0.9 if you search with "w" (and vice versa).

```
CREATE COLUMN TABLE abbrev
(
  id INTEGER PRIMARY KEY,
  name SHORTTEXT(200) FUZZY SEARCH INDEX ON
);
INSERT INTO abbrev VALUES ('1','Peter');
INSERT INTO abbrev VALUES ('2','Hans');
INSERT INTO abbrev VALUES ('3','H. ');
INSERT INTO abbrev VALUES ('4','P. ');
INSERT INTO abbrev VALUES ('5','Hans-Peter');
INSERT INTO abbrev VALUES ('6','H.-P. ');
INSERT INTO abbrev VALUES ('7','HP');
INSERT INTO abbrev VALUES ('8','G Gerd');
INSERT INTO abbrev VALUES ('9','G');
INSERT INTO abbrev VALUES ('10','Gerd');
```

Search one token with abbreviationSimilarity

```
SELECT SCORE() AS score, id, name FROM abbrev
WHERE CONTAINS(name, 'HP', FUZZY(0.5,
'abbreviationSimilarity=0.80,textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	NAME
1	7	HP

SCORE	ID	NAME
0.800000011920929	3	H.
0.565685451030731	6	H.-P.

Search two tokens with abbreviationSimilarity

```
SELECT SCORE() AS score, id, name FROM abbrev
WHERE CONTAINS(name, 'Hans Peter',FUZZY(0.5,
'abbreviationSimilarity=0.80,textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	NAME
1	5	Hans-Peter
0.800000011920929	6	H.-P.

Search two tokens with abbreviationSimilarity

```
SELECT SCORE() AS score, id, name FROM abbrev
WHERE CONTAINS(name, 'Go Gerd',FUZZY(0.5,
'abbreviationSimilarity=0.80,textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	NAME
0.905538558959961	8	G Gerd

4.3.4.8.4 Option minTextScore

The *minTextScore* option allows you to set the score a text field has to reach to be a match.

A text field can contain more than one token. Each token is evaluated against the *fuzzySimilarity* parameter which defines the minimum score a single token has to reach. The overall score of a text field differs from the *fuzzySimilarity* because the overall Text score is computed from the *fuzzySimilarity* of all tokens and parameters found, like *bestMatchingTokenWeight*, *considerNonMatchingTokens* and *term mapping weights*.

minTextScore defines the minimum score the whole content of a text field has to reach.

Option Name	Range	Default	Applies to Types	Description
<i>minTextScore</i>	0.0..1.0	0.0	TEXT	Minimum score that all records in the result have to reach.

A *minTextScore* value of 0.0 means that all records that match the conditions defined by *fuzzySimilarity* and the search options are returned. The result list will not be cut.

Note

- If you use a *fuzzySimilarity* of 0.0, the *minTextScore* parameter becomes redundant.
- *minTextScore* does not work with a *freestyle* or *fulltext* search.
- When using *minTextScore* in combination with the *emptyScore* parameter, rows found because of the *emptyScore* parameter are returned even if *emptyScore* is less than *minTextScore*. See the code example for *emptyScore*.

```
DROP TABLE tab_mintextscore;
CREATE COLUMN TABLE tab_mintextscore
(
  id INTEGER PRIMARY KEY,
  t TEXT FAST PREPROCESS ON FUZZY SEARCH INDEX ON
);
INSERT INTO tab_mintextscore VALUES ('1','Bert');
INSERT INTO tab_mintextscore VALUES ('2','Berta');
INSERT INTO tab_mintextscore VALUES ('3','Bart');
```

Search on a text column

```
SELECT SCORE() AS score, id, t FROM tab_mintextscore
WHERE CONTAINS(t, 'Ernie OR Bert', FUZZY(0.100, 'textSearch=compare,
bestMatchingTokenWeight=0,minTextScore=0.70'))
ORDER BY score DESC, id;
```

SCORE	ID	T	Description
0.7	1	Bert	<< rank value of 0.7 is reached, this is a match
0.65	1	Berta	<< minTextScore not reached - cut off
0.52	1	Bart	<< minTextScore not reached - cut off

4.3.4.8.5 Option textSearch

Option *textSearch* is used to select the search algorithm for TEXT columns:

- **textSearch=fulltext** (default value): A full-text search is performed on a TEXT column. IDF calculation or *specialOrRanking* (depending on search flags) is used. This is the 'old' NewDB behavior.
- **textSearch=compare**: A search similar to a Fuzzy Double search is performed. Additional search options are enabled.
- **textSearch=compareauto**: A search similar to a Fuzzy Double search is performed. Additional search options are enabled.
This option behaves the same as **compare** on columns, supporting **compare**.
But other than **compare**, it will cause no error on columns that do not support **compare**, but is silently ignored.

The value of the *textSearch* search option defines which other search options are allowed for a search.

Rank calculation

When 'fulltext' is specified, the search is performed using IDF or specialOrRanking (depending on the search flags). The fuzzy score is not calculated.

When 'compare' is specified, the fuzzy score is calculated using `bestMatchingTokenWeight` and `considerNonMatchingTokens`. The user does not have to set these options. In this case, the default values are used.

Example

```
SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'eins', FUZZY(0.5, 'textSearch=compare'))
ORDER BY score DESC, id;
```

Select with 'Fuzzy Score' (textSearch=compare)

```
SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'eins', FUZZY(0.5, 'textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	T
1.0	1	eins
0.7071067690849304	2	eins zwei
0.5773502588272095	3	eins zwei drei

Select with 'IDF Score' (textSearch=fulltext)

```
SELECT SCORE() AS score, * FROM test_soft_and
WHERE CONTAINS(T, 'eins', FUZZY(0.5, 'textSearch=fulltext'))
ORDER BY score DESC, id;
```

SCORE	ID	T
0.888888955116272	1	eins
0.6666666865348816	2	eins zwei
0.5333333611488342	3	eins zwei drei

4.3.4.8.6 Option phraseCheckFactor

Option `phraseCheckFactor` defines the score of a search when the terms in a text field are not in the same order as in the user input.

Option `phraseCheckFactor` defines the score of a search when the terms in a text field are not in the same order as in the user input (without any additional terms). The value of this option is multiplied with the overall

fuzzy score of a text column if the search terms do not appear in the correct order. Search results returning terms in the exact term order as the search input receive get a higher score (see example below). The default value of this option is 1.0, so it has no influence on the score.

Search option `phraseCheckFactor` is available for TEXT, SHORTTEXT and FULLTEXT INDEXES only. It is allowed for attribute searches only (no freestyle search).

Search option `phraseCheckFactor` is available for CONTAINS() only.

Note

Search rule sets are not supported at present.

Stopwords in the search input and in the database are ignored when comparing the order of the terms. Stopwords still influence the overall score however.

Example

```
CREATE COLUMN TABLE TAB_TEST (ID INT PRIMARY KEY, TEXT TEXT FAST PREPROCESS
ON) ;
INSERT INTO TAB_TEST VALUES ('1','International Business Machines');
INSERT INTO TAB_TEST VALUES ('2','Business Machines International');
SELECT to_decimal(score(),10,2) as SCORE, ID, TEXT
FROM TAB_TEST
WHERE CONTAINS (TEXT, 'International Business Machines', FUZZY(0.8,
'textSearch=compare, phrasecheckfactor=0.9'))
ORDER BY SCORE DESC, ID;
DROP TABLE TAB_TEST;
```

Score	ID	Text
1.0	1	International Business Machines
0.9	2	Business Machines International (phraseCheckFactor got used)

4.3.4.8.7 Stopwords

4.3.4.8.7.1 Usage

Stopwords are terms that are less significant for a search and are, therefore, not used to generate the result set. In other words, the search is carried out as though the stopwords did not exist (either in the user input or in the database column).

Stopwords do influence the score that is calculated, however. A record with stopwords identical to the user input gets a higher score than a record with differing or missing stopwords.

Stopwords can be defined either as single terms or as stopword phrases consisting of multiple terms. Stopword phrases are only applied when all terms of the stopword appear in the exact given order.

Use case example: When searching for company names, the legal form (Ltd, SA, AG, and so on) is less significant and less selective than the other parts of the name.

Stopwords are stored in a column-store table with the following format:

```
CREATE COLUMN TABLE mystopwords
(
  stopword_id    VARCHAR(32)    PRIMARY KEY,
  list_id        VARCHAR(32)    NOT NULL,
  language_code  VARCHAR(2),
  term           NVARCHAR(200) NOT NULL
);
```

Note

Beginning with SAP HANA 2.0, it is also possible to use SQL type `SHORTTEXT` instead of type `NVARCHAR` for a column term.

Stopwords are language-dependent. It is possible to define the language that a stopword is valid for. You can also define stopwords for all languages by not setting a language.

As with term mappings, stopwords can be grouped together in multiple groups. Groups of stopwords are identified by the value of the `list_id` column that is part of the stopword table.

```
INSERT INTO mystopwords VALUES (1, 'legalform', '', 'Ltd');
INSERT INTO mystopwords VALUES (2, 'legalform', 'de', 'GmbH');
INSERT INTO mystopwords VALUES (3, 'legalform', 'de', 'Gesellschaft mit
beschränkter Haftung');
INSERT INTO mystopwords VALUES (4, 'legalform', 'de', 'AG');
INSERT INTO mystopwords VALUES (5, 'legalform', 'de', 'Aktiengesellschaft');
```

To activate stopwords for a search on a `TEXT` column, you need to provide two search options (similar to the options used for term mappings):

- `stopwordListId=mylist1,mylist2,mylist3`
- `stopwordTable=[<schemaname>.<tablename>]`

```
SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId=legalform'))
ORDER BY score DESC;
```

To activate **language-specific stopwords**, you have to provide the language parameter:

```
SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId=legalform'), language('de'))
ORDER BY score DESC;
```

Note

In this case, all stopwords where `language_code` is set to 'de' or empty will be used. Any stopwords with other language codes will be ignored.

i Note

As a prerequisite, the column to be searched in has to have the LANGUAGE parameter set. This requires the parameter FAST PREPROCESS set to OFF for this column.

Stopwords are removed from the search term first. In this example, the result set of the search is the same as for the search '... WHERE CONTAINS(company, 'xy', ...)'.

When calculating the score, the fuzzy scores of the non-stopword terms have the biggest influence on the resulting score. Stopwords in the user input and in the database records are also given less weight than the non-stopword terms, so records with matching stopwords get a higher score than records with differing or missing stopwords.

By default, a score of 0.98 is assigned to differing or missing stopwords. The parameter `unmatchedStopwordScore` can be used to change this default value.

The result of the above example is as follows:

Score	Company	Comment
1.00	XY GmbH	
0.99	XY	Missing stopword
0.99	XY Aktiengesellschaft	Differing stopword
0.98	XY Gesellschaft mit beschränkter Haftung	Many differing stopwords
0.70	XY Company	Additional non-matching term, no stopword

The value given for `stopwordTable` can be any valid SQL identifier as defined in the SQL reference manual. If no schema is given, the current one is used. The following examples all reference the same stopword table.

```
SET SCHEMA schema1;
SELECT ... WHERE CONTAINS(c, 'xy', FUZZY(0.7,
'stopwordTable=schema1.mystopwords, ...'))...;
SELECT ... WHERE CONTAINS(c, 'xy', FUZZY(0.7,
'stopwordTable="SCHEMA1"."MYSTOPWORDS", ...'))...;
SELECT ... WHERE CONTAINS(c, 'xy', FUZZY(0.7,
'stopwordTable=mystopwords, ...'))...;
```

Using Multiple Stopword Lists

It is possible to use more than one stopword list in a single call to `CONTAINS()`. The names of the stopword lists have to be specified as a comma-separated list enclosed in double quotation marks.

The following example shows how to specify one or more stopword lists:

```
/* use one stopword list */
SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId=list01'))
ORDER BY score DESC;
/* or */
```

```

SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId="list01"'))
ORDER BY score DESC;
/* use multiple stopword lists */
SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId="list01,list02,list03"'))
ORDER BY score DESC;
/* use all stopword lists */
SELECT TO_DECIMAL(SCORE(),3,2) as score, company FROM mydata
WHERE CONTAINS(company, 'xy gmbh', FUZZY(0.7, 'textsearch=compare,
stopwordTable=MYSTOPWORDS, stopwordListId=*'))
ORDER BY score DESC;

```

4.3.4.8.7.2 Stopword Example

Sample Code

```

CREATE COLUMN TABLE stopwords
(
  stopword_id    VARCHAR(32)    PRIMARY KEY,
  list_id        VARCHAR(32)    NOT NULL,
  language_code  VARCHAR(2),
  term           NVARCHAR(200)  NOT NULL
);

CREATE COLUMN TABLE companies
(
  id              INTEGER        PRIMARY KEY,
  companyname     SHORTEXT(200)  FUZZY SEARCH INDEX ON LANGUAGE COLUMN language
FAST PREPROCESS OFF,
  language        VARCHAR(2)
);

INSERT INTO companies VALUES ('1', 'SAP AG', 'de');
INSERT INTO companies VALUES ('2', 'SAP Aktiengesellschaft', 'de');

INSERT INTO stopwords VALUES ('1', '01', 'de', 'AG');
INSERT INTO stopwords VALUES ('2', '01', 'de', 'Aktiengesellschaft');
INSERT INTO stopwords VALUES ('3', '01', 'de', 'blub');

```

Example query 1: User input without stopwords. Stopwords in the database table only.

```

SELECT TO_DECIMAL(SCORE(), 3, 2) AS score, *
FROM companies
WHERE CONTAINS(companyname, 'sap', FUZZY(0.8, 'stopwordTable=stopwords,
stopwordListId=01, textSearch=compare'))
ORDER BY score DESC, ID;

```

SCORING	ID	COMPANYNAME	LANGUAGE
0.99	1	SAP AG	de
0.99	2	SAP Aktiengesellschaft	de

Example query 2: User input with stopword. Other stopwords in the database table.U

```
SELECT TO_DECIMAL(SCORE(), 3, 2) AS score, *
FROM companies
WHERE CONTAINS (companyname, 'sap blub', FUZZY(0.8, 'stopwordTable=stopwords,
stopwordListId=01, textSearch=compare'))
ORDER BY score DESC, ID;
```

SCORING	ID	COMPANYNAME	LANGUAGE
0.99	1	SAP AG	de
0.99	2	SAP Aktiengesellschaft	de

Example query 3: User input with stopword. One record with matching stopword, one record with differing stopword.

```
SELECT TO_DECIMAL(SCORE(), 3, 2) AS score, *
FROM companies
WHERE CONTAINS (companyname, 'sap aktiengesellschaft', FUZZY(0.8,
'stopwordTable=stopwords, stopwordListId=01, textSearch=compare'))
ORDER BY score DESC, ID;
```

SCORING	ID	COMPANYNAME	LANGUAGE
1	2	SAP Aktiengesellschaft	de
0.99	1	SAP AG	de

Example query 4: User input with two stopwords. Database records with one matching stopword.

```
SELECT TO_DECIMAL(SCORE(), 3, 2) AS score, *
FROM companies
WHERE CONTAINS (companyname, 'sap ag aktiengesellschaft', FUZZY(0.8,
'stopwordTable=stopwords, stopwordListId=01, textSearch=compare'))
ORDER BY score DESC, ID;
```

SCORING	ID	COMPANYNAME	LANGUAGE
0.99	1	SAP AG	de
0.99	2	SAP Aktiengesellschaft	de

4.3.4.8.7.3 Stopwords Combined with Composition and Decomposition of Tokens

When stopwords and the `composeWords/decomposeWords` parameters are combined in a single query, the stopword definition is ignored when building the composed and decomposed search terms.

- If a decomposition results in a phrase containing at least one stopword token, this token is not considered a stopword. Instead, it is searched for as a mandatory token.
- If a composition of tokens results in a stopword, this stopword token is not considered a stopword. Instead, it is searched for as a mandatory token.

4.3.4.8.7.4 Stopword Table Names

The name of the stopword table that is given in the `stopwordTable` parameter follows the same rules as a table name in an SQL statement. The table name may optionally contain a schema name. The table name and schema name are converted to uppercase characters if they are not enclosed in double quotes. In other words, the names follow the definition of a 'simple_identifier' in the *SAP HANA SQL Reference*.

When using a table name with special characters ('special_identifier' in the *SAP HANA SQL Reference*), the table name has to be enclosed in double quotes.

The following example shows simple identifiers and special identifiers used as stopword table names.

Sample Code

Stopword Table Name Examples

```
stopwordTable=mystopwords
stopwordTable=myschema.mystopwords
stopwordTable="my stopwords"
stopwordTable=myschema."my stopwords"
stopwordTable="myschema"."my stopwords"
```

4.3.4.8.7.5 Multi-Token Stopword Entries Stored in the Stopword Table

Multi-token stopwords in the stopword table are tokenized using the set of token separators that are defined for the full-text index of the column that is searched. The token separators of this column are defined using the `TOKEN SEPARATORS` option of the `CREATE FULLTEXT INDEX` statement.

Note

Version-Dependent Implementation: Up to API version 20305, multi-token stopword entries stored in the stopword table had to be 'normalized' by removing all token separators and by replacing these separators by a space character.

For example, the stopword 'in-memory' had to be stored as 'in memory'.

4.3.4.8.76 Stopwords Combined With Term Mappings

When stopwords and term mappings are combined in a single query, term mappings are applied first. Stopwords are then applied to all variations of the search term created by the term mappings.

Let us assume that you have defined the following term mapping:

Term 1	Term 2
Incredible Busy Machines	IBM
Ltd	Limited

Now you search for "Incredible Busy Machines Ltd".

The search would be carried out for all possible search terms:

Search Terms
Incredible Busy Machines Ltd
Incredible Busy Machines Limited
IBM Ltd
IBM Limited

Let us assume that you have defined the following stopwords:

Stopword
busy machines
ltd

The stopwords will not be searched for, so the resulting search terms would be:

Search Terms
Incredible
Incredible Limited
IBM
IBM Limited

4.3.4.8.77 Stopword Tables and ABAP Client Columns

When using search with ABAP applications, it is possible to add a client column called `CLIENT` to the stopword table. For convenience reasons, the older name `MANDT` which has been used in DDIC tables before, is supported as well. As soon as a client is given in the database session context the stopword behavior changes. Whenever `CONTAINS ()` is called with stopword options, stopwords for the current client only are used.

In the definition of the stopword table using both a `CLIENT` AND a `MANDT` column is not allowed.

i Note

ABAP clients always set the client information in the session context to the client of the application user, and as a result only stopwords for the application user's client are used in a search.

Beginning with API version 20301 the session variable `CDS_CLIENT` is preferred to get the client number. If this variable is not set, or when using an older version, the session variable `CLIENT` defines the client number.

Sample Code

Stopword Table with Client Column

```
CREATE COLUMN TABLE mystopwords
(
  client          VARCHAR(3)      NOT NULL,
  stopword_id    VARCHAR(32)     NOT NULL,
  list_id        VARCHAR(32)     NOT NULL,
  language_code  VARCHAR(2),
  term           NVARCHAR(200)   NOT NULL,
  PRIMARY KEY (client, stopword_id)
);
```

4.3.4.8.7.8 Performance Optimizations for Large Stopword Tables

When using large stopwords tables, loading the stopwords definitions from the table increases the response time of search calls. To reduce the impact of the load time, it is possible to add a full-text index to the term column of the stopwords table.

The full-text index on the term column of the stopwords table has to use the same definition of token separators as the full-text index on the column that is searched, otherwise the full-text index on the stopwords table will be ignored.

4.3.4.8.8 Term Mappings

Facts About Term Mappings

Term mappings have the following characteristics:

- Term mappings can be used to extend the search by adding additional search terms to the user input. When the user enters a search term, the search term is expanded, and synonyms, hypernyms, hyponyms, and so on are added. The result that is returned to the user contains additional records or documents related to the search term that could be useful to the user.
- Term mappings are used to replace single tokens or a sequence of tokens in the search query by other tokens. It is not possible to replace only parts of a token, so it is, for example, not possible to replace the ending of a word by another ending.

- Term mappings are defined in a column table and can be changed at any time.
The current term mapping definition is applied when a search is started. The definition of term mappings does not change the data that is stored in the database tables (unlike the definition of synonyms in Text Analysis, where a change of synonyms requires the text data to be reloaded or reindexed).
- Term mappings can be grouped.
Each group of term mappings is identified by a list_id that is stored in the term mapping table. By grouping term mappings, it is possible to apply different sets of term mappings to different columns of a table. You may want to use certain term mappings when searching company names for example, and other term mappings when searching documents. When starting a search, it is possible to specify which term mapping list_ids to apply to each column.
- Term mappings can be assigned a weight.
In this case, records that are found because of a term mapping will receive a lower score than records found with the original user input. From the user's view, the sorting of the result list is more meaningful.
- Term mappings are defined as a unidirectional replacement.
For a term mapping definition of 'term1' -> 'term2', 'term1' is replaced with 'term2', but 'term2' is not replaced with 'term1'. This is helpful if you want a search with a hypernym to find all hyponyms, but not the other way round. If a bidirectional replacement is needed (as for synonyms), both directions have to be added to the term mapping table.
- Term mappings are language-dependent.
It is possible to define the language that a term mapping is valid for. You can also define term mappings for all languages by not setting a language.

Use Cases

Synonyms

If you have a large database of company names, you might want to map the legal forms of companies.

For example:

Searching for	You would also like to find	With a weight of
AG	Aktiengesellschaft	1.0
Ltd	Limited	1.0

Since these are synonyms, the term mappings have to be added to the term mapping table in both directions, as shown in the example below.

Usually, synonym definitions get a weight of 1.0, because records found when the term mapping is applied are as good as records found with the original user input.

Hypernyms, Hyponyms

If you search with a hypernym, you might also find other documents related to this topic.

For example:

Searching for	You would also like to find	With a weight of
car	VW Golf	0.8

Since these are not synonyms, and a search with 'VW Golf' should not return all documents about cars, the term mapping is added to the term mapping table in this direction only.

Format of the Term Mapping Table

Column Name	Type	Primary Key	Description	Comment
MAPPING_ID	VARCHAR(32)	x	Primary key	For example, a GUID
LIST_ID	VARCHAR(32)		Term mapping list ID	Used to group term mappings
LANGUAGE_CODE	VARCHAR(2)		Language code (ISO2)	NULL or empty: term mapping is valid for all languages
TERM_1	NVARCHAR(200)		Term 1, the token or the sequence of tokens to be replaced	Terms have to be entered in a standardized form with tokens separated by spaces only. Other token separators are not allowed. (example: 'term mapping' instead of 'Term-Mapping')
TERM_2	NVARCHAR(200)		Term 2, the token or the sequence of tokens that replaces term 1	Terms have to be entered in a standardized form with tokens separated by spaces only. Other token separators are not allowed.
WEIGHT	DECIMAL, DECIMAL(n,m)		Weight, 0.0 <= Weight <= 1.0	

The definition of the term mapping table is checked, so tables with other column names or data types cannot be used for a fuzzy search. Nevertheless, the table may contain additional columns that are ignored by the fuzzy search engine.

Example code for creating a term mapping table via SQL:

```
CREATE COLUMN TABLE termmappings
(
  mapping_id    VARCHAR(32)    PRIMARY KEY,
  list_id      VARCHAR(32)    NOT NULL,
  language_code VARCHAR(2),
  term_1      NVARCHAR(200) NOT NULL,
  term_2      NVARCHAR(200) NOT NULL,
  weight      DECIMAL        NOT NULL
);
```

i Note

You cannot create a DECIMAL column using the ABAP DDIC. Instead you have to use the SQL type DECIMAL (n,m) or the DDIC type DEC (n,m), for example DEC (3,2).

Beginning with SAP HANA 2.0 it is also possible to use SQL type SHORTTEXT instead of type NVARCHAR for columns term_1 and term_2.

Support of Client-Dependent Term Mappings

Since ABAP applications support multiple clients, and each individual client should only see their own data, Fuzzy Search provides the option of using client-specific term mappings.

To limit term mappings to the current client in ABAP, you have to create an extra view on top of your custom term mapping table (including the client information) and limit the data to the current client with a WHERE condition (WHERE CLNT = SESSION_CONTEXT('CLIENT')).

Basic Example

The value given for the termMappingTable parameter can be any valid SQL identifier as defined in the SQL reference manual. If no schema is specified, the current schema is used.

```
CREATE COLUMN TABLE termmappings
(
  mapping_id    VARCHAR(32)    PRIMARY KEY,
  list_id       VARCHAR(32)    NOT NULL,
  language_code VARCHAR(2),
  term_1        NVARCHAR(200)  NOT NULL,
  term_2        NVARCHAR(200)  NOT NULL,
  weight        DECIMAL        NOT NULL
);
CREATE COLUMN TABLE companies
(
  id            INTEGER        PRIMARY KEY,
  companyname   SHORTTEXT(200) FUZZY SEARCH INDEX ON LANGUAGE COLUMN language
FAST PREPROCESS OFF,
  language      VARCHAR(2)
);
INSERT INTO companies VALUES ('1','SAP AG', 'de');
INSERT INTO companies VALUES ('2','SAP Aktiengesellschaft', 'de');
INSERT INTO termmappings VALUES ('1','01','de','AG','Aktiengesellschaft','0.9');
INSERT INTO termmappings VALUES ('2','01','de','Aktiengesellschaft','AG','0.9');
SELECT TO_DECIMAL(SCORE(),3,2) AS score, *
FROM companies
WHERE CONTAINS(companyname, 'sap aktiengesellschaft',
FUZZY(0.8,
'termMappingTable=termmappings,termMappingListId=01,textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1.0	2	SAP Aktiengesellschaft
0.9	1	SAP AG

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8,'termMappingTable=TERMMAPPINGS,termMappingListId=01,textSearch=compare'
))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1.0	1	SAP AG
0.9	2	SAP Aktiengesellschaft

To activate **language-specific term mappings**, you must provide the language parameter:

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8,'termMappingTable=TERMMAPPINGS,termMappingListId=01,textSearch=compare'
), language('de'))
ORDER BY score DESC, id;
```

i Note

In this case, all term mappings where `language_code` is set to 'de' or is empty are used. Any term mappings with other language codes are ignored.

i Note

As a prerequisite the column to be searched in (here: `companyname`) has to have the `LANGUAGE` parameter set. This requires the parameter `FAST PREPROCESS` set to `OFF` for this column.

Using Multiple Term Mapping Lists

It is possible to use more than one term mapping list in a single call to `CONTAINS()`. To do this, specify the names of the term mapping lists as a comma-separated list enclosed in double quotes.

The following example shows how to specify one or more term mapping lists.

```
/* use one term mapping list */
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8,'termMappingTable=TERMMAPPINGS,termMappingListId=01,textSearch=compare'
), language('de'))
ORDER BY score DESC, id;
/* or */
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8,'termMappingTable=TERMMAPPINGS,termMappingListId="01",textSearch=compare'
), language('de'))
ORDER BY score DESC, id;
```

```

/* use multiple term mapping lists */
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8, 'termMappingTable=TERMMAPPINGS,termMappingListId="01,02,03",textSearch=
compare'), language('de'))
ORDER BY score DESC, id;
/* use all term mapping lists */
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8, 'termMappingTable=TERMMAPPINGS,termMappingListId=*,textSearch=compare')
, language('de'))
ORDER BY score DESC, id;

```

Term Mappings and String Columns

It is also possible to use term mappings with string-type columns. In this case the term mapping replacement is **not** done on a token-by-token basis. Instead, the complete string is replaced if it matches the term mapping definition.

The following example shows how to use term mappings for string-type columns.

```

CREATE COLUMN TABLE termmappings
(
  mapping_id  VARCHAR(32)  PRIMARY KEY,
  list_id     VARCHAR(32)  NOT NULL,
  language_code VARCHAR(2),
  term_1      NVARCHAR(200) NOT NULL,
  term_2      NVARCHAR(200) NOT NULL,
  weight      DECIMAL      NOT NULL
);

INSERT INTO termmappings VALUES ('1', 'colors', NULL, 'gray', 'light gray', 0.9);
INSERT INTO termmappings VALUES ('2', 'colors', NULL, 'grey', 'gray', 0.9);

CREATE COLUMN TABLE products
(
  id INTEGER PRIMARY KEY,
  product NVARCHAR(100) NOT NULL,
  color NVARCHAR(100)
);

INSERT INTO products VALUES (1, 'a product', 'gray');
INSERT INTO products VALUES (2, 'another product', 'light gray');
INSERT INTO products VALUES (3, 'new product', 'grey');
INSERT INTO products VALUES (4, 'latest product', 'light grey');

SELECT TO_DECIMAL(SCORE(),3,2), * FROM products WHERE CONTAINS(color, 'gray',
EXACT('termMappingTable=termmappings, termMappingListId=colors'));
SELECT TO_DECIMAL(SCORE(),3,2), * FROM products WHERE CONTAINS(color, 'light
grey', EXACT('termMappingTable=termmappings, termMappingListId=colors'));

```

The following tables show the search results:

SCORE	ID	PRODUCT	COLOR
1	2	a product	gray
0.9	1	another product	light gray

SCORE	ID	PRODUCT	COLOR
1	4	latest product	light grey

```

/* add fulltext index to see the differences between string-type column and text-
type column */
CREATE FULLTEXT INDEX products_color ON products(color) SYNC;
SELECT TO_DECIMAL(SCORE(),3,2), * FROM products WHERE CONTAINS(color, 'gray',
EXACT('termMappingTable=termmappings, termMappingListId=colors'));
SELECT TO_DECIMAL(SCORE(),3,2), * FROM products WHERE CONTAINS(color, 'light
grey', EXACT('termMappingTable=termmappings, termMappingListId=colors'));

```

SCORE	ID	PRODUCT	COLOR
1	1	a product	gray
0.9	2	another product	light gray

SCORE	ID	PRODUCT	COLOR
1.0	4	latest product	light grey
0.9	2	another product	light gray

Multi-Token Term Mapping Entries Stored in the Term Mapping Table

Multi-token term mappings in the `term_1` and `term_2` columns of the term mapping table are tokenized using the set of token separators that are defined for the full-text index of the column that is searched. The token separators of this column are defined using the `TOKEN SEPARATORS` option of the `CREATE FULLTEXT INDEX` statement.

Note

Up to API version 20305 multi-token term mapping entries stored in columns `term_1` and `term_2` of the term mapping table had to be 'normalized' by removing all token separators and by replacing these separators by a space character.

For example, the entry 'in-memory' had to be stored as 'in memory'.

Term Mapping Table Names

The name of the term mapping table that is given in the `termMappingTable` parameter follows the same rules as a table name in a SQL statement. The table name may optionally contain a schema name. Table name and schema name are converted to uppercase characters if they are not enclosed in double quotes. In other words, the names follow the definition of a 'simple_identifier' in the *SAP HANA SQL Reference*.

When using a table name with special characters ('special_identifier' in the *SAP HANA SQL Reference*), the table name has to be enclosed in double quotes.

The following example shows simple identifiers and special identifiers used as term mapping table names:

Sample Code

Term Mapping Table Name Examples

```
termMappingTable=mytermmappings
termMappingTable=myschema.mytermmappings
termMappingTable="my term mappings"
termMappingTable=myschema."my term mappings"
termMappingTable="myschema"."my term mappings"
```

Term Mapping Tables and ABAP Client/MANDT Columns

i Note

Beginning with API version 20301 the session variable `CDS_CLIENT` is preferred to get the client number. If this variable is not set, or when using an older version, the session variable `CLIENT` defines the client number.

When using search with ABAP applications, it is possible to add a client column called `CLIENT` to the term mapping table. For convenience reasons, the older name `MANDT` which has been used in DDIC tables before, is supported as well. As soon as a client is given in the database session context the term mapping behavior changes. Whenever `CONTAINS()` is called with term mapping options, term mappings for the current client only are used.

In the definition of the term mapping table using both a `CLIENT` AND a `MANDT` column is not allowed.

i Note

ABAP clients always set the client information in the session context to the client of the application user, and as a result only term mappings for the application user's client are used in a search.

Sample Code

Term Mapping Table with Client Column

```
CREATE COLUMN TABLE termmappings
(
  client          VARCHAR(3)      NOT NULL, -- alternatively mandt as the column
name is supported.
  mapping_id     VARCHAR(32)     NOT NULL,
  list_id        VARCHAR(32)     NOT NULL,
  language_code  VARCHAR(2),
  term_1         NVARCHAR(200)   NOT NULL,
  term_2         NVARCHAR(200)   NOT NULL,
  weight         DECIMAL         NOT NULL,
  PRIMARY KEY (client, mapping_id)
);
```

4.3.4.8.9 Compound Words

Introduction

A search on a TEXT column is very sensitive to compound spelling. This means that a search for a compound word (written without blanks) might not find a document if there is an additional blank character between the components. In some cases, compound words (for example in Finnic and Germanic languages) may be a combination of more than two words.

Examples of compound words:

- "Hans-Peter" vs. "Hanspeter"
- "Abfahrt Zeit" vs. "Abfahrtszeit"
- "Post Office" vs. "Postoffice"
- "soft ball" vs. "softball"
- "Example-Cola" vs. "ExampleCola"
- "hätauloskäytävä" vs. "hätä ulos käytävä" (emergency exit in finnish)

To mitigate this, it is possible to generate compositions and decompositions for a query on the fly. Each (de)composition can be thought of as a term mapping (see Fuzzy Search - Term Mappings)

In this context, a **word** is any sequence of at least two characters.

The following options are offered:

- `composeWords`
For more information, see [Option composeWords \[page 381\]](#).
- `decomposeWords`
For more information, see [Option decomposeWords \[page 382\]](#).
- `compoundWordWeight`
For more information, see [Option compoundWordWeight \[page 383\]](#).

Differences to Term Mappings

Generally, (de)compositions work like term mappings with a weight of `compoundWordWeight`. However, to limit the number of (mostly redundant) candidates, compound words and decomposition phrases are always searched with a special `similarCalculationMode` and `fuzziness` of the maximum of 0.7 and the value given by the user.

Composition/Decomposition and Stopwords

When new search terms are created using composition and decomposition of tokens, all tokens from the user input are processed, regardless of whether the token is a stopword or not. As a result, a search for 'SAPSE' is done in the following example, even if 'SE' is defined as a stopword.

```
CONTAINS (COMPANY, 'SAP SE', FUZZY(0.8, 'composeWords=2'))
```

If a composition or decomposition results in a new search term containing stopwords, these stopwords are searched as mandatory terms. In other words, the stopword tokens are not considered stopwords in this case.

Performance Considerations

Setting `decomposeWords>=3`, a large number of search terms and very long words can have a negative impact on performance, due to the large number of resulting combinations. This can be mitigated by raising `minTextScore` and lowering `compoundWordWeight`, as all combinations with an effective weight (product of all term mapping/compound word weights) less than `minTextScore` can be skipped during the search.

For more information, see [Option minTextScore \[page 361\]](#)

Setting `composeWords>=2` does not have a significant performance impact.

Let's have a look at impact factors in different data domains

Note

Factor: An impact factor of 2 means that your runtime might be doubled.

Data Domain	Table Rows	Dictionary Size	Request Base-line	composeWords Factor	decompose-Words Factor	Comment
lastnames	10 000 000	540 000	50ms	1	1.6	
full-text documents	130 000	1 200 000	70ms	2	6	IDF scoring
music tracks (short text documents)	6 400 000	1 250 000	70ms	5	7	text-Search=compare

Examples

Creating a table:

```
CREATE COLUMN TABLE SNACKS (TEXT TEXT FUZZY SEARCH INDEX ON);  
INSERT INTO SNACKS VALUES('Mini-Maxi YadaThing Comp.');
```

```
SELECT TO_DECIMAL(SCORE(),3,2) AS SCORE, TEXT FROM SNACKS  
WHERE CONTAINS(TEXT, 'minimaxi yada thing', FUZZY(0.7, 'ts=compare'));
```

Score	Text
<pre>SELECT TO_DECIMAL(SCORE(),3,2) AS SCORE, TEXT FROM SNACKS WHERE CONTAINS(TEXT, 'mini-maxi yadathing', FUZZY(0.7, 'ts=compare'));</pre>	

Score	Text
0.86	Mini-Maxi YadaThing Comp.

<pre>SELECT TO_DECIMAL(SCORE(),3,2) AS SCORE, TEXT FROM SNACKS WHERE CONTAINS(TEXT, 'minimaxi yada thing', FUZZY(0.7, 'ts=compare,composeWords=2,decomposeWords=2'));</pre>	
---	--

Score	Text
0.7	Mini-Maxi YadaThing Comp.

<pre>SELECT TO_DECIMAL(SCORE(),3,2) AS SCORE, TEXT FROM SNACKS WHERE CONTAINS(TEXT, 'minimaxi yada thing', FUZZY(0.7, 'ts=compare,composeWords=2,decomposeWords=2,compoundWordWeight=1.0'));</pre>	
--	--

Score	Text
0.86	Mini-Maxi YadaThing Comp.

<pre>SELECT TO_DECIMAL(SCORE(),3,2) AS SCORE, TEXT FROM SNACKS WHERE CONTAINS(TEXT, 'minimaxi yada thing', FUZZY(0.7, 'ts=compare,composeWords=2,decomposeWords=2,compoundWordWeight=0.8'));</pre>	
--	--

Score	Text
0.55	Mini-Maxi YadaThing Comp.

4.3.4.8.9.1 Option `composeWords`

The option `composeWords` defines how words in the user input are combined into compound words.

Option	Range	Default	Description
<code>composeWords</code>	1..5	1 (off)	Each consecutive series of at most <code>composeWords</code> words in the user input is concatenated into a compound word.

Examples

User Input	composeWords Value	Generated Compound Words
gene rat ion	=> 2	generat ion
		gen eration
		generation
	=> 3	generat ion
		gen eration
		generation

4.3.4.8.9.2 Option decomposeWords

The option `decomposeWords` defines how words in the user input are split into separate words, building a decomposition phrase.

Option	Range	Default	Description
<code>decomposeWords</code>	1..5	1 (off)	Each word in the user input is split into at most <code>decomposeWords</code> words.

Examples

User Input	decomposeWords Value	Generated Compound Words
generation	=> 2	ge neration
		gen eration
		gene ration
		gener ation
		genera tion
		generat ion
		generation
	=> 3	all of the above and
		ge ne ration
		ge ner ation
		ge nera tion
		ge nerat ion
		ge nerati on
		gen er ation

User Input	decomposeWords Value	Generated Compound Words
		gen era tion
		gen erat ion
		gen erati on
		gene ra tion
		gene rat ion
		gene rati on
		gener at ion
		gener ati on
		genera ti on

4.3.4.8.9.3 Option compoundWordWeight

The option `compoundWordWeight` defines how compound word hits affect the score of a document.

Option	Range	Default	Description
<code>compoundWordWeight</code>	0.0..1.0	0.9	Compound mapping weight.

For each applied (de)composition, the score of a document is multiplied by `compoundWordWeight`.

Examples

User Input	compoundWord-Weight	composeWords	decomposeWords	Document	Score Multiplier
minimaxi yada yada company	0.8	2	2	mini-maxi ya- dayada company	$0.8 * 0.8 = 0.64$
minimaxi yada yada company	0.8	2	1	mini-maxi ya- dayada company	0.8 (if found)

4.3.4.8.10 Speeding Up the Fuzzy Search on Text Columns

Context

You can speed up the fuzzy search for all SQL types except DATE by creating a special data structure known as a fuzzy search index. The additional data structures increase the total memory footprint of the loaded table, in some cases even doubling it.

TEXT Columns

TEXT columns offer the 'FUZZY SEARCH INDEX' option to enable and disable the indexes when creating a table:

```
CREATE COLUMN TABLE mytable
(
  id    INTEGER          PRIMARY KEY,
  col1  TEXT             FUZZY SEARCH INDEX ON
);
```

You can change this later using the ALTER TABLE command.

```
ALTER TABLE mytable ALTER
(
  col1  TEXT             FUZZY SEARCH INDEX OFF
);
```

The SYS.TABLE_COLUMNS view shows the current state of the fuzzy search indexes. When working with attribute views, this information is also visible in SYS.VIEW_COLUMNS.

SHORTTEXT Columns

SHORTTEXT columns offer the 'FUZZY SEARCH INDEX' option to enable and disable the indexes when creating a table:

```
CREATE COLUMN TABLE mytable
(
  id    INTEGER          PRIMARY KEY,
  col2  SHORTTEXT(100)  FUZZY SEARCH INDEX ON
);
```

You can change this later using the ALTER TABLE command.

```
ALTER TABLE mytable ALTER
(
  col2  SHORTTEXT(100)  FUZZY SEARCH INDEX OFF
);
```

Note

The following limitation applies: Since SHORTTEXT creates a hidden column of type Text, the state of the fuzzy search index is not visible in SYS.TABLE_COLUMNS and SYS.VIEW_COLUMNS.

SYS.FULLTEXT_INDEXES can be used to query the state of the fuzzy search indexes.

```
SELECT index_name, internal_column_name, fuzzy_search_index
FROM fulltext_indexes
WHERE table_name = 'MYTABLE';
```

Full-Text Indexes

A full-text index offers the 'FUZZY SEARCH INDEX' option to enable and disable the indexes when creating a full-text index:

```
CREATE COLUMN TABLE mytable
(
  col3  NVARCHAR(2000)
);
CREATE FULLTEXT INDEX myindex ON mytable(col3)
```

```
FUZZY SEARCH INDEX ON;
```

You can change this later using the ALTER FULLTEXT INDEX command:

```
ALTER FULLTEXT INDEX myindex FUZZY SEARCH INDEX OFF;
```

The SYS.FULLTEXT_INDEXES view shows the current state of the fuzzy search indexes.

```
SELECT index_name, internal_column_name, fuzzy_search_index  
FROM fulltext_indexes  
WHERE table_name = 'MYTABLE';
```

4.3.4.9 Fuzzy Search on DATE Columns

This topic describes the fuzzy search features that are available for date columns (SQL type DATE).

Fuzzy search on DATE columns supports two different types of searches:

- The search can be based on the fuzzy similarity between dates. This means that search handles date-specific typographical errors and finds dates lying within a user-defined maximum distance.
- Alternatively, the search can be based on a linear or gaussian score function that calculates the score depending on the distance between the dates.

Related Information

[DATE Columns with Fuzzy Similarity \[page 385\]](#)

[DATE Columns with Score Functions \[page 388\]](#)

4.3.4.9.1 DATE Columns with Fuzzy Similarity

Fuzzy search on DATE columns supports two types of errors: date-specific typographical errors and dates lying within a user-defined maximum distance.

It is not possible to create additional data structures for DATE columns to speed up the search. The performance of queries is perfectly satisfactory without the need for database tuning.

i Note

Fuzzy search for dates works with valid dates only. A search with an invalid date does not return any results.

The following example does not return any results, as '31' is not a valid month:

```
...WHERE CONTAINS(mydate, '2012-31-01', FUZZY(0.8))...
```

Score Calculation for Typographical Errors

Instead of using Levenshtein distance or other string comparison algorithms, the following date-specific typographical errors and errors are defined as similar:

1. One wrong digit at any position (for example, 2011-08-15 instead of 2011-08-25). This type of error gets a score of 0.90.
2. Two digits interchanged within one component (day, month, or year) (for example, 2001-01-12, 2010-10-12, or 2010-01-21 instead of 2010-01-12). This type of error gets a score of 0.85.
3. Month and day interchanged (US versus European date format) (for example, 2010-10-12 instead of 2010-12-10). This type of error gets a score of 0.80.

Only one of these errors is allowed. Dates with more than one error are not considered similar, so the score is 0.0.

Dates with a score less than the `fuzzySimilarity` parameter are not returned.

Example:

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM dates
WHERE CONTAINS(dateofbirth, '2000-01-10', FUZZY(0.8))
ORDER BY score DESC;
```

For this example we get:

2000-01-09 -> 0.00 (not returned to the user)

2000-01-10 -> 1.00

2000-01-11 -> 0.90

2000-01-12 -> 0.90

...

2000-01-21 -> 0.00 (not returned to the user)

...

2000-10-01 -> 0.80

Score Calculation for Date Distance

The maximum allowed distance between dates can be defined using the search option `maxDateDistance`, which defines a number of days.

The default for this option is 0, meaning that the feature is disabled. This is shown in the following example:

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM dates
WHERE CONTAINS(dateofbirth, '2000-01-10', FUZZY(0.95, 'maxDateDistance=5'))
ORDER BY score DESC;
```

This query returns all dates between 2000-01-05 and 2000-01-15.

The fuzzy score for dates is calculated as follows:

1. The identical date gets a score of 1.0.
2. The date that is `maxDateDistance` days away from the search input gets a score that equals the `fuzzySimilarity` parameter (0.95 in the example above).
3. The score of dates between the identical date and `maxDateDistance` is calculated as a linear function between the two dates defined above. In other words, for each day, the score is reduced by $((1 - \text{fuzzySimilarity}) / \text{maxDateDistance})$.
4. For dates outside the range of `maxDateDistance`, the score is 0.0.

With the example above, we therefore get:

2000-01-04 -> 0.00

2000-01-05 -> 0.95

2000-01-06 -> 0.96

...

2000-01-09 -> 0.99

2000-01-10 -> 1.0

2000-01-11 -> 0.99

2000-01-12 -> 0.98

...

2000-01-15 -> 0.95

2000-01-16 -> 0.00

The distance between dates is calculated following the rules of the Gregorian calendar.

The special case `fuzzySimilarity = 1.0` and `maxDateDistance=n` is allowed and returns all dates within a range of n days with a rank of 1.0.

Dates That Meet Both Conditions

If a date meets the conditions of a typo and the conditions of the `maxDateDistance` parameter, two scores are calculated for the same date. In this case, the `score()` function returns the highest of both scores. This is shown in the following example:

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM dates
WHERE CONTAINS(dateofbirth, '2000-01-10', FUZZY(0.8, 'maxDateDistance=5'))
ORDER BY score DESC;
```

This query returns the following:

2000-01-04 -> 0.00

2000-01-05 -> 0.80

2000-01-06 -> 0.84

2000-01-07 -> 0.88

2000-01-08 -> 0.92

2000-01-09 -> 0.96

2000-01-10 -> 1.0

2000-01-11 -> 0.96

2000-01-12 -> 0.92

2000-01-13 -> 0.90

2000-01-14 -> 0.90

2000-01-15 -> 0.90

2000-01-16 -> 0.90

4.3.4.9.2 DATE Columns with Score Functions

As an alternative to the fuzzy search for dates, score functions are available that calculate the score based on the distance between search term and dates stored in the column.

SQL types for dates (`DATE`, `SECONDDATE`, and `TIMESTAMP`) support score functions that return a score based on the difference between the search term and the value stored in the date column. Functions for linear and gaussian scores are available.

Linear Score Function

The linear score function for dates is similar to the linear score function for numeric columns.

The only difference is that for dates or datetime types the distance between two values is calculated as a number of days. This means that two dates that are two weeks apart have a distance of 14. Two timestamps that are 12 hours apart have a distance of 0.5.

The scale and offset parameters of the function are also interpreted as a number of days. To specify, for example, a scale of four weeks, `scoreFunctionScale=28` has to be given. For a scale of six hours, `scoreFunctionScale=0.25` has to be defined.

Gaussian Score Function

The gaussian score function for dates is also similar to the gaussian score function for numeric columns.

As for linear score functions, the only difference is that all distance, scale, and offset values are interpreted as a number of days.

Search Options for Score Functions

The following table shows the search options that are available for the score functions described above.

Search Option	Possible Values	Default Value	Description	Linear	Gaussian
scoreFunction	linear, gaussian	n/a	Name of the score function	yes	yes
scoreFunctionScale	scale > 0	n/a	Value of the score function parameter 'scale', given in days	yes	yes
scoreFunctionDecay	0 <= decay < 1 (linear), 0 < decay < 1 (gaussian)	0.5	Value of the score function parameter 'decay'	yes	yes
scoreFunctionOffset	offset >= 0	0	Value of the score function parameter 'offset', given in days	yes	yes

Example

Sample Code

Linear and Gaussian Score Functions for Dates

```
CREATE COLUMN TABLE datvalues
(
  id INTEGER GENERATED ALWAYS AS IDENTITY PRIMARY KEY,
  val DATE
);

INSERT INTO datvalues (val) VALUES ('2017-04-12');
INSERT INTO datvalues (val) VALUES ('2017-01-01');
INSERT INTO datvalues (val) VALUES ('2016-04-12');
INSERT INTO datvalues (val) VALUES ('2016-01-01');
INSERT INTO datvalues (val) VALUES ('2015-04-12');
INSERT INTO datvalues (val) VALUES ('2015-01-01');
INSERT INTO datvalues (val) VALUES ('2018-04-12');
INSERT INTO datvalues (val) VALUES ('2000-01-01');

/* linear score */
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4, 'scoreFunction=linear,scoreFunctionScale=365')) ORDER BY val;
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4,
'scoreFunction=linear,scoreFunctionScale=365,scoreFunctionDecay=0.75')) ORDER
BY val;
```

```

SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4,
'scoreFunction=linear,scoreFunctionScale=365,scoreFunctionDecay=0.75,scoreFunc
tionOffset=182')) ORDER BY val;
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4, 'sf=linear,sfs=365,sfd=0.75,sfo=182')) ORDER BY val;

/* gaussian score */
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4, 'scoreFunction=gaussian,scoreFunctionScale=365')) ORDER BY val;
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4,
'scoreFunction=gaussian,scoreFunctionScale=365,scoreFunctionDecay=0.75'))
ORDER BY val;
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4,
'scoreFunction=gaussian,scoreFunctionScale=365,scoreFunctionDecay=0.75,scoreFu
nctionOffset=182')) ORDER BY val;
SELECT SCORE(), val FROM datvalues WHERE CONTAINS(val, '2017-04-12',
FUZZY(0.4, 'sf=gaussian,sfs=365,sfd=0.75,sfo=182')) ORDER BY val;

DROP TABLE datvalues;

```

With the search term '2017-04-12', the example above returns the following scores.

Value	linear, scale=365 decay=0.75	linear, scale=365, decay=0.75, offset=182	linear, scale=365, decay=0.75, offset=182	gaussian, scale=365 decay=0.75, offset=182	gaussian, scale=365, decay=0.75, offset=182	gaussian, scale=365, decay=0.75, offset=182
2000-01-01						
2015-01-01		0.43	0.555			0.402
2015-04-12		0.5	0.624			0.522
2016-01-01		0.68	0.805		0.624	0.839
2016-04-12	0.5	0.75	0.875	0.5	0.75	0.93
2017-01-01	0.862	0.931	1	0.948	0.978	1
2017-04-12	1	1	1	1	1	1
2018-04-12	0.5	0.75	0.875	0.5	0.75	0.93

4.3.4.10 Fuzzy Search on Numeric Columns

For numeric columns, several score functions are available that calculate the score based on the distance between the search term and numbers stored in the column.

Without any further search options, a fuzzy search on numeric columns normally calculates scores based on the edit distance (Levenshtein distance) between the string representation of the search term and the string representations of the numbers stored in the column.

Score Functions

Numeric SQL types (`TINYINT`, `SMALLINT`, `INTEGER`, `BIGINT`, `DECIMAL`, `SMALLDECIMAL`, `REAL`, `DOUBLE`, and `FLOAT`) support score functions that return a score based on the difference between the numerical value of the search term and the value stored in the numeric column.

You can use functions for linear, Gaussian, and logarithmic scores.

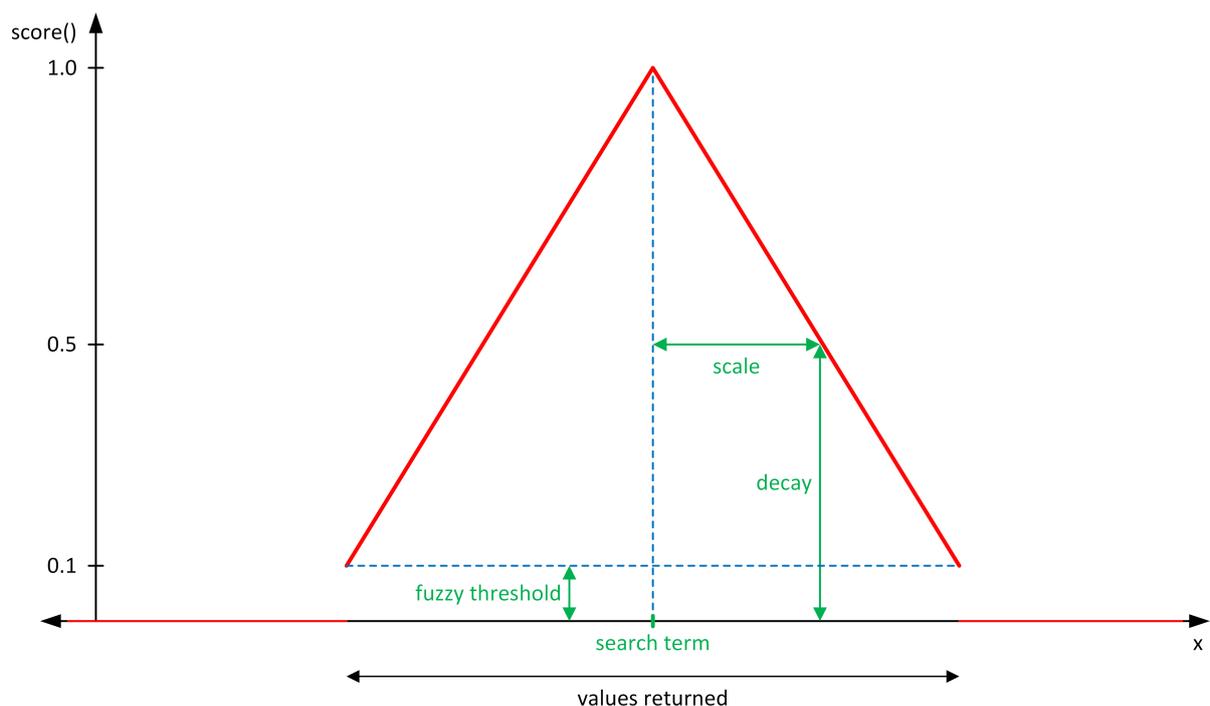

Linear Score Function

The linear score function has its highest point with `SCORE () = 1` at the given search term. The parameters `scale` and `decay` define a second point of the score function and the slope of the score function is defined as:

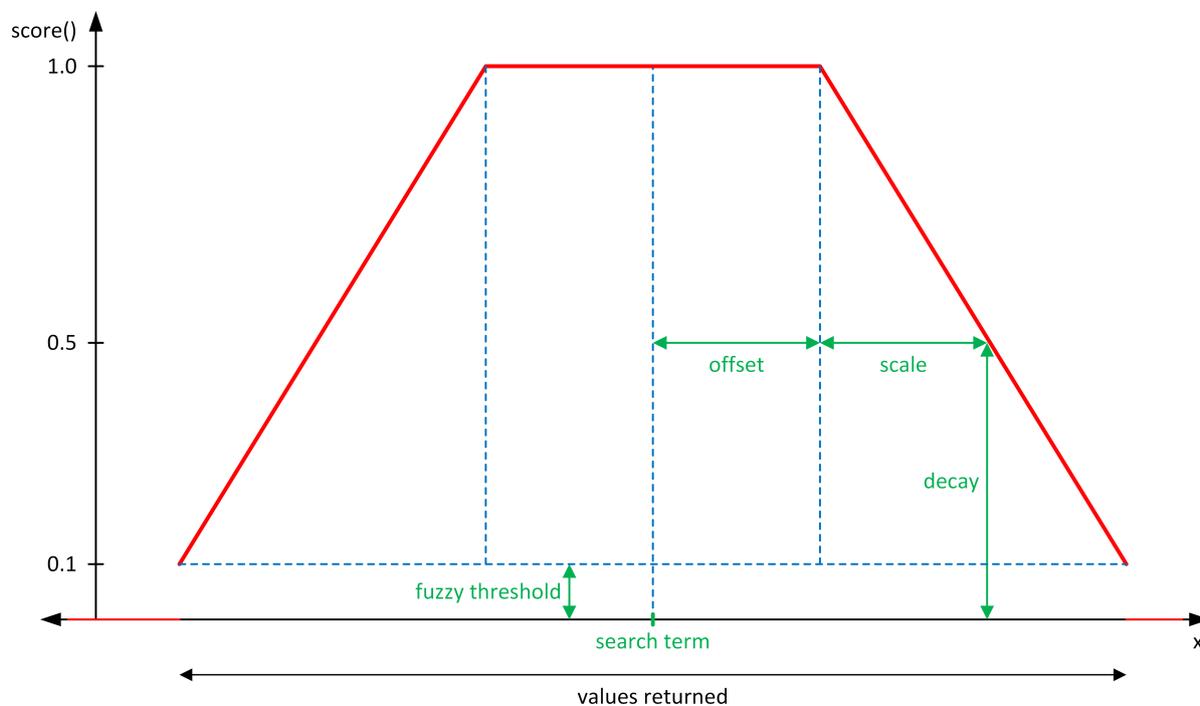

$$\text{slope} = (1 - \text{decay}) / \text{scale}$$

The fuzzy threshold given in the `CONTAINS ()` predicate, defines the range of values that is returned for a search. All values with a score lower than the fuzzy threshold are not returned.

The following image shows the linear score function:

The optional parameter `offset` defines a range of values that gets a score of 1. All values in the range between $(\text{search_term} - \text{offset})$ and $(\text{search_term} + \text{offset})$ get a score of 1 and the linear score function is shifted left and right by the given offset. This is shown in the image below:

For a set of parameters `offset`, `scale`, `decay`, `fuzzy_threshold` and `search_term`, the linear score of a value `x` stored in the column is calculated as follows:

```
slope = (1 - decay) / scale
h(x) = max(0, abs(x - search_term) - offset)
linear_score(x) = max(1 - slope * h(x), 0)
```

The score function returns:

- a score based on the linear score function, if the linear score is greater than or equal to the given fuzzy threshold;
`score(x) = linear_score(x)`
- a score of 0, if the linear score function is lesser than the given fuzzy threshold;
`score(x) = 0.`
 A score of 0 means that the value is not included in the search result.

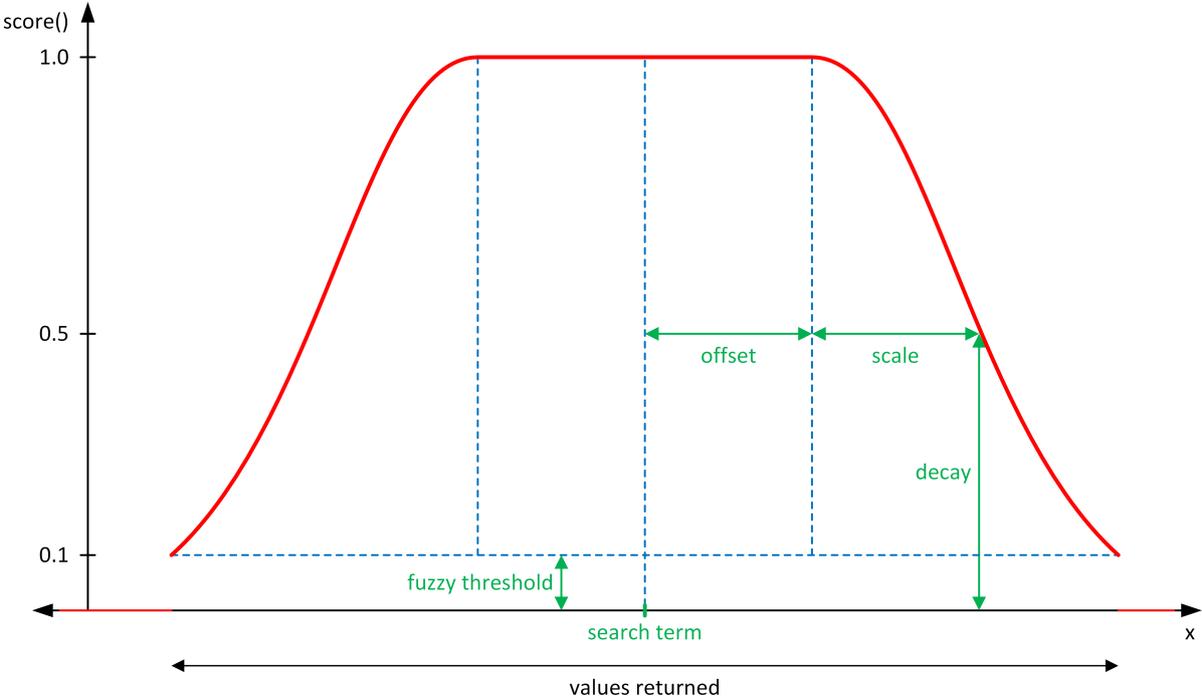

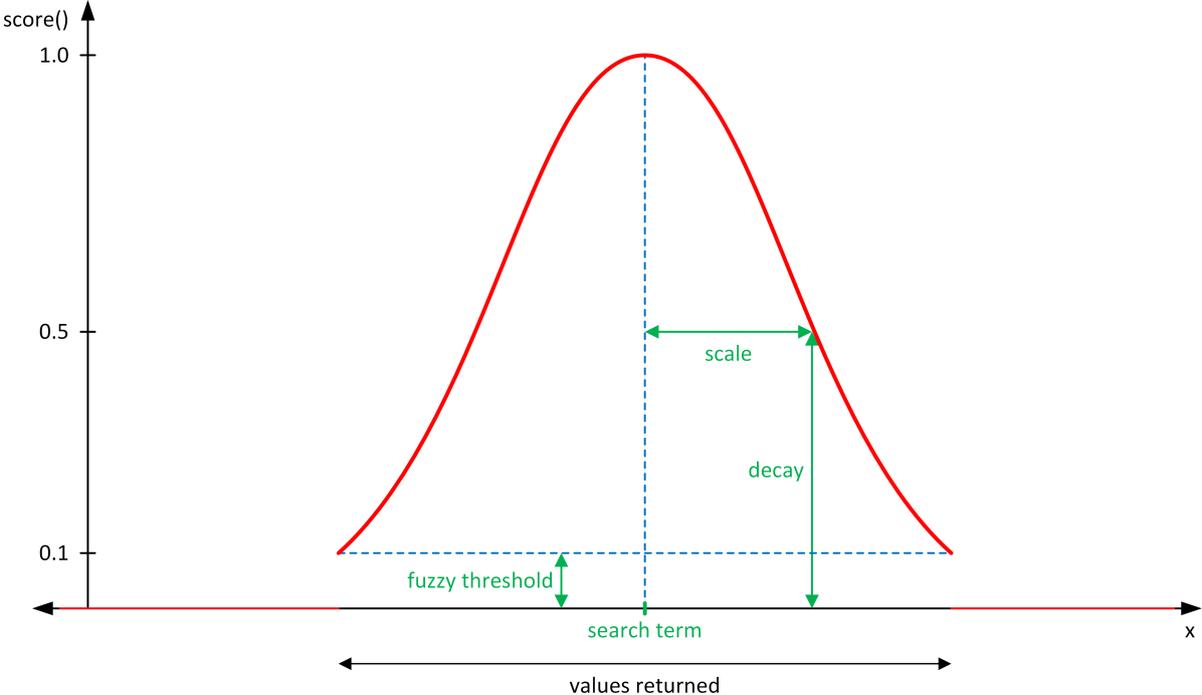

Gaussian Score Function

The Gaussian score function has its highest point with `SCORE()=1` at the given search term. The parameters `scale` and `decay` define a second point of the score function and the variance of the score function is defined as:

```
variance = - scale^2 / (2 * log(decay))
```

The fuzzy threshold given in the `CONTAINS ()` predicate, defines the range of values that is returned for a search. All values with a score lower than the fuzzy threshold are not returned.

The following images show the Gaussian score function with and without the optional parameter `offset`.

For a set of parameters `offset`, `scale`, `decay`, `fuzzy_threshold` and `search_term`, the Gaussian score of a value `x` stored in the column is calculated as follows:

```
variance = - scale^2 / (2 * log(decay))  
h(x) = max(0, abs(x - search_term) - offset)  
gaussian_score(x) = exp(-h(x)^2 / (2 * variance))
```

The score function returns:

- a score based on the Gaussian score function, if the Gaussian score is greater than or equal to the given fuzzy threshold;
`score(x) = gaussian_score(x)`
- a score of 0, if the Gaussian score function is lesser than the given fuzzy threshold;
`score(x) = 0.`
A score of 0 means that the value is not included in the search result.

Logarithmic Score Function

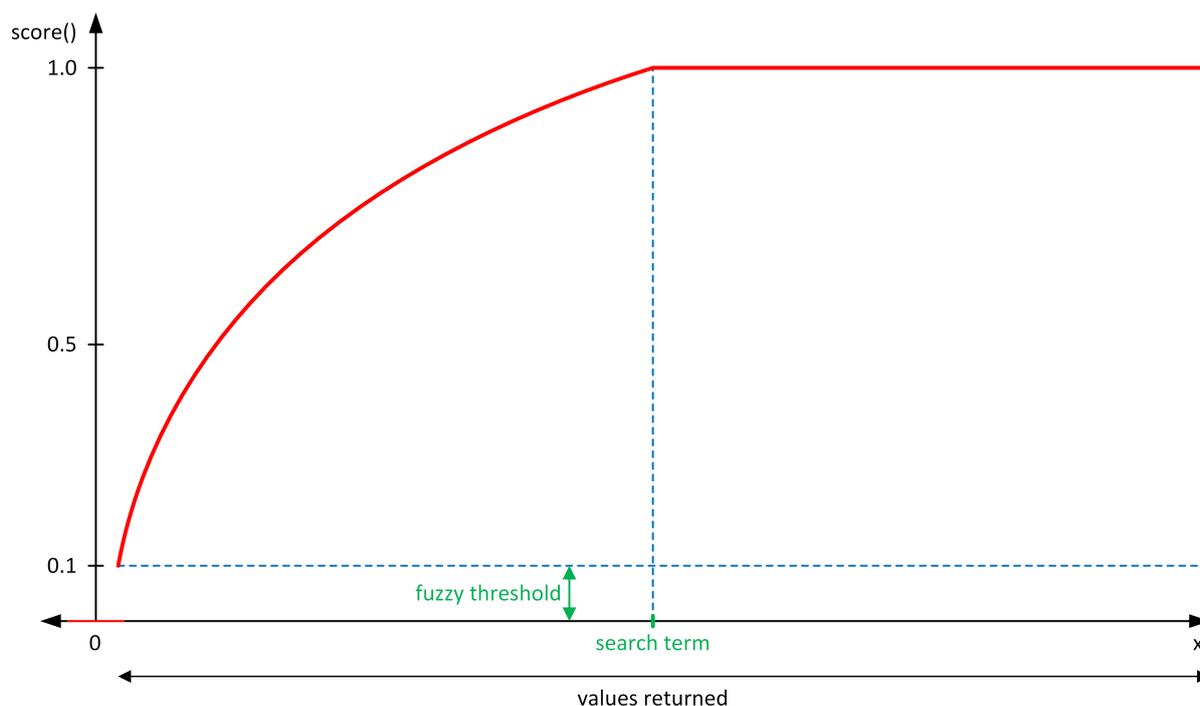

The logarithmic score function calculates scores using a logarithm function with a base that is given as a parameter or, if the parameter is not given, that is defined by the given search term:

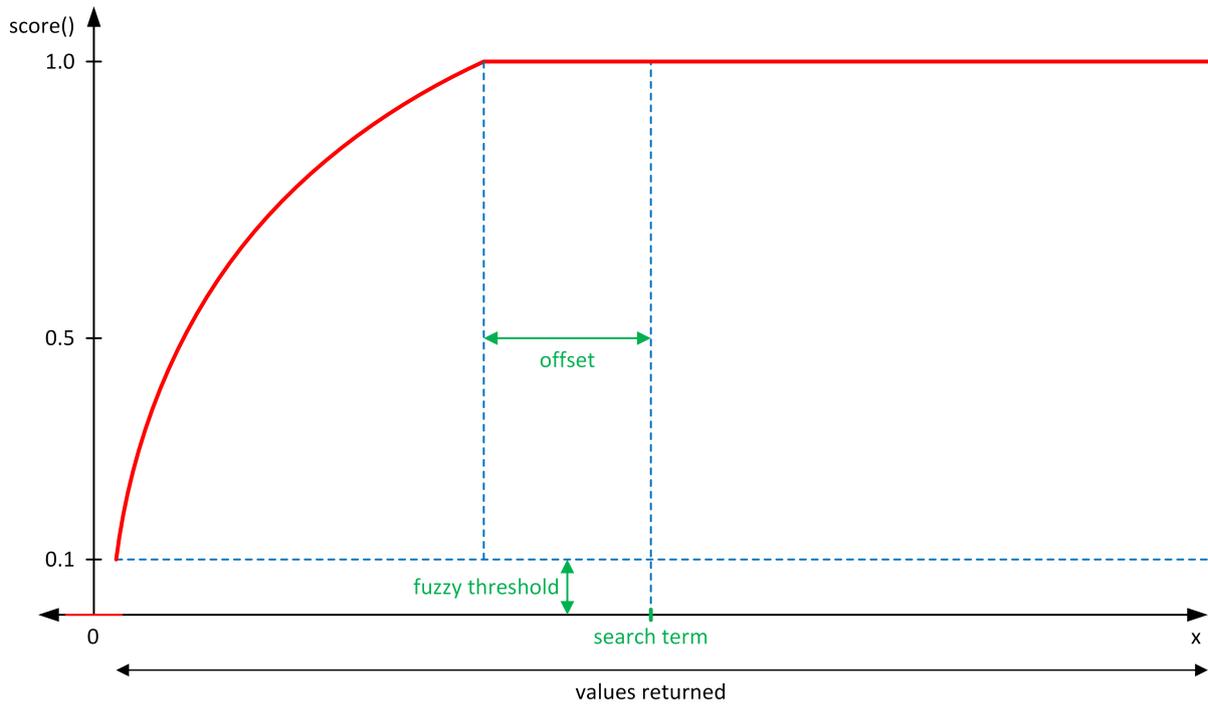

```
base = 1 + search_term
```

or, if the optional parameter `offset` is given;

```
base = (1 + Search_term - offset).
```

The images below show the logarithmic score function without and with optional `offset` parameter:

For a set of parameters `offset`, `base`, `fuzzy_threshold` and `search_term`, the logarithmic score of a value `x` stored in the column is calculated as follows:

`base = (1 + Search_term - offset)` (only if parameter `base` is not given)

`factor = (base - 1) / (search_term - offset)`

`logarithmic_score(x) = log(base, 1 + factor * x)`

The score function returns:

- a score based on the logarithmic score function, if the logarithmic score is greater than or equal to the given fuzzy threshold and if `x` is lesser than or equal to the given search term minus the given offset;
`score(x) = logarithmic_score(x)`
- a score of 1, if `x` is greater than the given search term minus the given offset;
`score(x) = 1`
- a score of 0, if `x` is lesser than 0 or the logarithmic score function is lesser than the given fuzzy threshold;
`score(x) = 0`.

A score of 0 means that the value is not included in the search result.

Note

When using a logarithmic score function, the search term has to be greater than 0. If the offset is given, `(search_term - offset)` also has to be greater than 0.

Search Options for Score Functions

The following table shows the search options that are available for the score functions.

Search Option	Possible Values	Default Value	Description	Linear	Gaussian	Logarithmic
scoreFunction	linear, Gaussian, logarithmic	n/a	Name of the score function	yes	yes	yes
scoreFunctionScale	scale > 0	n/a	Value of the score function parameter scale	yes	yes	no
scoreFunctionDecay	0 ≤ decay < 1 (linear), 0 < decay < 1 (Gaussian)	0.5	Value of the score function parameter decay	yes	yes	no
scoreFunctionBase	base > 1	1+ (searchterm - offset)	Value of the score function parameter base	no	no	yes
scoreFunctionOffset	offset ≥ 0	0	Value of the score function parameter offset	yes	yes	yes

Examples

Sample Code

Linear and Gaussian Score Functions

```

CREATE COLUMN TABLE numvalues
(
  id INTEGER GENERATED ALWAYS AS IDENTITY PRIMARY KEY,
  val INTEGER
);

INSERT INTO numvalues (val) VALUES (400);
INSERT INTO numvalues (val) VALUES (500);
INSERT INTO numvalues (val) VALUES (510);
INSERT INTO numvalues (val) VALUES (550);
INSERT INTO numvalues (val) VALUES (600);
INSERT INTO numvalues (val) VALUES (601);
INSERT INTO numvalues (val) VALUES (650);
INSERT INTO numvalues (val) VALUES (651);

/* linear score */
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=linear,scoreFunctionScale=50')) ORDER BY val;
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=linear,scoreFunctionScale=50,scoreFunctionDecay=0.6')) ORDER
BY val;
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=linear,scoreFunctionScale=50,scoreFunctionDecay=0.6,scoreFuncti
onOffset=50')) ORDER BY val;

```

```

SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'sf=linear,sfs=50,sfd=0.6,sfo=50')) ORDER BY val;

/* gaussian score */
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=gaussian,scoreFunctionScale=50')) ORDER BY val;
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=gaussian,scoreFunctionScale=50,scoreFunctionDecay=0.6')) ORDER
BY val;
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'scoreFunction=gaussian,scoreFunctionScale=50,scoreFunctionDecay=0.6,scoreFunc
tionOffset=50')) ORDER BY val;
SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '500', FUZZY(0.1,
'sf=gaussian,sfs=50,sfd=0.6,sfo=50')) ORDER BY val;

DROP TABLE numvalues;

```

With the search term '500', the example above returns the following scores:

Value	linear, scale=50, decay=0.6, offset=50	linear, scale=50, decay=0.6	linear, scale=50, decay=0.6, offset=50	Gaussian, scale=50	Gaussian, scale=50, decay=0.6	Gaussian, scale=50, decay=0.6, offset=50
400		0.2	0.6		0.13	0.6
500	1	1	1	1	1	1
510	0.9	0.92	1	0.973	0.98	1
550	0.5	0.6	1	0.5	0.6	1
600		0.2	0.6		0.13	0.6
601		0.192	0.592		0.124	0.59
650			0.2			0.13
651			0.192			0.124

The following example shows the logarithmic score function, as it could possibly be used for a column containing a click counter.

Sample Code

Logarithmic Score Function

```

CREATE COLUMN TABLE numvalues
(
  id INTEGER GENERATED ALWAYS AS IDENTITY PRIMARY KEY,
  val INTEGER
);

INSERT INTO numvalues (val) VALUES (0);
INSERT INTO numvalues (val) VALUES (1);
INSERT INTO numvalues (val) VALUES (5);
INSERT INTO numvalues (val) VALUES (10);

```

```

INSERT INTO numvalues (val) VALUES (15);
INSERT INTO numvalues (val) VALUES (100);
INSERT INTO numvalues (val) VALUES (105);
INSERT INTO numvalues (val) VALUES (150);
INSERT INTO numvalues (val) VALUES (1000);
INSERT INTO numvalues (val) VALUES (1005);
INSERT INTO numvalues (val) VALUES (10000);
INSERT INTO numvalues (val) VALUES (100000);
INSERT INTO numvalues (val) VALUES (200000);

SELECT SCORE(), val FROM numvalues WHERE CONTAINS(val, '10000', FUZZY(0.05,
'scoreFunction=logarithmic')) ORDER BY val;

DROP TABLE numvalues;

```

With the search term '10000', the example above returns the following scores:

Value	logarithmic
1	0.075
5	0.195
10	0.26
15	0.301
100	0.501
105	0.506
150	0.545
1000	0.75
1005	0.751
10000	1
100000	1
200000	1

4.3.4.11 Fuzzy Search on ST_POINT Columns

i Note

Score functions for columns of type `ST_POINT` can only be used in combination with the built-in search procedure `sys.esh_search()`.

It is currently not possible to run a fuzzy search in a `ST_POINT` column with SQL using the `CONTAINS()` predicate.

Score Functions

It is possible to do a fuzzy search for locations based on SQL data type `ST_POINT`. The fuzzy score is calculated based on the distance between the location given in the `ST_POINT` column and a reference point that is given as a search term. When using a score function for locations, it is possible to order the search results by distance so that search results that are nearer to the reference point get a higher `SCORE()`.

For location data, the score functions for linear and Gaussian scores are available.

Linear Score Function

The linear score function for `ST_POINT` is similar to the linear score function for numeric columns.

i Note

The distance between points is calculated in default units of the spatial reference system of the column. The scale and offset parameters of the function are also interpreted as distance in default units of the spatial reference system.

A parameter value set to 1 for a column with SRID 1000004326 (WGS 84 planar) means a distance of 1 degree as the default unit of measure of this spatial reference system is degree.

A parameter value set to 1000 for a column with SRID 4326 (WGS 84) means a distance of 1 kilometer as the default unit of measure of this spatial reference system is meter.

Distances are always greater than or equal to zero. This means that the left half of the function for negative input values is not used.

Gaussian Score Function

The Gaussian score function for `ST_POINT` is also similar to the Gaussian score function for numeric columns.

As for linear score functions, the distances are given in meters, and the negative half of the score function is not used.

Search Options for Score Functions

The following table shows the search options that are available for the score functions:

Search Option	Possible Values	Default Value	Description	Linear	Gaussian
scoreFunction	linear, Gaussian	n/a	Name of the score function	yes	yes
scoreFunctionScale	scale > 0	n/a	Value of the score function parameter 'scale', given in meters	yes	yes
scoreFunctionDecay	0 <= decay < 1 (linear), 0 < decay < 1 (Gaussian)	0.5	Value of the score function parameter 'decay'	yes	yes
scoreFunctionOffset	offset >= 0	0	Value of the score function parameter 'offset', given in meters	yes	yes

4.3.4.12 Language Specifics

This section includes information about language-specific behaviour of fuzzy search.

4.3.4.12.1 Limitations of Fuzzy Search when Using 'Non-Whitespace' Languages

Some languages do not use a space character to separate words. Examples are East-Asian languages like Chinese and Japanese. When using fuzzy search with these languages, there are limitations that are described below.

Limitations of NVARCHAR Columns

- Substring Search

Substring search uses word boundaries to search for results and to calculate the scores. Since there are no space characters between words in a 'non-whitespace' language, substring search cannot locate the word boundaries.

As a work-around, users can insert space characters between words when they type in the search term. Nevertheless, scores will not be as accurate as with 'whitespace' languages like English or French, because the word boundaries in the database entries are not known.

Limitations of Text Columns and Full-Text Indexes

- **Fast Preprocessing and Language Detection**
Since there are no space characters between words, language specific dictionaries are used to tokenize text. As a consequence, a language column has to be defined or automatic language detection has to be enabled. It is not possible to use fast preprocessing for text columns or full-text indexes.
- **Spelling Errors Change Number of Tokens**
The tokenizer uses a dictionary to split a text into single tokens. Spelling errors in the text lead to other matching dictionary entries, and as a result the length and number of tokens may be different to the same text without spelling errors. In some cases, no matching dictionary entries are found, so parts of the text may be split into very short tokens or even single characters (for example, with Chinese text).
Text search and fuzzy search search the user input, token by token. If the number of tokens is different because of spelling errors, fuzzy search does not find the results expected by the user. The user gets the expected results only if the spelling errors do not change the output of the tokenizer.

❖ Example

Let's use two names of provinces of the People's Republic of China: 黑龙江 in Pinyin: Heilongjiang 浙江. In Pinyin: Zhejiang. If we concatenate the two names, we get '黑龙江浙江'. The tokenizer is able to split this string correctly into two tokens: 黑龙江 and 浙江. Imagine a misspelling in Heilongjiang and we type '嘿笼奖' which has the same Pinyin representation. If we concatenate the misspelled first province name and the original name of the second province, we get '嘿笼奖浙江', And the tokenizer returns four tokens: 嘿, 笼, 奖, and 浙江. The difference in the tokenization makes it impossible for fuzzy search to find the entry containing the correctly spelled name.

- **Defining Term Mappings and Stopwords**
The language specific dictionaries are not used to tokenize the terms that are stored in a term-mapping table or in a stopwords table. You therefore have to add space characters between the tokens of a 'non-whitespace' language when adding data to the `term_1` and `term_2` columns of a term mapping table or to the `term` column of a stopwords table. Otherwise the term mappings and stopwords will not be applied.

Related Information

[Example for the Limitation on Defining Term Mappings and Stopwords \[page 402\]](#)

4.3.4.12.1.1 Example for the Limitation on Defining Term Mappings and Stopwords

First we create a table and insert two records. Both records refer to the same company name 'Sample' - as we do not matter about the extension 'limited partnership'.

```
CREATE COLUMN TABLE chinesetext (  
  id INTEGER PRIMARY KEY,  
  text_zh TEXT FAST PREPROCESS OFF LANGUAGE DETECTION ('ZH','EN'),  
  text_en TEXT);  
INSERT INTO chinesetext VALUES (101, '样品有限合伙', 'Sample  
limited partnership');  
INSERT INTO chinesetext VALUES (102, '样品', 'Sample');
```

The following SELECT statement retrieves only the record with id 102.

```
SELECT SCORE(), * FROM chinesetext  
WHERE CONTAINS(text_zh, '样品', FUZZY(0.8, 'textSearch=compare,  
minTextScore=0.6'));
```

Therefore we create a stopwords table with an entry for 'limited partnership'.

```
CREATE COLUMN TABLE mystopwords  
(  
  stopword_id VARCHAR(32) PRIMARY KEY,  
  list_id VARCHAR(32) NOT NULL,  
  language_code VARCHAR(2),  
  term NVARCHAR(200) NOT NULL  
);  
INSERT INTO mystopwords VALUES (1, 'list1', '', '有限合伙');
```

The following SELECT statement still retrieves only the record with id 102.

```
SELECT SCORE(), * FROM chinesetext  
WHERE CONTAINS(text_zh, '样品', FUZZY(0.8, 'textSearch=compare,  
minTextScore=0.6, stopWordTable=mystopwords, stopWordListID=list1'));
```

We need to INSERT another entry into the stopwords table having a blank between 'limited' and 'partnership'.

```
INSERT INTO mystopwords VALUES (2, 'list2', '', '有限 合伙');
```

The following SELECT statement retrieves both records.

```
SELECT SCORE(), * FROM chinesetext  
WHERE CONTAINS(text_zh, '样品', FUZZY(0.8, 'textSearch=compare,  
minTextScore=0.6, stopWordTable=mystopwords, stopWordListID=list2'));
```

4.3.4.12.2 Fuzzy Search - Chinese

This chapter describes the features of fuzzy search which are specific to Chinese script, meaning all strings or texts written with Chinese characters.

When comparing strings containing Chinese characters, fuzzy search does not just compare the Chinese characters. Fuzzy search also takes account of the Pinyin representation of the Chinese characters. Thus fuzzy

search does not just return hits based on the identical Chinese characters. It also returns hits which sound similar and have an identical or similar Pinyin representation. This allows fuzzy search to deal with errors based on the most commonly used input method for Chinese characters: to type in the Pinyin representation and to pick one of the suggestions.

When a user enters a Chinese word, s/he might enter a wrong pinyin transcription or select a wrong Chinese word from the proposed choices. The following table shows an example of Chinese words that are considered to be similar by fuzzy search:

Chinese Term	Pinyin Representation
北京	beijing
背景	beijing
被禁	beijin

4.3.4.12.2.1 Fuzzy Search on Chinese Strings

Fuzzy search on NVARCHAR columns compares the complete content of the search input against the complete string of the database field. This includes all characters including spaces and punctuation. At this point, there is no difference to fuzzy search on non-Chinese scripts.

i Note

Including the Pinyin representation for Chinese strings is active as soon as there are Chinese characters either in the search input or in a database entry.

4.3.4.12.2.2 Fuzzy Search on Chinese Texts

i Note

The Chinese text search feature described below is active as soon as the language of the search is set to Simplified Chinese (language code 'zh'). This is done either by setting a default language, by automatic language detection, or by defining the language in the CONTAINS() predicate.

If the language of the search is set to Simplified Chinese (language code 'zh'), the search options `composeWords`, `decomposeWords` and `compoundWordWeight` are ignored.

When comparing Chinese text values, each token of each text is compared as described above, taking the Pinyin representation into account.

Chinese script is a non-whitespace script. That means that tokens cannot easily be recognized by surrounding whitespaces. SAP HANA therefore has a sophisticated mechanism to recognize word boundaries and to split Chinese texts into words. Spelling errors can result in the wrongly entered character indicating the end of a word however, whereas the correct character would not. Alternatively, a wrongly entered character results in concatenation of subsequent characters.

A Chinese text containing a single spelling error might therefore be differently tokenized than the original text. The number of tokens and the length of the tokens can vary. In this case, it is very likely that you will get a lot of mismatches when you compare the tokens. Fuzzy search has to deal with these different tokenizations to find useful results.

For performance reasons, fuzzy search assumes that most of the spelling errors will be in the search input. Fuzzy search therefore assumes that the database entries are tokenized correctly and it handles varying tokenization in the search input only. This is done by creating alternative sets of tokens for the search input. An alternative set of tokens is built through concatenation of two or more adjacent tokens of the recognized tokens. The score for the comparison is determined by the best matching set of tokens. This behavior is similar to the behavior which could be achieved by using the search option `composeWords`.

Example

'Heilongjiang' is the name of a province of the People's Republic of China. '黑龙江' is the correct spelling in Chinese script. Let us assume that this is the value of TEXT field in a database table. If you perform fuzzy search with search input '黑隆江', fuzzy search has to deal with the following issue:

The search input contains a spelling error. The second character is incorrect, but has the same Pinyin representation as the correct character. Based on the spelling error, a standard tokenizer splits the search input into three tokens, whereas the correctly spelled word in the database is considered to be one token.

Token Set of Search Input	Token Set of Database Entry
'黑' AND '隆' AND '江'	'黑龙江'

Since every search token has to match a counterpart token in order to get a hit, the search input would never match the correctly spelled word. Only one of the three tokens of the search input has a chance of being matched to the one token in the database field. To overcome this, fuzzy search creates additional sets of tokens to be compared with the database content. These additional token sets are shown in the table below:

Additional Token Sets
'黑隆' AND '江'
'黑' AND '隆江'
'黑隆江'

The last set of tokens – consisting of only one token – will make the match.

4.3.4.12.2.3 Using the Search Option `interScriptMatching`

Use the search option `interScriptMatching` to search records that contain Simplified Chinese and, for example, English characters in a single column.

Context

You can search with Pinyin data (Latin characters) and find records written in Chinese characters and the other way round, so that you do not have to care about the character set used in the database records. As a default behavior, you can search with a character set (for example, Latin), and do not find data that uses a different character set (for example, Chinese or Greek), so that you do not get any search results that you cannot read.

If you use `interScriptMatching=on`, each of the three user inputs 'Shanghai 市', '上海市', and 'Shanghai Shi' finds all three strings as a result.

If you use `interScriptMatching=off`:

- A search with only Latin characters does not search the Pinyin transliteration
- A search with only Chinese characters does not use the Pinyin transliteration to search for Latin strings
- A search with mixed input finds only mixed strings

Related Information

[Option `interScriptMatching` \[page 296\]](#)

4.3.4.13 Support of Tables with Client Column

Fuzzy search supports the client column (e.g. 'MNDT', 'CLNT', or 'CLIENT') in tables of SAP business applications. Thus ensures that each user gets only those search results that belong to its own client only.

4.3.4.13.1 Adding the Client Information to a WHERE Condition

For SELECT statements that use the `CONTAINS()` predicate, you can limit the search results to the current client.

Context

Procedure

Add either the client condition directly or by using the session parameter `CLIENT` to the `WHERE` clause, as shown in the following examples.

i Note

For ABAP applications it may not be necessary to add the additional `AND` condition in the SQL statements as this is handled by the OpenSQL implementation for SAP HANA.

Example

```
SELECT SCORE(), ... FROM tab
WHERE CONTAINS((col1, col2, col3), 'a b c', FUZZY(0.8))
AND CONTAINS(col4, 'x y z', FUZZY(0.7))
AND MNDT = '100'
ORDER BY SCORE() DESC;
```

```
SELECT SCORE(), ... FROM tab
WHERE CONTAINS((col1, col2, col3), 'a b c', FUZZY(0.8))
AND CONTAINS(col4, 'x y z', FUZZY(0.7))
AND MNDT = SESSION_CONTEXT('CLIENT');
ORDER BY SCORE() DESC;
```

4.3.4.13.2 Enabling Client-dependent Term Mappings and Stopwords

By defining an additional column to your term mapping or stopwords table you can use them for multiple clients.

Context

As with any other SQL feature, the implementation of term mappings and stopwords inside SAP HANA is not aware of a client column. It is not possible to specify the client column in the `SELECT` statement as part of the fuzzy search options. Nevertheless, it is possible to use a term mapping or stopwords table with multiple clients as shown in the following example.

Procedure

1. Create a term mapping table with an additional client column.

```
CREATE COLUMN TABLE termmappings
(
  client          NVARCHAR(3)      NOT NULL,
  mapping_id     NVARCHAR(32)     NOT NULL,
  list_id        NVARCHAR(32)     NOT NULL,
  language_code  NVARCHAR(2),
  term_1         NVARCHAR(200)    NOT NULL,
  term_2         NVARCHAR(200)    NOT NULL,
  weight         DECIMAL          NOT NULL,
  PRIMARY KEY (client, mapping_id)
);
```

2. To add data to the term mapping table, you have to specify the client column in addition to the other columns of the table.

```
INSERT INTO termmappings VALUES ('100',
'1','01','','AG','Aktiengesellschaft','0.9');
INSERT INTO termmappings VALUES ('100',
'2','01','','Aktiengesellschaft','AG','0.9');
```

3. To use the term mappings in a search, define a view that selects the term mappings of a given client from the table.

```
CREATE VIEW termmappingsview AS
SELECT mapping_id, list_id, language_code, term_1, term_2, weight
FROM termmappings
WHERE client = SESSION_CONTEXT('CLIENT');
```

4. Instead of using a SQL view, you can also define an attribute view in the SAP HANA Studio. You can also define a join view using the `CREATE COLUMN VIEW` statement. In this case you have to define a filter condition (also called constraint) that uses the session variable `$$client$$` and that filters for `client eq '$$client$$'`.

5. When the client information is defined in the session context, you can use the term mapping view in a CONTAINS () predicate.

```
CREATE COLUMN TABLE companies
(
  id          INTEGER          PRIMARY KEY,
  companyname SHORTTEXT(200)  FUZZY SEARCH INDEX ON
);
INSERT INTO companies VALUES ('1','SAP AG');
INSERT INTO companies VALUES ('2','SAP Aktiengesellschaft');

SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM companies
WHERE CONTAINS(companyname, 'sap ag',
FUZZY(0.8,'termMappingTable=termmappingsview,termMappingListId=01,textSearch=compare'))
ORDER BY score DESC, id;
```

4.3.4.14 Search Rules

Overview

The fuzzy search in SAP HANA allows you to search for structured database content that is similar to the user input. In this case, the user input and the records in the database are nearly the same but differ in their spelling (typing errors for example) or contain additional information (additional or missing terms for example).

One of the use cases for the fuzzy search on structured data is the prevention of duplicate records. New database records can be checked for similar and existing records in real time, just before the new record is saved.

Before saving a new customer to the database for example, the application checks for similar customers that might be duplicates of the new customer that has been entered. The application performs a number of searches and then presents to the user any existing customers that are similar to the user input. The user then decides whether to create a new customer (because the records presented are similar, but not really duplicates) or to accept one of the existing customers and continue with this customer record.

The searches performed by the application are defined by business rules that define when two customers are similar. For example, the application might consider two customers to be similar if one of the following conditions is true:

1. The customers' names and addresses are similar.
2. The customers' last names and addresses are identical, but the first names are different (could be persons living in the same household).
3. The customers' names are similar, and the dates of birth are identical.

These rules can be hard-coded in the application by writing three SELECT statements that perform the three searches defined above. Whenever the requirements for the search rules change, the application code has to be changed, tested, and deployed to the productive system. This can be costly in terms of time and the development resources needed.

Alternatively, the application can use search rules to store the rules as a configuration object in the SAP HANA database. Instead of embedding the rules in SELECT statements that are part of the application code, the application has to call a database procedure to process all rules defined in the configuration object.

If the business requirements change, only the search rule definition in the configuration object has to be changed, tested, and deployed. The interface to the database procedure that is called by the application remains unchanged. Without any change to the application code, the definition of the search rules is therefore changed, and the user immediately receives search results according to the new requirements. This results in much less effort and more flexibility when changing search rules.

Search Rule Sets Stored in the Application

Applications that do not use the SAP HANA repository or XS Advanced do not want search rule sets to be the only configuration object that is stored in SAP HANA and that has to be transported from system to system in a different way than all other application data. These applications may store the search rule set configuration in their own database and pass it as a dynamic search rule set to every call of the search rule set procedure.

Batch Processing

Search rules support a batch processing mode. This batch mode allows to compare a set of records given in an input table with a reference set of records with a single call to the search rule set procedure to find any duplicates within these two sets of data.

Supported Database Objects

You can search on attribute views, column views of type Join, and SQL views.

Attribute Views have to be modeled using the SAP HANA studio and have to be stored as objects in the SAP HANA repository. Column views of type Join and SQL views can be created using SQL statements.

Other database objects, such as row store tables, column store tables, calculation views, or analytic views, are not supported.

Important Terms

A **search rule set** is the configuration object that is stored in the SAP HANA repository and that contains the definition of the search rules. When the database procedure is called in order to perform a search, a search rule set is executed. This means that all rules that are defined in the search rule set are executed.

A **search rule** defines a condition when two records – the user input and a record in the database – are considered similar. Each rule in a search rule set is converted to a SELECT statement and is executed when the search rule set is processed.

4.3.4.14.1 Creating Search Rule Sets

Prerequisites

Before you can create a search rule set in the SAP HANA studio, you have to create a workspace and a project there. In this workspace, you create a package that will contain your rule set.

To set up the project in the SAP HANA studio, use the connection of the user who modeled the attribute view (for example, the user from the `MODELOWNER` tutorial) and add the package that you want to contain the search rule sets to the project (for example, the package from the `apps.customer` tutorial).

Procedure

1. In the SAP HANA modeler, open the *Project Explorer* view and navigate to your package.
2. From the context menu of your package, choose **► New ► Other ► Search Rule Set ►**.
3. Enter a file name for your rule set. The file has to have the extension `.searchruleset`.
4. Open and edit the search rule set in the search rule set editor. See [Working with the Search Rule Set Editor \[page 411\]](#)

i Note

It is also possible to edit search rule sets in the SAP HANA Web-based Development Workbench even if there is no editor specific to search rule sets. A standard text editor has to be used to create the search rule set xml files.

When a `*.searchruleset` file is opened in the editor, it is possible to insert a code snippet that shows the xml structure of a search rule set. This can be used as a template to create a new search rule set.

5. Define the attribute view, key columns, score selection parameter, stopwords, and term mappings.
6. From the context menu of your package or search rule, choose **► Team ► Activate ►**.

Results

You can now execute a search with the rule set. See [Executing a Search With a Rule Set \[page 424\]](#)

Related Information

[Tutorial: Create and Use Search Rules \[page 434\]](#)

4.3.4.14.2 XML Structure of a Search Rule Set

Search rule sets are stored in XML files in the local file system. The search rule set editor reflects the structure of these files and displays the search rule set in a tree-like structure. To edit search rule sets, you need some basic knowledge of the structure of the XML files. The XML structure of a search rule set configuration is as follows:

```
+Document Root
  +Rule Set
    +Attribute View
      +Key Column 1
      +...
      +Key Column n
    +Rule 1
      +Column 1
        +optional: Column Options (text, string or date options)
      +...
      +Column n
        +optional: Column Options
    +...
    +Rule n
      +Column 1
        +optional: Column Options
      +...
      +Column n
        +optional: Column Options
```

4.3.4.14.3 Working with the Search Rule Set Editor

Context

To open a rule set in the editor, double-click a rule set file or, choose **► Open With ► Search Rule Set Editor ►** in the context menu.

Action	Description
Adding new nodes, children or siblings	<p>To add new nodes, children or siblings, you can use the context menu of each node.</p> <p>You can a new key column node in the following ways for example:</p> <ul style="list-style-type: none">• Select the attribute view node and, choose <i>New Key Column</i> in the context menu.• Select a key column node and choose <i>New Key Column</i> in the context menu.
Deleting a node	<p>To delete a node from the search rule set, select the node and choose <i>Delete</i> in the context menu.</p> <p>This deletes the node together with all its child nodes.</p>

Action	Description
Changing the order of nodes	<p>To change the order of nodes or to move nodes to other parent nodes, you can drag and drop them.</p> <p>With the SAP HANA studio running on Microsoft Windows, you can copy nodes below the same parent node or even to another parent node by pressing CTRL while dragging.</p>
Changing the node properties	<p>To change properties, click on the value of the property in the <i>Properties</i> view and enter the new value.</p> <p>Each node contains a set of properties that define the behavior of the search rules. Node properties are displayed in the <i>Properties</i> view in the SAP HANA studio when a node is selected in the tree. If the <i>Properties</i> view is not displayed, you can open it by choosing Window > Show View > Properties.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p>i Note</p> <p>Some node properties refer to database objects or to column names. These properties are case-sensitive, so be sure to enter all names in the correct notation.</p> </div>

4.3.4.14.4 Configuring Search Rule Sets

Procedure

1. Define the attribute view.

The search rule set can be used with different types of views. For more information, see [Search Rules \[page 408\]](#).

The view to be used is defined in the view node of the search rule set.

The name property contains the name of the view. The 'syntax' of the name depends on the type of the view:

View Type	Syntax	Example
Repository objects:	FQN notation (fully qualified name)	apps.customer::CUSTOMER
<ul style="list-style-type: none"> ○ Attribute View 		

View Type	Syntax	Example
Catalog objects:	"Schema"."View_Name"	"SAP_CRM"."CUSTOMERS_VIEW"
<ul style="list-style-type: none"> ○ Join View ○ SQL View 		"

There are two ways of setting the name of the view:

- You can type in the name of the view in the "Properties" view using the correct syntax for catalog and repository objects.
- You can use drag & drop. Drag the catalog and repository objects from the "SAP HANA Systems", view and drop them on the view node. You can also drag tables from the catalog and drop them on the "Stopwords (table-based)" and "Term Mappings (table-based)" nodes.

Once you have defined the view, and your project is shared with a HANA repository workspace, you do not need to enter all the column names and the names of the key columns manually. The "Property View" of the corresponding node (column or key column) provides you with a combobox containing all available fields.

Example attribute view name: `apps.customer::CUSTOMER`

2. Define the key columns and the score selection parameter.

A search might return the same record more than once, as it matches more than one rule.

To enable the search to return each record just once, key columns must be defined in a way that makes records in the result set unique. For an attribute view, there is no definition of key columns available, so the key columns have to be defined for each search rule set.

The key columns are a set of one or more columns of the attribute view that clearly identify a record in the view. The key columns are therefore similar to the primary key columns of a database table.

As for primary keys, LOB types (BLOB, CLOB, NCLOB, TEXT) are not allowed as key columns.

i Note

It is possible to create an invalid key column definition that does not make the result set unique. In this case, when running a search, an error is raised when records returned by a single rule are not unique.

By default, each search rule set contains one key column node below the attribute view node. If more columns are needed to make records unique, more key column nodes can be added below the attribute view node.

In each key column node, enter the name of the attribute view column in the properties panel.

In addition to the key columns, you have to define how the result set should be made unique. Records returned by more than one rule usually have different scores assigned. Only one combination of score and rule name can be returned in the result set.

The score selection parameter defines whether the values with the highest score or the values found with the first matching rule are returned.

You define the score selection parameter in the properties panel of the rule set node.

3. Optional: Define stopwords and term mappings.

To use stopwords and term mappings in a search rule set, the configuration options have to be added to the rule set.

First, open the context menu for the *Search Rule Set* node and choose *New Stopwords (table-based)* or *New Term Mappings (table based)*.

In the properties of the new nodes, you can define the stopwords table and term mapping table that is used.

On the *Stopwords (table-based)* or *Term Mappings (table-based)* node, select *New Column* to enable the stopwords or term mappings on a column. In the properties panel, you can define the name of the column where you want stopwords and term mappings to be applied.

Below the *Column* nodes, create new *List ID* nodes (open the context menu and choose *New List ID*). In each list ID node, you can configure a stopwords or term mapping list that is applied on the column.

The stopwords and term mapping settings are valid for a given column in all rules.

4. Add rules.

To add a new rule to the search rule set, open the context menu on the *Search Rule Set* node and choose *New Rule*.

You can change the order of the rules by dragging a rule with the mouse to a new position.

4.3.4.14.5 Configuration Settings and Properties

Search Rule Set Properties

The only property of a search rule set is the `Score Selection`. `Score selection` defines which rule number is returned for a record if it was found by multiple rules. `highestScore` will choose the rule that gives the highest score for the record (used for non-hierarchical views or together with `Rule Cut`) and `firstRule` will pick the first rule (top down) that found this record (used for hierarchical rules).

View Properties

A search rule set needs a view on which the rules are executed. To connect the search rule set with the view, the node `View` with the property `Name` is used. `Name` takes the full name consisting of schema or package name and view name. To activate the search rule set, `_SYS_REPO` needs `SELECT` granted on this view. Valid formats of the name property are shown below.

Value of 'name' Property	XML Example	Description
"SCHEMA"."VIEW"	<pre><attributeView name="&quot;DATA&quot;. &qu ot;VIEW&quot;"></pre>	Uses the SQL view 'VIEW' in schema 'SCHEMA'.

Value of 'name' Property	XML Example	Description
package1.package2::VIEW	<attributeView name="package1.package2::VIEW">	Uses the attribute view 'VIEW' in package 'package1.package2' that has been created using the SAP HANA repository.
"_SYS_BIC"."package1.package2/VIEW"	<attributeView name=""_SYS_BIC"."package1.package2/VIEW"">	Uses the same attribute view as above. Should not be used; use the reference to the repository object instead, as shown above.
"PUBLIC"."SYNONYM"	<attributeView name=""PUBLIC"."SYNONYM"">	Uses the SQL view or attribute view that is defined by the public synonym 'SYNONYM'.
"SCHEMA"."SYNONYM"	<attributeView name=""SCHEMA"."SYNONYM"">	Uses the SQL view or attribute view that is defined by the synonym 'SYNONYM' in schema 'SCHEMA'.

The `nonUniqueKeys` property defines the behavior of a search rule set when duplicate keys occur because of 1:n joins and incomplete key columns.

Key Columns

To make the results unique, the `EXECUTE_SEARCH_RULE_SET` function needs a definition of the 'key columns' that identify each row. This is done by adding a `Key Column` node for each column the key consists of. Its property `Name` takes the column's name. If the key consists of multiple columns, the same number of `Key Column` nodes have to be defined.

When searching with multiple search rules, it is likely that the same row is returned by more than one rule. In this case, the search rules runtime has to make a decision what score, rule id and rule number are returned for this record because `EXECUTE_SEARCH_RULE_SET` returns every row only once.

i Note

The key columns must be sortable and therefore the following types are not supported as Key Columns: `TEXT`, `BINTEXT`, `CLOB`, `NCLOB`, `BLOB`, `ST_POINT`, `ST_GEOMETRY`.

Stopwords and Term Mapping Properties

To use stopwords, the node `Stopwords` (table-based) has to be added. It takes `Schema` and `Table` names of the stopword table as properties. To activate the search rule set, `_SYS_REPO` needs `SELECT` granted on this table. For each column that uses stopwords, a `Column` node has to be added. Its property `Name` takes the column name for which stopwords are to be used. Multiple `List ID` nodes can be defined under the `Column` node. Their property `Id` indicates a list ID of the stopword table that is used for the given column.

In addition to the `List ID`, it is possible to use property `IdColumn` to define the name of a "list idColumn" which points to a column that stores the value of the list id's itself.

The same is valid for term mappings with the node `Term Mappings` (table-based).

Value of 'name' Property	XML Example	Description
"SCHEMA"."TABLE"	<code><attributeView name="&quot;DATA&quot;. &quot;TABLE&quot;"></code>	Uses the stopwords table or term mapping table 'TABLE' in schema 'SCHEMA'.
"PUBLIC"."SYNONYM"	<code><attributeView name="&quot;PUBLIC&quot;. &quot;SYNONYM&quot;"></code>	Uses the stopwords table or term mapping table that is defined by the public synonym 'SYNONYM'.
"SCHEMA"."SYNONYM"	<code><attributeView name="&quot;SCHEMA&quot;. &quot;SYNONYM&quot;"></code>	Uses the stopwords table or term mapping table that is defined by the synonym 'SYNONYM' in schema 'SCHEMA'.

Rule Properties

For each rule that shall be defined, a node `Rule` has to be added. The order of the rules (top down) in the resource set also defines the order of the execution. You name the rule by setting the `Name` property.

`Min Fuzziness` defines the minimum score that the rule's columns have to result in to trigger this rule. All records with a lower score will not show in the result. The property `Weight` is a factor that lowers the rule's score (for example, a score of 0.9 with a weight of 0.9 will result in 0.81). This is used to show that the rule's hits have a lower value. `Rule Cut` is used to stop the processing before a rule is used. Whenever the total number of hits of earlier rules exceeds the value of `Rule Cut`, no more rules are processed. A value of 0 (zero) deactivates `Rule Cut` for this rule.

`Rule Cut` is used for the following reasons:

- To separate rules (or groups of rules) that have a different hierarchy by putting a `Rule Cut = 1` into the next rule (or first rule of the next group). If you do this, the next rule (or next group) will not be executed if the previous rule (or group of rules) results in hits.
- To speed up processing. This is done by putting a `Rule Cut` with the desired number of hits into every rule. As soon as this number is reached, no more rules are processed.

Column Properties

A rule needs at least one column to search on. The column's `Name` property points to a column of the `View` defined above. `Min Fuzziness` corresponds to the fuzziness of the `fuzzy()` function within the `contains()` statement. The property `Weight` is a factor that lowers the column's score (for example, a score of 0.9 with a weight of 0.9 will result in 0.81). This is used to show that the column's hits have a lower value.

The column of the view has a certain type in the table it is based on. The fuzzy search allows certain column options for each type. These translate directly into column properties:

Column Type	Column Option Node	Available Properties
TEXT, SHORTTEXT, any STRING column with fulltext index	Text Column Options	<ul style="list-style-type: none"> • abbreviationSimilarity • andSymmetric • andThreshold • bestMatchingTokenWeight • composeWords • compoundWordWeight • considerNonMatchingTokens • decomposeWords • emptyScore • enableStopwords • enableTermMappings • excessTokenWeight • interScriptMatching • minTextScore • phraseCheckFactor • returnAll • similarCalculationMode • spellCheckFactor
Other STRING columns	String Column Options	<ul style="list-style-type: none"> • emptyScore • interScriptMatching • returnAll • searchMode • similarCalculationMode • spellCheckFactor
DATE, TIMESTAMP	Date Column Options	<ul style="list-style-type: none"> • emptyScore • maxDateDistance • returnAll

The column option nodes are optional; if not specified, default values for their properties will be used.

TEXT columns (as well as SHORTTEXT and any STRING columns with fulltext index) always get the fuzzy search option `textsearch=compare` set. This is to ensure that the fuzzy score will be retrieved instead of the TF/IDF score.

The two properties `enableStopwords` and `enableTermMappings` are not standard fuzzy() parameters. However, since stopwords and term mappings are defined for a column and are independent of the rules, these parameters are needed to individually switch them off (false) for single rules. The default value of `enableStopwords` and `enableTermMappings` is true.

4.3.4.14.5.1 Text vs. String Column Options on String Columns with Full-text Index

On string columns with full-text index, it is possible to define either `Text Column Option` or `String Column Options`. Based on the defined column options the search will select the string column itself for the search execution or the corresponding full-text index and behave according to the `Column Options` defined.

Using string column options means that a search rule set configuration can still be used or activated when a full-text index is added to this columns. And this also ensures that search results do not change when adding a full-text index.

4.3.4.14.5.2 Column Conditions

Each column in a rule can have different column conditions. These conditions steer the behavior of the column and/or the rule at runtime. Depending on how the queried rule is filled, either the column will be skipped from the where clause, or the whole rule will be skipped. It is also possible to change the requested value of the column.

The table below shows the various condition types, together with the properties that can be set for them:

Condition	Value	Action	Replace By	Description
If Equals	value to compare to	skipColumn	-	Column is given in the query to the <code>EXECUTE_SEARCH_RULE_SET</code> function. The condition matches if there is a request value given that equals the value of the column condition.
		skipRule	-	
		replace	new value	
If Not Empty		skipColumn	-	Column is given in the query to the <code>EXECUTE_SEARCH_RULE_SET</code> function. The condition matches if there is any request value given.
		skipRule	-	
		replace	new value	

Condition	Value	Action	Replace By	Description
If Missing		skipColumn	-	If no column condition is given, the behavior is as follows: Missing columns in a rule cause the rule to be skipped. Empty values will be requested as empty.
		skipRule	-	
		replace	new value	
If Not Equals	value to compare to	skipColumn	-	Column is given in the query to the EXECUTE_SEARCH_RULE_SET function. The condition matches, if there is a request value given that is not equal to the value of the column condition.
		skipRule	-	
		replace	new value	

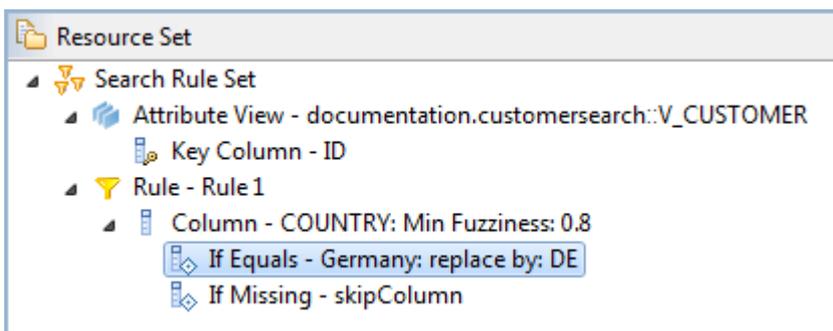

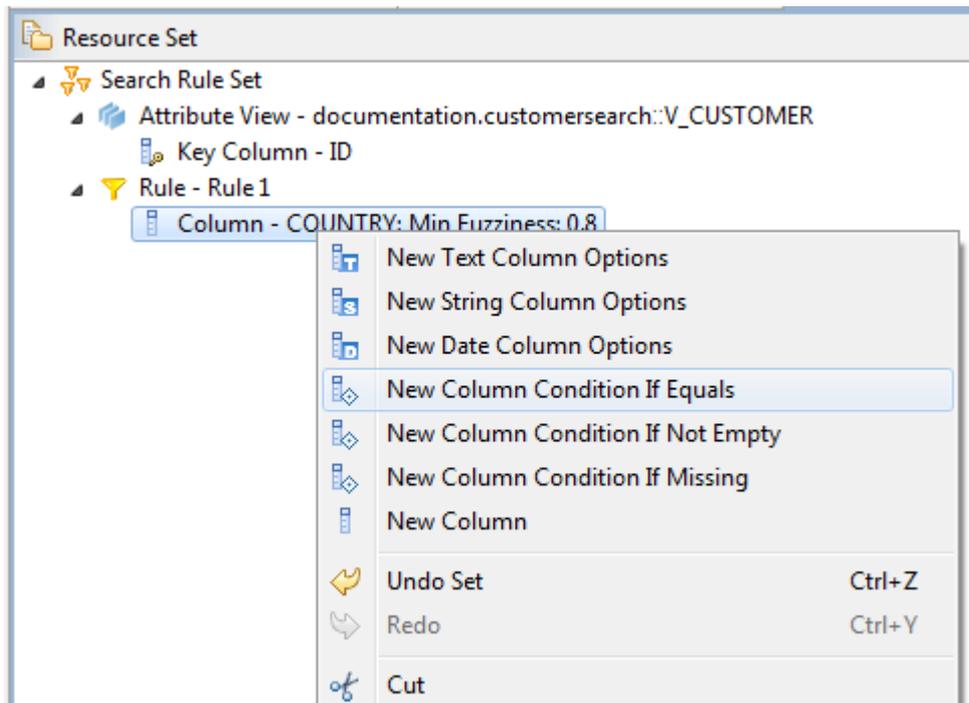

If the `if Equals` condition matches the value, the `if Not Empty` condition is also true. In this case, only the action for the `If Equals` condition will be performed.

The `If Equals` condition can be given more than once per column.

If no column condition is given, the behavior is as follows: Missing columns in a rule cause the rule to be skipped. Empty values will be requested as empty.

Configuring Column Conditions in the Search Rule Set Editor

1. Add a new column condition to your rule. Open the context menu on a column and choose a condition.

2. Set the properties for the column condition.
Example properties for a condition:

Property	Value
Action	skipColumn
Replace By	

Example properties for the If Equals condition:

Property	Value
Action	replace
Replace By	DE
Value	Germany

4.3.4.14.5.3 Non-Unique Keys: Using a View with an 'Anchor Table'

Sometimes, an application needs to search a view with one or more 1:n joins but is interested in the base objects (or 'anchor objects') only. For example, an application searches business partners and all of their addresses, but in the search result each business partner (the 'anchor object') should occur only once.

To get this behavior with search rule sets, only the columns of the primary key of the business partner are configured as key columns in the search rule set. Additional columns of the primary key (from the 1:n join) are not configured as key columns.

In addition, the property `nonUniqueKeys` of the `View` node in the Search Rule Set editor is set to `true`.

Note

If `nonUniqueKeys` is set to `false` a duplicate-keys error is returned in the following example.

Example

In this example, we assume that in the application a search for business partners (in this case companies) is done. Each business partner will be returned only once even if there are multiple addresses of the same business partner in the search result.

The business partner view contains the following two companies with three addresses in total. It is a 1:n join between a business partner table with primary key `Business Partner ID` and an address table with primary key `Address ID`.

The column **Business Partner ID** is configured as a key column in the search rule set. The **Address ID**, which is the second column of the view's primary key, is not configured as a key column in the search rule set. Therefore, the key in a search result may not be unique.

Business Partner ID	Company Name	Address ID	Street Name	House Number	Postcode	City Name	Country
1	Manufacturing Company	1	Norton Street	75	10016	New York	US
1	Manufacturing Company	2	Morton Street	74	10017	New York	US
2	Manufacturing Comp.	3	Norton Street	12	10020	New York	US

A search rule set with `nonUniqueKeys` set to `true` is called with the following search input:

Company Name	Street Name	City Name	Country
Manufacturing Company	Morton Street	New York	US

For the first business partner there are two rows found. The temporary internal search result ordered by score is shown below.

_Score	Business Partner ID	Company Name	Address ID	Street Name	House Number	Postcode	City Name	Country
1.0	1	Manufacturing Company	2	Morton Street	74	10017	New York	US
0.9	1	Manufacturing Company	1	Norton Street	75	10016	New York	US
0.8	2	Manufacturing Comp.	3	Norton Street	12	10020	New York	US

As the `nonUniqueKeys` parameter is set to `true`, only one of the rows with **Business Partner ID**=1 will be returned to the caller.

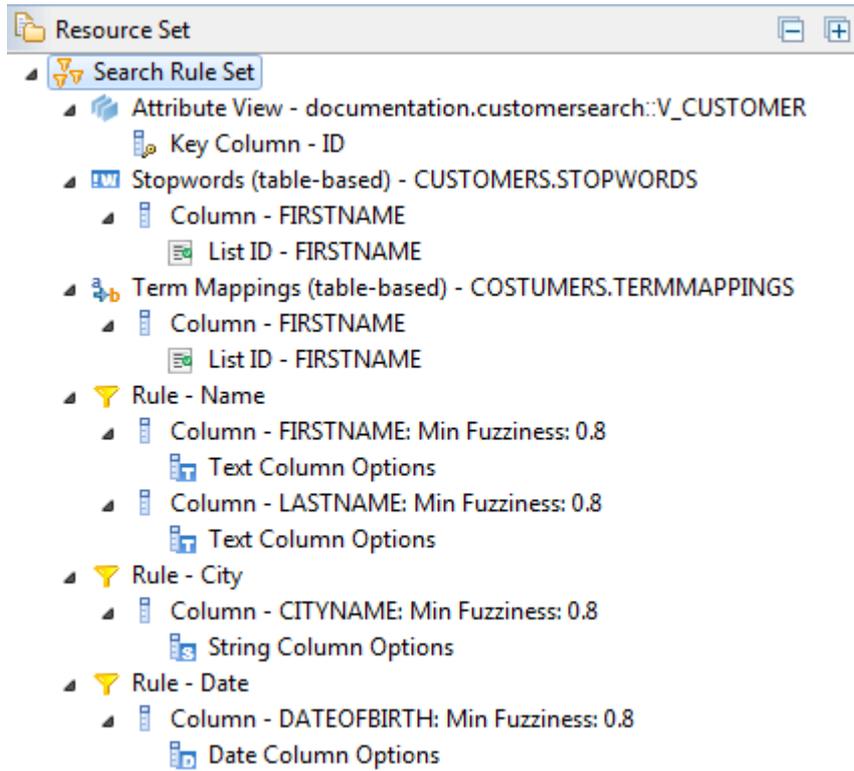

For each rule in the search rule set only the row with the highest score is selected. If needed, conflict resolution between rules would work as usual using the **Score Selection setting** (either `highestScore` or `firstRule`).

The final search result in this case is shown below:

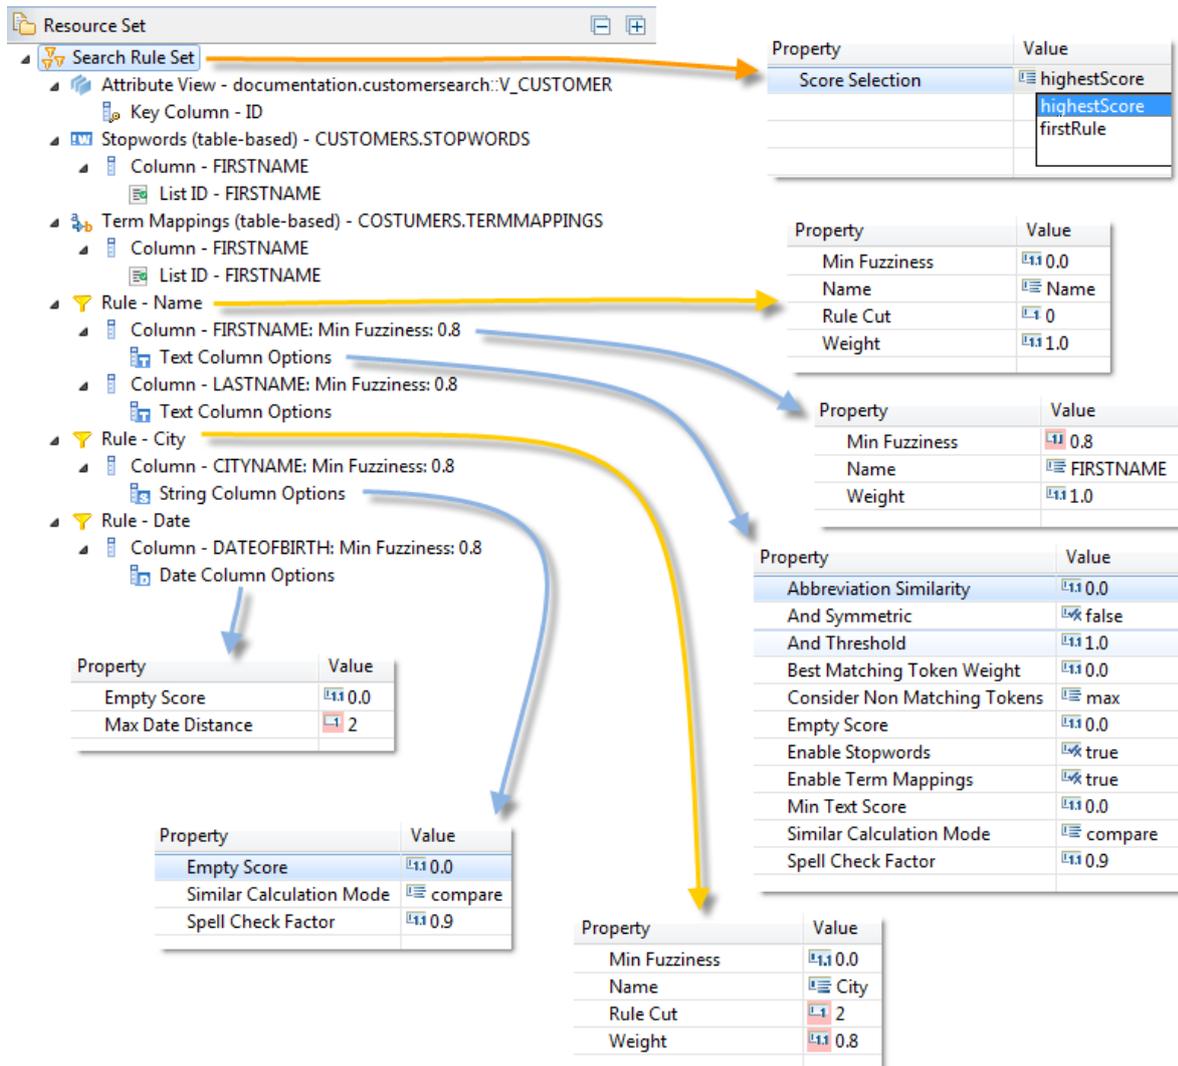

_Score	Business Partner ID	Company Name	Address ID	Street Name	House Number	Postcode	City Name	Country
1.0	1	Manufacturing Company	2	Morton Street	74	10017	New York	US
0.8	2	Manufacturing Comp.	3	Norton Street	12	10020	New York	US

4.3.4.14.5.4 Example Search Rule Set

Let us look at this example of a search rule set:

This rule set includes the following properties:

4.3.4.14.6 Executing a Search With a Rule Set

SAP HANA exports a new built-in function, `SYS.EXECUTE_SEARCH_RULE_SET`, that you can use to execute a previously-defined search rule set.

The function has one parameter, which is an XML string to run the search. In the XML, you have to specify the following:

- The ruleset to be executed
- How the result will be returned
- The limitation of the result
- The input values

By default, the `EXECUTE_SEARCH_RULE_SET` method returns a `ResultSet` object. This object contains all the columns from the referenced attribute view, plus the additional columns `_SCORE` and `_RULE_ID`. Alternatively, the `EXECUTE_SEARCH_RULE_SET` can write the result into a results table that needs to be created by the user.

Transaction Isolation Level

The `EXECUTE_SEARCH_RULE_SET` function creates one `SELECT` statement for each of the rules and runs the statements independently of each other. The statements are executed in the transaction context of the calling application, and use the same isolation level as the application. The isolation level influences the results of the `EXECUTE_SEARCH_RULE_SET` function if other transactions that change the contents of the database tables are running in parallel.

When the isolation level 'READ COMMITTED' is used, each of the `SELECT` statements of the search rule set sees all changes that had been committed when execution of the `SELECT` statement begins. The second rule of a rule set might see a new record that had not been committed when the first rule was executed, for example. In this case, the new record might be returned by the 'wrong' rule, and the user obtains an incorrect result.

If the isolation levels 'REPEATABLE READ' or 'SERIALIZABLE' are used, all `SELECT` statements see the same state of the database. The results returned by `EXECUTE_SEARCH_RULE_SET` are therefore always correct.

Available XML Tags and Parameters

XML Tag	Child of	Occurrence	Parameter	Description
query	none	1	limit	Defines the maximum number of rows that are returned
		1	offset	Defines the number of rows skipped
<div style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p><code>limit</code> and <code>offset</code> work in the same way as the SQL options <code>limit</code> and <code>offset</code></p> </div>				
ruleset	query	0..1	name	Name of the ruleset to be executed
resulttableschema	query	0..1	name	Schema name of the result table
resulttablename	query	1..n	name	Table name of the result table
batch	query	1	threads	Number of worker threads to run in parallel
			<div style="background-color: #f0f0f0; padding: 5px;"> <p>i Note</p> <p>If this parameter is not set, the default behaviour is to consume as much resources as possible. This is not recommended for production systems. It is recommended to reduce the number of threads to a meaningful amount.</p> </div>	
			scoretablename	Name of the table which contains the results (keys + scores) for each single request
			scoretableschema	Schema name of the score table

XML Tag	Child of	Occurence	Parameter	Description
			grouptablename	Name of the table which contains the final calculated match groups
			grouptablename eschema	Schema name of the group table
			errortablename	Name of the error table which stores the error message for each record which caused an error during processing
			errortablename eschema	Schema name of the error table
inputview	batch	1	name	Name of the input view
			schema	Schema name of the input view
			alias	Alias for the input view, used in score table to label/identify the requesting records source
			blocksize	Size of a processing block
			limit	Defines the maximum number of rows that are read and processed
keycolumn	inputview	1..n	name	Name of a key column in the input view
			alias	Alias which is used in score table column names (concatinated with inputview name/alias
mapcolumn	inputview	1..n	inputcolumn	Name of the column from the input view
			rulesetcolumn	Corresponding column name which is used in the rule set
column	query	0..n	name	Input column name
			null	null="true" indicates a NULL as a value

XML Tag	Child of	Occurrence	Parameter	Description
resultsetcolumn	query	0..n	name	Defines the column to be returned. Columns are returned in the order defined by these tags. If no resultsetcolumn is defined, all columns that are defined in the attribute view plus <code>_SCORE</code> and <code>_RULE_ID</code> are returned.
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>i Note</p> <p>This tag is not valid if you use a resulttable for the search result. In this case, the resulttable defines the structure of the result.</p> </div>				
constantcolumn	query	0..n	name	Defines an additional result column with a constant value.
scorecolumn	query	0..1	name	Overrides the name of the result score column, works for result set, as well as for result table. Default name: <code>_SCORE</code>
ruleidcolumn	query	0..1	name	Overrides the name of the result rule id column, works for result set, as well as for result table. Default name: <code>_RULE_ID</code>
rulenumcolumn	query	0..1	name	Overrides the name of the result rule number column, works for result set, as well as for result table. Default name: <code>_RULE_NUMBER</code>
sourceidcolumn	query	0..1	name	Overrides the name of the source id column, works only for batch score table. Default name: <code>_SOURCE_ID</code>
groupidcolumn	query	0..1	name	Overrides the name of the group id column, works only for batch output tables. Default name: <code>_GROUP_ID</code>
filter	query, inputview	0..1		SQL WHERE clause limiting the search to a subset of the view contents

Predefined Columns

Column	SQL Type	Description
<code>_SCORE</code>		The fuzzy score for each hit in the result. It can be used in combination with a resulttable and the resultset.
<code>_RULE_ID</code>		The name of the rule that provided this hit. It can be used in combination with a resulttable and the resultset.

Column	SQL Type	Description
<code>_RULE_NUMBER</code>		The number of the rule. The first rule is given <code>_RULE_NUMBER 1</code> .
		Note The <code>_RULE_NUMBER</code> column is only returned if the user specifies this. Can be used in combination with a resulttable and the resultset.
<code>_GROUP_ID</code>		The request number within the score table. This ties together the requesting record plus the matches from this request.
<code>_SOURCE_ID</code>		Identifies the source of the record, whether it comes from the input view (as a request) or from the search rule sets processing as a result.

XML Entities

Some characters have a special meaning in XML. When used as parameter values between XML tags, these characters should be replaced with character entities to avoid XML syntax errors.

Character	Entity	Description
"	"	double quotation mark
&	&	ampersand
'	'	apostrophe
<	<	less-than sign
>	>	greater-than sign

4.3.4.14.7 Code Examples: Searching with a Rule Set

This topic contains code examples for search rule sets.

Executing a Search and Returning the Result as a Result Set

```
CALL EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="apps.customer:Search.searchruleset" /> -- specifies the
SearchRuleSet
  <column name="FIRSTNAME">Herbert</column> -- specifies the input
value for column FIRSTNAME
  <column name="LASTNAME">Hofmann</column> -- specifies the input
value for column LASTNAME
</query>
');
```

Executing a Search and Passing a NULL Value

```
CALL EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="apps.customer:Search.searchruleset" /> -- specifies the
SearchRuleSet
  <column name="FIRSTNAME">Herbert</column> -- specifies the input
value for column FIRSTNAME
  <column name="LASTNAME" null="true"></column> -- specifies a NULL as
the input value for column LASTNAME
</query>
');
```

Executing a Search and Writing the Result to a Column Table Provided by the User

```
--First create the result table
set schema MY_SCHEMA;
CREATE COLUMN TABLE MY_RESULT_TABLE (
  _SCORE FLOAT,
  _RULE_ID VARCHAR(255),
  "FIRSTNAME" TEXT,
  "LASTNAME" TEXT
);
-- Afterwards you can execute the search using the created result table.
CALL EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="documentation.customersearch:Search.searchruleset" /> --
specifies the SearchRuleSet
  <resulttableschema name="MY_SCHEMA"/> -- specifies the schema of the
result table
```

```

<resulttablename name="MY_RESULT_TABLE"/> -- specifies the name of the
result table
  <column name="FIRSTNAME">Herbert</column> -- specifies the input value for
column FIRSTNAME
  <column name="LASTNAME">Hofmann</column> -- specifies the input value for
column LASTNAME
</query>
');
-- get the result
select * from MY_RESULT_TABLE;

```

Limiting the Number of Rows Returned by a Search

Note

When calling the system procedure `EXECUTE_SEARCH_RULE_SET`, the application can define the maximum number of rows that are returned by setting a `limit` parameter.

In the default setting, this parameter is undefined, meaning that an unlimited number of rows is returned. The limitation takes place after each rule and at the end, when all rules are performed. In the following example, a maximum number of 100 rows will be returned.

```

-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
<query limit="10" offset="100">
  <ruleset name="documentation.customersearch:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
</query>
');

```

You can use this parameter with the result set object and with the custom result table.

Getting a Paged Result List by Using the Parameter Offset

When calling the system procedure `EXECUTE_SEARCH_RULE_SET`, the application can return a paged result list by using the parameters `limit` and `offset`.

- `limit` defines the number of rows returned
- `offset` defines the number of rows skipped

The following example returns a result list starting from row number 101 and ending with row number 110:

```

-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
<query limit="10" offset="100">
  <ruleset name="documentation.customersearch:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
</query>
');

```

The parameter `offset` is only allowed together with the parameter `limit`.

Getting a User-Defined Result Set

When calling the system procedure `EXECUTE_SEARCH_RULE_SET`, the application can return a user-defined result set instead of all columns defined in the attribute view.

```
-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
<query limit="10" offset="100">
  <ruleset name="documentation.customersearch:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
  <resultsetcolumn name="_SCORE" />
  <resultsetcolumn name="_RULE_ID" />
  <resultsetcolumn name="_RULE_NUMBER" />
  <resultsetcolumn name="FIRSTNAME" />
  <resultsetcolumn name="LASTNAME" />
</query>
');
```

In this case, the application returns a result set with the columns `_SCORE`, `_RULE_ID`, `_RULE_NUMBER`, `FIRSTNAME`, and `LASTNAME`.

Using Custom Names for Predefined Columns

When calling the system procedure `EXECUTE_SEARCH_RULE_SET`, the application can return custom names for internal columns `_SCORE`, `_RULE_ID`, `_RULE_NUMBER`.

```
-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
<query limit="10" offset="100">
  <ruleset name="documentation.customersearch:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
  <scorecolumn name="score" />
  <ruleidcolumn name="ruleid" />
  <rulenumcolumn name="rulenum" />
  <resultsetcolumn name="score" />
  <resultsetcolumn name="ruleid" />
  <resultsetcolumn name="rulenum" />
  <resultsetcolumn name="FIRSTNAME" />
  <resultsetcolumn name="LASTNAME" />
</query>
');
```

In this case the application returns a resultset with the columns `_SCORE`, `_RULE_ID`, `_RULE_NUMBER`, `FIRSTNAME` and `LASTNAME`.

Adding Columns with a Constant Value to the Result Set

When calling the system procedure `EXECUTE_SEARCH_RULE_SET`, the application can return a result set with additional columns, defined in the call of the procedure.

```
-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
  <query limit="10" offset="100">
    <ruleset name="documentation.customersearch:Search.searchruleset" />
    <column name="FIRSTNAME">billy</column>
    <column name="LASTNAME">smith</column>
    <constantcolumn name="USER_NAME">Max</constantcolumn>
    <constantcolumn name="USER_ID">42</constantcolumn>
  </query>
');
```

In this case, the application returns a result set with the columns `_SCORE`, `_RULE_ID`, all the view columns, plus `USER_NAME`, and `USER_ID`. The last two columns have the values "Max" and "42", respectively, for all result rows.

This feature is also available for the result table. The additional columns have to be created in the result table with any SQL type. The columns have to be defined in the call to `EXECUTE_SEARCH_RULE_SET` as shown in the example above.

Example

```
--First create the result table
set schema MY_SCHEMA;
CREATE COLUMN_TABLE MY_RESULT_TABLE (
  "_SCORE" FLOAT,
  "_RULE_ID" VARCHAR(255),
  "FIRSTNAME" TEXT,
  "LASTNAME" TEXT,
  "USER_NAME" NVARCHAR(100),
  "USER_ID" INTEGER
);
-- Afterwards you can execute the search using the created result table.
CALL EXECUTE_SEARCH_RULE_SET('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />      -- specifies the
SearchRuleSet
  <resultsetschema name="MY_SCHEMA"/>      -- specifies the schema of the
result table
  <resulttablename name="MY_RESULT_TABLE"/>  -- specifies the name of the
result table
  <column name="FIRSTNAME">Herbert</column>  -- specifies the input value for
column FIRSTNAME
  <column name="LASTNAME">Hofmann</column>  -- specifies the input value for
column LASTNAME
  <constantcolumn name="USER_NAME">Max</constantcolumn>
  <constantcolumn name="USER_ID">42</constantcolumn>
</query>
');
```

This feature is also available in conjunction with `<resultsetcolumn>`. You need to define the constant columns as `resultsetcolumns` to specify the order. You also need to define the constant columns as shown above to specify the constant values.

```
-- run the search
```

```
CALL EXECUTE_SEARCH_RULE_SET('
<query limit="10" offset="100">
  <ruleset name="documentation.customersearch:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
  <resultsetcolumn name="USER_ID" />
  <resultsetcolumn name="_SCORE" />
  <resultsetcolumn name="_RULE_ID" />
  <resultsetcolumn name="_USER_NAME" />
  <resultsetcolumn name="FIRSTNAME" />
  <resultsetcolumn name="LASTNAME" />
  <constantcolumn name="USER_NAME">Max</constantcolumn>
  <constantcolumn name="USER_ID">42</constantcolumn>
</query>
');
```

Limiting the Search to a Subset of the View Contents

```
-- run the search
CALL EXECUTE_SEARCH_RULE_SET('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
  <resultsetcolumn name="_SCORE" />
  <resultsetcolumn name="_RULE_ID" />
  <resultsetcolumn name="_RULE_NUMBER" />
  <resultsetcolumn name="FIRSTNAME" />
  <resultsetcolumn name="LASTNAME" />
  <filter>"ORDER_DATE" BETWEEN '2012-09-01' AND '2012-12-31'</filter>
</query>
');
```

This filter limits the search to documents with an `ORDER_DATE` in the specified range. The filter condition is evaluated in every rule, before evaluating the rule cut option and the query parameters `limit` and `offset`.

The filter condition must be a valid SQL WHERE clause with some extra rules:

- Comparative operators are allowed, for example: `=`, `<`, `<=`, `>`, `>=`
- Only a limited set of SQL keywords is allowed: NOT, AND, OR, BETWEEN, IN, LIKE, ESCAPE, IS, NULL, UPPER, LOWER, SUBSTRING
- The `CONTAINS()` function is not allowed, since this would affect the `score()` that is returned
- Only columns defined in the attribute view are allowed
- All column identifiers must be enclosed in double quotes ("")
- All string values must be enclosed in a pair of two single quotes ("')

```
<filter>"CITY_NAME" = ''Walldorf''</filter>
```

Searching Views with a Client Column

The filter condition described above can be used to search views that have been created by SAP business applications. Usually these applications define tables and views with a client column. This column is, for

example, called `MNDT`, `CLNT`, or `CLIENT`. Limit search results to rows belonging to the same client as the current user. This can be done by adding an appropriate filter condition to the call to `EXECUTE_SEARCH_RULE_SET`, as shown in the following example.

```
-- run the search
CALL EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />
  <column name="FIRSTNAME">billy</column>
  <column name="LASTNAME">smith</column>
  <filter>"MNDT" = '100'</filter>
</query>
');
```

4.3.4.14.8 Tutorial: Create and Use Search Rules

This tutorial documentation describes the development of an application that uses the search rule sets to search on a table containing a company's customers.

Prerequisites

As a developer who wants to create search rule sets, you are familiar with the SAP HANA development environment.

The development tools for search rule sets are part of the development environment for native SAP HANA applications. Nevertheless, search rule sets can be used in all types of SAP HANA applications.

The Scenario

This tutorial documentation describes the development of an application that uses the search rule sets to search on a table containing a company's customers. The data model used for this tutorial is very simple. Let us assume that all customers are people, so no company information can be stored in the table.

Users and Roles

When building an application based on SAP HANA, different database users are created for modeling content and for running the application. Privileges have to be granted to give each user a minimum set of access rights needed to perform tasks corresponding to his or her role.

The scenario in this documentation uses the following database users:

- The data stored in the column tables is owned by the first user called `TABLEOWNER`.
- Attribute views and search rules are modeled by a second user called `MODELOWNER`.

- Finally, the application runs with a third user called `APPOWNER`.

Instead of granting privileges to users directly, you can use roles.

4.3.4.14.8.1 Creating the Application Package

Context

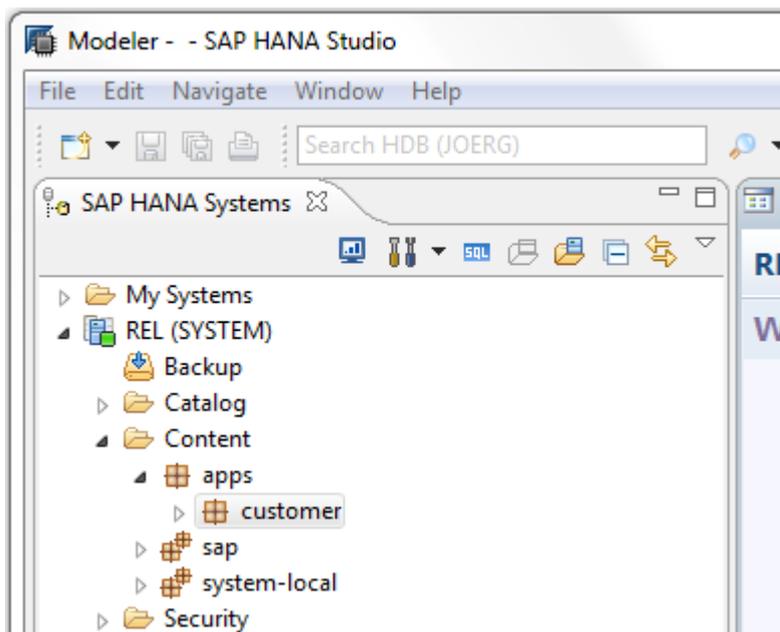

In our example, the database content (the attribute view and the search rule set) will be stored in a package called "apps.customer".

Procedure

In the SAP HANA studio, create a new package named `customer`.

You can create the package in the SAP HANA Systems view of the SAP HANA studio (either in the Modeler perspective or in the SAP HANA Development perspective).

Use the SYSTEM user or any other user with sufficient privileges.

4.3.4.14.8.2 Creating the Users

You have to create three users and assign a set of privileges to them. The users are created by the administration user SYSTEM or by any other user with sufficient privileges.

Procedure

1. Create the TABLEOWNER

The TABLEOWNER is created and gets the privileges to create a new database schema that will contain all tables of the new application.

```
CREATE USER tableowner PASSWORD "Password1234";
ALTER USER tableowner FORCE PASSWORD CHANGE;

-- privilege needed to create the application schema
GRANT CREATE SCHEMA TO tableowner;
```

2. Create the MODELOWNER

The MODELOWNER is created and gets the privileges required to create objects in the repository package "apps.customer", to activate search rule sets and attribute views and to execute the search rule sets.

i Note

Working with Attribute Views: In the example a standard SQL view is created and used to execute the search rule sets. Alternatively, attribute views can be used. In this case, some additional privileges granted to MODELOWNER are needed.

For SAP HANA revisions with a fuzzy search API version lesser than 20303, execute privileges on SYS.EXECUTE_SEARCH_RULE_SET are needed for database user MODELOWNER.

≡ Sample Code

```
-- privileges needed to run the search rules
GRANT EXECUTE ON sys.execute_search_rule_set TO modelowner;
```

Beginning with API version 20303 this privilege is part of the database role PUBLIC. Therefore users do not need any additional privileges to execute search rule sets.

```
CREATE USER modelowner PASSWORD "Password1234";
ALTER USER modelowner FORCE PASSWORD CHANGE;

-- Allow repository access from SAP HANA studio
GRANT EXECUTE ON _sys_repo.repository_rest TO modelowner;

-- Privileges needed to access the application package in the HANA repository
-- read access to packages and design-time objects (native and imported
objects)
GRANT REPO.READ ON "apps.customer" TO modelowner;
-- all kinds of inactive changes to design-time objects in native packages
GRANT REPO.EDIT_NATIVE_OBJECTS ON "apps.customer" TO modelowner;
-- activate / reactivate design-time objects in native packages
```

```

GRANT REPO.ACTIVATE_NATIVE_OBJECTS ON "apps.customer" TO modelowner;
-- create, update or delete native packages, or create subpackages of native
packages
GRANT REPO.MAINTAIN_NATIVE_PACKAGES ON "apps.customer" TO modelowner;

-- permission go grant and revoke privileges on activated content (like, for
example, attribute views)
GRANT EXECUTE ON GRANT_PRIVILEGE_ON_ACTIVATED_CONTENT TO modelowner;
GRANT EXECUTE ON REVOKE_PRIVILEGE_ON_ACTIVATED_CONTENT TO modelowner;

-- A user needs an analytical privilege to access activated attribute views.
--
-- The predefined privilege _SYS_BI_CP_ALL gives access to all activated
content.
-- Create your own analytical privilege if a limited access to activated
content is needed.
CALL _SYS_REPO.GRANT_ACTIVATED_ANALYTICAL_PRIVILEGE('_SYS_BI_CP_ALL',
'MODELOWNER');

```

If you do not want to assign a large number of privileges to each modeling user, you can create a new role containing all required privileges and assign this role to the users. This is the preferred option, but alternatively you can also use the predefined `MODELING` or `CONTENT_ADMIN` roles to grant the privileges.

3. Create the `APPOWNER`

The `APPOWNER` is created and gets the privileges needed to query attribute views.

```

CREATE USER appowner PASSWORD "Password1234";
ALTER USER appowner FORCE PASSWORD CHANGE;

-- A user needs an analytical privilege to access activated attribute views.
CALL _SYS_REPO.GRANT_ACTIVATED_ANALYTICAL_PRIVILEGE('_SYS_BI_CP_ALL',
'APPOWNER');

```

i Note

For SAP HANA revisions with a fuzzy search version lesser than 20303, execute privileges on `SYS.EXECUTE_SEARCH_RULE_SET` are needed for database user `APPOWNER`.

⇐, Sample Code

```

-- privileges needed to run the search rules
GRANT EXECUTE ON sys.execute_search_rule_set TO appowner;

```

Beginning with API version 20303 this privilege is part of the database role `PUBLIC`. Therefore users do not need any additional privileges to execute search rule sets.

4.3.4.14.8.3 Creating the Database Schema and Tables

Context

You have to create a new database schema called 'CUSTOMERS' to store the database tables.

Then, you create the table 'CUSTOMER' in the new schema to store information about customers such as name, address, phone number, and date of birth. The example uses a simple table definition only, but more complex table definitions including 1:n relationships between names and addresses are possible.

The schema and table are created by the user TABLEOWNER.

Procedure

Creating the Database Schema and Tables

```

CREATE SCHEMA customers;
SET SCHEMA customers;
-- create sample table
CREATE COLUMN TABLE customer
(
  id                INTEGER                PRIMARY KEY,
  firstname         SHORTTEXT(100)        FUZZY SEARCH INDEX ON,
  lastname          SHORTTEXT(100)        FUZZY SEARCH INDEX ON,
  streetname        NVARCHAR(100)         FUZZY SEARCH INDEX ON,
  housenumber       NVARCHAR(20)          FUZZY SEARCH MODE
'houenumber',
  postcode          NVARCHAR(20)          FUZZY SEARCH INDEX ON FUZZY SEARCH MODE
'postcode',
  cityname          NVARCHAR(100)         FUZZY SEARCH INDEX ON,
  countrycode       NVARCHAR(2),
  phone             NVARCHAR(20),
  dateofbirth       DATE
);
-- needed to model an attribute view on top of the table
GRANT SELECT ON customer TO modelowner;
-- needed to allow activation of attribute views that use this table
GRANT SELECT ON customer TO _sys_repo WITH GRANT OPTION;
-- for better performance, database indexes should be created
-- on all NVARCHAR columns that are used in the search rules
-- example:
CREATE INDEX customer_cityname ON customer(cityname);
-- insert a sample record:
INSERT INTO customer VALUES(1, 'Billy', 'Smith', 'Summerset Drv', '1001',
'123456789', 'Littleton', 'US', '555-1234', '1950-12-01');
-- to be able to use stopwords a stopword table is needed:
CREATE COLUMN TABLE stopwords
(
  stopword_id      VARCHAR(32)           PRIMARY KEY,
  list_id          VARCHAR(32)           NOT NULL,
  language_code    VARCHAR(2),
  term             NVARCHAR(200)        NOT NULL
);
GRANT SELECT ON stopwords TO _sys_repo WITH GRANT OPTION;
INSERT INTO stopwords VALUES('1', 'firstname', '', 'Dr');
-- and for term mappings another table:
CREATE COLUMN TABLE termmappings
(
  mapping_id       VARCHAR(32)           PRIMARY KEY,
  list_id          VARCHAR(32)           NOT NULL,
  language_code    VARCHAR(2),
  term_1           NVARCHAR(255)        NOT NULL,
  term_2           NVARCHAR(255)        NOT NULL,
  weight           DECIMAL              NOT NULL
);
GRANT SELECT ON termmappings TO _sys_repo WITH GRANT OPTION;
INSERT INTO termmappings VALUES('1', 'firstname', '', 'William', 'Will',
'1.0');

```

```

INSERT INTO termappings VALUES('2', 'firstname', '', 'William', 'Bill',
'0.9');
INSERT INTO termappings VALUES('3', 'firstname', '', 'William', 'Billy',
'0.9');
INSERT INTO termappings VALUES('7', 'firstname', '', 'Will', 'William',
'1.0');
INSERT INTO termappings VALUES('8', 'firstname', '', 'Will', 'Bill',
'0.9');
INSERT INTO termappings VALUES('9', 'firstname', '', 'Will', 'Billy',
'0.9');
INSERT INTO termappings VALUES('4', 'firstname', '', 'Bill', 'William',
'0.9');
INSERT INTO termappings VALUES('5', 'firstname', '', 'Bill', 'Will',
'0.9');
INSERT INTO termappings VALUES('6', 'firstname', '', 'Bill', 'Billy',
'1.0');

```

4.3.4.14.8.4 Defining the Attribute View

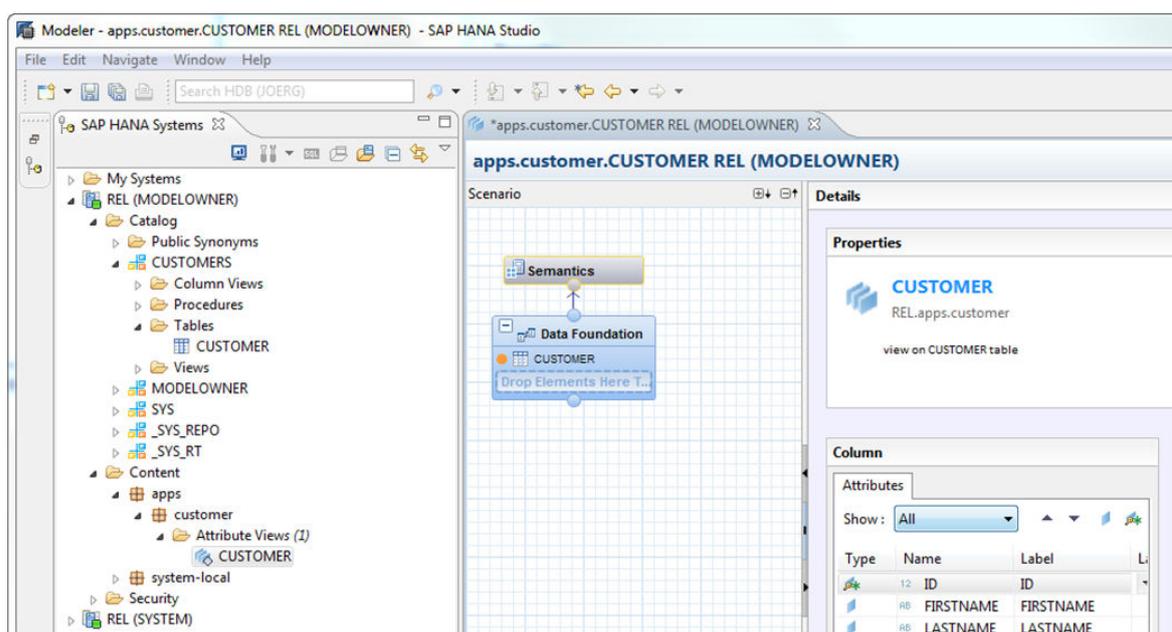

As the user MODELOWNER, you create the attribute view that is used for the search.

Context

The attribute view is created in the SAP HANA Systems view that is part of the SAP HANA studio (either in the Modeler perspective or in the SAP HANA Development perspective).

Procedure

1. In the package 'apps.customer', create a new attribute view called CUSTOMER (containing all columns from table CUSTOMERS.CUSTOMER).
2. Save and activate the attribute view.

A SELECT privilege is required for a user to see the contents of the activated attribute view.

```
-- allow users MODELOWNER and APPOWNER to see the contents of the attribute
view
CALL GRANT PRIVILEGE ON ACTIVATED_CONTENT('SELECT',
"apps.customer::CUSTOMER", 'MODELOWNER');
CALL GRANT PRIVILEGE ON ACTIVATED_CONTENT('SELECT',
"apps.customer::CUSTOMER", 'APPOWNER');
```

The contents of the view are now visible to users MODELOWNER and APPOWNER.

```
-- test the view
SELECT * FROM "apps.customer::CUSTOMER";
```

4.3.4.14.8.5 Creating the Search Rule Set

Read about the steps needed to define a search rule set and to run the final application.

Procedure

1. Preparing the Development Environment

The SAP HANA studio is used to create, modify, and activate search rule sets.

Before creating your first search rule set, you have to set up a native SAP HANA Development project in the SAP HANA studio:

1. Open the SAP HANA Development perspective.
2. Create a new repository workspace in the SAP HANA Repositories view.
Use the database connection of user MODELOWNER for the repository workspace.
3. Create a new project called 'project' in package 'apps.customer'.
 - Select 'General/Project' for a project that contains search rule sets only.
 - Select 'SAP HANA Development/XS Project' for native SAP HANA projects.
 - Use 'Team/Share Project' to move the project to the repository package 'apps.customer'.

2. Defining the Search Rule Set

The next step for user MODELOWNER is to define the search rule set that will be used by the application. This is done in the Project Explorer view in the SAP HANA studio.

The steps to define the search rule set are as follows:

1. In your project, create a new search rule set 'Search.searchruleset'.
The search rule set is created in the package 'apps.customer.project'.
2. Edit the search rule set.
 - Define view "apps.customer::CUSTOMER" as the view that will be searched.
 - Define at least one rule (for example, use columns FIRSTNAME and LASTNAME in the rule).
3. Save the search rule set.
4. Commit and activate your changes.

Now you can call the search in the SAP HANA studio:

```
-- run the search
CALL SYS.EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />
  <column name="FIRSTNAME">Dr. bill</column>
  <column name="LASTNAME">smiths</column>
  <column name="CITYNAME">littleton</column>
  <column name="DATEOFBIRTH">1950-12-02</column></query>
');
```

3. Running the Application

The application user (APPOWNER) can now build an application that uses the attribute view and the search rules defined previously.

In the application, you can call the following statements:

```
-- show contents of attribute view
SELECT * FROM "apps.customer::CUSTOMER";
-- run the search
CALL SYS.EXECUTE_SEARCH_RULE_SET ('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />
  <column name="FIRSTNAME">Dr. bill</column>
  <column name="LASTNAME">smiths</column>
  <column name="CITYNAME">littleton</column>
  <column name="DATEOFBIRTH">1950-12-02</column></query>
');
```

4.3.4.14.9 Information Views

Applications can query information about search rule sets to allow their UI to be aligned with the current configuration.

The following views provide the information needed by the search applications:

- `SYS.SEARCH_RULE_SETS`
- `SYS.SEARCH_RULE_SET_CONDITIONS`

SYS.SEARCH_RULE_SETS

Applications need to know which search rule sets are defined for a given database object. Example: When a database object is searched, the user can select from a list of available search rule sets valid for the database object.

The database objects used by the search rule sets can be either catalog objects like 'normal' SQL views, column tables or column views created using SQL, or design time objects like attribute views or column tables that are activated using the SAP HANA repository.

Catalog objects are referenced as `SEARCHED_SCHEMA_NAME` and `SEARCHED_OBJECT_NAME` in the view.

For design time objects, developers do not need to know the name of the resulting catalog object and it the search rule set the name of the design time object is used. Design time objects therefore are referenced as SEARCHED_REPOSITORY_PACKAGE_ID and SEARCHED_REPOSITORY_OBJECT_NAME.

When a search rule set is activated, no catalog objects are created. All information is written to the _SYS_REPO.SEARCH_RULE_SETS. table The search rule set can therefore be referenced as a design time object only.

Column	Type	Description
SEARCH_RULE_SET_PACKAGE_ID	NVARCHAR(256)	The name of the repository package of the search rule set.
SEARCH_RULE_SET_NAME	NVARCHAR(256)	The name of the search rule set.
SEARCHED_SCHEMA_NAME*	NVARCHAR(256)	The schema of the catalog object that is searched by the given search rule set.
SEARCHED_OBJECT_NAME*	NVARCHAR(256)	The name of the catalog object that is searched by the given search rule set.
SEARCHED_REPOSITORY_PACKAGE_ID *	NVARCHAR(256)	The name of the repository package of the repository object that is searched by the given search rule set.
SEARCHED_REPOSITORY_OBJECT_NAME*	NVARCHAR(256)	The name of the repository object that is searched by the given search rule set.

*: Either SEARCHED_SCHEMA_NAME and SEARCHED_OBJECT_NAME or SEARCHED_REPOSITORY_PACKAGE_ID and SEARCHED_REPOSITORY_OBJECT_NAME are given.

SYS.SEARCH_RULE_SET_CONDITIONS

Applications need to know which columns are accepted by a search rule set as input columns. This information is used to align the UI with the search rule set (for example by hiding columns that are part of the view that is searched, but are not used by the search rule set).

A rule in a search rule set contains conditions that define if a rule is executed or not. A rule may be skipped if a column is empty for example.

An application can use the definition of column conditions to inform the user of the minimal input, so that at least one rule is executed.

Column	Type	Description
SEARCH_RULE_SET_PACKAGE_ID	NVARCHAR(256)	The name of the repository package of the search rule set.
SEARCH_RULE_SET_NAME	NVARCHAR(256)	The name of the search rule set.
RULE_NUMBER	INTEGER	The number of the rule that contains the column.
RULE_ID	NVARCHAR(256)	The ID of the rule that contains the column.

Column	Type	Description
SEARCHED_COLUMN_NAME	NVARCHAR(256)	The name of a column that is used by a search rule set (a 'searchable column').
SEARCHED_COLUMN_CONDITION	NVARCHAR(20)	The condition. Possible values are 'EQUALS', 'NOT EMPTY', 'MISSING'.
SEARCHED_COLUMN_VALUE	NVARCHAR(5000)	The value to compare if condition is 'EQUALS'.
ACTION	NVARCHAR(20)	The action that is performed if the condition is true. Possible values are 'SKIP COLUMN', 'SKIP RULE', 'REPLACE'.

4.3.4.14.10 Search Rule Sets in Batch Mode

The batch mode is introduced to provide the possibility to do mass data processing with a high degree of parallelization.

The batch mode can be used with dynamic search rule sets as well. The data to be searched with, is not provided within the runtime XML itself, but via a table or view that gets iterated and search requests are processed for each row of this input view. The output is as well provided in two tables.

The score table stores each requesting record from the input view, along with all matches identified, within one request group. The group table is meant to calculate final match groups out of the request groups as the request groups likely store the same record in different match groups, but for reviewing purpose such groups should be molten together according to business needs.

The score table is based on the structure of the result table, in addition it consists of the predefined columns `_GROUP_ID` and `_SOURCE_ID` along with all keys from the search rule set definition and all keys from the input view. The column names for input view keys are concatenated of the input view alias + `"_"` + the key column name, in the example below `"INPUT_ID"`.

The batch mode is used with the definition of `<batch>` tag. Instead of a list of `<column>` as in transaction use case, the input is provided through the definition of an `<inputview>`.

Sample Code

```
-- run a search rule set in batch mode
CALL EXECUTE_SEARCH_RULE_SET('
<query>
  <ruleset name="apps.customer:Search.searchruleset" />
  <batch scoretableschema="MY_SCHEMA" scoretablename="MY_SCORE_TABLE"
  grouptableschema="MY_SCHEMA"
  grouptablename="MY_GROUP_TABLE" errortableschema="MY_SCHEMA"
  errortablename="MY_ERROR_TABLE" threads="20">
    <inputview schema="MY_SCHEMA" name="V_INPUT_DATA" alias="INPUT"
    blocksize="3000" limit="1000000">
      <keycolumn name="ID" alias="ID"/>
      <mapcolumn inputcolumn="FIRSTNAME" rulesetcolumn="FIRSTNAME"/>
      <mapcolumn inputcolumn="LASTNAME" rulesetcolumn="LASTNAME"/>
      <mapcolumn inputcolumn="CITY" rulesetcolumn="CITY"/>
      <mapcolumn inputcolumn="STREET" rulesetcolumn="STREET"/>
      <mapcolumn inputcolumn="BIRTHDATE" rulesetcolumn="BIRTHDATE"/>
    >
  </inputview>
```

```
</batch>
</query>
');
```

Handling of NULL values

In opposite to the single request XML call with `<COLUMN>` tags, in batch processing it is possible to read `NULL` values from the input table. When `NULL` values are read from the input table, they are handled by the `ifMissing` condition in the search rule set as if the whole `<COLUMN>` tag for this column is not provided in a single request.

Score Table

The score table, similar to the result table, is used to store the results of each request within a batch run. The structure of the score table is derived from the runtime XML and must match the expected structure. The score table expects the four predefined columns, `_SCORE`, `_RULE_ID`, `_GROUP_ID`, `_SOURCE_ID` plus all keycolumns defined in the search rule set plus all keycolumns defined in the input view. The input view keycolumn column names are the concatenated values of the input view alias plus a `"_"` plus the keycolumn alias.

The runtime XML example above expects a score table structure as following:

Column	Type
<code>_SCORE</code>	DOUBLE
<code>_RULE_ID</code>	VARCHAR
<code>_GROUP_ID</code>	VARCHAR
<code>_SOURCE_ID</code>	VARCHAR
<code>ID</code>	type of the IDs in the rule set
<code>INPUT_ID</code>	type of the keys defined in the input table

The names of these columns can be overwritten, the lengths of the `VARCHAR` fields must reflect the expected content.

Group Table

The group table provides final calculated match groups, where, different to the score table, each record is only part of one group.

Column	Type
_GROUP_ID	VARCHAR
_SOURCE_ID	VARCHAR
ID	type of the IDs in the rule set
INPUT_ID	type of the keys defined in the input table

Error Table

The error table provides error messages for each record which caused an error during processing.

Column	Type
ID	type of the keys defined in the input table
ERR_MSG	VARCHAR

4.3.4.14.11 Dynamic Search Rule Sets

With this feature you can use the functionality of search rule sets without having the need to first activate the search rule set via the SAP HANA repository or SAP HANA HDI. Within the XML-Tag `<ruleset>` you can store a complete rule set definition.

The name attribute of `<ruleset>` must be left out, the optional attribute `scoreSelection` can be set.

Sample Code

```
CALL EXECUTE_SEARCH_RULE_SET('
<query>

  <ruleset scoreSelection="firstRule">
    <attributeView name="APP.CUSTOMER">
      <keyColumn name="ID"/>
    </attributeView>
    <termMappingsTableBased schema="APP" table="TERMMAPPINGS">
      <column name="FIRSTNAME">
        <list id="firstname"/>
      </column>
      <column name="LASTNAME">
        <list id="lastname"/>
      </column>
    </termMappingsTableBased>
    <stopwordsTableBased schema="APP" table="STOPWORDS">
      <column name="COMPANYNAME">
        <list id="company"/>
      </column>
    </stopwordsTableBased>
  </ruleset>
</query>
')
```

```

<rule name="Rule 1">
  <column minFuzziness="0.8" name="FIRSTNAME">
    <ifMissing action="skipColumn"/>
  </column>
  <column minFuzziness="0.8" name="LASTNAME">
    <ifMissing action="skipColumn"/>
  </column>
  <column minFuzziness="0.8" name="COMPANYNAME">
    <textColumnOptions />
    <ifMissing action="skipColumn"/>
  </column>
</rule>
</ruleset>
<column name="FIRSTNAME">billy</column>
<column name="LASTNAME">smith</column>
</query>
');

```

4.3.4.15 Support Information

This section contains information on monitoring views, traces, and sizing.

4.3.4.15.1 Monitoring Views

This topic lists the monitoring views related to fuzzy search and fuzzy search indexes.

Checking the memory usage of all fuzzy search indexes with M_FUZZY_SEARCH_INDEXES

The M_FUZZY_SEARCH_INDEXES view shows the memory usage of all fuzzy search indexes. A fuzzy search index has no name and is described by its schema name, table name and column name.

The view shows all columns with a fuzzy search index in a table regardless of whether or not it is loaded.

Shadow columns (SHORTTEXT, FULLTEXT INDEX) are also shown in the view.

The view has the following columns:

View Column	SQL Data Type	Dimension	Default	Comment
HOST	VARCHAR	64		Host name
PORT	INTEGER			Internal port
SCHEMA_NAME	NVARCHAR	256		Schema name
TABLE_NAME	NVARCHAR	256		Table name
COLUMN_NAME	NVARCHAR	256		Column name
PART_ID	INTEGER			Partition ID; 0 for non-partitioned tables; 1 through n for the partitions
FUZZY_SEARCH_MODE	VARCHAR	16		'default' or 'postcode'/'house number' (same as in SYS.Columns view)
MEM-ORY_SIZE_IN_TOTAL	BIGINT			Sum of MEM-ORY_SIZE_IN_MAIN and MEM-ORY_SIZE_IN_DELTA
MEM-ORY_SIZE_IN_MAIN	BIGINT			Current memory consumption of the fuzzy search index of the column in main index
MEM-ORY_SIZE_IN_DELTA	BIGINT			Current memory consumption of the fuzzy search index of the column in delta index
LOADED	VARCHAR	5		'TRUE' or 'FALSE'. Flag to indicate that the fuzzy search index of the column is loaded

Example: Memory usage in delta index

```

ID INT PRIMARY KEY,
HNR VARCHAR(255));
INSERT INTO FUZZY_HOUSENUMBERS VALUES ('1','10');
INSERT INTO FUZZY_HOUSENUMBERS VALUES ('2','10-12');
INSERT INTO FUZZY_HOUSENUMBERS VALUES ('3','10a');
INSERT INTO FUZZY_HOUSENUMBERS VALUES ('4','10b');
ALTER TABLE FUZZY_HOUSENUMBERS ALTER (hnr nvarchar(255) FUZZY SEARCH INDEX ON);
SELECT to_int(score() * 100) AS s, id, hnr FROM FUZZY_HOUSENUMBERS WHERE
contains((hnr), '10a', FUZZY(0.8)) ORDER BY s DESC,id;
SELECT * FROM SYS.M_FUZZY_SEARCH_INDEXES WHERE TABLE_NAME = 'FUZZY_HOUSENUMBERS';

```

The result:

Column	Value
HOST	YOUR HOST

Column	Value
PORT	YOUR PORT
SCHEMA_NAME	SYSTEM
TABLE_NAME	FUZZY_HOUSENUMBERS
COLUMN_NAME	HNR
PART_ID	0
FUZZY_SEARCH_MODE	DEFAULT
MEMORY_SIZE_IN_TOTAL	2752
MEMORY_SIZE_IN_MAIN	0
MEMORY_SIZE_IN_DELTA	2752
LOAD	TRUE

Memory usage in main index:

```
MERGE DELTA OF FUZZY_HOUSENUMBERS;
SELECT * FROM SYS.M_FUZZY_SEARCH_INDEXES WHERE SCHEMA_NAME = 'SYSTEM' AND
TABLE_NAME = 'FUZZY_HOUSENUMBERS';
```

The result:

Column	Value
HOST	YOUR HOST
PORT	YOUR PORT
SCHEMA_NAME	SYSTEM
TABLE_NAME	FUZZY_HOUSENUMBERS
COLUMN_NAME	HNR
PART_ID	0
FUZZY_SEARCH_MODE	DEFAULT
MEMORY_SIZE_IN_TOTAL	2704
MEMORY_SIZE_IN_MAIN	2704
MEMORY_SIZE_IN_DELTA	0
LOAD	TRUE

i Note

The memory values can vary depending on your environment.

Checking the memory usage with M_HEAP_MEMORY

All data structures for fuzzy search share a common 'Pool/FuzzySearch' allocator. Statistics can be obtained from the system view `M_HEAP_MEMORY`.

```
SELECT * FROM m_heap_memory WHERE category LIKE '%FuzzySearch%';
```

Column	Value

4.3.4.15.2 Sizing Information

This topic contains information about the sizing of fuzzy search indexes.

When setting `FUZZY_SEARCH_INDEX ON`, index structures are created in memory to make the fuzzy search faster. It is important to be aware of the additional memory usage when sizing an SAP HANA server. It is not possible to give exact numbers here, since the size of a fuzzy search index depends on the contents of the column and on the compression mode used for this column. A fuzzy search index on a VARCHAR column for example is large if each row contains a distinct value. The index is much smaller if the number of distinct values in this column is small. The size of the fuzzy search index can be determined with the `M_FUZZY_SEARCH_INDEXES` monitoring view.

More information: [Monitoring Views \[page 446\]](#).

Fuzzy Search Indexes for String Types

When creating a fuzzy search index on a string-type column (VARCHAR, NVARCHAR), the size of the fuzzy search index can be up to twice the memory size of the column itself.

Fuzzy Search Indexes for Text Types

The fuzzy search index on a text-type column (SHORTTEXT, TEXT or a hidden column created with the `CREATE FULLTEXT INDEX` statement) needs about 10 percent of the memory size of the column. Labels parameters

4.3.4.15.3 Activating the Trace in the SAP HANA Studio

Context

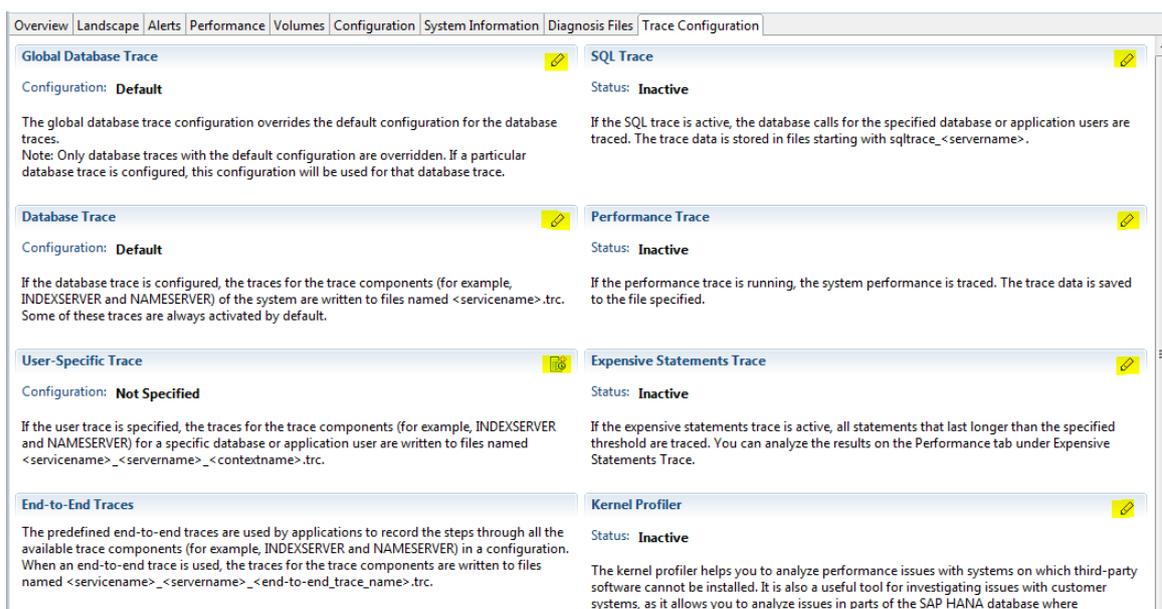

Useful tracing and logging information for a fuzzy search is stored in the database traces. The traces are written for several services of the system (for example, INDEXSERVER and NAMESERVER). If the database

trace is configured, trace information for the specified database will be written to files named as follows:
<servicename>_<hostname>.<portnumber>.000.trc.

Tracing the output of a fuzzy search is available for the components `fuzzysearch`, `searchrulesexecution`, and `searchruleruntime`. The trace of the component `fuzzysearch` shows information about selected search options and the scoring and number of search results. You should use this trace for single fuzzy search requests. If the trace for `searchrulesexecution` and/or `searchruleruntime` is configured, information about the search rule configuration and search rule set results are tracked. The components `searchrulesexecution` and/or `searchruleruntime` should be used if a search rule set that combines multiple fuzzy search requests is used.

Procedure

1. In the SAP HANA studio, open the Administration perspective by double-clicking your system name in the navigation pane.
2. Select the tab *Trace Configuration* and choose the icon *Edit Configuration* at the right corner of the tracing section you want to configure.

3. Set the trace levels in the window *Database Trace*.

Database Trace

To change the trace level of a specific component, select the trace level in the corresponding rows selection box.

4.3.4.16 Frequently Asked Questions

Why are there results with a score lower than the requested fuzzySimilarity?

In text fields, the parameter fuzzySimilarity sets the minimum similarity that a token has to match to be included in the search result. All other fuzzy search operations (for example, applying term mappings, considering stopwords, abbreviationSimilarity) can influence the score that you will see.

How many misspellings are allowed with a particular fuzzySimilarity?

This question is not easy to answer. The scoring algorithm is not linear to the number of misspellings; the position of the misspelling is also important. You can use the following example to familiarize yourself with it:

```
DROP TABLE test;
CREATE COLUMN TABLE test
(
  id INTEGER PRIMARY KEY,
  companyname SHORTTEXT(200) FUZZY SEARCH INDEX ON
);
INSERT INTO test VALUES ('1','abc');
INSERT INTO test VALUES ('2','abx');
INSERT INTO test VALUES ('3','xbc');
INSERT INTO test VALUES ('4','axc');
INSERT INTO test VALUES ('5','abcx');
INSERT INTO test VALUES ('6','xabc');
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test
WHERE CONTAINS(companyname, 'abc',
FUZZY(0.5,'textSearch=compare,bestMatchingTokenWeight=1'))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1	1	abc
0.89	5	abcx
0.82	2	abx
0.75	6	xabc
0.61	3	xbc
0.61	4	axc

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, * FROM test
WHERE CONTAINS(companyname, 'abcx',
FUZZY(0.5,'textSearch=compare,bestMatchingTokenWeight=1'))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1	5	abcx
0.89	1	abc
0.88	6	xabc
0.75	3	abx
0.59	3	xbc
0.59	4	axc

How do I find out if the fuzzy search index is enabled for column x?

See [The CONTAINS\(\) Predicate \[page 276\]](#).

How do I enable the fuzzy search index for a particular column?

See [The CONTAINS\(\) Predicate \[page 276\]](#).

The additional data structures will increase the total memory footprint of the loaded table. In unfavorable cases the memory footprint of the column can double.

How can I see how much memory is used for a fuzzy search index?

See [Monitoring Views \[page 446\]](#).

Is the score between request and result always stable for TEXT columns?

It depends on how you look at the topic. The algorithm is indeed deterministic, but you need to take all parameters into account. Cases can be constructed where a small change in the fuzzySimilarity will change the rank between the same strings.

Why is this? The fuzzySimilarity is the minimum score that tokens need to reach to be considered for the result. If you use andThreshold or the keyword "OR" in your search, not all tokens have to reach the fuzzySimilarity to be part of the result. This can lead to a change in the total score if you change the fuzzySimilarity. Let us look at an example:

```
DROP TABLE companies;
CREATE COLUMN TABLE companies
(
  id INTEGER PRIMARY KEY,
  companyname SHORTTEXT(200)
);
INSERT INTO companies VALUES(1, 'aktien gesellschaft');
INSERT INTO companies VALUES(2, 'aktiv gesellschaft');
```

Important: The similarity between "aktien" and "aktiv" is 0.77.

If the fuzzySimilarity is lower than 0.77, the token scoring will be part of the result score. If the fuzzySimilarity is higher than 0.77, the token scoring will not be considered, so the total scoring will be lower.

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, id, companyname
FROM companies
WHERE CONTAINS(companyname, 'aktiv OR gesellschaft', FUZZY(0.75,
'textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1	2	aktiv gesellschaft
0.89	1	aktien gesellschaft

```
SELECT TO_DECIMAL(SCORE(),3,2) AS score, id, companyname
FROM companies
```

```
WHERE CONTAINS(companyname, 'aktiv OR gesellschaft', FUZZY(0.80,
'textSearch=compare'))
ORDER BY score DESC, id;
```

SCORE	ID	COMPANYNAME
1	2	aktiv gesellschaft
0.71	1	aktien gesellschaft

4.4 Classification Search with Built-In Procedure `sys.esh_search()`

A classification model is used to add properties to a view dynamically at runtime. Thereby, the search model view formally contains two additional columns. The first contains property names and the second their values. The properties behave (from the user perspective) as regular view columns. Therefore, the properties are also called dynamic columns.

`sys.esh_search()` supports the search for such classification properties and the output in the response.

4.4.1 CDS Annotations for Classification Search

This topic describes the HANA CDS annotations related to the classification model.

The CDS annotation `@GenericPersistency` enables the classification model for search. Furthermore, the annotation `@Semantics` can be used to elaborate the value columns of the classification.

`@GenericPersistency` is an entity annotation and must be specified for the classification property column.

Element Annotations

Annotation	Value	Description
<code>@Semantics.unitOfMeasure</code>	true, false	Defines a column as unit column, i.e the column contains units entries.
<code>@Semantics.quantity.unitOfMeasure</code>	string	Reference to a unit column.
<code>@Semantics.currencyCode</code>	true, false	Defines a column as a currency column, i.e the column contains currency entries.

Annotation	Value	Description
<code>@Semantics.amount.currencyCode</code>	string	Reference to a currency column.
<code>@GenericPersistency.propertyValue</code>	array of strings	Specifies the columns that are relevant for the value of a property and is mandatory. For range values only the column that contains the lower boundary of an interval has to be given.
<code>@GenericPersistency.property</code>	true, false	Defines the property column of the classification and is mandatory.
<code>@EnterpriseSearchHana.initialValue</code>	string	Defines the initial value for this column.

View Annotations for intervals

In CDS, intervals can be defined via the view annotation `@Semantics.interval`.

In the same way, intervals for classification properties are defined, i.e the column including the lower bound is defined as property value and as well as lower bound element.

Annotation	Value	Description
<code>@Semantics.interval.qualifier</code>	string	The qualifier is used to distinguish intervals if more than one interval is defined. If only one interval is defined, the qualifier is optional.
<code>@Semantics.interval.lowerBoundaryElement</code>	string	Defines the name of the column that contains the lower boundary of an interval.
<code>@Semantics.interval.lowerBoundaryIncluded</code>	true, false	Indicator that defines if the lower boundary value is included in the interval or not. This is a static definition that is valid for all intervals stored in the view. This annotation cannot be used in combination with the boundary CodeElement annotation.

Annotation	Value	Description
<code>@Semantics.interval.upperBoundaryElement</code>	string	Defines the name of the column that contains the upper boundary of an interval.
<code>@Semantics.interval.upperBoundaryIncluded</code>	true, false	Indicator that defines if the upper boundary value is included in the interval or not. This is a static definition that is valid for all intervals stored in the view. This annotation cannot be used in combination with the boundary CodeElement annotation.
<code>@Semantics.interval.boundaryCodeElement</code>	string	Defines the name of the column that contains an indicator for the type of an interval. This is a dynamic definition that can be different for each interval stored in the view. The boundary code column contains a character between 1 and 9 that defines the type of the interval. 1 degenerated interval containing a single value (closed-closed, lower boundary equals upper boundary) 2 closed-open interval (lower boundary included, upper boundary excluded) 3 closed-closed interval 4 open-open interval 5 open-closed interval 6 unbounded-open interval (no lower boundary, upper boundary excluded) 7 unbounded-closed interval (no lower boundary, upper boundary included) 8 open-unbounded interval (no upper boundary, lower boundary excluded) 9 closed-unbounded interval (no upper boundary, lower boundary included)

The type of an interval can be expressed in two different ways:

- if no `boundaryCodeElement` is defined for the interval, we have a static definition valid for all rows in the view. The upper and lower boundaries are included/excluded according to the annotations

`lowerBoundaryIncluded` and `upperBoundaryIncluded`, where omitting any of the latter defaults to the corresponding boundary being included.

- if a `boundaryCodeElement` is given for the interval, we have a dynamic definition where for every specified interval in the view it is mandatory to specify a value for the `boundaryCode` according to the definition given above.

In case of a static definition it is possible to omit values for either the upper or the lower bound to obtain an unbound interval.

Due to technical reasons it is mandatory for `boundaryCode='1'` to give both the upper and the lower limit, even if they are the same.

Searching for a range within intervals with a query like `'length:BT:[1m 2m]'` results in a hit if the two ranges have an overlap of at least one point.

4.4.2 `sys.esh_config()`

For non CDS views the search configuration is defined by the built-in procedure `sys.esh_config()`.

To specify the classification model with `sys.esh_config()` entity type and property annotations are used.

4.4.2.1 Classification Example

This example studies the definition and configuration of a view `SHOPPINGCART` that include a product and classification properties.

Search Model Creation

Firstly, a table `PRODUCT` and a table `CLASSIFICATION` are created. Afterwards, the search view `SHOPPINGCART` is defined:

Sample Code

```
create column table PRODUCT
(
```

```

        id INTEGER not null,
        client NVARCHAR(3) not null,
        product NVARCHAR(100),
        primary key (id, client)
    );
insert into PRODUCT values(1, '001', 'Potatoes');
insert into PRODUCT values(2, '001', 'Tomatoes');
insert into PRODUCT values(3, '001', 'Pepper');
insert into PRODUCT values(4, '001', 'Carrot');
insert into PRODUCT values(5, '001', 'Eggplant');
insert into PRODUCT values(6, '001', 'Grapefruit');

create column table CLASSIFICATION (
    id INTEGER,
    client NVARCHAR(3),
    property NVARCHAR(100),
    string_value NVARCHAR(100),
    min_value DECIMAL(10,4),
    number_value DECIMAL(10,4),
    max_value DECIMAL(10,4),
    boundary NVARCHAR(1),
    unit_value NVARCHAR(20),
    min_date DATE,
    date_value DATE,
    max_date DATE);
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(1, '001', 'weight', 2, 'kg');
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(1, '001', 'weight', 5, 'kg');
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(2, '001', 'weight', 0.75, 'kg');
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(3, '001', 'weight', 0.5, 'kg');
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(4, '001', 'weight', 0.5, 'kg');
insert into CLASSIFICATION (id, client, property, number_value,
unit_value) values(4, '001', 'weight', 3, 'kg');
insert into CLASSIFICATION (id, client, property, string_value)
values(1, '001', 'size', 'big');
insert into CLASSIFICATION (id, client, property, string_value)
values(1, '001', 'size', 'medium');
insert into CLASSIFICATION (id, client, property, string_value)
values(1, '001', 'size', 'small');
insert into CLASSIFICATION (id, client, property, string_value)
values(2, '001', 'color', 'red');
insert into CLASSIFICATION (id, client, property, string_value)
values(2, '001', 'color', 'yellow');
insert into CLASSIFICATION (id, client, property, string_value)
values(3, '001', 'color', 'red');
insert into CLASSIFICATION (id, client, property, string_value)
values(3, '001', 'color', 'light red');
insert into CLASSIFICATION (id, client, property, string_value)
values(3, '001', 'color', 'green');
insert into CLASSIFICATION (id, client, property, string_value)
values(3, '001', 'color', 'orange');
insert into CLASSIFICATION (id, client, property, string_value)
values(3, '001', 'color2', 'red');
insert into CLASSIFICATION (id, client, property, string_value)
values(4, '001', 'color', 'orange');
insert into CLASSIFICATION (id, client, property, min_date, max_date)
values(1, '001', 'availability', '2019-01-01', '2019-12-31');
insert into CLASSIFICATION (id, client, property, min_date, max_date)
values(2, '001', 'availability', '2019-04-01', '2019-08-31');
insert into CLASSIFICATION (id, client, property, min_date, max_date)
values(3, '001', 'availability', '2019-03-01', '2019-06-30');
insert into CLASSIFICATION (id, client, property, min_date, max_date)
values(4, '001', 'availability', '2019-10-01', '2019-11-30');

```

```

insert into CLASSIFICATION (id, client, property, min_value,
max_value, boundary, unit_value) values(1, '001', 'temperature', 4, 8, '3',
'Celsius');
insert into CLASSIFICATION (id, client, property, min_value,
max_value, boundary, unit_value) values(2, '001', 'temperature', 0, 0, '1',
'Celsius');
insert into CLASSIFICATION (id, client, property, max_value,
boundary, unit_value) values(3, '001', 'temperature', 25, '7', 'Celsius');
insert into CLASSIFICATION (id, client, property, min_value,
max_value, boundary, unit_value) values(4, '001', 'temperature', 1, 2, '4',
'Celsius');
create view SHOPPINGCART ("id", "client", "product", "property",
"string_value", "min_value", "number_value",
"max_value", "boundary", "unit_value", "min_date", "date_value",
"max_date")
AS select t.id, t.client, t.product, c.property, c.string_value,
c.min_value, c.number_value, c.max_value, c.boundary,
c.unit_value,
c.min_date, c.date_value, c.max_date
from PRODUCT t inner join CLASSIFICATION c on t.id = c.id and
t.client = c.client WITH READ ONLY;

```

Configuration of the Search Model

Now, the search configuration is applied to the view SHOPPINGCART. Especially, the annotation @GenericPersistency is used to define the classification model.

Sample Code

```

call SYS.esh_config('[
{
  "uri":    "~/metadata/EntitySets",
  "method": "PUT",
  "content":
  {
    "Fullname": "SYSTEM/SHOPPINGCART",
    "EntityType": {
      "@Search.searchable": true,
      "@EnterpriseSearch.enabled": true,
      "@EnterpriseSearchHana.passThroughAllAnnotations": true,
      "@Semantics.interval": [
        {"qualifier": "numeric interval",
         "lowerBoundaryElement": "min_value", "upperBoundaryElement":
"max_value", "boundaryCodeElement": "boundary"},
        {"qualifier": "date interval",
         "lowerBoundaryElement": "min_date", "lowerBoundaryIncluded": true,
         "upperBoundaryElement": "max_date", "upperBoundaryIncluded": true}
      ],
      "Properties": [
        {
          "@EnterpriseSearch.key": true,
          "@EnterpriseSearch.presentationMode": ["TITLE"],
          "Name": "id"
        },
        {
          "@Search.defaultSearchElement": true,
          "@EnterpriseSearch.presentationMode": ["TITLE"],
          "Name": "product"
        },
        {
          "@GenericPersistency.property": true,

```

```

        "@GenericPersistency.propertyValue": [
            "string_value", "min_value", "number_value", "min_date",
            "date_value"],
        "@Search.defaultSearchElement": true,
        "Name": "property"
    },
    {
        "@Semantics.quantity.unitOfMeasure": "unit_value",
        "Name": "number_value"
    },
    {
        "@Semantics.quantity.unitOfMeasure": "unit_value",
        "Name": "min_value"
    },
    {
        "@Semantics.quantity.unitOfMeasure": "unit_value",
        "Name": "max_value"
    },
    {
        "@Semantics.unitOfMeasure": true,
        "Name": "unit_value"
    }
]
}
}]]', ?);

```

sys.esh_search()

This configuration above enables the search and especially the search in the classification data for the view SHOPPINGCART. Here are some possible requests:

☰ Sample Code

Field search with classification properties

```

call SYS.esh_search('[ "/v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART color:red')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ]', ?);

```

```

call SYS.esh_search('[ "/v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART property/color:red')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ]', ?);

```

☰ Sample Code

Freestyle search with hits in a property value

```

call SYS.esh_search('[ "/v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART red')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ]', ?);

```

Sample Code

Measure search

```
call SYS.esh_search([' /v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART 500g')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ], ?);
call SYS.esh_search([' /v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART weight:500g')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ], ?);
```

Sample Code

Search within ranges

```
call SYS.esh_search([' /v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART availability:BT:[2019-12-01
2020-05-31]')&$top=3&wherefound=true&whyfound=true&
$select=id,product,property/*" ], ?);
call SYS.esh_search([' /v20501/$all?$filter =
Search.search(query='SCOPE:SHOPPINGCART temperature:1Celsius')&
$top=3&wherefound=true&whyfound=true&$select=id,product,property/*" ], ?);
```

4.4.3 Representation of Property Names

Classification properties are qualified with the name of the property column as prefix with the slash character as separator. So, every property is assigned to its related classification. In this way, two properties with the same name but from different classifications could be differentiated.

In the response, only the qualified property names are used. In a request, if possible, also the short form can be used for convenience. To address all properties in `$select` the star qualifier must be used. For this one combines the property column with the star character (qualified star): `<property_column>/*`

4.4.4 sys.esh_search() Request

`sys.esh_search()` supports classification data starting with version `/v20411`. Older versions will ignore any classification relevant data.

Classification properties can be used to specify and restrict the search. They may be used inside the query language or with the query options `$select` and `facets`.

Selecting Classification Properties

Classification properties can be selected by the OData query option `$select` and only selected properties appear in the response. Here, the qualified property name and, if unique, also the short form can be used.

If the `$select` option is not specified no properties are returned in the result items. To select all properties the star qualifier must be used: `<property_column>/*`.

Facets

Facets of classification properties are requested by the OData query option `facets`. The response is analogue to normal attribute facets.

Here, the qualified property name and, if unique, also the short form can be used.

4.4.5 `sys.esh_search()` Response

All classification properties which are returned in the response shall be described by a section which contains the metadata of the properties. In this way, the properties can be used and be considered as normal view fields in the response.

Dynamic Metadata

The metadata section shall be specified only if the response contains any classification properties. The section shall have the same structure as the description of the view fields in the metadata document:

Sample Code

```
"@com.sap.vocabularies.Search.v1.Metadata": {
  "property/color": {
    "@SAP.Common.Label": "color",
    "@Search.defaultSearchElement": true,
    "@EnterpriseSearchHana.isSortable": true,
    "$Type": "Edm.String",
    "$MaxLength": 200,
    "$Nullable": false
  },
  "property/availability": {
    "@SAP.Common.Label": "availability",
    "@Search.defaultSearchElement": true,
    "@EnterpriseSearchHana.isSortable": true,
    "$Type": "ComplexType",
    "To": {
      "$Type": "Edm.DateTime",
      "$Nullable": false
    },
    "From": {
      "$Type": "Edm.DateTime",
      "$Nullable": false
    }
  },
  "property/temperature": {
    "@SAP.Common.Label": "temperature",
    "@Search.defaultSearchElement": true,
    "@EnterpriseSearchHana.isSortable": true,
```

```

    "$Type": "ComplexType",
    "To": {
      "$Type": "Edm.Decimal",
      "$Precision": 10,
      "$Scale": 4,
      "$Nullable": false
    },
    "From": {
      "$Type": "Edm.Decimal",
      "$Precision": 10,
      "$Scale": 4,
      "$Nullable": false
    }
  },
  "property/weight": {
    "@SAP.Common.Label": "weight",
    "@Search.defaultSearchElement": true,
    "@EnterpriseSearchHana.isSortable": true,
    "$Type": "Edm.Decimal",
    "$Precision": 10,
    "$Scale": 4,
    "$Nullable": false
  }
}

```

Response Fields

Classification properties are not returned as response fields by default. Individual properties or all properties must be requested via `$select` in order to be included in response.

Requested classification properties are returned as dynamical types using, if necessary, the OData control information `type`. A property value of type boolean, double or string does not need the control information `type`.

Sample Code

```

{
  "BooleanProperty": true,
  "StringProperty": "string_value",
  "NumericProperty": 3.14,

  "DateProperty@type": "Date",
  "DateProperty": "2016-09-22"
}

```

The unit of a value is specified via the OData vocabulary `Org.OData.Measures.V1.Unit`.

The currency is specified via `Org.OData.Measures.V1.ISOCurrency`.

Sample Code

```

{
  "NumericProperty@Org.OData.Measures.V1.Unit": "km",
  "NumericProperty": 2.71,
  "CurrencyProperty@Org.OData.Measures.V1.ISOCurrency": "EUR",
  "CurrencyProperty": 42,
}

```

Multi values are returned as an OData collection. If the values also have a unit, then the unit is specified outside the collection and refers to all entries in the collection. If necessary, the type information will be returned using the `#collection` annotation.

Sample Code

```
{
  "StringProperty": ["blue", "red"],
  "NummericArray@Org.OData.Measures.V1.Unit": "kg",
  "NummericArray": [2.71, 3.14, 42],
  "DateArray@type": "#collection(edm.Date)",
  "DateArray": ["2016-09-22", "2017-09-20", "2018-02-01"]
}
```

Ranges are returned as a structured entity with the two parts "from" and "to".

Sample Code

```
{
  "RangeProperty": {
    "From@Org.OData.Measures.V1.Unit": "m",
    "From": 10,
    "To@Org.OData.Measures.V1.Unit": "m",
    "To": 30
  }
}
```

Why Found

If the search entry is found inside the property values then the Why Found attribute contains the property and a snippet, analogous to normal view fields. Thereby, the snippet can be part of the property value or of the property value label, depending where the search term is found.

Sample Code

Example for a hit in the property value

```
"@com.sap.vocabularies.Search.v1.WhyFound": {
  "Property/COL": "<b>r</b>"
}
```

Sample Code

Example for a hit in the property value label

```
"@com.sap.vocabularies.Search.v1.WhyFound": {
  "Property/COL": "<b>red</b>"
}
```

Selection of Classification Properties

Classification properties can be selected by the OData query option `$select` and only selected properties appear in the response. Here, the qualified property name and, if unique, also the short form can be used.

If the `$select` options is not specified no properties are returned in the result items. To select all properties the star qualifier must be used: `<property_column>/*`

Facets

Facets of classification properties are requested by the OData query option `facets`. The response is analogue to normal attribute facets.

Here, the qualified property name and, if unique, also the short form can be used.

4.4.6 Query Language

The query language supports searches in property values. Thereby, a classification property can be used like a normal view field and it is case insensitive.

Here, the qualified property name and, if unique, also the short form can be used.

Assuming color, weight and height are existing properties, allowed queries would be:

'color:red'

'Property/color:blue'

'weight:(33 OR 101)'

'(weight height):10'

Additionally, the search supports also the other query language option as boosting, fuzzy and attribute conditions, e.g.

'color:red^0.7~0.8'

Finally, it is also possible to search for a measure, i.e. to search for a numeric value with a unit.

'weight: 10g'

'height: 20cm'

Labels for property values

Sometimes, the properties values themselves may have (language dependent) labels. In this case, the search is made in the property value column as well as in the property value label column, i.e. the search term finds also hits in the value labels.

Freestyle search

A freestyle search into the classification data is also possible but must be explicitly enabled by defining the property column of the classification as default search element.

By doing this, all the value columns of the classification are implicitly considered as default search elements, i.e. the freestyle search also uses these columns.

Measure search

A measure search is a simultaneous search of a numeric value and a unit and is possible only in the classification data. To trigger a measure search

- the classification must be enabled
- the requested property must have a unit (column).
- the search term begins with a numeric value followed by a unit (a word) without any spaces in between.

The measure search is customized for SI units and SI prefixes. If the search term contains a measure with a prefix, then the value is always converted to the base SI unit and is used for the numeric search.

Consequently the searches

'length:10000m'

'length:10km'

'length:100hm'

trigger the same search in the DB.

A freestyle search combined with measure search is also allowed.

The unit of a specific property must be unambiguous. If the search view is client dependent, then the unit must be unique per client.

The unit and the prefix are case sensitive.

The unit of a property is not verified to be an SI unit. Thus the customer may also use other units.

The SI unit of mass is kg. All unit conversions are performed to kg. In particular, 1g is converted to 0.001kg.

The metric ton (t) will be converted to kg. Additionally, a SI prefix is also allowed. Thus a search for '2mt' will find items with weight of 2kg.

For the unit conversions to work it is mandatory to use the base unit in the search view (e.g. m for length) without prefix. The only exception to this is the unit of mass which has to be given in kg.

Search for ranges

The search for ranges is allowed also for classification properties. Moreover, a range search is also possible for a list of search fields (properties and/or view columns).

Examples:

'quality-index:[1, 5]'

'weight:[10kg, 20kg]'

'(width height):[10cm 20cm]'

i Note

A range search without search fields is not allowed.

Searching for a range within intervals with a query like 'length:BT:[1m 2m]' results in a hit if the two ranges have an overlap of at least one point.

Initial Values

Initial values introduce the possibility to exclude property values from the search. Thereby, an initial value can be defined for each value column in the classification. Entries with initial values are considered as NULL and are not included in the search.

Numeric columns with initial value 0 have a special meaning: If a property has only initial values in all the value columns then this property is numeric and has the value 0. Therefore, a search for 0 (and only for 0) will also find such properties.

Initial Values are defined in `sys.ehs_config()` via the annotation `@EnterpriseSearchHana.initialValue` and can be only defined for classification value columns.

i Note

Initial values are often used in ABAP based classification.

Limitations

- Only one column with the annotation `@GenericPersistence.property` is allowed.
- It is not possible to mix single values and ranges for one property. If a specific property has a non-null entry in a one value column, non of the other entries for that property must have non-null entries in other value columns or in columns related to ranges, and vice versa. The consistency of the view concerning this point is not checked at runtime.
- For the unit conversions to work it is mandatory to use the base unit in the search view (e.g. m for length) without prefix. The only exception to this is the unit of mass which has to be given in kg.
- Time-dependent property values are not supported.
- Calculated property values are not supported.

4.5 Search, Security and Data Privacy

When using enterprise search in SAP HANA, there is a few things to consider regarding security and data privacy.

4.5.1 Security Information

Executable Code in the Search Response

When calling `sys.esh_search()`, the result returned by the procedure contains information stored in the SAP HANA database, like the contents of the database columns that are returned in the search response.

These contents may contain special characters, so they are escaped to get a valid JSON response.

When parsing the JSON results, the parsed content (like, for example, the value of a column) may contain executable code (as, for example, html or java script code). Therefore the client application that calls `sys.esh_search()` has to make sure that content returned by `sys.esh_search()` is never executed, but only displayed as plain text in the UI.

Auditing Search Activities

It is possible to write changes to search configurations and parameters of search calls to the audit log of the HANA system.

To audit changes to search configurations, an audit policy for the execution of procedure `sys.esh_config()` has to be created. In this case, all calls to `sys.esh_config()` including the parameters of the procedure call are written to the audit log.

To audit search calls, an audit policy for the execution of procedure `sys.esh_search()` has to be created. The audit log then contains all search calls including the search terms and other parameters.

See the SAP HANA Security Guide for details regarding auditing.

Working with a Technical User

If the search application is running on an application server that uses a single technical user to connect to the HANA database, all calls to `esh_search()` are done with this technical user instead of using different database users for the different end users of the application.

This has to be taken into account when working with user-specific authorizations or privileges like structured privileges (analytic privileges). The name of the end user of the search application may not be visible to the database, so privileges may not work as expected.

4.5.2 Data Privacy

Data Masking

The masking of column values (like, for example, hiding all but the last four digits of a credit card number) is not supported.

Masked columns are implemented as calculated columns using functions and constant expressions. This type of columns cannot be used in a search. As a result, search calls using columns with column masking fail with an error.

For details on data masking see the SAP HANA Security Guide.

Trace File Contents

When debug traces are enabled for component 'esh' or 'esh_querylanguage', the indexserver (or xs engine) trace files contain the name of the application user and the search terms entered by the user.

Parts of the search results that are found may also be contained in the trace file.

4.5.3 Tracing

All Enterprise Search features use the trace components 'esh' in the indexserver and in the xs engine.

To get details on query language processing the trace component 'esh_querylanguage' can be used.

Indexserver Trace

Activation of *.hdbdd and *.hdbcds files with @SearchIndex, @Search, or @EnterpriseSearch annotations.

Calls to the built-in procedures `sys.esh_config()` and `sys.esh_search()`.

XS Engine Trace

(or indexserver trace when embedded XS engine is used)

OData calls with custom query option search or facets.

5 Creating Search UIs With SAPUI5

SAPUI5 is a powerful, general-purpose user interface technology that is installed directly on the SAP HANA platform. SAPUI5 is tightly integrated into the SAP HANA programming model (Extended Application Services, OData). You can use SAPUI5 to develop flexible and domain-specific user interfaces that fully leverage the full-text search capabilities of SAP HANA.

To build rich, flexible search UIs for productive use, we recommended that you use the following technologies:

- Core Data Services (CDS) for defining data persistency and searchable views
- OData for web-based data access through CDS views
- SAPUI5 on OData

i Note

Note the following if you choose SAPUI5 on OData: To get access to the additional facet information in the OData response, you need to insert code for binding on a table and register for the `dataReceived` event. See the following code example:

```
//  
// SAP UI5 example coding for binding and registering for the dataReceived event  
//  
resultTable.bindItems({  
    path: "/" + settings.entitySet,  
    template: new sap.m.ColumnListItem({  
        cells: that.getDataBindingCells(properties, resultTable)  
    }),  
    parameters: {  
        custom: {  
            facets: 'all'  
            // format: "json"  
        }  
    },  
//  
// Include the following code to get access to the additional facet information  
// in the OData response.  
//  
    events: {  
        dataReceived: function(evt) {  
  
console.log(evt.mParameters.data["@com.sap.vocabularies.Search.v1.Facets"]);  
        }  
    }  
});
```

6 SAP File Processing for SAP HANA

SAP File Processing is a component of SAP HANA that provides structured information from unstructured files. The rich set of HTTP APIs enables application programmers to integrate SAP File Processing features in client applications.

The guide for SAP File Processing for SAP HANA is a detailed description of SAP File Processing including the concepts, programming APIs and operation. System architects will be able to integrate SAP File Processing in business processes and system landscapes. Administrators will learn how to set up and operate File Processing and developers will find detailed information on programming APIs.

Related Information

[SAP File Processing for SAP HANA](#)

7 SAP HANA File Loader

The file loader is a set of HTTP services that you can use to develop your own applications to search in file contents.

The file loader package also contains a basic example application with monitoring and statistical information about the current file loader schedule.

i Note

Technically, the file loader is an SAP HANA XS application that is shipped as a delivery unit. Accordingly the File Loader documentation is available in a separate document. It is linked under the related information section and describes the concept and the steps an application programmer has to follow to load binary files into SAP HANA with the file loader functionality. Afterwards, it is possible to run services like search on this content.

i Note

If you start the development of new projects on SAP HANA 2.0, we recommend the use of the new HTTP services that are delivered with *SAP File Processing for SAP HANA*.

SAP File Processing is a component of SAP HANA that provides structured information from unstructured files. The rich set of HTTP APIs enables application programmers to integrate SAP File Processing features in client applications.

Videos Hosted on External Platforms

Some videos may point to third-party video hosting platforms. SAP cannot guarantee the future availability of videos stored on these platforms. Furthermore, any advertisements or other content hosted on these platforms (for example, suggested videos or by navigating to other videos hosted on the same site), are not within the control or responsibility of SAP.

Beta and Other Experimental Features

Experimental features are not part of the officially delivered scope that SAP guarantees for future releases. This means that experimental features may be changed by SAP at any time for any reason without notice. Experimental features are not for productive use. You may not demonstrate, test, examine, evaluate or otherwise use the experimental features in a live operating environment or with data that has not been sufficiently backed up.

The purpose of experimental features is to get feedback early on, allowing customers and partners to influence the future product accordingly. By providing your feedback (e.g. in the SAP Community), you accept that intellectual property rights of the contributions or derivative works shall remain the exclusive property of SAP.

Example Code

Any software coding and/or code snippets are examples. They are not for productive use. The example code is only intended to better explain and visualize the syntax and phrasing rules. SAP does not warrant the correctness and completeness of the example code. SAP shall not be liable for errors or damages caused by the use of example code unless damages have been caused by SAP's gross negligence or willful misconduct.

Bias-Free Language

SAP supports a culture of diversity and inclusion. Whenever possible, we use unbiased language in our documentation to refer to people of all cultures, ethnicities, genders, and abilities.
