## Procedure

1. Create a communication arrangement based on the integration scenario `SAP_COM_0532`.
2. In the communication arrangement, enter the communication system and communication user that you created for the service binding (see *Prerequisites*).

## Related Information

[Integrating SQL Services Using SAP Datasphere \[page 2634\]](#)

### 4.2.10.9.8.2 Creating a Replication Flow for SQL Service Exposure

In SAP Datasphere, define a replication flow for CDS view entities using the SQL service exposure.

## Context

With defining a source of the replication flow, you specify the connection, the folder, and the replication objects (CDS view entities).

For more information about creating replication flows, see [Creating a Replication Flow](#) in the SAP Datasphere documentation.

## Procedure

1. To create a replication flow, follow the instructions of the SAP Datasphere documentation (see [Creating a Replication Flow](#)).
2. As a source connection, choose the communication system that you have created before for connecting SAP Datasphere to your ABAP environment (see also [Creating a Communication Arrangement to Enable Replication Flows in SAP Datasphere \[page 1127\]](#)).
3. As a source container, choose `SQL_SERVICE`.

#### Note

The `SQL_SERVICE` contains the SQL services that have been enabled for replication.

4. As source objects, choose the CDS view entity that you want to use for initial and delta replication.  
If an alias was provided, the alias name is shown.

You can choose among the custom CDS view entities that comply to the overall rules for data replication (see [Additional Prerequisites and Constraints for Replication \[page 1105\]](#)). CDS view entities that support delta replication must have been annotated using `@DataIntegration.deltaReplication.intended:true`. All other CDS view entities support only full replication.

5. Choose a target system.
6. As a load type, select *Initial and Delta*.

## 4.2.10.9.9 Developing SQL Queries on CDS Objects Exposed as SQL Service

You can develop your own SQL queries on objects exposed using an ABAP SQL service.

For example, in some cases, you want to use SQL client software applications to interact with the ABAP system using the ODBC driver and using your own defined SQL queries. In other cases, you want to access data using the ODBC driver with programs written in programming languages such as Python or Node.js.

In all these cases, you can access CDS view entities in an ABAP system using SQL via Open Database Connectivity (ODBC). However, you need to know more details on the supported SQL dialect of the ABAP SQL service to be able to define your SQL queries appropriately. This dialect is what is outlined in this documentation.

### Note

If you use standard tools with an ODBC client like MS Excel or LibreOffice, the tools themselves assemble the SQL queries executed over the ODBC driver. The tools assume some kind of ANSI SQL compatibility and can derive details about the supported SQL dialect from ODBC `SQLGetInfo()` attributes.

### 4.2.10.9.9.1 SQL Dialect of the ABAP SQL Service

The SQL dialect of the ABAP SQL service is a modified ABAP SQL dialect executed by the ABAP SQL engine.

#### Basic Features

The SQL dialect of the ABAP SQL service shares many features with ABAP SQL, which is a subset of SQL realized using ABAP statements. In fact, the SQL dialect of the ABAP SQL service is a modified ABAP SQL dialect executed by the ABAP SQL engine. It works on ABAP-managed entities and profits from many ABAP server-specific features like automatic client handling, table buffering, and DCL handling.

However, in some respects, the SQL dialect of the ABAP SQL service is more like ANSI SQL or HANA SQL, the native SQL dialect of the SAP HANA database. For example, in ODBC, there are no ABAP host variables or internal tables, which exist in ABAP SQL. Parameter markers and type casts in the SQL dialect of the ABAP SQL service are handled similar to HANA SQL.

The SQL dialect of the ABAP SQL service is restricted to read-only SQL queries that don't set locks on database level. No `INSERT/UPDATE/DELETE` statements and no `SELECT FOR UPDATE` are allowed on objects

exposed in an SQL service. Therefore, the SQL service has no concept of database transactions and `COMMIT` or `ROLLBACK` statements aren't needed.

In addition, there are also some features that are specific to the SQL dialect of the ABAP SQL service and that can't be found in ABAP or HANA SQL. For example, to access objects, a schema name and an object name must be used. What's also new is that the SQL service provides a set of system tables where metadata can be retrieved using SQL.

## Documentation Scope and More Information

This documentation gives you a brief overview of the supported SQL features, highlighting some of the differences and similarities to HANA SQL and ABAP SQL. For more information about HANA SQL and ABAP SQL, see the following documentation:

[ABAP SQL](#)

[SAP HANA SQL Reference Guide for SAP HANA Platform](#)

### 4.2.10.9.9.1.1 Using a Schema Name to Refer to the Service Binding Name

In SQL statements of the SQL dialect of the ABAP SQL service, all accessed objects must be fully qualified using a schema name and an object name. As a schema name, you use the SQL service binding name. The object names are the external names of the exposed CDS objects listed in the corresponding service definition. A simple example is the following SQL statement:

#### Sample Code

```
Select * from "ZData"."OrderItems"  
where "ZData"."OrderItems"."OrderId" = 42
```

### 4.2.10.9.9.1.2 Prepared Statements with Parameter Markers

Like in HANA SQL, statement texts can contain unnamed parameter markers ( '?' ).

These statements can be prepared once and executed multiple times using different value bindings at execution time. A simple example is the following SQL statement with four input parameters:

#### Sample Code

```
Select * from "ZData"."OrderItems"  
where "OrderId" = ? or "OrderId" IN ( ?, ?, ? )
```

The data types of the parameter markers are restricted to simple DDIC/ODBC types and no table-like input is supported.

## 4.2.10.9.9.1.3 Retrieving Metadata Using System Tables

In the SQL dialect of the ABAP SQL service, you can use system tables to retrieve table metadata. For example, the system table `SYS.VIEWS` provides data similar to the ODBC function `SQLTables()`, `SYS.COLUMNS` provides data similar to what you get using `SQLColumns()`. With `SYS.VIEW_PARAMETERS`, you can get view parameters.

### Motivation

In ODBC, object metadata can be retrieved using ODBC functions like `SQLTables()` or `SQLColumns()`. However, in SQL services, view entities with parameters can also be exposed and ODBC has no clear concept for these objects. Therefore, the SQL service also provides a set of system tables where metadata can be retrieved using SQL.

The system tables are automatically exposed and contain information about the objects that can be accessed in the current ODBC connection to the ABAP back end. The objects visible in an ODBC connection depend on the ABAP user privileges and on the service path used to open the ODBC connection (with a communication or a business user).

### SYS.VIEWS

The system table `SYS.VIEWS` works similar to the ODBC function `SQLTables()` and lists all CDS view entities visible in the current ODBC connection including the system tables themselves. The column `HAS_PARAMETERS` can be used to determine whether a view has parameters:

#### Sample Code

```
SQL> select schema_name, view_name from SYS.VIEWS where schema_name = 'SYS'
```

SCHEMA_NAME	VIEW_NAME
SYS	DUMMY
SYS	M_CONNECTION_INFO
SYS	VIEWS
SYS	VIEW_COLUMNS
SYS	VIEW_PARAMETERS

## SYS.VIEW\_COLUMNS

The system table `SYS.VIEW_COLUMNS` lists column information for the exposed entities containing both ODBC and ABAP metadata:

### Sample Code

```
SQL> select COLUMN_NAME, ODBC_DATA_TYPE OD,
           ODBC_BUFFER_LENGTH OBL, DDIC_TYPE_NAME, DDIC_LENGTH
       from SYS.VIEW_COLUMNS
       where schema_name = 'SYS' and view_name = 'VIEW_COLUMNS'
       order by column_position
```

COLUMN_NAME	OD	OBL	DDIC_TYPE_NAME	DDIC_LENGTH
SCHEMA_NAME	-8	60	CHAR	30
VIEW_NAME	-8	60	CHAR	30
COLUMN_NAME	-8	60	CHAR	30
SCHEMA_NAME_UPPER	-8	60	CHAR	30
VIEW_NAME_UPPER	-8	60	CHAR	30
COLUMN_NAME_UPPER	-8	60	CHAR	30
COLUMN_POSITION	4	4	INT4	10
DESCRIPTION	-8	500	CHAR	250
IS_KEY	-8	10	CHAR	5
ODBC_DATA_TYPE	5	2	INT2	5
ODBC_TYPE_NAME	-8	8	CHAR	4
ODBC_COLUMN_SIZE	4	4	INT4	10
ODBC_DECIMAL_DIGITS	5	2	INT2	5
ODBC_BUFFER_LENGTH	4	4	INT4	10
ODBC_NUM_PREC_RADIX	5	2	INT2	5
ODBC_NULLABLE	5	2	INT2	5
DDIC_TYPE_NAME	-8	8	CHAR	4
DDIC_LENGTH	4	4	INT4	10
DDIC_DECIMALS	5	2	INT2	5

## SYS.VIEW\_PARAMETERS

The system table `SYS.VIEW_PARAMETERS` contains ODBC and ABAP metadata for view parameters (`HAS_PARAMETERS = 'TRUE'` in `SYS.VIEWS`). For an example, see [Named Parameter Syntax on Views with Parameters \[page 1138\]](#).

## Other System and Monitoring Tables

`SYS.DUMMY` is a dummy table with one row and works like the corresponding SAP HANA database table. Many of the SQL examples throughout this documentation use this dummy table.

The monitoring view `SYS.M_CONNECTION_INFO` contains information about the current ODBC connection (for example, ABAP user name, alias, client, SQL service name, and EPP information).

## 4.2.10.9.9.1.4 Set Operations UNION, INTERSECT, EXCEPT

Like in ABAP SQL and HANA SQL, you can use the standard set operations `UNION`, `INTERSECT`, and `EXCEPT` to combine result sets of multiple queries in one query.

Here are some examples:

### Sample Code

```
select DUMMY FROM SYS.DUMMY A EXCEPT SELECT 'X' FROM SYS.DUMMY B
select DUMMY FROM SYS.DUMMY EXCEPT SELECT 'X' FROM SYS.DUMMY
```

In cases where the same table name is used in multiple `UNION ALL` branches, the ABAP SQL engine requires that these tables are given different alias names.

## 4.2.10.9.9.1.5 Supported JOIN Syntax

The supported `JOIN` syntax in the SQL dialect of the ABAP SQL service is similar to HANA SQL.

The commonly known ANSI SQL clauses `INNER JOIN`, `LEFT OUTER JOIN`, `RIGHT OUTER JOIN`, and `CROSS JOIN` are supported. For a `LEFT OUTER JOIN`, you can also add the SAP HANA-specific `LEFT OUTER MANY TO ONE JOIN` clause.

Instead of using explicit `JOIN` clauses, you can also use a comma-separated list of tables in the `FROM` clause to express an `INNER JOIN` or a `CROSS JOIN`. This feature isn't supported in ABAP SQL, but in the SQL dialect of the ABAP SQL service it is.

Here are some examples:

### Sample Code

```
select A.DUMMY FROM SYS.DUMMY A
CROSS JOIN SYS.DUMMY B
select A.DUMMY FROM SYS.DUMMY A , SYS.DUMMY B
select A.DUMMY FROM SYS.DUMMY A
LEFT OUTER MANY TO ONE JOIN SYS.DUMMY B
ON A.DUMMY = B.DUMMY
```

## 4.2.10.9.9.1.6 Common Table Expressions and Derived Tables

Common table expressions (CTE) can be used to define temporary view objects using a `WITH` clause at the beginning of a query that can later be used multiple times in the full select part.

Here's an example:

### Sample Code

```
WITH A AS ( SELECT SCHEMA_NAME S, VIEW_NAME V FROM SYS.VIEWS )
SELECT * FROM A WHERE A.S = 'SYS'
```

```
UNION ALL
SELECT * FROM A WHERE A.S = 'ZData'
```

Recursive SQL in CTEs isn't supported.

As an alternative to CTEs, derived table clauses can be directly used in the `FROM` clause of a query, as in the following example:

#### Sample Code

```
SELECT * FROM ( SELECT SCHEMA_NAME S, VIEW_NAME V FROM SYS.VIEWS ) A
WHERE A.S = 'SYS'
```

While CTEs are also supported in ABAP SQL, derived table clauses are only supported in the SQL dialect of the ABAP SQL service.

Both queries with CTEs and with derived tables work a little different regarding case sensitivity of object names. Whenever you define a name in double quotes for the CTE or derived table itself or for returned column names, you must use the name in double quotes throughout the whole SQL statement, as in the following example:

#### Sample Code

```
SELECT * FROM ( SELECT SCHEMA_NAME "s", VIEW_NAME V FROM SYS.VIEWS ) "a"
WHERE "a"."s" = 'SYS'
```

The following query doesn't work because the double quotes are not used consistently:

#### Sample Code

```
SELECT * FROM ( SELECT SCHEMA_NAME "s", VIEW_NAME V FROM SYS.VIEWS ) "a"
WHERE A.S = 'SYS'
```

## 4.2.10.9.9.1.7 Type Casts

You can also use type casts in the SQL dialect of the ABAP SQL service.

You can always insert type casts in ABAP CDS style directly in the definition of your exposed CDS entities. However, sometimes you may want to insert type casts in your SQL queries, for example, to make some data types better consumable or readable in standard ODBC applications.

The supported type casts in the SQL dialect of the ABAP SQL service are more HANA SQL-like. It's only possible to cast to a limited number of ABAP types. The general form of a type cast is the following, where `<expression>` can be an SQL expression, a literal value, or a column:

#### Sample Code

```
CAST( <expression> AS <data type> )
```

<data type> can be one of the data types from the second column of the following table:

	Data Type in Cast	Corresponding ABAP Data Type
Integer data types	SMALLINT, INTEGER, BIGINT	abap.int2, abap.int4, abap.int8
Fixed-point decimal types	DECIMAL( p, s ) where p <= 31 and s <= 14	abap.dec(p,s)
Double	DOUBLE	abap.double
Character-like types	CHAR(n) where n <=255  Synonyms: VARCHAR(n), NVARCHAR(n)	abap.char(n)
Decimal floating point types	DECIMAL, SMALLDECIMAL	abap.df34n, abap.df16n

A character string can be cast to an abap.string using the TO\_CLOB( <expression> ) function. A binary string can be cast to an abap.xstring using the TO\_BLOB( <expression> ) function. There are no special casts to date, time, or timestamp data types and also no type casts for some of the ABAP-specific data types like abap.numc, abap.curr, abap.cuky, and so on.

Here's an example:

#### ↔ Sample Code

```
select      CAST( 4711 AS SMALLINT ) AS C_INT2,
           CAST( 4711 AS INTEGER ) AS C_INT4,
           CAST( 1E-1200 AS DECIMAL) AS C_DF34N,
           CAST( 1.234 AS DECIMAL(10,3)) AS C_DEC103,
           CAST( 2.5 AS DOUBLE) AS C_DOUBLE
FROM SYS.DUMMY
```

## 4.2.10.9.9.1.8 Literals and ODBC Escape Sequences

Literal values can be used in the SQL dialect of the ABAP SQL service similar to HANA SQL.

For numeric literals, you can add an explicit type cast to enforce a specific data type in the result set. For character-like data types, you can enclose the literals in single quotes. A prefix *n* is optional. Raw (binary) literals must be enclosed in single quotes with prefix *x*. In the single quotes, you provide the hex string representation of the raw value. For DATE/TIME/TIMESTAMP (abap.datn/abap.timn/abap.utcl) literals, the prefixes *date*, *time*, or *timestamp* can be used.

Here's an example:

#### ↔ Sample Code

```
SQL> SELECT 'HELLO' AS C_CHAR5,
           x'123456ABCDEF' AS C_RAW6,
           date'2015-01-02' AS C_DATN,
           time'11:55:00' AS C_TIMN,
           timestamp '2015-01-02 11:55:00.1234567' AS C_UTCL
```

```

FROM SYS.DUMMY
+-----+-----+-----+-----+
| C_CHAR5 | C_RAW6   | C_DATN | C_TIMN | C_UTCL |
+-----+-----+-----+-----+
| HELLO   | 123456ABCDEF | 20150102 | 115500 | 2015-01-02T11:55:00,1234567 |
+-----+-----+-----+-----+

```

As an alternative for DATE/TIME/TIMESTAMP, you can use ODBC escape sequences, which are also supported in HANA SQL:

#### ↔ Sample Code

```

SQL> SELECT {d '2015-01-02'}           AS C_DATN,
           {t '11:55:00'}             AS C_TIMN,
           {ts '2015-01-02 11:55:00.1234567'} AS C_UTCL
FROM SYS.DUMMY
+-----+-----+-----+
| C_DATN | C_TIMN | C_UTCL |
+-----+-----+-----+
| 20150102 | 115500 | 2015-01-02T11:55:00,1234567 |
+-----+-----+-----+

```

## 4.2.10.9.9.1.9 SQL Functions

Most of the supported built-in scalar and aggregate ABAP SQL functions can be used, but there are some limitations.

### General Comments

Since the SQL dialect of the ABAP SQL service is eventually processed by the ABAP SQL engine, most of the supported built-in scalar ABAP SQL functions can be used.

In some of the date/time functions, ABAP data type names are reflected in the function names, as in the following example:

#### ↔ Sample Code

```

SQL> SELECT date'20150102'           AS C_DATN,
           ADD_DAYS( date'20150102', 5 ) AS C_DATN_P_5,
           DATN_ADD_DAYS( date'20150102', 10 ) AS C_DATN_P_10,
           DATS_FROM_DATN( date'20150102' ) AS C_DATS
FROM SYS.DUMMY
+-----+-----+-----+-----+
| C_DATN | C_DATN_5 | C_DATN_10 | C_DATS |
+-----+-----+-----+-----+
| 20150102 | 20150107 | 20150120 | 20150102 |
+-----+-----+-----+-----+

```

The functions DATS\_FROM\_DATN, DATS\_TO\_DATN, BINTOHEX, and HEXTOBIN can also be used for type casting.

Apart from scalar functions, ABAP SQL aggregate functions and ABAP SQL windowing functions can also be used in the SQL dialect of the ABAP SQL service.

It's not possible to access associations using path expressions in the SQL dialect of the ABAP SQL service. Columns of associated entities can only be accessed if they're explicitly exposed using a column name in the CDS view entity.

## Limitations for Built-In Functions

For the SQL dialect of the ABAP SQL service, the following limitations apply:

String Functions

Function	Supported	Comments
LIKE_REGEXPR	Yes	Only supported as comparison operator, the <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>LIKE_REGEXPR pcre</code>
LOCATE_REGEXPR	Yes	The <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>LOCATE_REGEXPR( pcre IN value [FROM start] [OCCURRENCE occ] [GROUP group] )</code>
LOCATE_REGEXPR_AFTER	Yes	The <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>LOCATE_REGEXPR( AFTER pcre IN value [FROM start] [OCCURRENCE occ] [GROUP group] )</code>
OCCURENCES_REGEXPR	Yes	The <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>OCCURENCES_REGEXPR( pcre IN value )</code>

Function	Supported	Comments
REPLACE_REGEXPR	Yes	The <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>REPLACE_REGEXPR( pcre IN sql_exp1 WITH sql_exp2 [FROM start] [OCCURRENCE occ])</code>
SUBSTRING_REGEXPR	Yes	The <code>case_sensitive</code> parameter is not supported.  Different syntax: <code>SUBSTRING_REGEXPR( pcre IN value [FROM start] [OCCURRENCE occ] [GROUP group] )</code>

#### Time Zone Functions

Function	Supported	Comments
ABAP_SYSTEM_TIMEZONE	Yes	Only with default parameters, named parameters are not supported.
ABAP_USER_TIMEZONE	Yes	Only with default parameters, named parameters are not supported.

The following conversion functions are not supported:

- UNIT\_CONVERSION
- CURRENCY\_CONVERSION

## More Information

For more information about the ABAP SQL functions, see the ABAP SQL documentation.

### 4.2.10.9.9.1.10 Named Parameter Syntax on Views with Parameters

The SQL dialect of the ABAP SQL service supports named parameter syntax on views with parameters.

#### Note

The named parameter syntax is also supported in HANA SQL. However, the SQL dialect of the ABAP SQL service doesn't support positioned parameter syntax.

Here's a simple example with a CDS entity with one parameter to illustrate how it works:

#### Sample Code

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_ALLOWED
@EndUserText.label: 'Test entity with parameter'
define view entity ZENTITYWITHPARAM with parameters
  im_int: abap.int4
as select from svers {
  key version as keyCol,
  $parameters.im_int as IntCol
}
```

Let's also assume you've exposed this entity in your service definition with external name `ZEntityWithParam` and with corresponding service binding `ZData`.

After activating all ABAP objects, the system views will now show the following entries:

#### Sample Code

```
SQL> select HAS_PARAMETERS from SYS.VIEWS
      WHERE schema_name = 'ZData'
      and view_name = 'ZEntityWithParam'
+-----+
| HAS_PARAMETERS |
+-----+
| TRUE           |
+-----+
SQL> select PARAMETER_NAME, ODBC_DATA_TYPE, DDIC_TYPE_NAME, DDIC_LENGTH
      from SYS.VIEW_PARAMETERS
      WHERE schema_name = 'ZData'
      and view_name = 'ZEntityWithParam'
+-----+-----+-----+-----+
| PARAMETER_NAME | ODBC_DATA_TYPE | DDIC_TYPE_NAME | DDIC_LENGTH |
+-----+-----+-----+-----+
| im_int         | 4              | INT4           | 4           |
+-----+-----+-----+-----+
SQL> select COLUMN_NAME, ODBC_DATA_TYPE, DDIC_TYPE_NAME, DDIC_LENGTH
      from SYS.VIEW_COLUMNS
      WHERE schema_name = 'ZData'
      and view_name = 'ZEntityWithParam'
+-----+-----+-----+-----+
| COLUMN_NAME    | ODBC_DATA_TYPE | DDIC_TYPE_NAME | DDIC_LENGTH |
+-----+-----+-----+-----+
| keyCol         | -8             | CHAR           | 72          |
| IntCol         | 4              | INT4           | 4           |
+-----+-----+-----+-----+
```

Now, you can run SQL queries on the new entity with named parameter syntax:

#### Sample Code

```
SQL> select * from ZData.ZEntityWithParam ( im_int => 4711 )
+-----+-----+
| keyCol         | IntCol         |
+-----+-----+
| 7xx           | 4711          |
+-----+-----+
```

## 4.2.10.9.9.1.11 ABAP to ODBC Data Type Mappings

The ODBC driver for ABAP allows you to configure the mapping of ABAP data types to ODBC SQL data types.

To configure this mapping, you can use the connection parameter `Typemap`. Regardless of the ODBC SQL data type reported by the ODBC driver, the ODBC application is still free to use an ODBC C data type of its choice to retrieve a given ODBC SQL data type.

### Typemap=semantic

In most cases, you want to retrieve the ABAP data in a way that's easy to consume. With the `Typemap=semantic` configuration, the ODBC driver can do the following:

- Map all date like data types like `abap.dats` and `abap.datn` to ODBC type `SQL_DATE/SQL_TYPE_DATE`
- Map all time like data types like `abap.tims` and `abap.timn` to ODBC type `SQL_DATE/SQL_TYPE_DATE`
- Map all decimal floating point-like data types like `abap.d16n`, `abap.d34n`, `abap.d16r`, `abap.d34r`, `abap.d16d`, and `abap.d34d` to ODBC type `SQL_DECFLOAT`
- Perform an automatic decimal shift for type `abap.curr` and maps this data type also to ODBC type `SQL_DECFLOAT`
- Perform an ISO conversion for type `abap.lang` and maps this data type to ODBC type `SQL_WCHAR` with length 2

### Typemap=semanticDatsTimsAsWchar

For some ODBC applications that want to safely access the ABAP data, the `Typemap=semantic` configuration might have the problem that not all data in the old `abap.dats` and `abap.tims` columns can be mapped to a date. The ABAP system doesn't prevent that some applications store date/time literals in those columns (for example, the string `TODAY` in an `abap.dats` column).

To ensure that these use cases work without data loss, a slightly different `Typemap=semanticDatsTimsAsWchar` is available. This type mapping is similar to the semantic type mapping, with the exception that the ABAP data type `abap.dats` is mapped to `SQL_WCHAR` with length 8 and ABAP data type `abap.tims` is mapped to `SQL_WCHAR` with length 6. As a result, no conversions happen, and no potential conversion errors occur.

### Typemap=native

Other applications might want to read data from an ABAP system as-is without any semantic conversion. With the `Typemap=native` configuration, the ODBC driver does the following:

- Map data type `abap.dats` to ODBC type `SQL_WCHAR` with length 8
- Map data type `abap.datn` to ODBC type `SQL_DATE/SQL_TYPE_DATE`

- Map data type `abap.tims` to ODBC type `SQL_WCHAR` with length 6
- Map data type `abap.timn` to ODBC type `SQL_TIME/SQL_TYPE_TIME`
- Map data types `abap.d16n` and `abap.d34n` to ODBC type `SQL_DECFLOAT`
- Map data types `abap.d16r` and `abap.d34r` to ODBC type `SQL_BINARY`
- Map data types `abap.d16d` and `abap.d34d` to ODBC type `SQL_DECIMAL`
- Not shift `abap.curr` data and maps of this type to ODBC type `SQL_DECIMAL`
- Return ABAP type `abap.lang` as is and map it to ODBC type `SQL_WCHAR` with length 1

All other ABAP data types are mapped to their corresponding ODBC SQL types independent of the typemap setting, such as the following, for example:

ABAP Data Type	Mapped ODBC SQL Type
INT1 / INT2	SQL_SMALLINT
INT4	SQL_INTEGER
INT8	SQL_BIGINT
DEC	SQL_NUMERIC
UTCL	SQL_TIMESTAMP/SQL_TYPE_TIMESTAMP

## 4.2.10.9.9.1.12 Data Conversions for `abap.lang` and `abap.curr` Data Types

There's a special handling of ABAP data types `LANG` and `CURR` in the ODBC driver.

### `abap.lang` Data Type

In ABAP tables, `abap.lang` data is stored as single-byte Unicode character (for example, `D` for German or `E` for English). However, in external interfaces (for example, the SAP logon screen), the language is typically shown as two-character string (for example, `DE` for German or `EN` for English). The table `T002` in the ABAP back-end system defines the mapping between these values.

If you're using one of the `Typemap=semantic*` settings, `abap.lang` values in the result set of a query are automatically mapped to the 2-character strings. Conversely, if you're using `abap.lang` values as input parameters, you must provide them as 2-character strings. The same SQL queries return different `abap.lang` values and need different `abap.lang` input values if `Typemap=native` is used.

### `abap.curr` Data Type

The `abap.curr` data type has been developed in times where no decimal floating point data type existed. For historic reasons, on database level, `abap.curr` data is stored in fixed-point decimal values. These values can only be interpreted correctly if the corresponding `abap.cuky` value is known. The fixed-point decimal

values need to be shifted depending on its currency key. For an innocent or generic ODBC application that doesn't know the ABAP shifting algorithm, it comes handy that the ODBC driver for ABAP directly returns the shifted `abap.curr` values. As a price, a fixed-point decimal data type can no longer hold values for all possible currencies. Therefore, the ODBC driver for ABAP returns shifted `abap.curr` values as decimal floating point (ODBC data type `SQL_DECFLOAT`) if one of the `Typemap=semantic*` settings is used.

The following example uses `Typemap=semantic`:

```

❏ Sample Code

SQL> SELECT LANG, CUKY, CURR from ZData.TestView
+-----+-----+-----+
| LANG | CUKY | CURR          |
+-----+-----+-----+
| EN   | USD  | 999999999999.99 |
| DE   | EUR  | 0.01           |
| LT   | BHD  | 1234.5         |
+-----+-----+-----+

```

The following example uses `Typemap=native`:

```

❏ Sample Code

SQL> SELECT LANG, CUKY, CURR from ZData.TestView
+-----+-----+-----+
| LANG | CUKY | CURR          |
+-----+-----+-----+
| E    | USD  | 999999999999.99 |
| D    | EUR  | 0.01           |
| X    | BHD  | 12345.00       |
+-----+-----+-----+

```

The examples here demonstrate different query results with and without active language conversion and currency shift. Note the changed values for column `LANG`, the change in data type for column `CURR`, and the shifted decimal point in the currency value for currency `BHD`. Currency values for currencies `USD` and `EUR` are stored unshifted in the ABAP database tables.

It's also possible to use shifted `abap.curr` values as input values for SQL queries if they correspond to predicates on a CDS entity column. However, you can't use shifted `abap.curr` values as input parameters for CDS entities with parameters. In this case, the corresponding `abap.cuky` value can't be automatically determined.

## 4.2.10.9.9.1.13 The Driver-Specific `SQL_DECFLOAT` Type

For the decimal floating-point types, the ODBC driver for ABAP has its own ODBC SQL data type `SQL_DECFLOAT=-360` defined.

### Motivation

The ODBC standard doesn't define a decimal floating-point type. However, there are databases like the SAP HANA database or the ABAP system itself (if it's viewed as a database) that support such types. The main

reason for using these types is to avoid rounding problems that would occur when using the double floating-point type with radix 2. ABAP applications often use decimal floating-point data for business data where such rounding could cause problems.

Note the rounding artifacts in the following query result:

#### Sample Code

```
SQL> select cast (10000 as double) * cast (1.11 as double) as c_DOUBLE,  
          cast (10000 as DECIMAL) * cast (1.11 as DECIMAL) as c_D34N  
        from sys.dummy
```

C_DOUBLE	C_D34N
11100.0000000000001818989403545856	11100.00

### ODBC SQL Data Type `SQL_DECFLOAT=-360`

The ODBC standard allows that ODBC drivers define their own driver-specific data types if needed. The ODBC driver for ABAP has taken this way for the decimal floating-point types: It has defined its own ODBC SQL data type `SQL_DECFLOAT=-360` with two different octet lengths corresponding to the `abap.d16n` and `abap.d34n` data types. ODBC applications that want to retrieve such `SQL_DECFLOAT` data must use default target data type `SQL_C_CHAR` or `SQL_C_WCHAR` to return the data in readable string format.

## 4.2.10.9.9.1.14 Client Handling and Table Buffering

The SQL dialect of the ABAP SQL service is processed by the ABAP SQL engine. As a result, ABAP session variables like the session client are automatically set. On CDS view entities, this ensures that only data from the logon client of the current user is visible. The ABAP SQL engine can also use other ABAP application server-specific mechanisms like table buffering and not all SQL statements need to be routed to the underlying SAP HANA database.

## 4.2.10.10 Connectivity-Related Timeout Settings

The processing timeout for HTTP requests in the ABAP environment is 600 seconds. After this time period, requests are aborted.

### Note

Request processing usually only takes a short amount of time during development because just small data sets are used. Make sure to keep the processing time also for production data set sizes.

## 4.2.10.11 Integrating Enterprise Event Enablement

Get an overview of integrating the enterprise event enablement framework into your SAP BTP, ABAP environment system.

The enterprise event enablement framework enables the exchange of events across different platforms for seamless event-driven communication. To successfully exchange events between the respective event exchange infrastructure and an ABAP environment system, an upright connection is required. This connection is maintained by the enterprise event enablement framework during the creation of the corresponding *Communication Management* artifacts like *Communication Arrangements* and *Communication Systems*.

You can publish events triggered from ABAP environment applications through [RAP Business Events](#) and consume events delivered through the respective event exchange infrastructure from external applications.

The respective event exchange infrastructure service provided on the SAP Business Technology Platform is the message broker as a service, which provides real-time messaging capabilities. All events are exposed in a standard way with a well-defined hierarchy and metadata so they can easily be consumed on different platforms.

### Prerequisites

The following prerequisites must be met to integrate the enterprise event enablement:

- You have a subaccount in SAP BTP, Cloud Foundry environment. Refer to [Getting Started with a Trial Account in the Cloud Foundry Environment](#).
- You have created a service instance for SAP Event Mesh or SAP Advanced Mesh Service Plan.
- The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### 4.2.10.11.1 Communication Management

The *Communication Management* app helps you to integrate your SAP BTP, ABAP environment system with SAP BTP, Cloud Foundry environment systems to enable data exchange.

You can use the `SAP_COM_0092` and `SAP_COM_0492` communication scenario IDs to configure a connection with the SAP Event Mesh service to enable the exchange of events. To set up a communication scenario using the *Communication Management* app, follow the steps in the following topics:

- [Creating Technical Communication User \[page 1145\]](#)

To set up the communication arrangement, refer to the respective topics in:

- [Integration with SAP Enterprise Messaging 1.0 for Cloud Foundry \[page 1150\]](#)
- [Integration with Advanced Mesh Service Plan for Service Cloud \[page 1157\]](#)

## 4.2.10.11.1.1 Creating Technical Communication User

You use this procedure to create a communication user for inbound communication from SAP BTP, ABAP environment to SAP S/4HANA Cloud systems.

### Prerequisites

- You have a subaccount in SAP BTP, Cloud Foundry environment. Refer to [Getting Started with a Trial Account in the Cloud Foundry Environment](#).
- You have created a service instance for SAP Event Mesh or SAP Advanced Mesh Service Plan.
- The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Context

A communication user enables the integration with other solutions.

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, choose the *Maintain Communication Users* artifact.
3. Choose *New* to create a new user.
4. Enter a *User Name* for the user.
5. Enter a *Description* for the user.
6. Assign a *Password* for the user.
7. Choose *Create*.
8. Make a note of the *User Name*.

The user name is required when you create the communication arrangement.

### Results

You have created a communication user. It is listed in the *Maintain Communication Users* artifact.

## 4.2.10.11.2 CloudEvents Context Attributes

Events published through the enterprise event enablement are compliant with the CloudEvents specification. Context attributes contained in events are listed in this topic.

The following table lists required and optional context attributes of the CloudEvents specification (<https://cloudevents.io> ).

Context Attribute	Requirement	Description
<code>id</code>	required	identifies the event instance
<code>source</code>	required	identifies the issuer of the event containing: <ul style="list-style-type: none"> <li><code>region</code> <ul style="list-style-type: none"> <li>the region where the application service is located</li> <li>value: <code>default</code></li> </ul> </li> <li><code>applicationNamespace</code> <ul style="list-style-type: none"> <li>the registered namespace of the application, which emits the event</li> <li>value               <ul style="list-style-type: none"> <li><code>sap.s4.beh</code> for SAP released events</li> <li><code>sap.abap.custom</code> for events created by customers</li> </ul> </li> </ul> </li> <li><code>instanceID</code> <ul style="list-style-type: none"> <li>identifier of the application instance issuing the event</li> <li>value: represented through the cloud landscape directory (CLD) tenant ID of the ABAP environment tenant.</li> </ul> </li> </ul>
<code>specversion</code>	required	specifies the version of the CloudEvents specification, which the event uses currently: 1.0
<code>type</code>	required	specifies the type of event
<code>datacontenttype</code>	optional	content type of the event
<code>time</code>	optional	timestamp of the occurrence of the event
<code>data</code>	optional	business payload of the event

### Note

All contained values are set for events published in the ABAP environment.

## 4.2.10.11.3 Event Consumer

In this topic, you can find information about how to enable the event consumption for an event consumption model defined using the `ABAP Development Tools` and how to set up the corresponding communication arrangement.

The communication arrangements `SAP_COM_0092` or `SAP_COM_0492` define the connection from ABAP environment to the respective event exchange infrastructure. Via these communication arrangements, the ABAP environment receives events from the event queue and transfers the events to the event consumption model, which then processes the event. The event is processed according to the logic implemented in the method for handling the event in the consumer extension class.

The following steps are required to configure the event consumer:

[Creating a Communication Arrangement for the Communication Scenario bound to an Event Consumption Model \[page 1147\]](#)

To be able to receive events from the event exchange infrastructure service instance, you must configure the inbound communication from the event exchange infrastructure to the consuming event consumption model.

[Checking Channel Binding \[page 1149\]](#)

This topic describes how to check the channel binding for the enterprise event enablement.

### Related Information

[Queue Subscriptions \[page 1156\]](#)

## 4.2.10.11.3.1 Creating a Communication Arrangement for the Communication Scenario bound to an Event Consumption Model

To be able to receive events from the event exchange infrastructure service instance, you must configure the inbound communication from the event exchange infrastructure to the consuming event consumption model.

### Prerequisites

- You've set up a communication arrangement for `SAP_COM_0092` or `SAP_COM_0492` as described in [Communication Management \[page 1144\]](#).
- You've created an event consumption model and a *Communication Scenario* as described in [Event Consumption \[page 1166\]](#).

## Context

Following the procedure, you create an inbound communication arrangement.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Choose *New*.
4. Select the *Communication Scenario* that was created for the respective event consumption model.

You can recognize the scenario by its `Inbound Service`. An `Inbound Service` is created for each event consumption model and later on assigned to the respective communication scenario.

5. Choose an *Arrangement Name* and click on *Create*.
  6. To assign a communication system, proceed as follows:
    - Assign an existing communication system by selecting a *Communication System*. You can ignore the substeps.
    - Create a communication system as described in [How to Create Communication Systems](#).
- a. In the *General* tab under *Technical Data*, pull the switch for *Event Mesh* to *ON*.

Note that communication arrangements created for an event consumption model only support inbound communication. That's why the *Inbound Only* flag is activated when switching *Event Mesh* on.

- b. In the *General* tab under *Technical Data*, select the *Event Channel* that you've configured as described in [Communication Management \[page 1144\]](#).

The *Event Channel* name you see in the value help is the name that was assigned in the property *Channel* of the respective `SAP_COM_0092` or `SAP_COM_0492` communication arrangement.

- c. In the *Users for Inbound Communication* tab, add an inbound user.

### Note

The *User for Inbound Communication* (inbound user) and the *Communication User* must be maintained as two different users. Make sure to create a dedicated inbound user, apart from your communication user. To create a new inbound user, follow the steps described in [How to Create Communication Users](#).

The inbound user is used later for event processing. This user has authorizations maintained in the `Authorization Default Values` as described in [Adjusting the Generated Artifacts](#).

- d. Choose *Save*.

In general, you can assign multiple event consumption models via the corresponding communication scenarios to the same `SAP_COM_0092` or `SAP_COM_0492` communication arrangement.

## Results

You've created an inbound communication arrangement for your event consumption model.

## Related Information

[How to Create a Communication Arrangement](#)

### 4.2.10.11.3.2 Checking Channel Binding

This topic describes how to check the channel binding for the enterprise event enablement.

## Prerequisites

- You've set up a communication arrangement for `SAP_COM_0092` or `SAP_COM_0492` as described in [Communication Management \[page 1144\]](#).
- You've created an event consumption model and a communication scenario as described in [Event Consumption \[page 1166\]](#).

## Context

Inbound topic bindings are automatically created during generation and configuration of an event consumption model by assigning the communication system of your event consumption model to the corresponding communication arrangement. Maintaining inbound topic bindings can only be done through changes of the communication system of your event consumption model.

Follow the steps below to view the inbound topic bindings.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Select the *Channel* name of the corresponding communication arrangement to which the communication system of your event consumption model has been assigned to in [Creating a Communication Arrangement for the Communication Scenario bound to an Event Consumption Model \[page 1147\]](#).

In the *Inbound Topic Bindings* tab under *Inbound Topics*, the event topics of the event consumption model are displayed. The topics you see here correspond to the event types you've selected during the creation of the event consumption model. Since these are created automatically, the *Maintained by* field has the value *Communication Management*.

4. Maintain the subscriptions in the *Subscriptions* tab as described in [Queue Subscriptions \[page 1156\]](#).

Here you can add all subscription addresses of the respective event exchange infrastructure queues from which you want to consume events.

If a subscription to a queue of the respective event exchange infrastructure service instance is maintained and acknowledged, all events on this queue are consumed by the ABAP environment. Only if the event topics are maintained under *Inbound Topics*, the incoming events are handed over to the consumer extension class of the corresponding event consumption model. If the event topic isn't maintained, the event is consumed without any further processing.

## 4.2.10.11.4 Integration with SAP Enterprise Messaging 1.0 for Cloud Foundry

This section describes the integration of the enterprise event enablement with the integration scenario SAP\_COM\_0092.

### Note

The SAP Enterprise Messaging 1.0 for Cloud Foundry is also referred to as SAP Event Mesh.

### 4.2.10.11.4.1 Communication Arrangements

A communication arrangement is required for the event exchange between ABAP environment and SAP BTP, Cloud Foundry environment.

To use a communication arrangement, you need to create a service instance for the SAP Event Mesh. The service instance contains all information required to establish a connection. This required information, such as endpoints and credentials, is stored in the service key. The enterprise event enablement extracts the information of the service key and creates the corresponding destination and OAuth 2.0 client configuration automatically.

## 4.2.10.11.4.1.1 Creating Communication Arrangements

In this topic, a communication arrangement is created.

### Prerequisites

- You have a subaccount in SAP BTP, Cloud Foundry environment. Refer to [Getting Started with a Trial Account in the Cloud Foundry Environment](#).
- You have created a service instance for SAP Event Mesh. If you haven't created a service instance before, refer to [Creating an Enterprise Messaging Service Instance](#).

#### Note

When defining the *Service Descriptor* for the service instance of the SAP Event Mesh service, make sure that the length of the *namespace* property does not exceed the maximum of 24 characters.

For more information about the syntax, see [Syntax for Service Descriptor](#).

- The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Context

Create a communication arrangement to enable the exchange of events.

#### Note

Events can only be published if the topic space matches the namespace of the SAP Event Mesh service.

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Choose *New* to create a new communication arrangement.
4. Enter or select the *Scenario* `SAP_COM_0092` (communication scenario ID) for *Enterprise Eventing Integration*.
5. Adapt the *Arrangement Name*.
6. To specify additional properties, proceed as follows:
  - You can either use the default values and can ignore the following substeps.
  - To maintain additional properties, choose the *Additional Properties* button and see the following substeps.

- a. Specify the *Channel* name. The *Channel* name is required in the next steps to configure topic bindings.

📌 Note

Optional. If the *Channel* name is not specified, the *Channel* name equals the *Arrangement Name*. The channel name is used as a key in all enterprise event enablement SAP Fiori applications.

- b. Enter a *Description*.

📌 Note

Optional. If you don't enter a description, this field will be filled with a default description similar to **Channel CHANNEL\_NAME for Enterprise Event Enablement**.

- c. Enter the *Topic Space*.

📌 Note

Optional. The *Topic Space* is extracted from the service key.

- d. Enter the *QoS* (Quality of Service) value. The default QoS value is 1.

📌 Note

Optional.

0	1
At most once delivery.	At least once delivery.
The message is delivered according to the capabilities of the underlying network. No response is sent by the receiver and no retry is performed by the sender. The message arrives at the SAP Event Mesh either once or not at all.	This Quality of Service ensures that the message arrives at the SAP Event Mesh at least once.

- e. Enter the *Reconnect Attempts* value. The default value of the reconnection attempts is 0.

📌 Note

Optional. The reconnect attempts value is the number of attempts the enterprise event enablement framework tries to reestablish the connection if the connection is lost.

If the value is 0, the framework tries to reconnect infinitely (until the connection is reestablished).

If any value greater than 0 is specified, the framework tries to reestablish the connection as many times as specified. If the connection is not established after reaching the specified reconnect attempts, the communication arrangement and the underlying channel are deactivated. You can reactivate the communication arrangement and channel by selecting the corresponding communication arrangement and choosing *Reactivate*.

- a. Define the *Reconnect wait time(sec)*. The default wait time for reconnection is 10 seconds.

### Note

Optional. The enterprise event enablement framework waits for the mentioned time (in seconds) and then tries to reconnect. The value entered here is the initial wait time. For all subsequent wait times, the enterprise event enablement framework increases the wait time according to the internal logic. If the attempts fail, the framework increases the wait time until the reconnect wait time (1800 seconds) is reached.

7. Choose *Close* to confirm your entries.
8. Select a *Communication User*.

For information about how to create a communication user, see [Creating Technical Communication User \[page 1145\]](#).

9. Enter the *Service Key*.
10. Choose *Create*.

### Note

The connection is checked automatically. If the check fails, the communication arrangement is not created and the end user is informed about the failure reasons.

The edit page is opened.

11. Optional: In the *Outbound Services* section, under *Delivery of Events*, you can unmark the *Active* checkbox to save the communication arrangement in status "inactive". This can be useful, for example, if you want to complete the allowlisting before activating the communication arrangement. To activate the communication arrangement at a later time, open the edit screen again and set the mark for the *Active* checkbox.
12. Choose *Save*.

After saving the communication arrangement, the channel is activated and the connection is established. The result of the connection test is displayed in the message view on the bottom left.

## Results

You have created a communication arrangement.

### Note

To maintain inbound and outbound bindings, refer to [Configuration of Event Publishing and Event Consumption Scenarios \[page 1162\]](#)

## 4.2.10.11.4.1.2 Maintaining Communication Arrangements

In this topic, a communication arrangement is maintained.

### Prerequisites

The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Context

After creating a communication arrangement, you can still change parameters, either via a service key or by entering parameters manually. You can change the default values for the Quality of Service (QoS), the number of reconnect attempts, the reconnect wait time, and the topic space.

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Select the communication arrangement you want to maintain.

#### Update by Service Key

4. To change connection details, click the *Update by Service Key* button.
5. Enter the service key with the new connection details.
6. Choose *Update* to save your entries.

#### Update Additional Properties

7.  Note

Updating via the additional properties reactivates the communication arrangement and channel (if deactivated).

To change additional properties, choose *Edit*.

8. To save your changes, choose *Save*.

### Results

You have maintained a communication arrangement.

## 4.2.10.11.4.1.3 Deleting Communication Arrangements

In this topic, a communication arrangement is deleted.

### Prerequisites

The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Context

After creating a communication arrangement, you can still delete the communication arrangement.

### Procedure

1. Log on to the SAP Fiori launchpad in the SAP BTP, ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Select the checkbox of the communication arrangement you want to delete.
4. Choose *Delete*.

### Results

You have deleted a communication arrangement.

#### Note

When a communication arrangement is deleted, all events belonging to the channel – including those that have not yet been successfully published to the respective service – are deleted from the event queue. Additionally, the configuration for the underlying channel, such as inbound and outbound bindings, is deleted.

### Next Steps

After deleting the communication arrangement, you need to delete the communication system belonging to the communication arrangement manually.

## 4.2.10.11.4.2 Queue Subscriptions

Events published through an ABAP environment instance can be consumed at the SAP Event Mesh. Events published to a queue defined in your SAP Event Mesh service instance can also be consumed in ABAP environment. Queues can be used to buffer events until a consumer can process them. For the right events to arrive at a queue, the queue must be subscribed to the corresponding topics. A consumer can then subscribe to the queue.

### Context

Once a queue has been subscribed to the corresponding topic and you have subscribed to the queue, you can view the list of applications and service instances. The SAP Event Mesh dashboard enables you to create queues and bind incoming message topics to such queues.

#### Note

The syntax used to compose topics and the payload for ABAP environment business events supports the standardized **CloudEvents** format (<https://cloudevents.io>).

For more information about the syntax, see also [Syntax for Service Descriptor](#).

Ensure that the pattern of the topic, to which the queue is subscribed, consists of the following three parts:

Name	Description
Topic namespace	<ul style="list-style-type: none"><li>• Contains three segments: vendor, product information, and a technical identifier.</li><li>• The topic namespace originates from the namespace of the service key created for the respective SAP Event Mesh instance.</li></ul>
Abbreviation	Value <code>ce</code> for cloud events
Event topic	Value as displayed in the value help in the previous <a href="#">Outbound Topic Binding</a> configuration step.

#### Note

When defining the [Service Descriptor](#) for the service instance of the SAP Event Mesh service, make sure that the length of the `namespace` property does not exceed the maximum of 24 characters.

You can also use wildcards, such as `<namespace> /*`.

#### Example

If you want to create a queue-topic subscription for the `sap/s4/beh/businesspartner/v1/BusinessPartner/Changed/v1` event topic, you need to add the topic namespace and the `ce` abbreviation at the beginning of the topic: `<namespace>/ce/sap/s4/beh/businesspartner/v1/BusinessPartner/Changed/v1`.

## Related Information

[Manage Queue Subscriptions](#)

[Configuration of Event Publishing and Event Consumption Scenarios \[page 1162\]](#)

[CloudEvents Context Attributes \[page 1146\]](#)

### 4.2.10.11.5 Integration with Advanced Mesh Service Plan for Service Cloud

With the SAP Event Mesh Advanced Plan, you can connect directly to your own SAP AEM instance. You can use SAP Event Mesh Advanced Plan for very large projects, where performance is crucial.

If you have a valid subscription to the SAP Integration Suite, advanced event mesh, you can use the Virtual Message Router (VMR) endpoint of SAP AEM broker obtained from the SAP AEM Console UI. The SAP AEM's validation service then only checks if a valid SAP AEM broker instance is available. If a valid SAP AEM instance is available, a direct connection to this instance is established.

This section describes the integration of the enterprise event enablement with the communication scenarios *SAP Advanced Event Mesh Integration* (SAP\_COM\_0492) and *SAP Advanced Event Mesh Validation Service Integration* (SAP\_COM\_0493).

The communication scenario SAP\_COM\_0492 is the prerequisite for SAP\_COM\_0493. To integrate with the SAP Advanced Event Mesh service, you need to create both the scenarios.

For the integration of an ABAP Platform Cloud tenant, you require a subscription to the SAP Advanced Event Mesh service and to the SAP AEM Validation service.

#### 4.2.10.11.5.1 Uploading the Client Certificate

### Context

To connect your ABAP environment system with the SAP AEM broker, you need to upload the client certificate to the SAP AEM broker.

### Procedure

1. To prepare the Client Certificate, proceed as follows:
  - a. On the SAP Fiori launchpad in the ABAP environment system, open the app *Maintain Client Certificate*.
  - b. Open the *Client Default* from the *Client Certificates* list.

- c. Choose *Export*.
- d. On the *Export Certificate* dialog box, choose the *X.509 Certificate (.pem)* format.
- e. Choose *Export*.

#### ⓘ Note

Remove any line breaks from the downloaded certificate before you proceed.

2. To upload the certificate to the SAP AEM broker, proceed as follows:
  - a. Open the SAP AEM broker UI console.
  - b. On the *Manage* tab, choose the *Certificate Authorities* tile.
  - c. Choose the *Add Client Certificate Authority* button.
  - d. Provide a *Certificate Authority Name*.
  - e. Copy the content of the client certificate you downloaded from your ABAP environment system before.
  - f. Paste the the content into *Client Certificate Content* field.
  - g. Choose *Save*.

## 4.2.10.11.5.2 Creating a Communication Arrangement for the Advanced Event Mesh Integration Scenario (SAP\_COM\_0492)

### Context

This communication arrangement is the prerequisite for the *AEM Validation Service* (SAP\_COM\_0493).

### Procedure

To create a communication arrangement, proceed as follows:

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Choose *New*.
4. Enter or select the *Scenario* SAP\_COM\_0492 (communication scenario ID) for *SAP Integration Suite, Advanced Mesh Integration*.
5. Adapt the *Arrangement Name*.
6. Choose *Create*.
  - a. Specify the *Channel* name. The *Channel* name is required in the next steps to configure topic bindings.
  - b. Enter a *Description*.

### Note

Optional.

- c. Enter the *Topic Space*. The topic space is the identifier for events that originate from the same source.

### Tip

You can enable a sender verification for your *Advanced Event Mesh* instance by configuring the access control per client in the *SAP Integration Suite, advanced event mesh*. The following steps are required in your *Advanced Event Mesh* instance:

1. Choose **Access Control** > **ACL Profiles**.
2. Select the client profile for which you want to configure the ACL profile.
3. Choose **Publish Topic**.
4. Select **Disallow** as **Publish Default Action**.
5. Choose the **+ Exception** button.
6. Enter the topic space of your event channel in ABAP environment and a wildcard. For example: topic space/> with SMF or topic space/# with MQTT.

For more information, refer to [Using Client Profiles and Client Usernames](#).

### Note

Mandatory. The topic space has to match regex: `[A-Za-z0-9]{1}(/[A-Za-z0-9\-.]{1,}){2}`

- Segments: exactly three (firstSegment/secondSegment/thirdSegment)
- Allowed characters:
  - First segment: `[a-zA-Z0-9]`
    - Hyphens and dots aren't allowed.
    - Recommended value: Default.
  - Second segment: `[a-zA-Z0-9-.]`
    - Starts with a character or number.
    - Followed by `.` or `-`
    - Must contain at least one character or number before or after the period or hyphen.
  - Third segment: `[a-zA-Z0-9-.]`
  - Use the same guidelines given for the second segment.
  - Max Length: 24

- d. Enter the *QoS* (Quality of Service) value. The default QoS value is 1.

### Note

Optional.

0

At most once delivery.

1

At least once delivery.

0	1
The message is delivered according to the capabilities of the underlying network. No response is sent by the receiver and no retry is performed by the sender. The message arrives at the SAP AEM broker either once or not at all.	This Quality of Service ensures that the message arrives at the SAP AEM broker at least once.

- e. Enter the *Number of Publish Connections*. Defines the number of available parallel connections to the SAP AEM broker for this channel. The default value is 1, the maximum value is 10.

**Note**  
Optional.

- f. Enter the *Reconnect Attempts* value. The default value of the reconnection attempts is 0.

**Note**  
Optional. The reconnect attempts value is the number of attempts the enterprise event enablement framework tries to reestablish the connection if the connection is lost.  
If the value is 0, the framework tries to reconnect infinitely (until the connection is reestablished).  
If any value greater than 0 is specified, the framework tries to reestablish the connection as many times as specified. If the connection is not established after reaching the specified reconnect attempts, the communication arrangement and the underlying channel are deactivated. You can reactivate the communication arrangement and channel by selecting the corresponding communication arrangement and choosing *Reactivate*.

- g. Enter the *Reconnect wait time* in seconds.

**Note**  
Optional. The default time is 10 seconds.

To create a communication system, proceed as follows:

7. In the *Common Data* section, press *New* to create a *Communication System*.
8. In the *New Communication System* dialog box, proceed as follows:
  - a. Enter the *System ID*.
  - b. Enter the *System Name*.
  - c. Choose *Create*.
9. In the *General* tab, in the *Host Name* field, enter the host name of the AMQP connectivity endpoint specified in the cluster manager of the broker instance.

In your *AEM UI Console*, open the *Connect* tab. Find the destination URL under **▶ Connection Details**  
**▶ Secured AMQP Host ▶** Copy the **host name** only.

**Example**  
In this destination URL example:  
`amqps://mr-connection-demo4xyz.messaging.solace.cloud:1234`

The host name is: `mr-connection-demo4xyz.messaging.solace.cloud`

10. Copy the digits from end part of the URL into the *Port* field.

#### ❖ Example

In the above mentioned destination URL example, the port number is 1234.

11. In the *Users for Inbound Communication* tab, press +.

This user is used to run the background process that keeps the connection up and running.

12. In the *New Inbound Communication User* dialog box, proceed as follows:

- a. Choose the *Authentication Method User Name and Password*.
- b. Enter the *User Name*.
- c. Enter a *Description*.
- d. Choose the *Propose Password* button.

#### 🕒 Note

The password is optional. You can leave the field empty.

- e. Choose *Create*.
  - f. Choose *OK*.
13. In the *Users for Outbound Communication* tab, press +.
  14. In the *New Outbound User* dialog box, proceed as follows:
    - a. Choose the *Authentication Method SSL Client Certificate*.
    - b. Choose the *Client Default* for the *Client Certificate* from the value help.
    - c. Choose *Create*.
  15. Choose *Save* to save the communication system.
  16. Choose *Save* to save the communication arrangement.

Note that the connection to the SAP Advanced Event Mesh only becomes active after creation of SAP\_COM\_0493.

### 4.2.10.11.5.3 Creating a Communication Arrangement for the Advanced Event Mesh Validation Service Integration (SAP\_COM\_0493)

## Context

This communication arrangement is needed to validate the SAP AEM broker destination URL.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Communication Arrangements* artifact.
3. Choose *New* to create a new communication arrangement.
4. Enter or select the *Scenario* SAP\_COM\_0493 (communication scenario ID) for *SAP AEM Validation Service*.
5. Adapt the *Arrangement Name*.
6. Choose the *Additional Properties* button.
  - a. For *Channel*, enter the name of the first channel you created in the previous chapter (SAP\_COM\_0492).
7. Choose *Close* to confirm your entries.
8. Enter the *Service Key*.

You find the service key in your SAP BTP Cockpit Subaccount under *View Credentials*.
9. Choose *Create*.

To check the connection, proceed as follows:

10. In the *Communication Management* app, go to *Communication Arrangements*.
11. Open the SAP\_COM\_0492 channel you created before.
12. Under *Outbound Services*, choose the *Check Connection* button.

The connection is tested. You get a status message from the Fiori Launchpad whether the connection check was successful.

## Results

### Note

To maintain inbound and outbound bindings, refer to [Configuration of Event Publishing and Event Consumption Scenarios \[page 1162\]](#)

### 4.2.10.11.6 Configuration of Event Publishing and Event Consumption Scenarios

You can define which event types shall be published or consumed using a connection defined through the communication arrangement. Each event type is assigned to one topic. Topics form a logical tree to organize events, such as a folder hierarchy in a file system. Thus, the topics appear as strings that consist of multiple segments and are separated by one defined delimiter, similar to file paths.

### Note

Only events, which are bound to a connection, can be exchanged between an ABAP environment system and the SAP Business Technology Platform.

The following steps are required to configure event publishing and event consumption scenarios:

[Event Publishing \[page 1163\]](#)

[Event Consumption \[page 1166\]](#)

[Event Metadata \[page 1170\]](#)

## 4.2.10.11.6.1 Event Publishing

The following chapters describe how to publish events to a consumer using outbound event topics. You can also use filters to determine the type of events that are published.

### Note

Event publishing is only relevant for the integration with SAP Event Mesh and Advanced Event Mesh. It is not relevant for the integration with SAP Event Broker.

### 4.2.10.11.6.1.1 Maintain Outbound Event Topics

#### Prerequisites

- You have established a connection through the configuration of the communication arrangement in the previous steps. For more information, refer to [Communication Arrangements \[page 1150\]](#).
- The *Enterprise Event Enablement – Configure Channel Bindings* app is visible.  
If the *Enterprise Event Enablement – Configure Channel Bindings* app is not visible, add the *Enterprise Event Enablement* business catalog to the `SAP_BR_ADMINISTRATOR` role using the *Maintain Business Roles* app. The change in your role becomes effective after you have logged out and logged in again.

#### Context

You can configure outbound event topic bindings for publishing events.

#### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.

3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)).
4. In the *Outbound Topic Bindings* tab, you can do the following:

Option	Description
<b>Create a new topic.</b>	<ol style="list-style-type: none"> <li>1. Choose <i>Create</i>.</li> <li>2. Enter a topic name.</li> <li>3. Choose <i>Create</i> to save your entries.</li> </ol> <p>The new topic will be listed in the <i>Topic</i> table.</p>
<b>Delete an existing topic.</b>	<ol style="list-style-type: none"> <li>1. Select the checkbox of the topic you want to delete.</li> <li>2. Choose <i>Delete</i>.</li> </ol>
<b>Define table parameters.</b>	Click the gear icon to define the table parameters.

## Next Steps

Events reside in an internal queue of the enterprise event enablement. Once the processing of an event is finalized, it is deleted from the queue. The processing of an event is finalized if:

<b>Status: Ok</b>	The event has been successfully published according to the chosen quality of service.
<b>Status: Failed</b>	The enterprise event enablement failed to publish the event after 5 attempts.

## Related Information

[Queue Subscriptions \[page 1156\]](#)

### 4.2.10.11.6.1.2 Maintain Filters for Outbound Event Topics

You can filter the events that should be sent via a channel by defining filters per channel and topic.

## Prerequisites

- You have created an outbound event topic as described here: [Maintain Outbound Event Topics \[page 1163\]](#)

- **Note**

Event filters for event topics containing wildcards are not supported.

## Context

You can define filters for context and extension context attributes defined for the corresponding event type. In the *RESTful Application Programming* framework (RAP), you can define a custom context attribute for your RAP business object with the CDS annotation `@event.context.attribute`.

For more information on the CDS annotation, see: [Event Annotations](#)

The custom defined context attribute is then available as a property in the event filter creation wizard in the *Enterprise Event Enablement – Configure Channel Binding* app.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Choose a channel.

In the *Outbound Topics* table, the column *Has Event Filters* indicates whether filters are defined for the outbound topic.

4. Open an *Outbound Topic*.

Choose the *Event Filter* tab to display existing filters for the outbound topic.

5. To add a filter to the outbound topic, choose *Create Event Filter*.
6. On the *Create Event Filter* dialog box, proceed as follows:
  - a. Select a *Property* from the dropdown menu. The properties available in the dropdown menu are defined by the extension attributes.
  - b. Choose an *Option* from the dropdown menu to define the filter behavior.
  - c. Define a *Low Value*. You can use the value help, if available for the respective property.
  - d. If applicable, define a *High Value*.
  - e. Choose *Create Event Filter*.

The new filter is added to the outbound topic. In accordance with existing filters, the new filter is added with an *OR* logic for inclusive options such as *EQUALS*. New filters are added with an *AND* logic for exclusive options such as *NOT EQUALS*. Different Properties are always *AND* connected.

To delete a filter from an outbound event topic, select one or more filters and choose the *Delete* button.

### Note

For more information on the usage of event filters, refer to [3343266](#).

## 4.2.10.11.6.2 Event Consumption

Event consumption can be configured manually for some event types (for example subscription billing). These configuration options are described in this section. For all other event types, follow the steps described in [Creating an Event Consumption Model](#).

You can configure the consumption of events. To do so, proceed as follows:

[Configuring Inbound Event Topic Bindings \[page 1166\]](#)

[Configuring Subscriptions \[page 1168\]](#)

[Simulating Consumption \[page 1169\]](#)

### 4.2.10.11.6.2.1 Configuring Inbound Event Topic Bindings

#### Prerequisites

- You have established a connection through the configuration of the communication arrangement in the previous steps. For more information, refer to [Communication Arrangements \[page 1150\]](#).
- The *Enterprise Event Enablement – Configure Channel Bindings* app is visible.  
If the *Enterprise Event Enablement – Configure Channel Bindings* app is not visible, add the *Enterprise Event Enablement* business catalog to the `SAP_BR_ADMINISTRATOR` role using the *Maintain Business Roles* app. The change in your role becomes effective after you have logged out and logged in again.

#### Context

You can configure event consumers delivered by SAP manually.

#### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)).
4. In the *Inbound Topic Bindings* tab, you can do the following:

Option	Description
Create a new topic.	<ol style="list-style-type: none"> <li>1. Choose <i>Create</i>.</li> <li>2. Enter a topic name.</li> <li>3. Choose <i>Create</i> to save your entries.</li> </ol> <p>The new topic is listed in the <i>Inbound Topics</i> table.</p>
Delete an existing topic created by an end user.	<ol style="list-style-type: none"> <li>1. Select the checkbox of the topic you want to delete.</li> <li>2. Choose <i>Delete</i>.</li> </ol>
Define table parameters.	Click the gear icon to define the table parameters.

## Next Steps

The *Inbound Topics* table contains all inbound event topic bindings that exist for the selected channel and communication arrangement. The fields can have the following values:

Status: Ok

Status: Incomplete	No topic consumer exists for current topic binding.
Status: Invalid	The current topic binding is invalid for at least one topic consumer. This means either the topic filter doesn't exist or the corresponding destination is incorrect.
Topic	Is the topic presentation.
Maintained by: End User	The event inbound topic binding was created manually by a user.
Maintained by: Communication Management	The event inbound topic binding was created automatically during the configuration of a generated event consumption model.

### Note

In case invalid bindings maintained by an end user exist, you can delete this binding by:

- choosing *Delete invalid bindings* on top of the page or
- selecting the respective topic and choosing *Delete*.

### Note

To enable the consumption of events, the AMQP protocol replaces the MQTT protocol. New communication arrangements use the AMQP protocol by default. Existing communication arrangements can be updated via the service key. To do so, refer to [Maintaining Communication Arrangements \[page 1154\]](#)

## 4.2.10.11.6.2.2 Configuring Subscriptions

### Prerequisites

- You have established a connection through the configuration of the communication arrangement in the previous steps. For more information, refer to [Communication Arrangements \[page 1150\]](#).
- The *Enterprise Event Enablement – Configure Channel Bindings* app is visible.  
If the *Enterprise Event Enablement – Configure Channel Bindings* app is not visible, add the *Enterprise Event Enablement* business catalog to the `SAP_BR_ADMINISTRATOR` role using the *Maintain Business Roles* app. The change in your role becomes effective after you have logged out and logged in again.

#### Note

Subscriptions are only available for SAP Event Mesh and Advanced Event Mesh.

### Context

Subscriptions, which are based on a queue, provide all incoming events. These incoming events are forwarded to the corresponding consumer.

#### Note

Events are only forwarded to an event consumer when an inbound event topic binding exists for the related event topic.

### Procedure

1. Log on to the SAP Fiori launchpad in the SAP S/4HANA Cloud system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)).
4. In the *Subscriptions* tab, you can do the following:

Option	Description
<b>Create a new subscription.</b>	<ol style="list-style-type: none"><li>1. Choose <i>Create</i>.</li><li>2. Enter a valid subscription address that corresponds to the name of the queue created in the respective event exchange infrastructure.</li><li>3. Choose <i>Create</i> to save your entries.</li></ol>

Option	Description
	The new subscription is listed in the <a href="#">Subscriptions</a> table.
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>When working with SAP Event Mesh, you can create a maximum of 10 subscriptions.</p> </div>
<b>Delete an existing subscription.</b>	<ol style="list-style-type: none"> <li>Select the checkbox of the subscription you want to delete.</li> <li>Choose <a href="#">Delete</a>.</li> </ol>
<b>Define table parameters.</b>	Click the gear icon to define the table parameters.

## Next Steps

Subscriptions must have a valid subscription address provided by the respective event exchange infrastructure. Both subscriptions and inbound bindings are required to consume events. For more information, refer to [Configuring Inbound Event Topic Bindings \[page 1166\]](#).

The [Subscriptions](#) table contains all subscriptions that exist for the selected channel. The different fields can have the following values:

<b>Status: New</b>	Subscription was newly created and has not been acknowledged by the respective event exchange infrastructure service instance yet.
<b>Status: Acknowledged</b>	Subscription is active and acknowledged by the respective event exchange infrastructure service instance.
<b>Status: Rejected</b>	The channel has been deactivated and the subscription is rejected by the respective event exchange infrastructure service instance.
<b>Status: Inactive</b>	Subscription wasn't acknowledged by the respective event exchange infrastructure service instance.
<b>Subscription Address</b>	Depicts the current address.
<b>Type Kind</b>	Queue-Based Subscription

### 4.2.10.11.6.2.3 Simulating Consumption

#### Prerequisites

- The [Enterprise Event Enablement – Configure Channel Bindings](#) app is visible.

If the *Enterprise Event Enablement – Configure Channel Bindings* app is not visible, add the *Enterprise Event Enablement* business catalog to the `SAP_BR_ADMINISTRATOR` role using the *Maintain Business Roles* app. The change in your role becomes effective after you have logged out and logged in again.

- You have an inbound topic binding with status *Ok* in your *Inbound Topics* table.

## Context

To allow you to test your consumer implementation, you can use the *Simulate Consumption* action. Then a dummy event of a given *Topic Consumer* will be sent to its consumer implementation.

## Procedure

1. Log on to the SAP Fiori launchpad in the SAP S/4HANA Cloud system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)).
4. Select an *Inbound Topic*.

If you have no *Inbound Topic* with *Status: Ok*, refer to [Configuring Inbound Event Topic Bindings \[page 1166\]](#)

5. Select the radio button of the *Topic Consumer* you want to simulate consumption with.
6. Choose *Simulate Consumption*.

## Results

In case of a wildcard in the topic, the wildcard is resolved and events for all resolved topics are created. The dummy events are sent to the corresponding consumer implementation. Then the simulated event is retrieved from the internal event queue and the status is checked. A short message is raised, informing the user on the success or failure of the simulation.

### 4.2.10.11.6.3 Event Metadata

## Prerequisites

- You have established a connection through the configuration of the communication arrangement in the previous steps. For more information, refer to [Communication Arrangements \[page 1150\]](#).

- The *Enterprise Event Enablement – Configure Channel Bindings* app is visible.  
If the *Enterprise Event Enablement – Configure Channel Bindings* app is not visible, add the *Enterprise Event Enablement* business catalog to the `SAP_BR_ADMINISTRATOR` role using the *Maintain Business Roles* app.  
The change in your role becomes effective after you have logged out and logged in again.

## Context

The enterprise event enablement is applying the CloudEvents specification (<https://cloudevents.io>) for the runtime representation of an event. CloudEvents is a specification for describing event data in common formats to ensure interoperability across services, platforms, and systems.

You can find all released SAP events on the SAP Business Accelerator Hub (<https://api.sap.com>). The SAP Business Accelerator Hub is the central catalog of SAP and selected partner APIs to search, discover, test, and consume these APIs to build extensions or integrations using the SAP Business Technology Platform.

The enterprise event enablement applies the AsyncAPI specification to describe a catalog of events.

### Note

You can find the corresponding AsyncAPI event catalogs for released events in the *Event Resources* section of the individual released events on the SAP Business Accelerator Hub. This specification is required for example to create an event consumption model.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Configure Channel Binding* app.
3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)).
4. Select *Event Metadata*.

## Next Steps

In the *Event Metadata* tab, you can view the metadata for the event types selected on the *Outbound Topic Bindings* tab for event publishing. This metadata contains the definition of the structure of all event types, which you have selected for publishing from the ABAP environment system. The metadata is represented as an AsyncAPI catalog of events and can contain released SAP events as well as customer events. You can also use the AsyncAPI representation for creating your event consumption model.

## Related Information

[CloudEvents Context Attributes \[page 1146\]](#)

[Creating an Event Consumption Model](#)

### 4.2.10.11.7 Read Access Logging (RAL)

With [Read Access Logging](#) (RAL) for events, you can monitor and log read access to sensitive data because of diverse data privacy regulations. The categorization of sensitive data can vary: it can depend on your country's code of law or on your external or internal company policies. RAL thus helps you to find out who had access to sensitive data, in which way and at what time.

RAL is offered for different channels. A channel is a way for data to leave the system, for example dynpros of Web services. The enterprise event enablement is another channel that is supported in the central RAL monitor.

For more information on RAL in the context of SAP NetWeaver, see [Read Access Logging](#).

#### Note

Using RAL requires system resources. This can have a strong impact on your system performance, depending on the number and type of logs.

Events can be logged for two scenarios:

- Read access of events during support (monitoring)  
This is the case when the event monitor was opened by SAP support to check the payload of sent or consumed events.
- Read access of events during sending (runtime)  
This is the case when an outbound binding exists and an event is to be sent to the respective event exchange infrastructure by the enterprise event enablement. For more information, refer to [Configuration of Event Publishing and Event Consumption Scenarios \[page 1162\]](#).

You can define which properties of an event are to be logged to avoid that all events are logged. Consider this carefully as it may affect the system performance.

The following types can be logged once a corresponding configuration exists:

Channel Fields	Condition Fields	Access Context
	Cloud Event Context Fields	<ul style="list-style-type: none"><li>• Source</li><li>• Type</li><li>• Id</li><li>• Time</li></ul>
	Payload Types	Payload types of a selected producer or consumer. A producer or consumer is a set of event types belonging to a business entity.

System Fields

User Name

---

Screen Title

---

Transaction code

---

## 4.2.10.11.7.1 Searching for Existing Configurations

### Prerequisites

The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Read Access Logging Configuration* app, select the *Administration* tab.
3. Choose *Configuration*.
4. Choose *Enterprise Event Enablement* as *Channel*.
5. Specify your *Search Criteria*:
  - Registration ID
  - Registration Version
  - Repository ID
  - Event Scenario
  - Description
  - State
6. Click *Search*.

### Results

A list of existing configurations is displayed.

## 4.2.10.11.7.2 Creating Configurations

### Prerequisites

The key user must have the business role `SAP_BR_ADMINISTRATOR` (Administrator) that contains the business catalog `SAP_CORE_BC_COM` (Communication Management).

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
  2. In the *Read Access Logging Configuration* app, select the *Administration* tab.
  3. Choose *Configuration*.
  4. Choose *Enterprise Event Enablement* as *Channel*.
  5. Click *Create* at the bottom of the page.
  6. On the *Create Configuration* screen, you can search for existing event consumers or event producers to which you can assign a configuration. To do so, specify your search criteria:
    - Registration ID
    - Registration Version
    - Repository ID
    - Event Scenario
    - Busi Object Name
- a. Click *Search*.  
A list of existing producers (P) and consumers (C), matching your search criteria, is displayed.

#### Note

If you do not specify your search criteria and click *Search*, all existing producers and consumers are displayed.

- b. Choose one producer or consumer.
- c. Click *Create*.  
For the chosen consumer or producer, the following sections are displayed:

#### Attributes

- *Application/Software Component* that is assigned to a consumer or producer
- Description for the *Application/Software Component*

---

#### Administrative Information

- *Technical Data*
  - *Created*
  - *Changed*
-

## Log Groups

Log groups are groups of fields that are displayed in one log entry in the read access log.

To add a log group, do the following:

- Click the button with the tooltip *Create Log Group*.
- In the *Create Log Group* dialog box, do the following:
  - Define the *Purpose*.
  - Define the *Description*.
- Click *Create*.

### Note

Keep in mind to drag and drop *Channel Fields* and/or *System Fields* from the *Field list* to the *Fields* section of the log group.

### Tip

You can create log groups without adding conditions. If you want to add conditions, uncheck the *Without Condition* flag.

---

## Conditions

To add a condition, do the following:

- Click the button with the tooltip *Create Condition*.
- In the *Create Condition* dialog box, do the following:
  - Define the *Condition*.
  - Define the *Description*.
- Click *Create*.

---

## Field list

---

- d. Click *Save as Active* to activate your configuration.

## Related Information

[Defining Conditions for Configurations \[page 1176\]](#)

## 4.2.10.11.7.3 Defining Conditions for Configurations

### Prerequisites

You've created a configuration in the *Read Access Logging Configuration* app. Refer to [Creating Configurations \[page 1174\]](#).

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Read Access Logging Configuration* app, select the *Administration* tab.
3. Choose *Configuration*.
4. Choose *Enterprise Event Enablement* as *Channel*.
5. Search for your configuration in the *Search Criteria* section. Refer to [Searching for Existing Configurations \[page 1173\]](#).
6. Click the *Edit Configuration* icon of the configuration you want to define a condition for.
7. In the *Conditions* section, click the button with the tooltip *Create Condition*.
  - a. Define the *Condition*.
  - b. Define the *Description*.
  - c. Click *Create*.

### Next Steps

Adding conditions is recommended to specify configurations (refer to [Adding Expressions to Conditions \[page 1176\]](#)). This can influence the system performance depending on the logging scenario you have chosen. If you have chosen read access of events during support (monitoring), the system performance is improved. If you have chosen read access of events during sending (runtime), the system performance can become worse.

## 4.2.10.11.7.4 Adding Expressions to Conditions

### Prerequisites

You've created a condition for a configuration in the *Read Access Logging Configuration* app. Refer to [Defining Conditions for Configurations \[page 1176\]](#).

## Context

Once you've created a condition and you want to log events only in a certain context, like at runtime, add an expression to your condition.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Read Access Logging Configuration* app, select the *Administration* tab.
3. Choose *Configuration*.
4. Choose *Enterprise Event Enablement* as *Channel*.
5. Search for your configuration in the *Search Criteria* section. Refer to [Searching for Existing Configurations \[page 1173\]](#).
6. Click the *Edit Configuration* icon of the configuration you want to define a condition for.
7. In the *Conditions* section, select the condition you want to add expressions for.
8. Click *Create* in the *Expressions* section of the condition.
  - a. Define a name for the *Expression*.
  - b. Choose *Create*.

The *Attributes* and *Select options* are displayed in the *Details of Expression* section.

9. Drag and drop the *Access Context* condition field from the **Field List** **Channel Fields** **Condition Fields** to the *Select options* section under *Details of Expression*.
10. Click *Save as Active* to activate your configuration including assigned conditions.

## Related Information

[Defining Configurations in Read Access Logging](#)

## 4.2.10.11.7.5 Monitoring Logged Events

### Prerequisites

The user must have the business role BR\_DATA\_PRIVACY\_SPECIALIST (Data Privacy Specialist). If the user doesn't have the business role BR\_DATA\_PRIVACY\_SPECIALIST, add the business role in the *Maintain Business Roles* app.

Using the business role `BR_DATA_PRIVACY_SPECIALIST`, you can block, unblock, and display blocked personal data. Refer to [Access Control and Data Protection](#).

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. Select the *Read Access Logging: Monitor* app.
3. Choose *Raw Database* as *Source* in the *Data Source* section.
4. Specify your search criteria:
  - Channel
  - Date/Time
  - User Name
  - Application Comp.
  - Software Component
5. Specify the *Maximum Number of Hits*.
6. Choose *Search*.  
A list of logs according to the search criteria is displayed.

### 4.2.10.11.8 Message Monitoring

The `/IWXBE_TECHNICAL` interface allows you to receive messages in case a technical error occurs. You can monitor the messages using the *Message Monitoring for Integration Experts* app, provided by the SAP Application Interface Framework (SAP AIF).

To display messages in the *Message Monitoring for Integration Experts* app, proceed as follows:

[Assigning Recipients to Users \[page 1178\]](#)

[Assigning users to the SAP Application Interface Framework \[page 1180\]](#)

[Using Message Monitoring \[page 1181\]](#)

#### 4.2.10.11.8.1 Assigning Recipients to Users

### Prerequisites

The user must have the business role `BR_CONF_EXPERT_BUS_NET_INT` (Configuration Expert – Business Network Integration). If the user doesn't have the business role `BR_CONF_EXPERT_BUS_NET_INT`, add the business role in the *Maintain Business Roles* app.

## Context

Before you can display messages in the *Message Monitoring for Integration Experts* app, you must assign a user to a specific recipient.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. Open the *Assign Recipients to Users* app.  
A list containing all users that are already assigned to recipients is displayed.
3. Click the + in the bottom row of the left-hand side of the screen.

### Note

If you want to add additional recipients to a user who is already assigned to a recipient, use the *Search Users with Assigned Recipients* search field.

4. On the *Add User* dialog box, enter a user name or a user ID.
5. Choose *Add*.
  - a. In the *Assign Recipients* dialog box, enter the following:
    - *Namespace*: /IWXBE
    - *Recipient Name*: RECIPIENT\_CHANNEL
    - *Message Type*: *Technical Error*
  - b. Choose *Assign* to save the user assignment.  
The assigned recipient is now displayed in the *Recipients for User* list.

## Next Steps

If you want to assign additional recipients to the user, click the *Assign* button on the right hand side of the *Recipients for User* list and repeat the steps.

## 4.2.10.11.8.2 Assigning users to the SAP Application Interface Framework

### Prerequisites

The user must have the business role BR\_CONF\_EXPERT\_BUS\_NET\_INT (Configuration Expert – Business Network Integration). If the user doesn't have the business role BR\_CONF\_EXPERT\_BUS\_NET\_INT, add the business role in the *Maintain Business Roles* app.

### Context

In order to receive alerts for the consumption with the given event consumption model, you can assign your user to the SAP Application Interface Framework interface by a corresponding recipient.

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. Open the *Assign Recipients to Users* app.  
A list containing all users that are already assigned to recipients is displayed.
3. Click the + in the bottom row of the left-hand side of the screen.

#### Note

If you want to add additional recipients to a user who is already assigned to a recipient, use the *Search Users with Assigned Recipients* search field.

4. On the *Add User* dialog box, enter a user name or a user ID.
5. Choose *Add*.
  - a. In the *Assign Recipients* dialog box, enter the following:
    - *Namespace*: / IWXBE
    - *Recipient Name*: Choose the generated recipient name.  
The generated recipient name is a <generic\_hash> with the description <event\_consumption\_model\_id> <event\_consumption\_model\_version> ##GENERATED.
    - *Message Type*: Choose a *Message Type*.

#### Tip

There is also a general monitoring case with the *Recipient Name RECIPIENT\_CHANNEL*. Refer to *Assigning Recipients to Users* [page 1178].

- b. Choose [Assign](#) to save the user assignment.  
The assigned recipient is now displayed in the [Recipients for User](#) list.

## Next Steps

If you want to assign additional recipients to the user, click the [Assign](#) button on the right hand side of the [Recipients for User](#) list and repeat the steps.

## 4.2.10.11.8.3 Using Message Monitoring

### Context

Before you can display messages in the [Message Monitoring for Integration Experts](#) app, you must assign a user to a specific recipient. Refer to [Assigning Recipients to Users \[page 1178\]](#).

### Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. Open the [Message Monitoring for Integration Experts](#) app.
  - a. Enter the following parameters:
    - [Time](#): Define the period of time to be considered.
    - [From](#): Specify the period of time.
    - [To](#): Specify the period of time.
    - [Interface](#): Enter `/IWXBE_TECHNICAL` or select `/IWXBE_TECHNICAL` from the combo box.
    - [Additional Interface Options](#): Specify the interface that should be displayed.
  - b. Choose [Go](#).

The [Message Status Overview](#) screen displays your interfaces and all error messages with the following states:

- All
- Error
- Warning
- Success
- In Process
- Canceled

## Next Steps

You can click the number of received messages of a specific status to display the corresponding list of messages. Select a message from the [Log Details](#) section to display the log message details on the right-hand side of the screen. If there is a correlation between the error message and the related communication arrangement, the [Display Communication Arrangement](#) link is displayed in the [Functions](#) section. Click the link to open the [Communication Arrangements](#) app and to display the related communication arrangement.

### Note

You need authorization to open the [Communication Arrangements](#) app. For more information, refer to [Creating Technical Communication User \[page 1145\]](#).

## Related Information

[Message Monitoring for Integration Experts](#)

## 4.2.10.11.9 Monitoring Events

### Prerequisites

- You have established a connection through the configuration of the communication arrangement in the previous steps. For more information, refer to [Communication Arrangements \[page 1150\]](#).
- The [Enterprise Event Enablement – Event Monitor](#) app is visible.  
If the [Enterprise Event Enablement – Event Monitor](#) app is not visible, add the [Enterprise Event Enablement](#) business catalog to the `SAP_BR_ADMINISTRATOR` role using the [Maintain Business Roles](#) app. The change in your role becomes effective after you have logged out and logged in again.

### Context

Using the [Enterprise Event Enablement – Event Monitor](#) app, you can monitor events by status and access the payload.

## Procedure

1. Log on to the SAP Fiori launchpad in the ABAP environment system.
2. In the *Communication Management* app, select the *Enterprise Event Enablement – Event Monitor* app. You will see an overview of all configured channels. The columns filled with numbers correspond to the number of events for a given status.
3. Choose a channel name (created in [Creating Communication Arrangements \[page 1151\]](#)) to access detailed information. The *Inbound Events* and *Outbound Events* tabs contain all inbound or outbound events by topic and status.
4. Select a *Topic*. All events for the given topic and status are listed.
5. Select an event to access detailed information. The detailed view of a consumer inbound event contains:

<i>Times</i>	<ul style="list-style-type: none"> <li>• <i>Publish Time</i></li> <li>• <i>Arrival Time</i></li> <li>• <i>Consume Time</i></li> <li>• <i>Fail Time</i></li> </ul>
<i>Event Data</i>	<ul style="list-style-type: none"> <li>• <i>Cloud Event Source</i></li> <li>• <i>Cloud Event ID</i></li> <li>• <i>Quality of Service</i></li> </ul>
<i>Consumed by</i>	<ul style="list-style-type: none"> <li>• <i>Consumer ID</i></li> <li>• <i>Consumer Version</i></li> </ul>
<i>Payload</i>	<ul style="list-style-type: none"> <li>• <i>Payload</i></li> <li>• <i>Size (kB)</i></li> </ul>

Events reside in an internal queue of the enterprise event enablement. Once the processing of an event is finalized, it is deleted from the queue after a certain time period. Processing an event is finalized if the status is acknowledged or failed.

Deletion timeline	Event status	Description
Hourly before the current full hour	Acknowledged	The event has been successfully published or consumed according to the chosen quality of service. An hourly background job deletes all acknowledged events from the event monitor.
No deletion	Failed	The enterprise event enablement either failed to publish the event after 5 attempts or the event could not be consumed by the corresponding consumer. Failed events are stored until you either delete or retry them again.

Deletion timeline	Event status	Description
No deletion	Not processed yet	All events that have a different status than acknowledged or failed are not deleted since they are not yet fully processed.

The timeline for deleting is subject to change.

## 4.2.11 SaaS Applications and Multitenancy

Find out how to develop and operate SaaS applications by using add-ons in the ABAP environment, see [Developing and Operating SaaS Applications \[page 1184\]](#).

Learn more about multitenancy in the ABAP environment, the multitenant application, tenant business types and lifecycle, and see the multitenancy development guideline: [Multitenancy in the ABAP Environment \[page 1290\]](#).

Find out how to use the [Landscape Portal \[page 1302\]](#), the central tool that allows providers to perform system administration tasks and lifecycle management operations.

Read about how SaaS applications can be extended, see [Extending SaaS Applications \[page 1342\]](#).

### 4.2.11.1 Developing and Operating SaaS Applications

Learn how to develop and operate SaaS applications by using add-ons in the ABAP environment.

#### Introduction

The ABAP environment allows you to leverage existing ABAP know-how to create custom add-ons in the cloud. This add-on build process is orchestrated by using the ABAP environment. Delivery tools, such as the Add-on Assembly Kit as a Service for the registration and publishing of the add-on as a software product, and deployment tools to carry out test installations and to make the add-on available for productive use, simplify this process. See [Delivery Tools](#) and [Deployment Tools](#).

#### Note

You should only consider using add-on delivery if you intend to offer a Software as a Service (SaaS) solution.

Following the add-on build process, you can develop a multitenant application to share the add-on with multiple consumers (tenants) simultaneously. See [Multitenant Applications \[page 1259\]](#). The application is registered with the Software-as-a-Service provisioning service (saas-registry) to make the application available for subscription to consumers. See [Register the Multitenant Application to the SaaS Provisioning Service](#).

In this context, the [ABAP Solution Service \[page 1262\]](#) accounts for the provisioning of new ABAP service instances, including the installation of the add-on, and the creation of tenants whenever required for a new consumer subscription.

The way ABAP service instances and tenants are used for consumer subscription applications can be configured as follows:

- **Single-tenant enabled:** With each new consumer, a new ABAP service instance is created
- **Multi-tenant enabled:** For multiple consumers, the same ABAP service instance is used

For more information, see [Multitenancy in the ABAP Environment](#).

## What Is This Guide About?

This guide describes the end-to-end process of developing and offering a SaaS solution using the ABAP environment. The following chapters cover all aspects of this scenario, from the initial setup and development tasks to the final productive use by consumers.

The [Concepts \[page 1210\]](#) chapter gives you an overview about important concepts that are relevant throughout the end-to-end process.

The [Glossary \[page 1205\]](#) contains a list of all the technical terms and phrases used in this scenario.

Chapter [Develop, Test, Build \[page 1234\]](#) describes the actual development activities. This includes the setup of the required account structure and system landscape, as well as the recommended testing process and subsequent build of the add-on.

Chapter [Order and Provide \[page 1255\]](#) illustrates how a developed add-on can be deployed and made available to consumers. It also shows how consumers order solutions and what steps you, as the provider, need to perform to provision the solution.

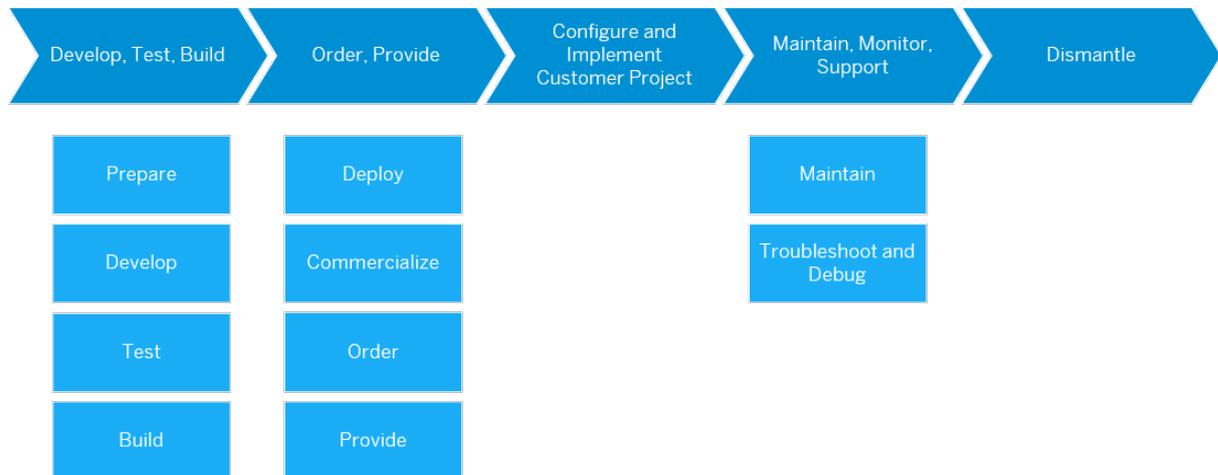

Chapter [Configure and Implement a Customer Project \[page 1278\]](#) describes how to configure and implement a customer project in the consumer tenant, including the setup of identity and authentication management, integration with other systems or services, and adjustment of business configuration.

Chapter [Maintain, Monitor, Support \[page 1281\]](#) gives you an overview about the activities involved in maintaining an already commercialized product, as you usually continue to support the add-on, fix bugs, and potentially offer new functionalities as time goes on.

Chapter [Dismantle \[page 1290\]](#) provides information about consumer offboarding, in particular about deleting and restoring tenants.

### Note

If you decide to use gCTS transport instead of add-on delivery, please refer to the gCTS Delivery boxes across the guide. See [Delivery via Add-On or gCTS \[page 1228\]](#).

### ⚠ Caution

The tutorial group "Convert Your Add-on Product into a Tenant-aware SaaS Solution" is now replaced by the functionality of the [Maintain Solution app](#).

## Related Information

## 4.2.11.1.1 Overview

### Develop, Test, Build

Phase	Step	Description	User/Role
<a href="#">Prepare [page 1235]</a>	Register a namespace. See <a href="#">Register a Namespace [page 1236]</a> .	A namespace is mandatory and must be reserved at <a href="https://support.sap.com/namespaces">https://support.sap.com/namespaces</a> .	S-user

**Note**

You have to register a namespace before the first ABAP system is provisioned. To create namespaces after system provisioning, see [Maintain Namespaces \[page 1308\]](#).

Namespaces should have 5–8 characters due to length restrictions of certain objects. See SAP note [105132](#) and [395083](#).

Phase	Step	Description	User/Role
	Set up a global account for development. See <a href="#">Set Up a Global Account for Development [page 1237]</a> .	<p>Get a partner development license for discounted systems used for development, test, or demo purposes. These systems are provisioned in the global account for development.</p> <p>Required entitlements:</p> <ul style="list-style-type: none"> <li>• Services: <ul style="list-style-type: none"> <li>• abap/standard and abap/saas_oem</li> <li>• Application runtime for approuter</li> <li>• abap-solution (ABAP Solution Provider)</li> </ul> </li> <li>• Applications: <ul style="list-style-type: none"> <li>• Landscape Portal</li> <li>• Web access for ABAP</li> <li>• SAP Business Application Studio for UI development</li> </ul> </li> </ul> <p>The <code>saas-registry</code> and <code>xsuaa</code> service are available without entitlement.</p> <p>See <a href="#">SAPPartnerEdge Test, Demo and Development Price List</a>.</p>	Operator

Phase	Step	Description	User/Role
	Set up a global account for production. See <a href="#">Set Up a Global Account for Production [page 1239]</a> .	<p>Get a partner production license for systems used for production purposes. These systems are provisioned in the global account for production.</p> <p>Required entitlements:</p> <ul style="list-style-type: none"> <li>• Services: <ul style="list-style-type: none"> <li>• abap/saas_oem</li> <li>• Application runtime for approuter</li> <li>• abap-solution (ABAP Solution Provider)</li> <li>• saas-registry (without entitlement)</li> <li>• xsuaa (without entitlement)</li> </ul> </li> <li>• Applications: <ul style="list-style-type: none"> <li>• Landscape Portal</li> <li>• Web access for ABAP</li> </ul> </li> </ul> <p>See <a href="#">SAPPartnerEdge: Resources for OEM Partners</a>.</p>	Operator

Phase	Step	Description	User/Role
	Create ABAP instance(s). See <a href="#">Create ABAP Instances [page 1241]</a> .	<p>Set up your development/test subaccounts and ABAP system and create the following:</p> <ul style="list-style-type: none"> <li>• Development system DEV with parameter <code>is_development_allowed = true</code> <ul style="list-style-type: none"> <li>• abap/abap_compute_unit (standard: 1)</li> <li>• abap/hana_compute_unit (standard: 4)</li> </ul> </li> <li>• Test system TST with parameter <code>is_development_allowed = false</code> <ul style="list-style-type: none"> <li>• abap/abap_compute_unit (standard: 1)</li> <li>• abap/hana_compute_unit (standard: 4)</li> </ul> </li> <li>• Subscriptions in development/test subaccount to ABAP Web Access</li> </ul> <p>See <a href="#">Getting Started with a Customer Account: Workflow in the ABAP Environment</a> and <a href="#">Create an ABAP System</a>.</p>	Operator
	Set up UI development. See <a href="#">Set Up UI Development [page 1242]</a> .	Configure SAP Business Application Studio for UI development.	Operator
	Set up add-on development. <a href="#">Set Up Add-On Development [page 1243]</a> .	Create a new software component for add-on development and clone the main branch of the software component to the development and test system.	Add-on administrator

Phase	Step	Description	User/Role
	Transport from development to test system. See <a href="#">Set Up Transport from Development to Test System [page 1243]</a> .	<p>Plan and set up the transport of software components from development to test systems.</p> <p><a href="#">Tutorial: Transport a Software Component Between two Systems</a></p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>A CI/CD server that is running the ABAP Environment Pipeline is required. See <a href="#">ABAP Environment Pipeline [page 1215]</a>.</p> </div>	Add-on administrator
<a href="#">Develop [page 1244]</a>	ABAP development. See <a href="#">ABAP Development [page 1245]</a> .	<p>Follow the guidelines to enable multitenancy for applications built on the ABAP environment.</p> <p>See <a href="#">Multitenancy Development Guideline [page 1295]</a> and <a href="#">Tutorials</a>.</p>	Developer
	UI development. See <a href="#">UI Development [page 1247]</a> .	<p>Develop UIs using SAP Business Application Studio. See <a href="#">Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio [page 1716]</a>.</p>	Developer
	[Optional] Code migration. See <a href="#">(Optional) Code Migration from On-Premise [page 1247]</a> .	<p>Migrate your ABAP code from on-premise.</p> <p>See <a href="#">Blog: How to bring your ABAP custom to the ABAP Environment</a> and <a href="#">Blog: How to check your custom ABAP code for the ABAP Environment</a>.</p>	
<a href="#">Test [page 1247]</a>	Test in cloud system. See <a href="#">Test in the ABAP Environment SAP Fiori Launchpad [page 1248]</a> .	<p>Import the ABAP service and the UI into your test system.</p> <p>Create a role and assign it to users, then test the service and UI.</p>	Test user

Phase	Step	Description	User/Role
	Test in the ABAP Test Cockpit. See <a href="#">Test in the ABAP Test Cockpit [page 1249]</a> .	Run ABAP Test Cockpit checks in DEV and/or TST systems.  See <a href="#">ABAP Test Cockpit in the Cloud – What is already possible</a> and <a href="#">ABAP Test Cockpit Configurator [page 2352]</a> .	Developer
<a href="#">Build [page 1250]</a>	Prepare your add-on build. See <a href="#">Set Up Add-On Build [page 1251]</a> .	Set up a CI/CD server and pipeline for the add-on build.  Create a technical communication user to access AA-KaaS.  See <a href="#">Build and Publish Add-on Products on SAP BTP, ABAP Environment</a> .  Register the add-on product in the global account for development and production as described in <a href="#">Register Add-on Product for a Global Account</a> and <a href="#">Register Product [page 1318]</a> .	<ul style="list-style-type: none"> <li>• Jenkins administrator for access to CI/CD Server</li> <li>• S-user to create technical communication user</li> <li>• Operator to assign technical platform user as space developer</li> <li>• DevOps engineer to configure the pipeline</li> </ul>
	Build your first add-on version. See <a href="#">Build the First Add-On Version [page 1253]</a> .	Create a maintenance branch.  Configure the addon.yml file.  Trigger the add-on product build/test/release.	Add-on administrator to create maintenance branch, configure addon.yml file, and trigger build pipeline

## Order and Provide

Phase	Step	Description	User/Role
<a href="#">Deploy [page 1255]</a>	Configure the sizing of the SaaS application. See <a href="#">Sizing [page 1255]</a> .	<p>Decide on the metric of your offering (for example users, documents, space) and map the metric of your offering to the service plan of the ABAP environment service.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>For multitenancy offerings, there is no sizing/quota per customer (client). You must decide on an overall sizing depending on the expected load in a region (for example Europe/Frankfurt).</p> <p>As a DevOps engineer using parameter <code>tenant_mode</code> in the ABAP Solution service, you can define whether a customer gets a tenant in a dedicated system (single) or a shared system (multi).</p> <p>Determine the number of ABAP compute units and HANA compute units for the creation of an ABAP system by using parameters <code>size_of_runtime</code> and <code>size_of_persistence</code>.</p> </div>	DevOps engineer
	Implement a multitenant application and deploy it to the provider subaccount in the global account for development. See <a href="#">Multitenant Applications [page 1259]</a> .	Create the multitenant application with SaaS registry, XSUAA, and ABAP Solution Provider. Deploy to the provider subaccount with parameters used for development phase.	DevOps engineer

Phase	Step	Description	User/Role
	Access the Landscape Portal. See <a href="#">Access to Landscape Portal [page 1235]</a> .	Subscribe to the Landscape Portal application in the global accounts for development and production.  See <a href="#">Accessing the Landscape Portal [page 1303]</a> .	Operator
	Test the multitenant application deployed to the global account for development.	Subscribe to the SaaS solution from the consumer subaccount.	DevOps engineer
	Deploy the multitenant application to the provider subaccount in the global account for production.	Deploy to the provider subaccount with parameters used for production phase.	DevOps engineer
<a href="#">Commercialize [page 1275]</a>	[Optional] SAP Store registration. See <a href="#">(Optional) Register SaaS Solution in SAP Store [page 1275]</a> .	Register your SaaS solution in SAP Store.  See <a href="https://store.sap.com/dcp/en/">https://store.sap.com/dcp/en/</a> .	
	[Optional] Certification. See <a href="#">(Optional) Certification [page 1276]</a> .	Get an optional certification for your product.  See <a href="#">Certification</a> and <a href="#">Certified Solutions</a> .	
<a href="#">Subscribe [page 1276]</a>	Create a consumer subaccount. See <a href="#">Create Consumer Subaccount [page 1276]</a> .	Set the account structure for the consumer subaccount.	Operator
	Subscribe to the SaaS solution. See <a href="#">Subscribe to SaaS Solution [page 1276]</a> .		Operator
	Configure consumer subaccount. See <a href="#">Configure Consumer Subaccount [page 1277]</a> .	Configure customer subaccount.  <ul style="list-style-type: none"> <li>Option A: provider configures the subaccount</li> <li>Option B: customer configures subaccount</li> </ul>	Consumer subaccount administrator
	Initial user onboarding. See <a href="#">Initial User Onboarding [page 1278]</a>	Create an initial administrator user for the customer.	Consumer subaccount administrator

## Configure and Implement a Customer Project

Phase	Step	Description	User/Role
<a href="#">Configure and Implement a Customer Project [page 1278]</a>	Set up Identity and Access Management in the consumer tenant of the customer.	Create and assign business roles.  Create spaces and pages for business roles.	Business user
	Integrate the customer project in the consumer tenant of the customer.	Create communication arrangements.	Business user
	Configure the customer project in the consumer tenant of the customer.	Create business configuration.  Configure key user extensibility.	Business user

## Maintain, Monitor, Support

Phase	Step	Description	User/Role
<a href="#">Maintain [page 1281]</a>	Set up your test and maintenance system landscape and processes. See <a href="#">Set Up Maintenance System Landscape [page 1282]</a> .		Operator
	Create an update. See <a href="#">Create Add-On Update [page 1283]</a> .	Create a new patch version, support package version, or release/product version. See <a href="#">Deploy Product [page 1331]</a> .	<ul style="list-style-type: none"> <li>Developer to implement update and double-maintenance</li> <li>Test user to verify changes in test systems</li> <li>Add-on administrator to check out maintenance branch, import software components into test systems, configure add-on.yml file</li> </ul>
	Trigger the add-on product build. See <a href="#">Trigger Add-On Build Pipeline [page 1286]</a> .	Trigger the execution of the configured ABAP environment pipeline for an add-on build. See <a href="#">Operations Dashboard [page 1340]</a> .	Add-on administrator

Phase	Step	Description	User/Role
	Apply update for SaaS solution (=add-on product). See <a href="#">Deploy Add-On Update [page 1287]</a> .	Deploy your add-on update by using the Landscape Portal.  See <a href="#">Landscape Portal [page 1302]</a> .	Operator
Troubleshoot and debug. See <a href="#">Troubleshoot and Debug [page 1288]</a> .	<ul style="list-style-type: none"> <li>Identify ABAP system and consumer tenant</li> <li>Access the consumer tenant of the ABAP system</li> <li>Troubleshoot</li> </ul>		Operator

## Dismantle

Phase	Step	Description	User/Role
<a href="#">Dismantle [page 1290]</a>	Delete tenants.	Unsubscribe the SaaS solution. See <a href="#">Dismantle [page 1290]</a> .	Consumer subaccount administrator or operator using Subscription Management Dashboard
	(Optional) Restore deleted tenants.	Restore the deleted tenants within a grace period of 30 days. See <a href="#">Dismantle [page 1290]</a> .	Operator

## 4.2.11.1.2 Users and Roles

User	Role	Description	Tasks/Usage
Provider	Add-On Administrator	The add-on administrator is responsible for everything related to the add-on production, for example, releasing an add-on product version.	<ul style="list-style-type: none"> <li>• Creating software component</li> <li>• Importing changes in software component to test systems</li> <li>• Adjusting add-on descriptor file <code>addon.yml</code> for new versions</li> <li>• Registering add-on product for installation in global account for development and production. See <a href="#">Register Product [page 1318]</a>.</li> <li>• Executing add-on build pipeline in Jenkins instance</li> <li>• Confirming Integration Tests stage in add-on build pipeline</li> <li>• Trigger publishing in Confirm stage during add-on build pipeline</li> <li>• Creating maintenance branches (for example v1.0.0) per support package level in <i>Manage Software Components</i> app. See <a href="#">Manage Software Components [page 2592]</a>.</li> <li>• Checking out maintenance branch in correction system COR and quality assurance system QAS using the <i>Manage Software Components</i> app.</li> </ul>

User	Role	Description	Tasks/Usage
	DevOps Engineer	The DevOps engineer is responsible for the configuration of the pipeline and implementation of the multitenant application that needs to be deployed to enable the add-on as a SaaS solution.	<ul style="list-style-type: none"> <li>Initial configuration of add-on pipeline, especially <code>config.yml</code> file in git repository</li> <li>Implementing pipeline extensions if necessary</li> <li>Implementing a multi-tenant application. See <a href="#">Multitenant Applications [page 1259]</a>.</li> <li>Deploy multitenant application to provider subaccount in global account for development</li> <li>Subscribe to multitenant application from consumer subaccount in global account for development</li> <li>Deploy multitenant application to provider subaccount in global account for production</li> </ul>

User	Role	Description	Tasks/Usage
	Developer	Developer users use ABAP Development Tools (ADT) to create backend service artifacts and UI developers create and deploy SAP Fiori apps in SAP Business Application Studio. See <a href="#">What is SAP Business Application Studio</a> .	<ul style="list-style-type: none"> <li>Developing backend services in ABAP Development Tools (ADT) using ABAP RESTful Application Programming Model. See <a href="#">Eclipse Tool for the ABAP Environment</a> and <a href="#">ABAP RESTful Application Programming Model [page 657]</a>.</li> <li>Developing SAP Fiori based UI in SAP Business Application Studio and deploying back to ABAP system. See <a href="#">Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio [page 1716]</a>.</li> <li>Supporting and troubleshooting customer issues via provider support access in the Landscape Portal. See <a href="#">Landscape Portal [page 1302]</a>.</li> </ul>
	Test User	Test users are business users in test systems TST and QAS that validate the correct implementation of the add-on. This involves, among others, maintaining business roles and communication arrangements delivered as part of the add-on.	<ul style="list-style-type: none"> <li>Maintaining business roles. See <a href="#">Maintain Business Roles</a>.</li> <li>Creating spaces and pages for business roles. See <a href="#">How to Create and Assign Spaces and Pages</a>.</li> <li>Maintaining communication arrangements. See <a href="#">Communication Arrangements</a>.</li> <li>Creating business configuration</li> <li>Creating key user extensibility</li> <li>Testing ABAP backend services</li> <li>Testing SAP Fiori UIs</li> </ul>

User	Role	Description	Tasks/Usage
	Provider Identity Authentication Administrator	An Identity Authentication service tenant can be configured for authentication in development/test/assembly systems. The Identity Authentication administrator configures the trust setup between the subaccount and Identity Authentication application. See <a href="#">SAP Cloud Identity Services - Identity Authentication</a> .	<ul style="list-style-type: none"> <li>• Configuring Identity Authentication application for trust setup in development/test/assembly subaccounts. See <a href="#">Create New Application</a>.</li> <li>• Configuring corporate identity provider in Identity Authentication tenant. See <a href="#">Corporate Identity Providers</a>.</li> </ul>

User	Role	Description	Tasks/Usage
	Operator	The SaaS solution operator is responsible for creating the account model on the provider side (creating consumer subaccounts), adding subaccount members etc.	<ul style="list-style-type: none"> <li>Setting up global accounts for development and production including entitlements, subaccounts, Cloud Foundry org, spaces, services, and apps, as well as trust configuration and connectivity per subaccount. See <a href="#">System Landscape/Account Model [page 1210]</a>.</li> <li>Consumer tenant onboarding: creating consumer subaccount and subscription. See <a href="#">Subscribe to Multitenant Applications Using the Cockpit</a>.</li> <li>Creating users in ABAP systems. See <a href="#">Creation of Additional Administrator Users</a>. <ul style="list-style-type: none"> <li>Developer users in DEV/COR systems. See <a href="#">Creation of Developer Users</a>.</li> <li>Tester users in TST/QAS systems</li> </ul> </li> <li>Add-on update of existing systems in the Update Product Version app. See <a href="#">Deploy Product [page 1331]</a>.</li> <li>Monitoring of system/tenant provisioning and user onboarding. User	Role	Description	Tasks/Usage
	Jenkins Administrator	<p>A Jenkins CI/CD server is used as the infrastructure for automation purposes. Pipeline configuration, user management, credentials management etc. is handled by the Jenkins administrator. See <a href="#">Continuous Integration and Delivery (CI/CD)</a> [page 107].</p>	<div data-bbox="1155 344 1394 819" style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>tomor production systems instead of using add-ons, you are responsible for cloning software components and pulling the latest changes into the system using the <a href="#">Manage Software Components</a> app.</p> <p>See <a href="#">Delivery via Add-On or gCTS</a> [page 1228].</p> </div> <ul style="list-style-type: none"> <li>• Creating Jenkins instance via Cx server</li> <li>• Maintaining Jenkins credentials for: <ul style="list-style-type: none"> <li>• Cloud Foundry technical platform user</li> <li>• Technical communication user</li> <li>• Credentials of service user for git repository of pipeline configuration</li> </ul> </li> <li>• Maintaining Jenkins pipeline with reference to git repository of pipeline configuration</li> <li>• Adding additional Jenkins users, for example for add-on administrator user</li> </ul>

User	Role	Description	Tasks/Usage
	S-User	S-users are used by partners and customers to log on to SAP ONE Support Launchpad to reserve development namespaces or to create technical communication users. User management is taken care of by user administrators in the <i>User Management</i> app. If customer numbers are assigned to a Partner ID, S-users are registered via PartnerEdge. See <a href="#">User Management</a> and SAP note <a href="#">2261006</a> .	<ul style="list-style-type: none"> <li>Reserving development namespace in Namespace Application See <a href="https://launchpad.support.sap.com/#/namespaces">https://launchpad.support.sap.com/#/namespaces</a>.</li> <li>Activating new namespaces in already existing systems using Landscape Portal. See <a href="#">Maintain Namespaces [page 1308]</a>.</li> <li>Creating technical communication user. See SAP note <a href="#">2532813</a>.</li> </ul>
Technical Users of Provider	Technical Cloud Foundry Platform User	A platform user is added as a member to subaccounts in the Cloud Foundry environment to create or delete ABAP service instances, create service keys etc. This user should be a non-personalized user, for example based on a distribution list. The user does not need authorizations in SAP ONE Support Launchpad. The user does not need authorizations in SAP ONE Support Launchpad. Platform users are created by default in SAP ID Service. See <a href="#">User and Member Management</a> and <a href="#">Default Identity Provider</a> .	<ul style="list-style-type: none"> <li>Creating ABAP system AMT via ABAP solution service for consumer tenants. See <a href="#">Define Your ABAP Solution</a>.</li> <li>Creating ABAP system BLD via add-on build pipeline for add-on assembly</li> <li>Creating ABAP system ATI via add-on build pipeline for add-on installation test</li> <li>Deleting ABAP systems</li> </ul>
	Service User Git	Jenkins pipeline definitions are source-code-based and stored in a source code repository, usually a Git repository. To retrieve the pipeline definition from the repository, a (technical) service user is configured.	<ul style="list-style-type: none"> <li>Pulling changes in git repository of pipeline configuration</li> <li>Pulling changes in SAP/Jenkins library to project "Piper" library steps</li> </ul>

User	Role	Description	Tasks/Usage
	Technical Communication User	A technical communication user (created via SAP ONE Support Launchpad) is used for system-to-system connections with the SAP Support backbone. For information on how technical communication users are different from S-users, see SAP note <a href="#">2668288</a>  .	Used for communication with the AAKaaS. See <a href="#">Add-on Assembly Kit as a Service (=AAKaaS)</a>  .
Consumer	Consumer Identity Authentication Administrator	An Identity Authentication Service tenant can be configured for authentication at consumer tenants in the productive ABAP systems. The Identity Authentication admin configures the trust setup between consumer subaccount and Identity Authentication application. See <a href="#">Identity Authentication Service</a> .	<ul style="list-style-type: none"> <li>Configuring Identity Authentication application for trust setup in consumer subaccount</li> <li>Optional: Configuring corporate identity provider in Identity Authentication tenant</li> </ul>
	Consumer Subaccount Administrator	The consumer subaccount administrator is responsible for the configuration of: <ul style="list-style-type: none"> <li>Trust settings (custom identity provider), see <a href="#">Trust and Federation with Identity Providers</a>.</li> <li>Connectivity via Cloud Connector, see <a href="#">Connectivity in the Cloud Foundry Environment</a></li> <li>Destinations, see <a href="#">Managing Destinations</a> in the consumer subaccount created for the customer.</li> </ul>	<ul style="list-style-type: none"> <li>Setting up connectivity via Cloud Connector</li> <li>Adding destinations in consumer subaccount</li> <li>Setting up trust configuration</li> </ul>

User	Role	Description	Tasks/Usage
	Business User	Business users make use of the SaaS solution in the consumer tenant for their daily work.	<ul style="list-style-type: none"> <li>Initial administrator onboarding</li> <li>Creating additional business users</li> <li>Creating business roles</li> <li>Creating spaces and pages for business roles. See <a href="#">How to Create and Assign Spaces and Pages</a>.</li> <li>Creating communication arrangements</li> <li>Creating business configuration</li> <li>Creating key user extensibility</li> <li>Using SAP Fiori UIs</li> </ul>
	Cloud Connector Administrator	To connect on-premise systems on the customer side to the consumer tenant with the SaaS solution, Cloud Connector can be configured in the consumer subaccount. The Cloud Connector administrator maintains the consumer subaccount, cloud-to-on-premise system mappings etc. See <a href="#">Cloud Connector</a> .	<ul style="list-style-type: none"> <li>Adding a consumer subaccount to Cloud Connector. See <a href="#">Managing Subaccounts</a>.</li> <li>Configuring cloud to on-premise system mappings. See <a href="#">Configure Access Control</a>.</li> <li>Synchronizing trust configuration for principal propagation. See <a href="#">Set Up Trust for Principal Propagation</a>.</li> </ul>

### 4.2.11.1.3 Glossary

Add-on Assembly Kit as a Service (AAKaaS)

The Add-on Assembly Kit as a Service registers and publishes the software product. It is accessible via APIs with a technical communication user.

ABAP environment pipeline

The ABAP environment pipeline enables continuous integration for the ABAP environment. The pipeline contains several stages and supports different scenarios. See [ABAP Environment Pipeline](#) .

ABAP System	The ABAP environment service ( <code>abap/standard</code> ) is used to create development and test systems. See <a href="#">Creating an ABAP System</a> .
ABAP System (SaaS, OEM)	The ABAP environment ( <code>abap/saas_oem</code> ) service is used to create the add-on installation test system and production systems, where a specific add-on product needs to be installed in the system.
Add-on build pipeline	A pipeline configured for the add-on build scenario of the ABAP environment pipeline. See <a href="#">Build and Publish Add-on Products on SAP BTP ABAP Environment</a> .
Add-on descriptor	The build process is controlled by an add-on descriptor file called <code>addon.yml</code> . This file must be created manually and stored in the Git repository of the pipeline. It must contain information about the software product version to be delivered and the containing software component versions. See <a href="#">Add-On Descriptor File</a> .
Add-on installation test system	To verify that the delivery packages included in the add-on product version being built are installable, a target vector is published in "test" scope. In the integration tests stage, an ABAP system of service plan <code>saas_oem</code> is created. This ABAP OEM service allows you to install a specific add-on product version into an ABAP system that is provisioned.
Add-on product version (software product version)	To install and maintain ABAP software, software product versions are used. A software product version is a bundle of software component versions made available at the same time for implementing a well-defined scope of functionality. See <a href="#">Software Product Version</a> .
ABAP Solution (Provider)	The ABAP Solution service maintains ABAP systems and tenants to provide an add-on product as a SaaS solution.
Assembly System	The ABAP system responsible for the add-on build.  It is created during the pipeline and eventually deleted. All actions related to the ABAP source code are executed on this system, e.g. running checks with the ABAP Test Cockpit or the build of the software components.
ABAP Test Cockpit	ABAP Test Cockpit checks can be executed using <code>abapEnvironmentRunATCCheck</code> . The step can receive software components or packages configured in a YML file. The results are returned in checkstyle format. With the use of a pipeline extension, you can configure quality gates. See <a href="#">ATC</a> and <a href="#">ABAP Test Cockpit Configurator [page 2352]</a> .
Branch	Git repository branches can be used to control the flow of changes through the test and production landscape. They separate changes from each other, which shall or might not be delivered together (i.e. development vs. correction, feature A vs. feature B). A branch is created on the current state of another branch, the parent branch, and reflected by a new copy of all included objects. Depending on which branch is supposed to be changed, the corresponding copy is worked on.

Business role	A business role provides users with authorizations to access apps.
CI/CD server	The pipeline for building ABAP add-ons has been created specifically for Jenkins. Therefore, a Jenkins server is required. The project "Piper" provides a Jenkins image, which already includes the necessary configurations. Note that you can also configure an existing server.
Cloud Foundry environment	The Cloud Foundry environment enables you to develop new business applications and business services, supporting multiple runtimes, programming languages, libraries, and services. See <a href="#">Cloud Foundry Environment [page 44]</a> .
Communication arrangement	A communication arrangement describes a communication scenario with a remote system during configuration time. It provides the necessary metadata for service configuration. See <a href="#">Communication Arrangement [page 848]</a> .
Communication scenario	<p>A communication scenario in the ABAP environment is a design time description of how two communication partners communicate with each other.</p> <p>It provides technical information, such as the used inbound and outbound services and their service type, for example OData or SOAP, and the number of allowed communication arrangement instances. See <a href="#">Communication Scenario [page 847]</a>.</p>
Consumer	The service consumer is an end-customer of the service provider and has access to the SaaS application in a specific tenant
Correction codeline	Corrections need to run in parallel to development and on a released state. This is performed in the correction codeline and on a maintenance branch.
Cx server	Cx server is a life-cycle management tool to bootstrap a preconfigured Jenkins instance within minutes on your own (virtual) server, that uses Docker images. To avoid manual startup of the Docker image with all the required parameters and sidecar images, this command line tool automates the bootstrapping. See <a href="#">Cx Server</a> .
Destination service	The Destination service lets you find the destination information that is required to access a remote service or system from your Cloud Foundry application. See <a href="#">Consuming the Destination Service</a> .
Development codeline	Infinity development (infinity codeline) is done based on the latest software component state in the main branch.
Development namespace	Naming conflicts can be avoided through agreements on naming conventions or by carrying out development in separate namespaces. See SAP note <a href="#">84282</a> and <a href="#">Maintain Namespaces [page 1308]</a> .

Global account	A global account is the realization of a contract you made with SAP. A global account is used to manage subaccounts, members, entitlements, and quotas. You receive entitlements and quotas to use platform resources per global account and then distribute the entitlements and quotas to the subaccount for actual consumption. See <a href="#">Getting a Global Account [page 127]</a> .
Identity Provider	SAP Business Technology Platform supports identity federation, a concept of linking and reusing digital identities of a user base across loosely coupled systems. Identity federation frees applications on SAP Business Technology Platform from the need to obtain and store the credentials of users to authenticate them. Instead, the application user base is reused from identity providers, which support the administration of digital user identities, authentication, and authorizations in a centralized and decoupled manner. See <a href="#">Trust and Federation with Identity Providers [page 2014]</a> .
Landscape Portal	The Landscape Portal app acts as a central tool to allow service providers to perform lifecycle management operations such as add-on updates, provisioning new consumers as new tenants, and more. See <a href="#">Landscape Portal [page 1302]</a> .
Multitenancy	A multitenant service/application serves requests from different customers - the tenants - and processes their data strictly isolated from one another.
Patch level	<p>Patch deliveries shall only contain small corrections. They are shipped with delivery packages of type <i>Correction Package</i>.</p> <p>For both the add-on product version and the software component version, the patch level is denoted in the third digit.</p>
Project "Piper"	SAP implements tooling for continuous delivery in project "Piper". The goal of project "Piper" is to substantially ease setting up continuous delivery in your project using SAP technologies. See <a href="#">Project Piper</a> .
Provider	The provider is responsible for the development and maintenance of the SaaS application. This is typically an independent software vendor or development partner.
Release	<p>Release deliveries contain the whole software component and deliver new features and enhancements of existing functionalities.</p> <p>For both the add-on product version and the software component version, the release is denoted in the first digit.</p>

SAP Business Application Studio	Available as a cloud service, SAP Business Application Studio provides a desktop-like experience similar to leading IDEs, with command line and optimized editors. At the heart of SAP Business Application Studio are the dev spaces, which are similar to isolated virtual machines in the cloud containing tailored tools and pre-installed runtimes per business scenario, such as SAP Fiori, SAP S/4HANA extensions, Workflow, Mobile and more. This simplifies and saves time in setting up your development environment and allows you to efficiently develop, test, build, and run your solution locally or in the cloud. See <a href="#">What is SAP Business Application Studio</a> .
SAP Cloud Identity Services - Identity Authentication	The Identity Authentication service provides you with controlled cloud-based access to business processes, applications, and data. It simplifies your user experience through authentication mechanisms, single sign-on, on-premise integration, and convenient self-service options. See <a href="#">What Is Identity Authentication?</a> .
SAP Cloud Identity Services - Identity Provisioning	The Identity Provisioning service automates identity lifecycle processes. It helps you provision identities and their authorizations to various cloud and on-premise business applications. See <a href="#">What is Identity Provisioning</a> .
SAP ID service	The default platform identity provider and application identity provider of SAP Business Technology Platform is SAP ID service. See <a href="#">Default Identity Provider [page 2072]</a> .
SAP ONE Support launchpad	SAP ONE Support Launchpad provides you access to task-driven support resources in an intuitive interface. By using customizable role profiles, it displays only the relevant applications and insights to you. See <a href="#">SAP ONE Support Launchpad</a> .
SAP PartnerEdge	Get information, training, tools, and resources regarding partner licensing at <a href="#">SAP Partner Portal</a> .
SAP Store	SAP Store is the enterprise marketplace where we bring together customers and partners on a single, easy-to-use, global online platform. Here, customers can discover, try, and buy SAP-validated partner applications that are built on or extend their existing SAP technology and solutions. For partners, it's the only place they can market and deliver their apps, add-ons, and integration kits to SAP's global customers — solutions that help customers grow their business. See <a href="#">SAP Store</a> .
Software component	In ABAP environment systems, you develop within software components (also called repositories). The add-ons being built in this scenario are made up by one or multiple software components combined to an add-on product. See <a href="#">Software Components [page 662]</a> .
Software component version	A software component version is a technically distinguishable unit of software and is installed and patched as a whole. See <a href="#">Software Component Version</a> .

Subaccount	Subaccounts allow you to structure a global account according to your organization's and project's requirements with regard to members, authorizations, and entitlements. See <a href="#">Subaccounts</a> .
Support Package (Stack) Level	Support package deliveries contain a larger collection of corrections and may contain smaller functional enhancements. For both the add-on product version and the software component version, the support package level is denoted in the second digit.
Web Access for ABAP	Subscribe to the Web access for ABAP to get direct browser access to your instances in the ABAP environment, including access to the administration launchpad for ABAP. See <a href="#">Subscribing to the Web Access for ABAP [page 168]</a> .

---

## 4.2.11.1.4 Concepts

Learn more about the system landscape/account model, ABAP environment pipeline, as well as versioning and branches.

### 4.2.11.1.4.1 System Landscape/Account Model

#### gCTS Delivery

If you use gCTS transport delivery instead of add-on delivery, no discounted development licenses are available: ABAP systems created for development purposes (development, test, demo) cost the same as ABAP systems created for production purposes. For creation on system AMT instead of `saas_oem`, the standard service plan is used since no add-on is installed.

Additionally, the same global account is used for development/production purposes because gCTS repositories are only available across the same global account.

ABAP systems for development and for production purposes are created based on different partner contracts and licenses.

Discounted development licenses can be used for development, test, and demo purposes.

#### Note

You have to acquire a development license for partners. See [SAP PartnerEdge Test, Demo & Development Price List](#).

Production licenses are used whenever one of your customers is consuming the solution provided by you in one of your systems.

#### Note

You have to acquire a production license for partners. See [Resources for OEM Partners](#).

To separate development and production purposes, you have to create different global accounts:

- **Global account for development**

The global account for development is used for add-on/UI development and testing. Also, add-on assembly and add-on test installation triggered by the add-on build pipeline are performed in this global account.

All ABAP systems created in this global account are used for development, test, or demo purposes.

- **Global account for production**

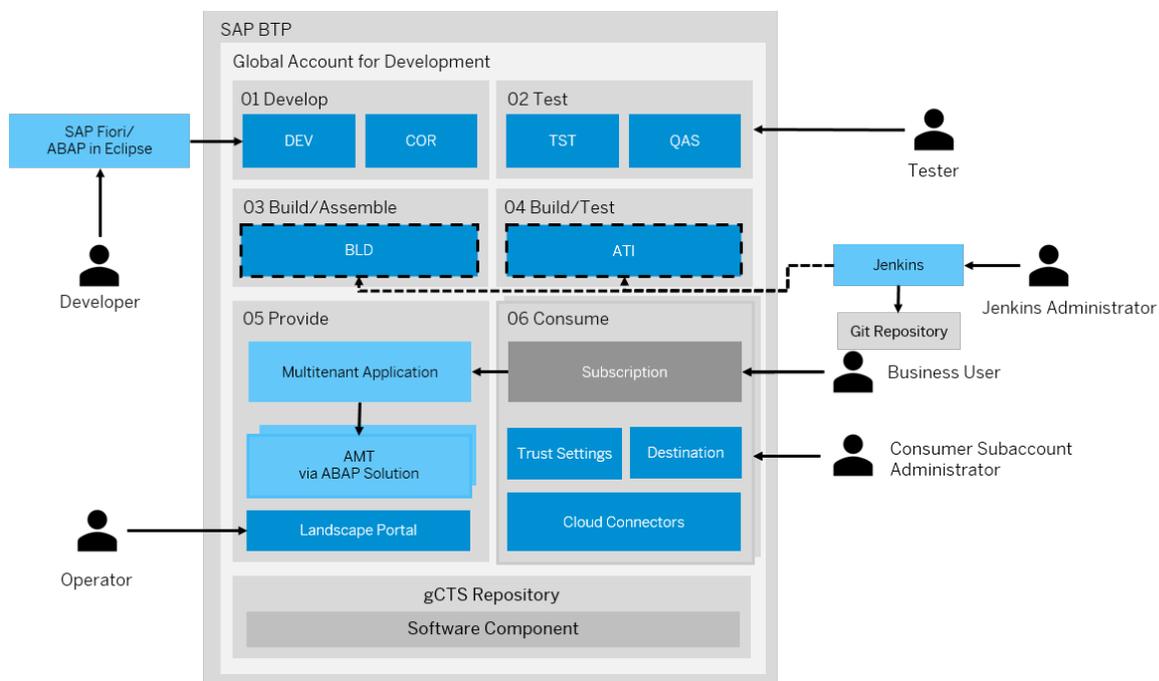

All ABAP systems created in this global account are used for production purposes. That means, the systems are used to provide the SaaS solution to your customers. Consumer subaccounts are also created in the global account for production.

→ Recommendation

We recommend creating subaccounts for the different stages of the SaaS solution enablement.

Using different subaccounts for the different phases has multiple advantages: Trust settings and destination/connectivity settings can be adjusted for each subaccount. That means, you can connect the development subaccount to the developer user identity provider and the test subaccount to the test user identity provider. In terms of connectivity, the development subaccount can be connected to the development on-premise system and the test subaccount can be connected to the test on-premise system.

## Global Account for Development

### 1. 00 Landscape Portal

Since the Landscape Portal service is only available in region eu10, we recommend creating a dedicated subaccount in this region. This subaccount will contain your Landscape Portal & CI/CD service subscriptions for you to freely choose other regions for your other subaccounts.

### Note

If you plan to create any of the other subaccounts in eu10, then you can simply reuse one of those subaccounts.

#### 2. **01 Develop: Development subaccount including development space**

ABAP development system DEV and correction system COR are created in this subaccount. You need to subscribe to SAP Business Application Studio to develop SAP Fiori UIs and implement multitenant applications. See [Setup of UI Development in SAP Business Application Studio](#).

#### 3. **02 Test: Test subaccount including test space**

ABAP test system TST and quality assurance system QAS are created in this subaccount. See [Use Case 2: One Development and Correction Codeline in a 5-System Landscape \[page 689\]](#). Since development is structured with software components that are stored in a repository for each global account, these software components can automatically be imported to the test system on a regular basis automated by the CI/CD server. See [Test Integration \(SAP\\_COM\\_0510\) \[page 727\]](#). The CI/CD server uses a Git repository to read the pipeline definition and configuration.

#### 4. **03 Build/Assemble: Subaccount for add-on assembly including build/assemble space**

### Note

The ABAP environment platform version of the assembly system is used to determine the minimum platform version for the add-on product version that is created.

Such a system should not be nominated for the pre-upgrade option of the ABAP environment because this would lead to the add-on product only being able to be installed in systems with the pre-upgrade release.

For the add-on build process, an assembly system BLD is provisioned in this subaccount by the CI/CD server. See [Software Assembly Integration \(SAP\\_COM\\_0582\) \[page 737\]](#). After the add-on has been successfully built, the system is deleted. In this case, the CI/CD server reads the add-on definition from a Git repository (add-on descriptor).

#### 5. **04 Build/Test: Subaccount for add-on installation test including build/test space**

After the add-on has been assembled during the build of an add-on version, an installation test is required to verify that the add-on can be installed without errors into a system. As part of the add-on build pipeline, an `abap/saas_oem` system ATI is provisioned in this subaccount and the add-on is installed. In this case, the CI/CD server reads the add-on definition (add-on descriptor) and the provisioning parameters for the add-on installation test system from a Git repository.

#### 6. **05 Provide: Provider subaccount including provider space**

During the development phase, the multitenant application is deployed to this space for testing purposes. The ABAP solution service can then provision `abap/saas_oem` systems AMT, tenants, and users in this account, once a consumer subscribes to the provided SaaS solution.

#### 7. **06 Consume: Consumer subaccount**

To test the subscription to the SaaS solution during the development phase of the multitenant application, a consumer subaccount is created in the global account for development. This allows your consumers to have their own configuration of:

- Trust settings (custom identity provider)

### Note

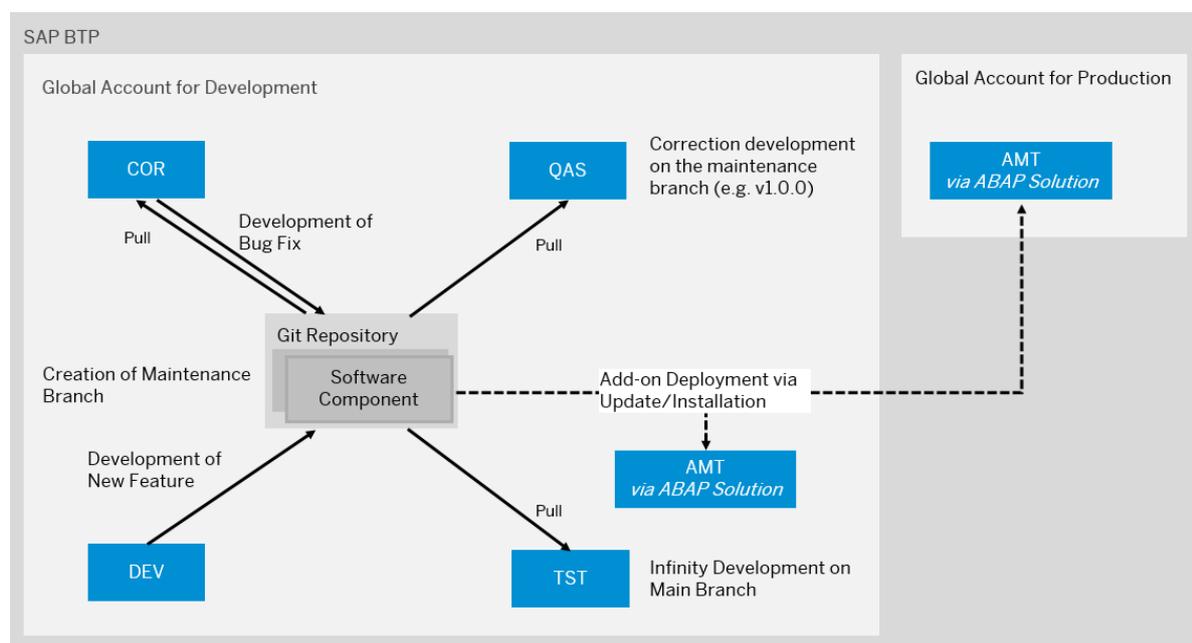

If you want to integrate an existing corporate identity provider for authentication/authorization in subaccounts of the global account for development, see [Trust and Federation with Identity](#)

**Providers.** To restrict access based on certain criteria, such as the IP address, you need to use the Identity Authentication service. See [SAP Cloud Identity Services - Identity Authentication](#).

- Connectivity via SAP Cloud Connector. See [Connectivity in the Cloud Foundry Environment](#).
- Destinations. See [Managing Destinations](#).
- Subscriptions

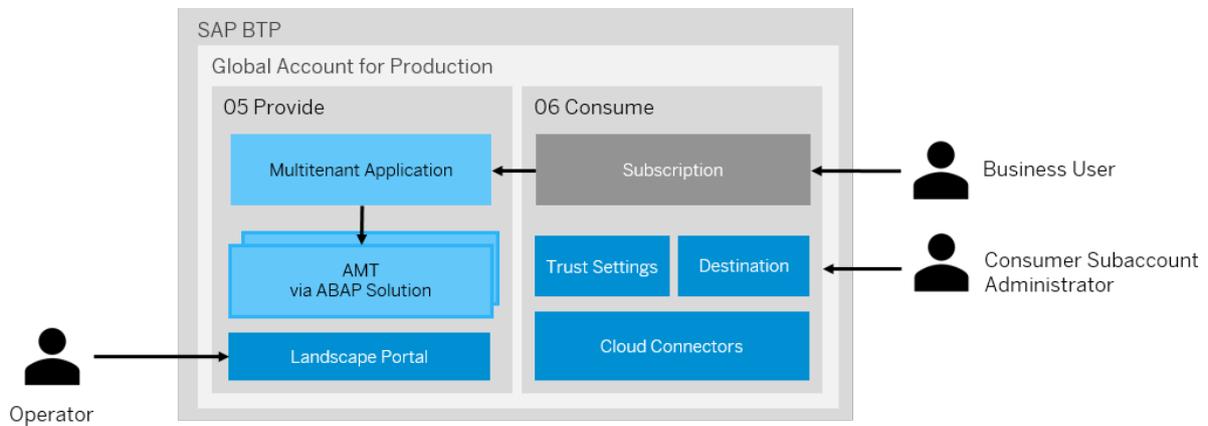

## Development Flow

For development and maintenance processes, the steps mentioned below, that are similar to the ones described in [Use Case 2: One Development and Correction Codeline in a 5-System Landscape \[page 689\]](#), are performed.

- ABAP system COR and QAS have the same software state, unless a new change is tested and released. This means, transport requests are released in ABAP system DEV only if development is completed and it's planned to import the changes to the production ABAP system.
- Upon cutoff date, development is finished. All development that is released at this time must be tested and be of good quality. From then on, you must fix defects in the COR system and maintain them in parallel in the DEV system.
- Upon release date, all defects must be fixed. If, during testing in the QAS system, you make the decision that a complete functionality isn't delivered, developers must delete, revert, or disable the functionality in the COR system and release the corresponding transport requests. You can't remove objects from the release branch, e.g. by deselecting transport requests. To revert objects to a previous transported state, use the Compare editor of the Eclipse History view. If you want to withdraw the functionality in the DEV system as well, it's considered a correction and you have to perform double maintenance of corrections into the DEV system. See [Double Maintenance of Corrections into Development \[page 701\]](#).
- Users in ABAP system COR are locked during ongoing development and only unlocked when a correction has to be implemented
- For the consumption as a SaaS solution, instead of importing a release branch into a productive system, software components are installed via add-on delivery packages into multitenancy-enabled production systems AMT provisioned via the ABAP Solution service. See [ABAP Solution Service \[page 1262\]](#).

## Global Account for Production

### 1. 00 Landscape Portal

Since the Landscape Portal service is only available in region eu10, we recommend creating a dedicated subaccount in this region. This subaccount will contain your Landscape Portal & CI/CD service subscriptions for you to freely choose other regions for your other subaccounts.

#### Note

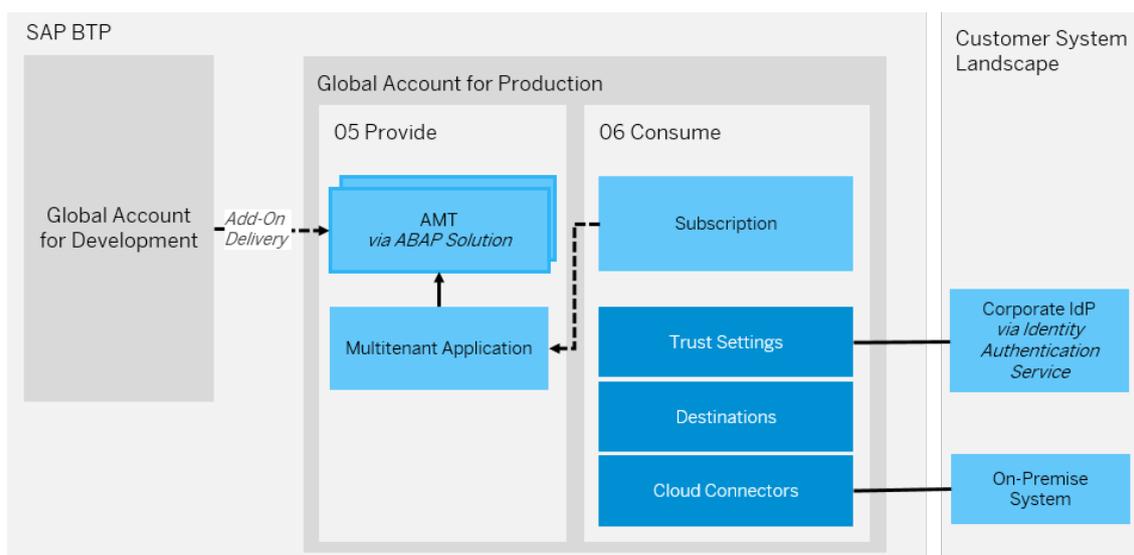

If you plan to create any of the other subaccounts in eu10, then you can simply reuse one of those subaccounts.

### 2. 05 Provide: Provider subaccount including provider space

The multitenant application is deployed to the provider subaccount in the global account for production. The ABAP solution service can then provision `abap/saas_oem` systems (AMT), tenants, and users in this account once a consumer subscribes to the provided SaaS solution.

### 3. 06 Consume: Consumer subaccount

For each customer, a consumer subaccount is created in the global account for production.

This allows consumers to have their own configuration of:

- Trust settings (custom identity provider).

### 📘 Note

If you want to integrate an existing corporate identity provider for authentication/authorization in subaccounts of the global account for production, see [Trust and Federation with Identity Providers \[page 2014\]](#). To restrict access based on certain criteria, such as the IP address, you need to use the Identity Authentication service. See [SAP Cloud Identity Services - Identity Authentication](#).

- Connectivity via SAP Cloud Connector. See [Connectivity in the Cloud Foundry Environment](#).
- Destinations. See [Managing Destinations](#).
- Subscriptions

### ⚠️ Restriction

As of now, you can only expose SaaS applications for subscription from consumer subaccounts in the provider global accounts.

## 4.2.11.1.4.2 ABAP Environment Pipeline

The goal of the ABAP environment pipeline is to enable continuous integration for the ABAP environment.

The pipeline contains several stages and currently supports two relevant scenarios:

- Add-on build using AAKaaS
- Continuous testing via gCTS

A pipeline definition, containing all configuration, and a running CI/CD server are required to execute the ABAP environment pipeline. You can consume the different scenarios by enabling different pipeline stages in the configuration. For more information on how to configure the ABAP environment steps and stages, see [Configuration](#) 🗨️ and [ABAP Environment Pipeline](#) 🗨️ .

The Landscape Portal offers the option to configure and execute the add-on build scenario using the [Build Product Version app](#), without the need for external repositories or Jenkins servers.

### 📘 Note

The *Continuous Testing* scenario is currently not supported by the Landscape Portal. This means that a running Jenkins server is required, even when using the Build Product Version app. See [Add-On or gCTS](#).

## Jenkins Setup

### 📘 Note

This is only required for running the Continuous Testing scenario. The add-on build scenario can be realized using the Build Product Version app in the Landscape Portal.

The general configuration of the ABAP environment pipeline always follows the same approach regardless of the scenario that you want to configure:

### 1. Prepare Git Repository

As a DevOps engineer, you need to prepare a Git repository by including the Jenkins file, initializing the pipeline, and the pipeline configuration file `.pipeline/config.yml`. See [Jenkins File](#) and [Technical Pipeline Configuration](#).

**2. Create Service User for Git Repository**

To enable read access to the Git repository, you need to create a service user and assign it to the repository. Later, this user's access credentials are stored in the Jenkins credentials by the Jenkins administrator. See [Using Credentials](#).

**3. Create Jenkins Instance via Cx Server**

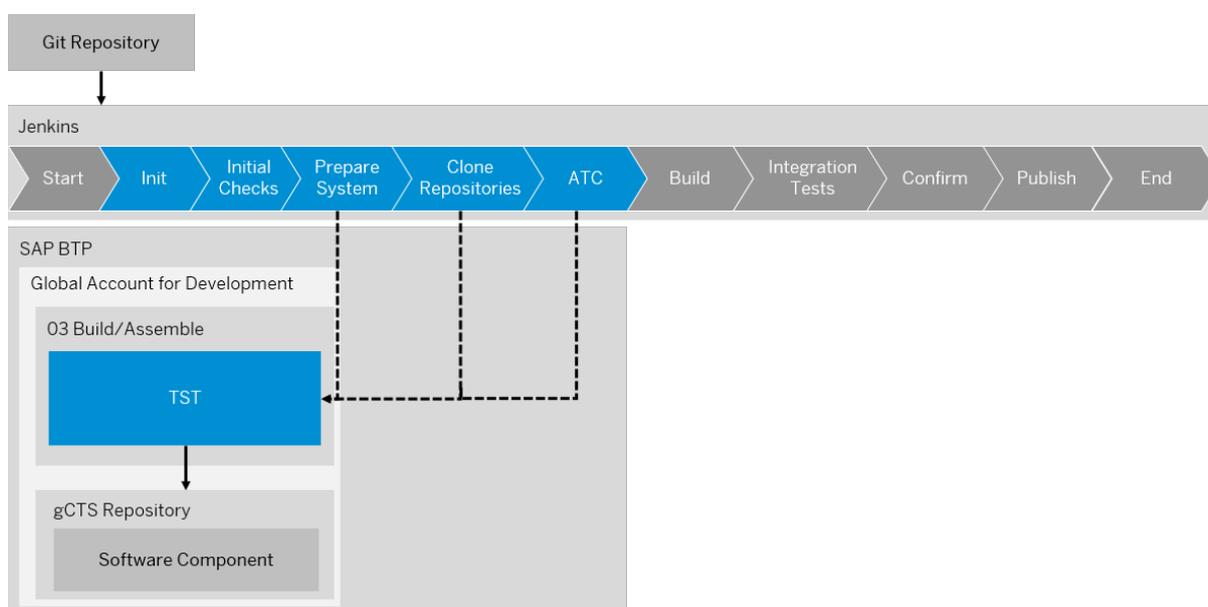

As a Jenkins administrator, you need to set up a new Jenkins instance using Cx Server Lifecycle Management. After initializing the Cx server that is based on a set of docker images, you can start the Jenkins server with `./cx-server start`. See [Cx Server](#) and [Docker Hub](#).

**4. Configure Jenkins Instance**

As a Jenkins administrator, you need to add technical Git user credentials and platform user credentials to the integrated secure store. Make sure that a shared library `piper-lib-os` is configured pointing to the project "Piper" library. See [Piper Library](#).

For more information on how to configure the ABAP environment steps and stages, see [Configuration](#).

## Transport from DEV to TST System via gCTS

Development system DEV and test system TST stay on the same main branch. To make the latest implementations available in the test system, the developed software components can be imported on a regular basis to test system TST and tested using the ABAP Test Cockpit by scheduling a planned execution of the ABAP environment pipeline. See [Continuous Testing on SAP BTP ABAP Environment](#) and [Running ATC Checks and ABAP Unit Tests on a Static ABAP Environment System](#).

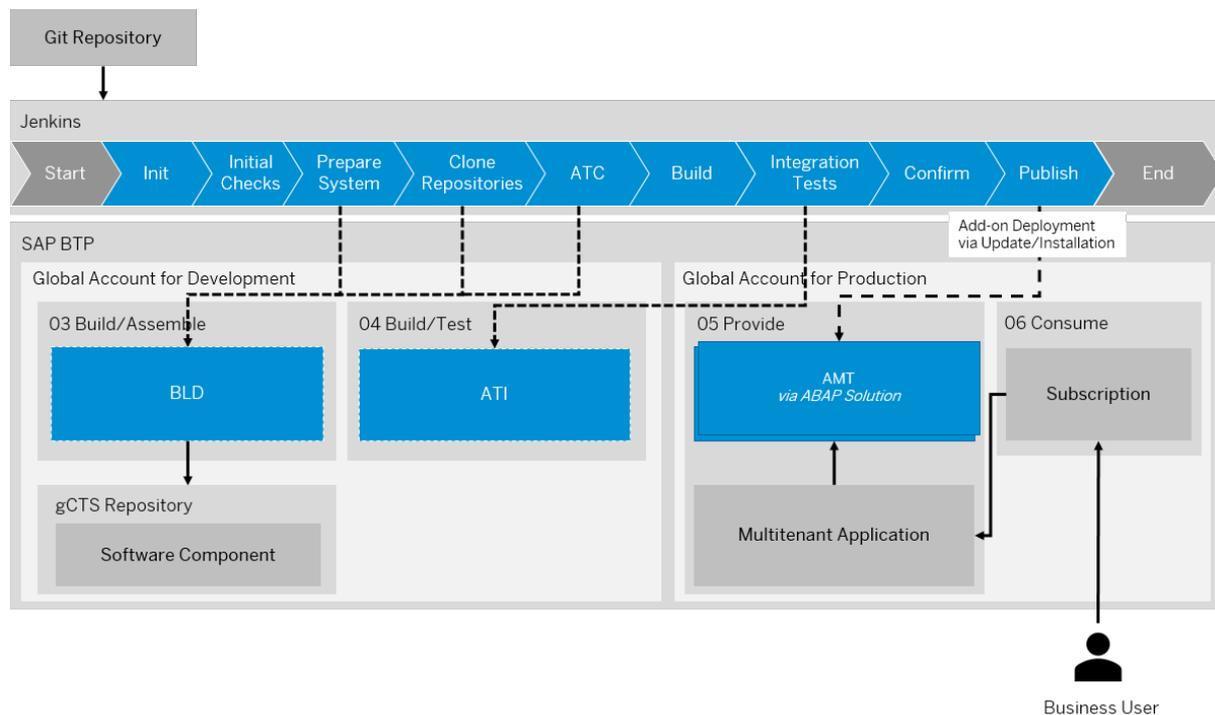

The ABAP environment pipeline is executed in a Jenkins server that is connected to subaccount **02 Test** in the global account for development by authenticating via a technical Cloud Foundry platform user. The permanent test system TST is used to import software components and run ABAP Test Cockpit checks.

## Build Add-On Version

The ABAP environment pipeline can automate the build and assembly process of ABAP add-ons. From creating the delivery packages in the assembly system to publishing the add-on release, all steps are part of this pipeline.

This scenario can be run in the Landscape Portal using the [Build Product Version app](#), or it can be configured manually and run on a local Jenkins server. In both cases, the same pipeline stages will be executed.

See [Build and Publish Add-on Products on SAP BTP ABAP Environment](#).

- <https://www.project-piper.io/pipelines/abapEnvironment/stages/confirm/> [https://www.project-piper.io/pipelines/abapEnvironment/stages/confirm/]

- <https://www.project-piper.io/pipelines/abapEnvironment/stages/publish/>  [<https://www.project-piper.io/pipelines/abapEnvironment/stages/publish/>]

The ABAP environment pipeline is executed in a Jenkins server that is connected to subaccount *03 Build/Assemble* and *04 Build/Test* in the global account for development by authenticating via a technical Cloud Foundry platform user. Transient systems are then provisioned for add-on assembly (BLD) and installation tests (ATI).

### Add-On Assembly System

Add-on assembly system BLD includes an instance of communication scenario `SAP_COM_0510` and an instance of communication scenario `SAP_COM_0582`. See [Test Integration \(SAP\\_COM\\_0510\) \[page 727\]](#) and [Software Assembly Integration \(SAP\\_COM\\_0582\) \[page 737\]](#). Service keys with parameters referring to the communication scenarios are created in the BLD system, which leads to the creation of communication arrangements that can be used by the pipeline for inbound communication.

In the **Prepare System** pipeline stage, a new transient system BLD is provisioned for the add-on assembly. See [Prepare System](#) . ABAP Test Cockpit checks, software component imports, and the local build of deliveries are performed in this stage. By default, the system is deleted again in the **Post** pipeline stage. See [Post](#) .

The communication with remote components is enabled via communication scenario [Test Integration \(SAP COM 0510\)](#) and communication scenario [Software Assembly Integration \(SAP COM 0582\)](#).

By default, the system is created from scratch for each new add-on version. If you are configuring your pipeline manually, you can choose to reuse a permanent BLD system instead of provisioning a new one each time. This has the advantage of reducing the pipeline execution time, as system provisioning is one of the most time-consuming tasks. See [Build Add-Ons on a Permanent ABAP Environment System](#) .

To reduce costs, it is recommended that you shut down the permanent system when no builds are scheduled. See [Manage System Hibernation](#). Please note that hibernated systems still incur costs.

### Add-on Installation Test System

To verify that the delivery packages included in the add-on product version are installable, a target vector is published in "test" scope during the **Build** stage.

In the **Integration Tests** pipeline stage, a new transient system ATI is then provisioned for an add-on deployment test that installs the add-on product version. See [Integration Tests](#) . After the successful add-on installation is confirmed, the system is deleted, unless otherwise specified.

The communication with remote components is enabled via communication scenario [Test Integration \(SAP COM 0510\)](#).

By default, the ATI system is created from scratch for each new add-on version. If you are configuring your pipeline manually, you can choose to reuse a permanent ATI system instead of provisioning a new one each time. This has the advantage of reducing the pipeline execution time, as system provisioning is one of the most time-consuming tasks. We recommend that you provision a new ATI system at least for each new major release of your add-on.

### Add-on Assembly Kit as a Service

The Add-on Assembly Kit as a Service (AAKaaS) is used for registering and publishing the software product.

The service is offered in the SAP Service and Support systems, which means that access is granted via a technical communication user that packs the delivery into an importable package format. It is similar to the

Software Delivery Assembler (SDA, transaction SSDA) as a part of the SAP Add-On Assembly Kit. See [SAP Add-On Assembly Kit](#) and [Add-On Assembly Kit as a Service](#) .

### Add-on Consumption

For the consumption of the add-on as a SaaS solution, software components are installed via add-on delivery packages into multitenancy-enabled production systems (AMT) provisioned via the ABAP Solution service. This is orchestrated via a multi-tenant application deployed to the Cloud Foundry environment on SAP BTP. See [Multitenant Application](#) and [Deploy](#).

#### Note

If you need support or experience issues during the add-on build, see [Troubleshooting](#) .

## 4.2.11.1.4.3 Multitenancy

The ABAP environment provides capabilities for multitenancy, meaning to host different customers on a single ABAP system. See [Multitenancy in the ABAP Environment \[page 1290\]](#).

The way ABAP service instances and tenants are used for consumer subscriptions application can be configured via parameter `tenant_mode` of the ABAP Solution service. See [ABAP Solution Service \[page 1262\]](#):

- **Single:** With each new consumer, a new ABAP service instance is created.
- **Multi:** For multiple consumers, the same ABAP service instance is used.  
In case of a multitenancy-enabled solution, with another parameter `consumer_tenant_limit`, you can define the maximum number of tenants per system until a new ABAP system is created.

#### → Tip

You should align your decision whether to enable multitenancy mode for your solution based on whether the [Multitenancy Development Guideline \[page 1295\]](#) can be followed during ABAP development.

## 4.2.11.1.4.4 Versioning and Branches

### 4.2.11.1.4.4.1 Add-On Versioning

For the add-on delivery process, certain versioning principles apply. Learn how software components are combined to an add-on product and what versioning rules are used for both parts. Software components and add-on products follow a similar versioning pattern.

## Add-on Product Version

Instead of importing software components into productive systems, when providing a SaaS solution in the ABAP environment, software components are packaged and installed into ABAP systems based on so-called add-on products/software products.

You can only install one add-on product for each system using the ABAP environment `saas_oem` service plan instead of the `standard` service. During provisioning of this service, parameters `addon_product_name` and `addon_product_version` are used to install a certain add-on product version into the system, after the system has been provisioned. See [ABAP Solution Service \[page 1262\]](#).

The add-on product name includes a reserved development namespace to separate the name from other customers/partners. See SAP note [84282](#).

The versioning pattern `<Release>.<Support Package Stack Level>.<Patch Level>` applies to the add-on product version.

### Note

Only in a new release, you can change the bundled software components of the add-on product.

Technically, the allowed number range is 1.0.0 to 9999.9999.9999.

For the release, there are no technical restrictions regarding the number of new versions. You only have to consider that the version has to be ascending across builds and there must be no gaps between versions. The initial release is always 1.0.0.

The support package stack level count starts again from 0 with each release.

The patch level count starts again from 0 with each support package.

While providing a specific add-on version, leading zeroes should be omitted (1.2.3 instead of 0001.0002.0003).

The add-on product version should be increased analogous to the version of the leading software component. The leading software component is the software component that is, as opposed to a reuse software component, exclusively used as part of one add-on product.

An exception to this recommendation is the patch level in the add-on production version: In case of an add-on product with a reuse software component, the patch level of the add-on product version might be higher than the patch level of the leading software component version.

For more information about software product versioning, see [Add-On Product Version](#).

## Software Component Version

Software components are self-contained and include packages as well as development objects. They are used in combination with a reserved development namespace to separate the name from other customers/partners. See [Software Components \[page 662\]](#).

The versioning pattern `<Release>.<Support Package Level>.<Patch Level>` also applies to the software component version.

### Note

Software component versions are delivered with delivery packages. However, software component versions are not individual shipment entities. They can only be delivered to customers as part of a software product version.

Software component versions are only built once, independent from add-on product versions where the software component version was referenced. If an add-on product version is referring to a software component version that has already been created as part of a different add-on build, the created delivery package is reused.

Technically, the allowed number range is 1.0.0 to 9999.9999.9999.

For the release, there are no technical restrictions regarding the number of new versions. You only have to consider that the release has to be ascending across builds and there must be no gaps between versions. The initial release is always 1.0.0.

The support package level can only go up until 369 because of technical limitations. The support package level count starts again from 0 with each new release.

For the patch level, there is a technical limit of  $36^3$ , limited to 9999. The patch level count starts again from 0 with each support package.

For more information on software component versioning, see [Software Component Version](#).

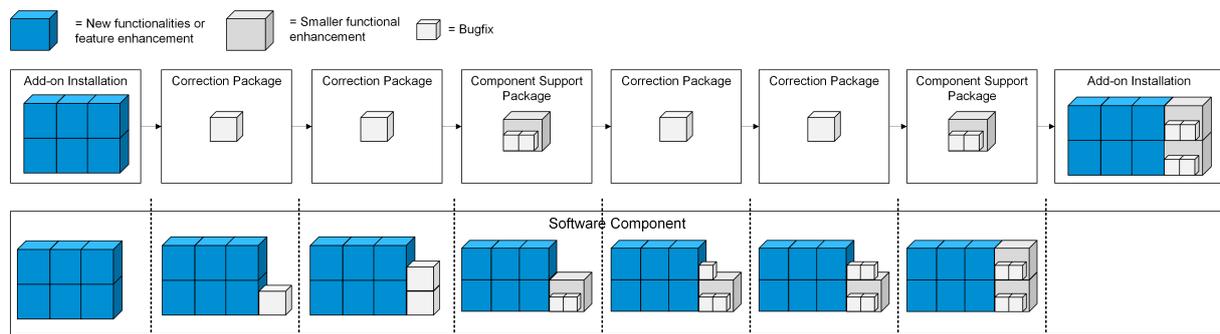

## 4.2.11.1.4.4.2 Add-On Package Types

For the delivery of add-on packages, there are three package types that serve different purposes: AOI, CSP, and CPK.

The different add-on package types are used for different purposes. The set of objects to be included depends on the package type.

### Note

The required type of delivery is automatically determined by the delivery production tools based on how the version number of software components is changed.

### AOI (Add-On Installation)

Delivery packages of type Add-on Installation (AOI) are created for all new release versions, e.g. version 1.0.0, and should be used to deliver new functionalities or feature enhancements.

These delivery packages include all the objects in the software component and are usually created on a regular basis (e.g. quarterly).

## CSP (Component Support Package)

Delivery packages of type Component Support Package (CSP) are created for all new support package deliveries, e.g. version 1.1.0, and should be used to deliver a collection of patch deliveries or to deliver smaller functional enhancements.

These delivery packages include either the objects that were changed since the previous release delivery or since the previous support package delivery. They are usually created on a regular basis (e.g. bi-weekly).

## CPK (Correction Package)

Delivery packages of type Correction Package (CPK) are created for all new patch deliveries, e.g. version 1.0.1, and should be used to deliver bugfixes.

These delivery packages include only those objects that were changed since the previous patch delivery and are only created when necessary (e.g. emergency patch).

For more information on the add-on package types and how these are determined based on changes to the software component version, see [Software Component Version](#) .

## 4.2.11.1.4.4.3 Branching

### Note

Keep in mind that there are some restrictions for using branches in your development processes, for example the merging of branches is not supported and has to be done manually. See [ABAP Environment Specifics \[page 664\]](#).

Development in the ABAP environment is done in software components. For each software component, different branches can be created that include a different list of commits. For each system, only one branch can be active at a time. Branches are used to separate changes from each other that shall or might not be delivered together (development vs. correction).

To separate development of new features from the development of bug fixes for the active version of a software component, you can use branches for different purposes:

- **Main Branch:** Implementation of new planned features that are to be delivered in the future (development codeline)
- **Maintenance Branch:** Implementation of unplanned bug fixes for the active version of a software component that is deployed to customer systems (maintenance codeline)

The main branch is the default branch of each software component and therefore already exists when the software component is created. This branch is not deleted throughout delivery of different software component versions.

A maintenance branch should be created for each support package level of a software component and is named accordingly, for example v1.1.0 for support package level 1 in release 1. Maintenance branches can be deleted once the successor support package level is the currently deployed support package level in customer systems.

#### → Recommendation

Create a new maintenance branch with each new support package level, and thus with each new AOI and CSP package delivered for a software component.

For the first release, the main branch of software components is used to create a maintenance branch for the add-on build process. In subsequent versions, the development and correction code line are separated by using the main branch and the maintenance branch. See [Use Case 2: One Development and Correction Codeline in a 5-System Landscape \[page 689\]](#).

All corrections to a software component based on a certain support package level are released in the corresponding maintenance branch and need to be maintained as new commits in the main branch (double maintenance). See [Double Maintenance of Corrections into Development \[page 701\]](#).

For each ABAP system, only one branch can be active at a time. Therefore, in development system DEV and test system TST, the main branch of a software component is checked out. Whereas in correction system COR and quality assurance system QAS, the currently relevant maintenance branch is checked out.

## 4.2.11.1.4.4.4 Delivery Models

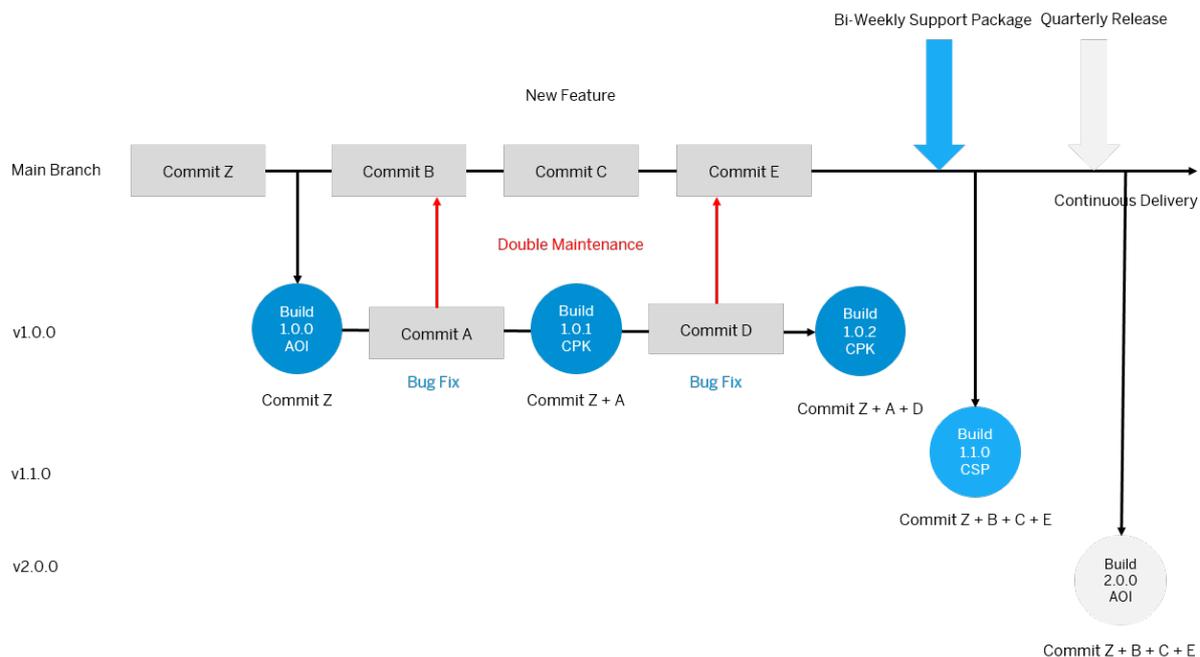

Based on the mentioned software component versioning principles, the add-on package types, and branching approach, you can use different delivery models.

#### → Recommendation

You should choose the delivery model based on the existing processes in your development/shipment environment. Shorter delivery cycles have the advantage that new features are delivered more frequently. Therefore, we recommend following the continuous delivery approach whenever possible.

### Continuous Delivery

With the continuous delivery approach, new features should be delivered as soon as possible: In this case, new features can be shipped with support packages more often than new releases of a software component. These short development cycles ensure that changes can be deployed on short notice and in smaller increments. See [Continuous Integration and Delivery \(CI/CD\)](#).

In this example, commit Z represents all the commits prior to the first build.

The maintenance branch v1.0.0 is used for bug fixes that must be manually maintained in the main branch, which requires double maintenance to make sure that the development code line is up to date.

Commit Z and commit C are new features implemented in the development code line on the main branch. Development of these features is done in the DEV system, testing in the TST system.

Commit A and commit D are small corrections that are implemented in the correction code line on the maintenance branch for support package level zero of software component release one.

Development of these bug fixes is done in the COR system, testing in the QAS system.

After releasing these corrections in the maintenance branch, you have to maintain them as well in the main branch in the DEV system to secure consistency of changes in the correction and development code lines. As a result, commit B and E are created in the main branch to reflect the corrections made in the maintenance branch (commit A and commit D).

The new support package build for version 1.1.0 is derived from the main branch and includes new features and bug fixes since the last support package level 1.0.0 has been released. With the new support package build for version 1.1.0 of the software component, a new maintenance branch v1.1.0 is created. All corrections for this support package level are developed on this branch.

For a new release, add-on version 2.0.0 is released. The resulting AOI package includes all features and bug fixes since the last AOI build for version 1.0.0 has been released.

Branch v1.1.0, that is based on the main branch, includes same commits as the main branch (Z, B, C, and E). For the build of CPK v1.0.2 and CSP v1.1.0, however, only the objects that have been changed since the previous CSP/AOI are included in the object list.

### Note

With this delivery model, support packages not only include the corrections for the current support package level but also new features allowing shorter development cycles.

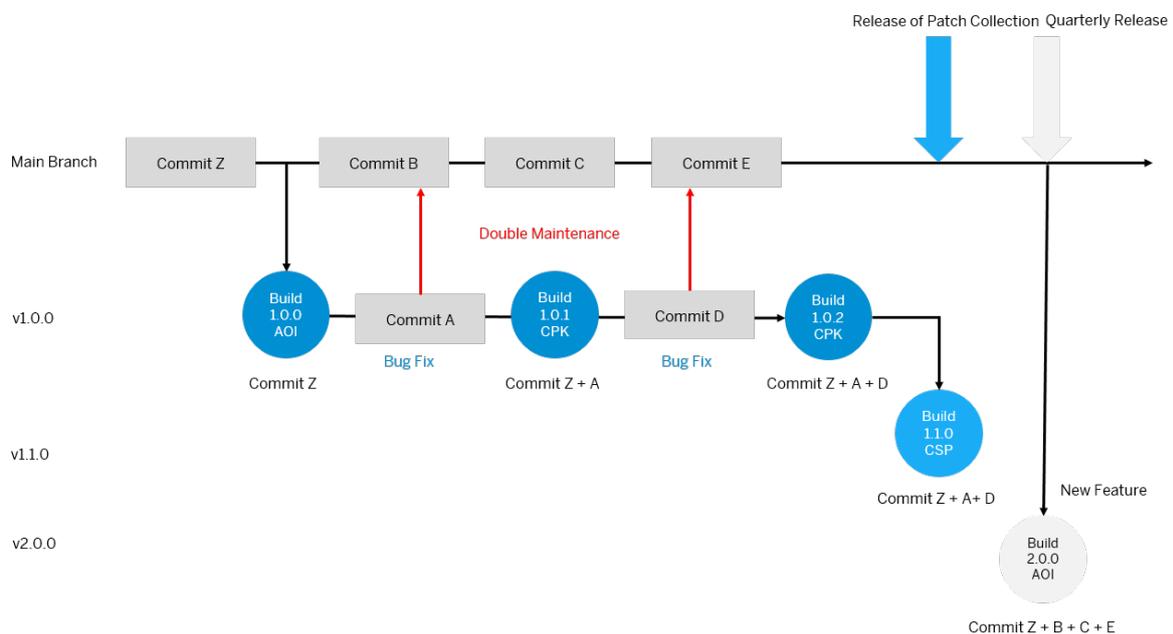

## → Recommendation

In a continuous delivery model, we recommend:

- Building and deploying a new CSP on a weekly or biweekly basis.
- Shipping new software component releases on a quarterly basis. These AOI packages contain every object that has been built and delivered with the support packages, including all the patches.

## Quarterly Shipment

The quarterly delivery approach is recommended whenever longer test cycles are necessary and faster incremental development is not feasible. This might be required due to industry requirements, legal requirement etc.

Compared to the continuous delivery model, the maintenance branches for each support package level are not created based on the main branch but on the previous maintenance branch: e.g. branch v1.1.0 is based on v1.0.0.

That way, support packages are only used for the purpose of patch collections: only the corrections in commit A and D that were already delivered as patches in version 1.0.1 and 1.0.2 are included in support package 1.1.0.

## Note

With this delivery model, new features are only delivered with new release versions (AOI packages). The build for version 1.1.0 does not include commit C. As late as with the build for version 2.0.0, this feature is shipped. Consequently, new features take longer until they are available in production systems.

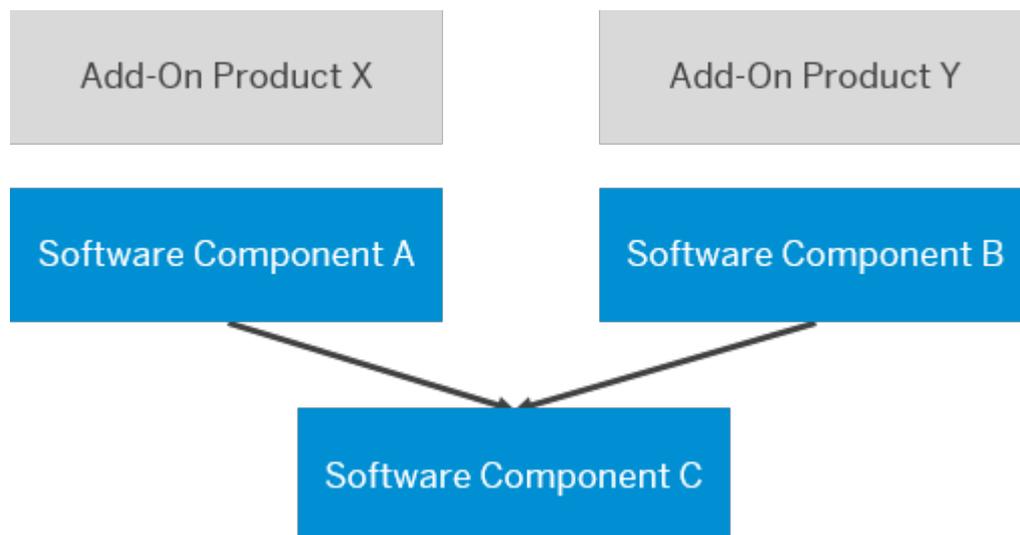

This delivery model is similar to processes commonly used to ship on-premise solutions where upgrades are much more complex and usually performed on a quarterly basis. Instead of shipping more often but in smaller packages, this approach promotes building larger shipment packages with a lot of new features.

Branch v1.1.0, that is based on branch v1.0.0, includes the same commits as branch v1.0.0 (Z, A, and D). For the build of CPK v1.0.2 and CSP v1.1.0, however, only the objects that have been changed since the previous CSP/AOI are included in the object list.

## 4.2.11.1.4.4.5 Reuse Software Components

Add-On products can consist of multiple software components. However, objects of one software component can't be used in another software component by default. Software components provide their functionality to other software components via explicitly released APIs. This means, you must set the API state of an object to *Released* if you want to use it from another software component. See [Released APIs](#) and [Finding Released APIs and Deprecated Objects](#).

Having this in mind, you can structure development into reuse components that are used across several components.

In this example, one add-on product consists of a leading software component A and software component C, whereas another add-on product consists of a leading software component B and C. Software component A and B use released objects of software component C, and thereby depend on this software component.

Once you have released an object, we recommend not changing it incompatibly because this can lead to errors for its consumers.

Software components must not have cyclic dependencies. In the example above, reuse software component C must not use objects from leading software component A. For more information on software component restrictions, see [Software Components \[page 662\]](#).

In the add-on descriptor file, dependencies are reflected by the order of the components in the repositories list:

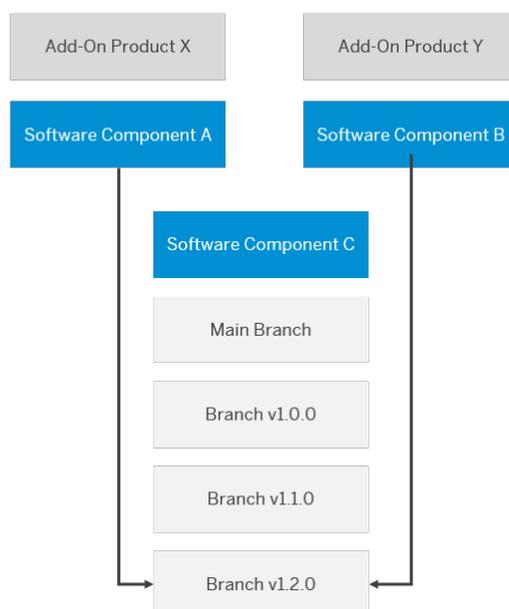

```
---
addonProduct: "/NAMESPC/PRODUCT_X"
addonVersion: "1.2.0"
repositories:
  - name: "/NAMESPC/COMPONENT_C"
    branch: "v1.2.0"
    version: "1.2.0"
    commitID: "7d4516e9"
  - name: "/NAMESPC/COMPONENT_A"
    branch: "v2.0.0"
    version: "2.0.0"
    commitID: "9f102ffb"
```

In this case, component `/NAMESPACE/COMPONENT_C` is the reuse component. It has no dependencies to any other top components and is therefore listed first. This is important for the right order during software component import. `/NAMESPACE/COMPONENT_C` needs to be imported before `/NAMESPACE/COMPONENT_A` to avoid import errors. In addition to that, software components in the bundle can use different namespaces in the software component name.

### → Recommendation

In a software component bundle with a reuse component, this component is assembled whenever the software component version is defined for the first time in the add-on descriptor file. Therefore, make sure to define the correct software component version to prevent building the wrong software component version for `/NAMESPACE/COMPONENT_C`.

We recommend following the same delivery model (identical shipment cycles) for all involved software components in a delivery scenario with a reuse component.

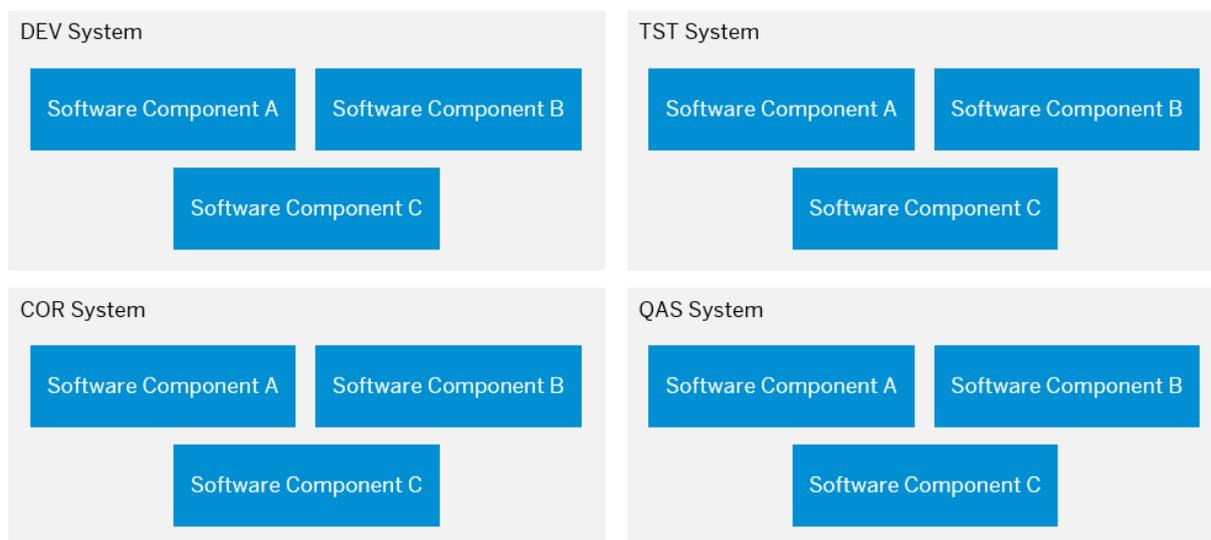

In this scenario, add-on product X and Y are based on the continuous delivery model and still undergo development. That means, for both add-on products, a new version can be shipped on a bi-weekly basis.

Consequently, the leading software components A and B refer to objects in the same branch of the reuse software component C, for example branch v1.2.0

Let's assume that development and correction of both software components is performed in one DEV and COR system. If there has to be a bug fix in reuse software component C, corrections to the corresponding software components A and B are still possible. This is due to the fact that branch v1.2.0 can remain checked out in software component C, while these changes are made.

The same applies to the development process: A new feature can be developed in leading software component A using the main branch of reuse software component C. Since only the main branch of reuse software component C is used in the DEV system, the development in the corresponding software components A and B can continue in parallel.

This scenario is resource-efficient: only one system is required for development in system DEV and one for corrections in COR. With respect to the developer experience, it is more convenient to have all implementation components in one development system because everything is in one place and the whole system landscape is easily understandable.

The system setup regarding the testing and quality assurance for corrections depends on how you want to test the add-on products:

- Do you want to provide a test environment that is identical to a production system with the add-on product installed? Then you should establish one TST and one QAS system for each add-on product in the sense that only those software components used for each add-on product are imported into these systems.
- Do you want to reduce the number of systems without restricting the test environment? Then you only need one TST and one QAS system, where all software components are imported.

#### → Recommendation

The number of required systems for DEV, COR, TST, and QAS depends on the number of branches that are actively used in dev, test, and build processes. Whenever more than one branch is actively used, one ABAP system is required per branch because an ABAP system always checks out only one branch of a software component.

### 4.2.11.1.4.5 Delivery via Add-On or gCTS

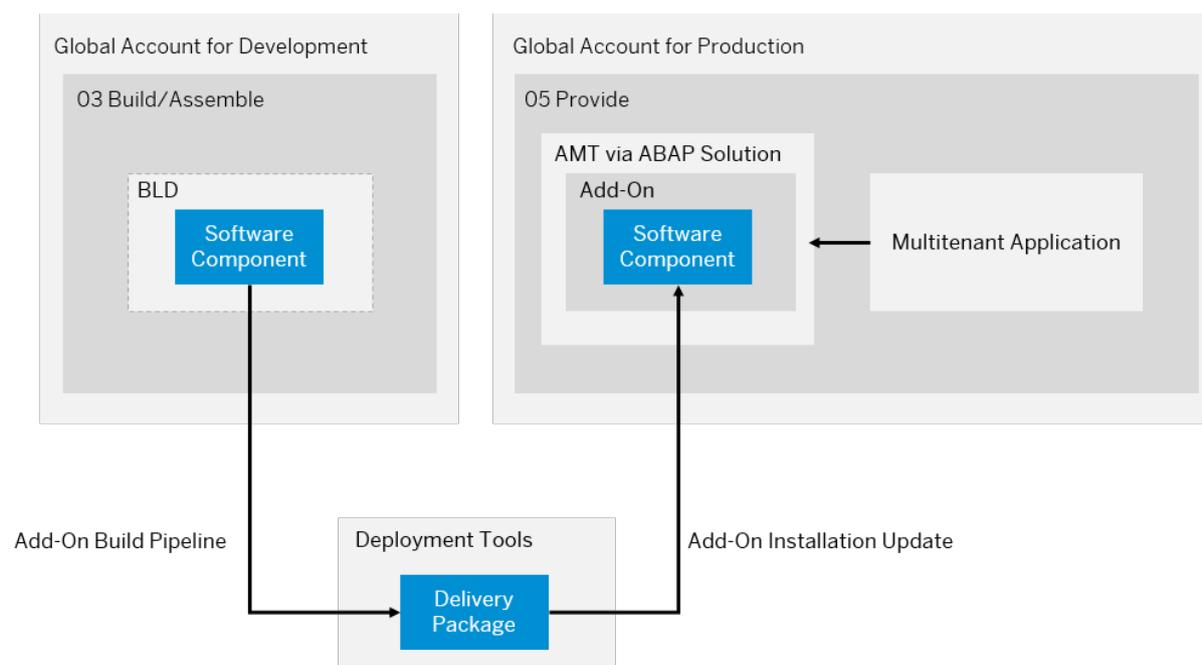

For SaaS solutions in the ABAP environment, software components including ABAP development objects have to be delivered to your production system. This is referred to as upstream process.

Afterwards, the SaaS solution is provided by offering a multitenant application that facilitates a subscription mechanism. This is referred to as downstream process.

There are multiple options to deliver software components to the systems. The delivery process described in this documentation mainly focuses on using add-on products as a means to deliver software components by installing or updating delivery packages in a system. See [The Add-On Product](#) .

As an alternative, you can choose a delivery process using the gCTS-transport-based import of software components. See [Transport Mechanisms \[page 662\]](#).

## Add-On Build Delivery Process

An add-on is a bundle of software components. To create an add-on, a build process orchestrated by an add-on build pipeline has to be triggered.

With delivery tools, the software components are packaged into deliveries that are then further processed. Eventually, the deliveries are stored as delivery packages using the deployment tools provided by SAP.

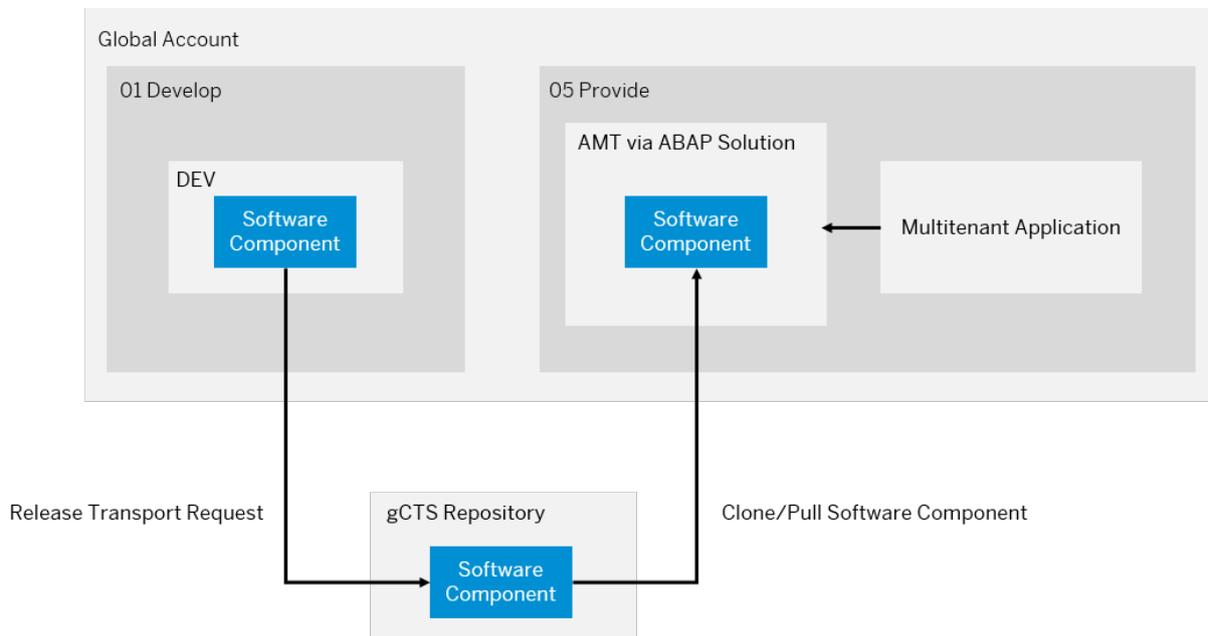

Add-on deployment is either performed by using an add-on installation during system provisioning or as an add-on update triggered in the [Landscape Portal](#) application.

Delivery packages are of different types, which means that the build and deployment of these packages differ accordingly. For example, the import of a software component for an add-on installation package or delta-import for correction packages.

BLD and AMT systems are based on different service plans: `abap/standard` for a plain ABAP system and `abap/saas_oem` for an ABAP system with installed add-on. The usage of these service plans is separated in two different global accounts for development and production purposes. Making software components available across different global accounts is only possible by using the add-on delivery process.

Making software components available across different global accounts is only possible by using the add-on delivery process. You can't use software components imported via add-on in the [Manage Software Components](#) app.

## gCTS Transport Delivery Process

The gCTS-transport-based delivery process takes place in one global development account only. This is due to the fact that the underlying gCTS repository is only shared among systems in the same region in the same global account.

ABAP development objects are released with a transport request in a particular software component in the development system. The transport request release automatically exports the changes into an SAP-managed gCTS repository by creating a new commit. Once the changes are exported into the gCTS repository, they are centrally available and can be imported into any other systems in the same region in the same global account. By cloning a software component into a customer production system using the *Manage Software Components* app, implemented ABAP objects become available to customers subscribed to the multitenant application.

The customer production system AMT is provisioned during the initial subscription to the multitenant application. Since the SaaS solution needs to include the implemented software, software components must be cloned right after the first subscription.

**Add-On Build Delivery (Productive Build Pipeline)**

**gCTS Transport Delivery (Transport Mechanism)**

## System Landscape/Account Model

- ABAP systems for development purposes (development, test, demo) are of type `abap/standard` or `abap/abap_saas_oem`, and are provisioned in the global account for development based on a discounted development license
- ABAP systems for production purposes (used by partner customers) are of type `abap/standard` or `abap/abap_saas_oem`, and are provisioned in the global account for production based on a production license
- Software components are made available across these different global accounts by using add-ons
- For execution of the add-on build pipeline, an add-on assembly system BLD and add-on installation test system ATI are (temporarily) required
- All ABAP systems are of type `abap/standard` and are provisioned in the same global account
- No additional ABAP systems, apart from already existing development and test systems, are required to facilitate the delivery
- Single global account because gCTS repositories are only shared among ABAP systems in the same region in the same global account

---

## Ease of Use

- Initial efforts to set up ABAP environment pipeline for add-on build
  - ABAP environment pipeline needs to be executed in a Jenkins CI/CD Server
  - Initial configuration effort and requires to set up Jenkins server infrastructure. See [Infrastructure](#) .
  - Resulting delivery packages are either installed as part of an add-on during system provisioning or updated centrally in the systems using the [Landscape Portal](#) application. See [Perform Add-on Updates \[page 1306\]](#).
  - No build process required; deployment triggered locally using [Manage Software Components](#) app
  - Changes to software components are released and exported to a central remote repository using transport requests
  - The [Manage Software Components](#) app, that is part of every ABAP system, is used to trigger the import of new changes locally for each system
  - As an alternative, software component import can be triggered by using the ABAP environment pipeline. See [ABAP Environment Pipeline](#) .
-

## Quality Measures/Resilience

Add-on build pipeline for delivery to production provides a guided process with strict checks:

- ABAP Test Cockpit checks before transport release
- Optional: ABAP Test Cockpit checks as part of ABAP environment pipeline for continuous testing
- ABAP Test Cockpit checks as part of ABAP environment pipeline for add-on build
- Checks during add-on build
- Add-on installation test
- Check for minimum platform version during add-on installation/update
- Checks for import conditions during add-on installation/update that prevent import of unwanted software component states

gCTS transport includes basic checks, for strict checks additional processes need to be established:

- ABAP Test Cockpit checks before transport release
- Optional: ABAP Test Cockpit checks as part of ABAP environment pipeline for continuous testing

---

## Auditability/Traceability

- Reliable, secure, traceable, and automated process based on add-on build using ABAP environment pipeline
  - Resulting delivery packages created as part of add-on build are signed and stored permanently so that they can't be altered or deleted after a release
  - Import conditions are assigned to delivery packages so that it's technically verified, during add-on update/installation, that all prerequisite package requirements are met
  - Delivery packages can be traced back to a specific commit ID of a software component, also dependencies between delivery packages can be translated into dependencies between different commit IDs
  - Build logs are archived as part of the add-on build pipeline execution
  - Anonymization of build results (*Created by* information)
  - Add-on build pipeline guarantees that only tested changes are delivered to consumers
- Logs of software component import are not archived, only locally available in ABAP environment system
  - Commit IDs in software component branches can be deleted by accident if not contained in any other existing branch
  - Import dependencies between software components need to be taken care of manually, a specific import order must be adhered to
  - Software component states are only identified by a specific commit ID instead of a readable version number

## Scalability

- Online deployment only possible with add-on-based delivery
- With the *Landscape Portal* as a central tool for orchestration of software lifecycle activities, the add-on version can be updated centrally in multiple systems at the same time
- Add-ons are automatically installed during system provisioning of ABAP systems and application content is immediately available in systems after subscription to the multitenant application
- Application content is initially not available: Software components need to be cloned locally into the provisioned systems using the *Manage Software Components* app. See [How to Clone Software Components \[page 2596\]](#).

### Note

You can use a separate test subscription that is not related to a consumer to trigger the creation of the system before the consumer subscribes to the solution. This initial system creation and import of the software components needs to be performed for each consumer production system.

- Latest changes can be pulled locally into a system by using the *Manage Software Components* app. See [How to Pull Software Components \[page 2597\]](#).
- Software component states installed in a system can only be identified locally in the *Manage Software Components* app.

### Note

Especially for SaaS solutions deployed using multiple ABAP environment systems, a gCTS-transport-based delivery process results in a lot of manual effort.

## SAP Software Certification

Possible, check details here:

- [SAP Extension Suite Certification](#)
- <https://www.sap.com/icc>

Not possible

## Certifications and Compliance of Solution

SAP Compliance Offerings available in SAP Trust Center. See <https://www.sap.com/about/trust-center/certification-compliance.html>.

Requires less effort to be compliant because a strict process, supported by SAP delivery/deployment tools, is provided.

Requires additional effort to be compliant because a strict process needs to be established without SAP tooling support.

### → Recommendation

We recommend using the **add-on build delivery** process because it offers a bundling that can be used to implement a sophisticated delivery approach with separate codelines, versioning, and, as a result, different delivery package types. See [Delivery Models \[page 1223\]](#). It also comes with a separation of ABAP system licenses for development and production purposes, with the development systems being available at a discounted rate.

Example scenarios: Long-term projects with frequent maintenance deliveries, expected growth of consumers over time, and adherence to specific standards/certifications.

The **gCTS transport delivery** approach is a more lightweight approach that might be used especially if a simple setup and quick readiness are important. Ease-of-use of the approach comes with disadvantages in auditability, traceability, scalability, and resilience. These trade-offs might be resolved by establishing additional manual process steps or documentation requirements.

If the multitenant application is configured with `tenant_mode = single`, a dedicated system is created per subscription. See [ABAP Solution Service \[page 1262\]](#). In that case, gCTS delivery is only recommended if the SaaS solution is expecting a small set of customers or if the subscription is performed together with the customer. Otherwise, the effort for executing manual tasks, such as importing software components would be too high.

Example scenarios: Prototyping projects, quick time-to-market launch, in-house solutions, predictable number of consumers, and no expected exceptional growth rate

Once a first customer is using the SaaS solution and a first production system is provisioned, there is no migration path available to switch from one approach to the other, which means that systems would have to be deleted. However, it is likely to start out with gCTS transport delivery in the prototyping phase of a project and establish an add-on build delivery approach once the initial version needs to be delivered and customer systems need to be created.

## 4.2.11.1.5 Develop, Test, Build

To develop and provide add-ons, you have to set up a suitable system landscape and Cloud Foundry environment account structure.

You need a partner contract to create the account structure. The accounts for the upstream (add-on development, test, build) and downstream (providing add-on as SaaS solution) parts of the process need to be separated from each other and therefore are handled in dedicated global accounts. We refer to these as global accounts for development and production account. For more information regarding the development license, see [SAP PartnerEdge Test, Demo & Development Price List](#). To find out more about production licenses, see [SAP PartnerEdge: Resources for OEM Partners](#).

### → Tip

For in-depth information about the system landscape/account model, check out [System Landscape/Account Model \[page 1210\]](#).

For the initial add-on delivery, you should create a development and test landscape following the guidelines mentioned in [Concepts \[page 1210\]](#). Once backend and frontend development is completed, you can test the add-on implementation in a persistent test system. Upon successful completion of this step, set up a CI/CD server along with a Jenkins pipeline to execute the add-on build allowing for an automated and efficient assembly. This automated pipeline can then be reused transforming all upgrade and update activities into a straightforward process.

Once the add-on build/assembly is finished, you can release the add-on for installation/update. First, the add-on build is installed in a test system in the global account for development to verify that it works correctly. If successful, you can provide the add-on to customers.

### ⓘ gCTS Delivery

Besides using add-ons for delivering software components to production systems, gCTS transports can be used as an alternative approach. It is used for transporting software components between different ABAP systems.

See [Delivery via Add-On or gCTS \[page 1228\]](#).

## 4.2.11.1.5.1 Access to Landscape Portal

The *Landscape Portal* acts as a central tool that allows you to perform lifecycle management operations, such as provisioning new consumers tenants, users, and more. See [Landscape Portal \[page 1302\]](#).

As an operator, subscribe to the *Landscape Portal* application in the *05 Provide* subaccount in both the global account for development and global account for production. The `LandscapePortalAdminRoleCollection` needs to be assigned to the users in the default identity provider of the subaccount that you want to provide access to the *Landscape Portal* app. See [Accessing the Landscape Portal \[page 1303\]](#).

### ⓘ gCTS Delivery

In the Landscape Portal, you can access the provider system and choose the provider tenant (client 100). Via the provider tenant, you get access to Fiori Apps, for example the *Manage Software Components* app, which is used for importing software components via gCTS.

See [Delivery via Add-On or gCTS \[page 1228\]](#).

## 4.2.11.1.5.2 Prepare

Before you can proceed with the development of the add-on, you have to perform several preliminary steps.

- Register the development namespaces before any system is set up. To start the actual add-on development process, you have to set up the system landscape and global account structure for development. For pipeline automation, set up a CI/CD server, in this case a Jenkins server.
- Create one or more software components that make up the add-on in the namespaces registered for you. In this scenario, namespaces are required for both the add-on product name and software components. You can register these namespaces with the development namespace/license keys tool.
- Purchase the SAP BTP, Cloud Foundry environment entitlements necessary for the account setup, which includes the service ABAP environment for development. The ABAP environment (service plan `saas_oem`), Application runtime, SaaS provisioning, ABAP Solution service as well as the Landscape Portal are used for providing the SaaS app.

#### → Recommendation

We recommend using the browser-based IDE SAP Business Application Studio for UI development. In this case, additional configuration is required to enable developers to use this service.

Once you've completed these steps, you can start developing an add-on.

## Prerequisites

- To register a namespace, you need an S-user in SAP One Support Launchpad with authorization to reserve a development namespace. See SAP note [1271482](#).
- To set up global accounts for development and production, you need two global accounts on the SAP Business Technology Platform with the corresponding entitlements for services and applications. See [Entitlements and Quotas](#).
- To create ABAP instances, you have to set up the account structure in the global account for development, and assign entitlements for each subaccount. See [Configure Entitlements and Quotas for Subaccounts](#).
- To develop UIs, you need an entitlement for SAP Business Application Studio and an assignment to a subaccount for development. See [SAP Business Application Studio](#).
- To set up transports from the development to the test system, you need a test system and optionally a pipeline in a Jenkins CI/CD server that is provisioned using a Cx Server to automatically import new changes. See [Jenkins](#) and [Cx Server](#).
- To set up add-on development, you need a development system.

### 4.2.11.1.5.2.1 Register a Namespace

Using a reserved namespace for add-on development and build is necessary for a unique add-on product and software component name.

#### 📘 Note

You need to register a namespace before the first ABAP system is provisioned. To activate namespaces in already existing systems after system provisioning, see [Maintain Namespaces \[page 1308\]](#).

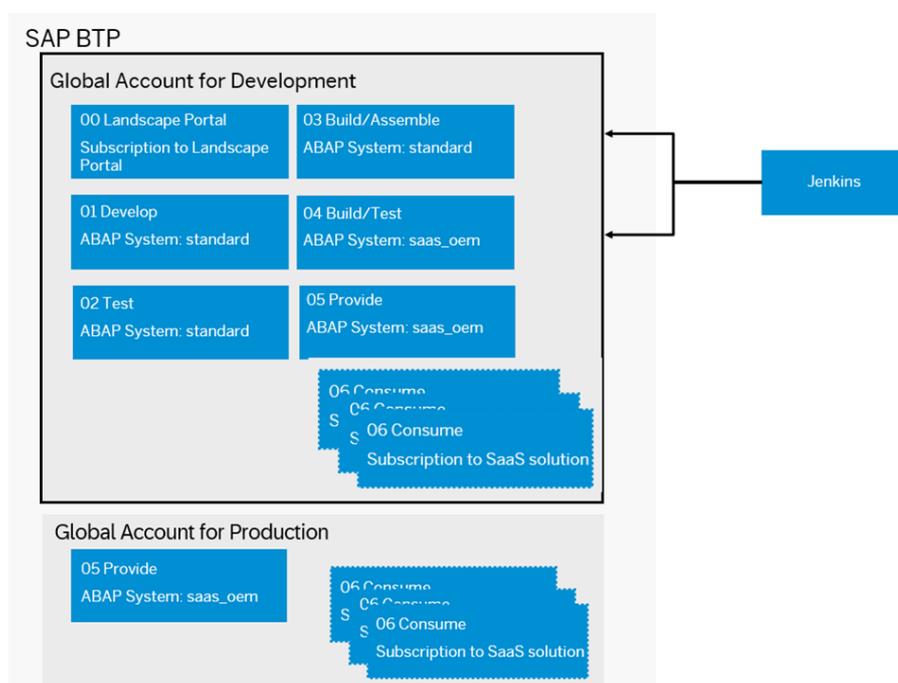

If you need a new S-user, get in touch with a user administrator in SAP ONE Support Launchpad.

As an S-user with authorization *Reserve Namespaces*, you have to reserve a namespace for your partner customer ID to register a namespace with the *Namespace* app. See [Namespace Application](#).

Due to length restrictions of some objects, namespaces should have 5–8 characters. See SAP note [105132](#) and [395083](#).

## 4.2.11.1.5.2.2 Set Up a Global Account for Development

As a SaaS solution operator, you have to configure the global account for development (used for development, testing, and demo purposes).

### → Recommendation

We recommend the following subaccount structure:

- In the *00 Landscape Portal* subaccount, your subscription to the Landscape Portal is created. If required, the CI/CD service should also be subscribed in this subaccount. No Cloud Foundry environment is required.
- In the *01 Develop* subaccount, add-on development is performed in a permanent development system. See [Development in the ABAP Environment \[page 651\]](#).
- In the *02 Test* subaccount, the developed software components are tested after a successful import into a permanent test system.
- In the *03 Build/Assemble* subaccount, the add-on package assembly is performed in a transient assembly system that is created and deleted automatically by the build pipeline.
- In the *04 Build/Test* subaccount, the add-on product is installed and tested again.
- In the *05 Provide* subaccount, the add-on product is provided as a SaaS solution for testing purposes in the development phase.

## 📘 gCTS Delivery

If you use gCTS instead of add-ons for delivering software components to production systems, the setup and usage of the following subaccounts is redundant:

- *03 Build/Assemble* (used for the add-on assembly)
- *04 Build/Test* (used for add-on installation test)

Additionally, considering the availability of software components only in the same global accounts, you have to create the production systems as well as development and test systems in the same global account (only one global account is used).

In the provider subaccount, the entitlement for an ABAP instance of service plan type `abap/standard` instead of `abap/saas_oem` needs to be available.

See [Delivery via Add-On or gCTS \[page 1228\]](#).

You should configure a Cloud Foundry space in each subaccount. Dividing the development, testing, and assembling activities into different subaccounts allows for maximum flexibility. For instance, you may want to use different identity providers or consume different connectivity services during testing and development.

The ABAP systems that you use for development, testing, and add-on assembly are of type `abap/standard` and made available via entitlements. ABAP systems for add-on installation are of type `abap/saas_oem`. These service entitlements must be assigned by an administrator to different subaccounts, according to the following structure:

Global Account	Subaccount	Space	Services
Global Account for Development	01 Develop	Develop	1x abap/standard
			abap/hana_compute_unit (standard: 2)
			abap/abap_compute_unit (standard: 1)
	02 Test	Test	1x abap/standard
			abap/hana_compute_unit (standard: 2)
			abap/abap_compute_unit (standard: 1)
	03 Build/Assemble	Build/Assemble	1x abap/standard
			abap/hana_compute_unit (standard: 2)
			abap/abap_compute_unit (standard: 1)

Global Account	Subaccount	Space	Services
	04 Build/Test	Build/Test	1x abap/saas_oem abap/hana_compute_unit (standard: 2) abap/abap_compute_unit (standard: 1)
	05 Provide	Provide	1x abap/saas_oem abap/hana_compute_unit (standard: 2) abap/abap_compute_unit (standard: 1) Application Runtime abap-solution saas-registry xsuaa

Additionally, the following entitlements for SaaS application subscriptions are required:

- SAP Business Application Studio for UI development. See [SAP Business Application Studio \[page 220\]](#).
- Web access for ABAP for access to systems during development phase. See [Subscribing to the Web Access for ABAP \[page 168\]](#).
- Landscape Portal to manage systems and tenants in the provider subaccount. See [Landscape Portal \[page 1302\]](#).

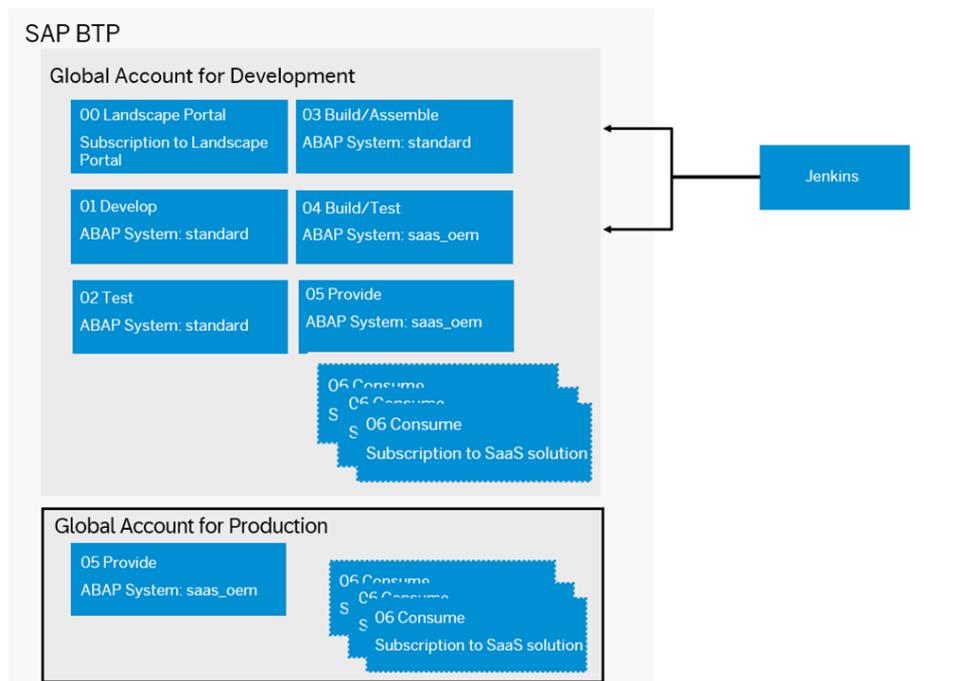

If you want to integrate an existing corporate identity provider in the subaccounts of the global account for development for authentication/authorization, see [Trust and Federation with Identity Providers \[page 2014\]](#). To restrict access based on certain criteria such as the IP address, you need to use the [SAP Cloud Identity Services - Identity Authentication](#).

→ Tip

For in-depth information about the system landscape/account model, check out [System Landscape/Account Model \[page 1210\]](#).

### 4.2.11.1.5.2.3 Set Up a Global Account for Production

As a SaaS solution operator, you have to configure the global account for production.

3

## → Recommendation

We recommend the following subaccount structure:

In the *00 Landscape Portal* subaccount, your subscription to the Landscape Portal is created. If required, the CI/CD service should also be subscribed in this subaccount. No Cloud Foundry environment is required.

In the *05 Provide* subaccount, the add-on product is provided as a SaaS solution for production purposes in the production phase. The solution is consumed by your customers from consumer subaccounts.

In the provider context, the ABAP environment (`saas_oem`) service plan is used.

## ⓘ gCTS Delivery

In the provider subaccount, the entitlement for an ABAP instance of service plan type `abap/standard` needs to be available.

Additionally, considering the availability of software components only in the same global accounts, you have to create the production systems as well as development and test systems in the same global account.

See [Delivery via Add-On or gCTS \[page 1228\]](#).

These provider ABAP instances allow flexible sizing, multitenancy, and the possibility to install an add-on product during provisioning.

For the provisioning of these ABAP systems of service plan `saas_oem`, another set of services comes into play: With the ABAP Solution Provider and the `saas-registry` service, you can provide your add-ons as SaaS solution offerings. See [ABAP Solution Service \[page 1262\]](#).

Note that these service entitlements must be assigned to different subaccounts, according to the following structure:

Global Account	Subaccount	Space	Services
Global Account for Production	05 Provide	Provide	abap/saas_oem abap/hana_compute_unit (standard: 4) abap/abap_compute_unit (standard: 1) Application Runtime abap-solution saas-registry xsuaa

Additionally, the following entitlements for SaaS application subscriptions are required:

- Web access for ABAP for access to systems during the development phase. See [Subscribing to the Web Access for ABAP](#).
- Landscape Portal to manage systems and tenants in the provider subaccount. See [Landscape Portal \[page 1302\]](#).

If you want to integrate an existing corporate identity provider in the subaccounts of the global account for production for authentication/authorization, see [Trust and Federation with Identity Providers \[page 2014\]](#). To restrict access based on certain criteria such as the IP address, you need to use the [SAP Cloud Identity Services - Identity Authentication](#).

→ Tip

For in-depth information about the system landscape/account model, check out [System Landscape/Account Model \[page 1210\]](#).

## 4.2.11.1.5.2.4 Create ABAP Instances

As a SaaS solution operator, you have to create ABAP instances.

For development and testing in the development codeline, one system is provisioned in each of the development and test subaccounts. Use service parameter `is_development_allowed` to differentiate between development and production systems. The test and assembly systems must be productive to avoid changes being made to the add-on outside of the development system.

Global Account	Subaccount	Space	ABAP Instances
Global Account for Development	01 Develop	Develop	Create an ABAP instance (abap/standard) DEV  Set parameter <code>is_development_allowed = true</code>
	02 Test	Test	Create an ABAP instance (abap/standard) TST  Set parameter <code>is_development_allowed = false</code>

### Note

You don't have to create an ABAP instance in the *03 Build/Assemble*, *04 Build/Test*, and *05 Provide* subaccount because the system is created automatically.

In the *03 Build/Assemble* account, assembly systems are provisioned by the add-on build pipeline. These systems are used to import the desired software components that are then packaged for add-on delivery (see [Software Assembly Integration \(SAP\\_COM\\_0582\) \[page 737\]](#)). As an operator, you don't have to provision these systems manually.

In the *04 Build/Test* subaccount of the global account for production, an add-on installation test system is automatically created. This ABAP environment service instance of plan `saas_oem` is provisioned with parameter `is_development_allowed = false`.

In the *05 Provide* subaccount of the global accounts for development and production, a customer production system is created automatically by the ABAP Solution Service during the first subscription. For more information on how to get started with your customer account, see [Getting Started with a Customer Account in the ABAP Environment \[page 149\]](#) and [Creating an ABAP System](#).

Use service parameter `is_development_allowed` to differentiate between development and production systems. The test and assembly systems must be productive to avoid changes being made to the add-on outside of the development system.

Subscribe to the Web Access for ABAP to gain access to the SAP Fiori launchpad in all subaccounts of the global production account.

## 4.2.11.1.5.2.5 Set Up UI Development

As a SaaS solution operator, you have to set up SAP Business Application Studio for development.

As a developer user, you can then create an SAP Fiori dev space and generate UI projects.

### → Recommendation

For frontend development, we recommend using SAP Business Application Studio. See [Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#).

## 4.2.11.1.5.2.6 Set Up Add-On Development

Learn how to set up add-on development by creating and importing software components. Furthermore, read about configuring ABAP Test Cockpit checks and check variants, as well as enabling transport blocking to fix issues early on during development.

### Create and Import Software Components

To transport new developments from system to system, the add-on development is structured by software components. Software components are independent development containers.

To create a new software component for add-on development, as an add-on admin user, use the [Manage Software Components](#) app and create a new component of type `Development`. The name of the software component begins with a namespace that was activated in the development system. By default, all namespaces of the global account owner are enabled in the systems. See [How to Create Software Components](#).

Clone the main branch of the software component to the development and test system.

Software components in the development and test system should always stay on the main branch. If you want to work on maintenance branches to develop bug fixes and other maintenance deliveries, create a dedicated hotfix development and test system (maintenance codeline).

#### → Tip

For in-depth information about versioning and branches, check out [Versioning and Branches](#).

### Configure ABAP Test Cockpit Checks, Check Variants

By default, a check variant `ABAP_CLOUD_DEVELOPMENT_DEFAULT` is generated in ABAP environment systems. You should use this variant for ABAP Test Cockpit check runs or create a custom check variant based on the default check. See [Creating ATC Check Variants](#). You can also create custom ABAP Test Cockpit checks. See [Creating ATC Checks](#).

Custom ABAP Test Cockpit checks and check variants are created as part of a software component, whereas the default check variant is generated locally.

### Configure ABAP Test Cockpit to Interrupt Transport Releases

We recommend enabling the blocking of transport releases in case of priority 1 (error) findings using the default check variant `ABAP_CLOUD_DEVELOPMENT_DEFAULT` or a custom check variant. You can enable transport blocking in the ABAP Test Cockpit Configurator app. See [ABAP Test Cockpit Configurator](#).

Interrupting a transport release in case of severe findings can help to fix issues early on during development. The later errors are detected in the development process, the more costly it is to resolve them. See [Launching ATC Check Implicitly](#).

## 4.2.11.1.5.2.7 Set Up Transport from Development to Test System

You can perform the import of your software components into a test system either manually by using the [Manage Software Components](#) app or in an automated way using the [ABAP Environment Pipeline \[page 1215\]](#).

## Manual Import into Test System

As an add-on admin user, you can pull the latest released changes of a software component to the test system by using the main branch. You can test these changes in the test system independent from ongoing development. See [How to Pull Software Components \[page 2597\]](#) and [ABAP Lifecycle Management \[page 660\]](#).

## Automatic Import into Test System with ABAP Environment Pipeline

### → Tip

For in-depth information about the ABAP environment pipeline used for automatic import into a test system, see [ABAP Environment Pipeline \[page 1215\]](#).

As a DevOps engineer, you can configure the ABAP environment pipeline for an automated import of software components to test system TST. With the pipeline, the pulling of specified software components is automated and performed on a regular schedule.

The continuous testing scenario of the ABAP environment pipeline is described in detail in [Continuous Testing on SAP BTP ABAP Environment](#) .

## 4.2.11.1.5.3 Develop

Both the initial implementation and any further development of the add-on are performed in the development system of the development subaccount.

You can use various SAP technologies at this point, such as the ABAP RESTful application programming model (RAP) for modeling and implementing business objects and the browser-based IDE SAP Business Application Studio for developing SAP Fiori UIs. Depending on the business use case, some additional development effort may be necessary to implement suitable launchpad content, Identity & Access Management artifacts, or communication management artifacts.

Once you've completed these development activities, the solution is ready to be tested in a suitable test system.

## Prerequisites

- For ABAP development, you need a developer user using ABAP Development Tools. See [Getting Started as a Developer in the ABAP Environment \[page 198\]](#).
- For UI development, you need a developer user using SAP Business Application Studio. See [Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#).
- For custom code migration, you need a business user that is assigned the business role based on business role template `SAP_BR_IT_PROJECT_MANAGER`, and a communication arrangement instance for `SAP_COM_0464`. See [Custom Code Migration \[page 2408\]](#).

## 4.2.11.1.5.3.1 ABAP Development

As a developer user, implement your custom business services with the ABAP RESTful application programming model. See [ABAP RESTful Application Programming Model](#). Maintain business catalogs (see [Identity and Access Management \(IAM\) \[page 739\]](#)) and communication scenarios (see [Communication Management \[page 846\]](#)) to expose services to business users and communication users. See [SAP Business Technology Platform \[page 7\]](#), [ABAP Environment Learning Journey](#), and [ABAP Environment Community](#). Also consider starting out with a free tier option for the ABAP environment to get hands-on development experience. See [Trial Accounts and Free Tier](#).

### Identity and Access Management

SAP Fiori applications and business services are represented by IAM apps and can be used to define the necessary authorizations. In an IAM business catalog, you bundle multiple IAM apps and their predefined authorizations, for example, for a specific business area.

Additionally, you can define business role templates to make it easier for administrators to find the relevant business catalogs to create business roles. See [Identity and Access Management \(IAM\) \[page 739\]](#).

### Communication Management

#### Note

Use customer-managed communication scenarios as a design time description to store technical information, such as inbound and outbound services and their service type, for example OData or SOAP by using the `create_by_comm_arrangement` method. See [Service Consumption via Communication Arrangements \[page 854\]](#).

Instead of coding against destination names, using communication scenarios allows consumers of the SaaS solution to create communication arrangements based on provided communication scenarios. Therefore, you don't have to create specific destinations in the consumer subaccount.

#### Restriction

The ABAP environment only supports one communication configuration layer intended to be used by the consumer. It's currently not possible to enforce a communication configuration exclusively managed by the service provider within the consumer tenant.

Services with the following protocols supported for **inbound communication** can be included as part of customer-managed communication scenarios:

- HTTP
- SOAP
- RFC Internet/Cloud Connector

#### Restriction

RFC is currently not supported for inbound communication in consumer tenants.

For **outbound communication**, the following protocols are supported:

- HTTP (Internet)

- HTTP (Cloud Connector)
- SOAP (Internet)
- SOAP (Cloud Connector)
- RFC (Internet)
- RFC (Cloud Connector)

See [Supported Protocols and Authentication Methods \[page 850\]](#).

## Business Configuration

Business configuration plays a major role in SaaS solutions. It refers to a predefined set of configuration options that affect its functionality and behavior. See [Business Configuration in SAP BTP ABAP Environment \(1\): Overview and BC Maintenance Apps](#).

To maintain these configuration options, you have to create dedicated apps using the ABAP RESTful Application Programming Model. See [Create a Business Configuration App for Factory Calendar Using the ABAP RESTful Application Programming Model](#).

Using the business configurations API, you can register business configurations. These business configurations are then displayed in the list of all maintainable business configurations in the SAP Fiori App Maintain Business Configurations, if the user has the necessary authorizations for the service of the business configuration. See [Business Configuration Maintenance Object Cloud Platform API \[page 831\]](#).

## Key User Extensibility Enablement

Using SaaS solutions, you can provide key user extensibility for system-internal use (contract C1) and use in key user apps. This allows customers who use the solution to extend it to their specific requirements.

As a developer user, you have to implement key user extensibility in the development system in the Partner Development tenant (client 100) using ABAP Development Tools.

See [Providing Business Add-Ins \[page 1342\]](#) for guidance on how to prepare business add-ins (BADIs) so that customers can add their own business logic in the solution by using the *Custom Logic* app.

See [Configuring Predefined Custom Fields \[page 2434\]](#) for guidance on how to equip your SaaS solution with support for customer-specific extension fields.

## Stability of Released APIs

Released APIs, such as BADIs or predefined custom fields, must only be changed compatibly. Otherwise, for example, runtime errors might occur or an upgrade might fail. To ensure that released APIs are not changed incompatibly, run an ATC compatibility check. This check uses snapshots that are created using the *Manage API Snapshots* app and which are set to check-relevant, to check whether incompatible changes have been made to the released API. For more information, see [Manage API Snapshots \[page 2355\]](#).

## Multitenancy

With the ABAP environment, you can build multitenancy-enabled SaaS solutions. To do so, the add-on implementation has to follow certain guidelines. See [Multitenancy Development Guideline \[page 1295\]](#).

### → Recommendation

If the add-on implementation is aligned with the development guideline for multitenancy, we recommend configuring your solution by setting `tenant_mode = multi` so that the same ABAP service instance is used for multiple consumers.

→ Tip

For in-depth information about multitenancy, check out [Multitenancy \[page 1219\]](#).

### 4.2.11.1.5.3.2 UI Development

SAP Fiori applications are developed in SAP Business Application Studio on top of business services in the ABAP development system and then deployed to the ABAP development system to be part of the same software component as backend artifacts.

As a developer user, once business services are implemented as UI services, you can create SAP Fiori elements apps using SAP Business Application Studio. See [Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#).

#### ⓘ Note

Launchpad spaces and pages offer more flexibility to influence the launchpad layout for specific user groups. As of now, there is no possibility to create templates for a specific spaces/pages setup and to deliver this as part of an add-on. Therefore, for every consumer, this needs to be configured manually.

To simplify this process, we recommend structuring the IAM business catalogs that include IAM apps for the UI according to business roles by using business role templates. See [Providing Access to the SAP Fiori Application \[page 788\]](#).

### 4.2.11.1.5.3.3 (Optional) Code Migration from On-Premise

Optionally, you can migrate existing custom ABAP code for add-on development purposes. This custom code migration process analyzes your existing code for cloud-readiness. See [How to Check your Custom ABAP Code for SAP BTP ABAP Environment](#) and [Custom Code Migration \[page 2408\]](#).

After adapting the code and making necessary changes, you can migrate the code via abapGit. See [How to Bring your ABAP Custom Code to SAP BTP ABAP Environment](#).

### 4.2.11.1.5.4 Test

Once development has been completed, you can test the solution in the test subaccount that you have previously set up. The software components that make up the solution are imported into a provisioned test system, while any additionally required configuration has to be carried out by you. This may entail creating suitable business roles, maintaining communication arrangements, or other administrative tasks performed via the SAP Fiori launchpad of your ABAP system.

You can also use a CI/CD server and a Jenkins pipeline to automate the test process. This allows you to schedule regular tests and to be notified as soon as issues arise within the solution.

If the solution is successfully tested and works correctly, you can proceed with the add-on build.

## Prerequisites

- For testing in SAP Fiori launchpad in your ABAP environment, you need a business user in the test system that has the required authorizations to use the [Manage Software Components](#) app as well as authorizations that are required as a test user.
- For testing in the ABAP Test Cockpit, you need a developer user using ABAP Development Tools. See [Getting Started as a Developer in the ABAP Environment \[page 198\]](#).
- (Optional) For running ATC checks as part of the ABAP environment pipeline, you have to create a pipeline in a Jenkins CI/CD server that is provisioned using the Cx Server tool. See [Jenkins](#) and [Cx Server](#).

### 4.2.11.1.5.4.1 Test in the ABAP Environment SAP Fiori Launchpad

#### Import Software Components

Before testing new developments in a software component in the test system, as an add-on admin, you have to import the latest changes from the remote repository. After you have cloned a software component into the test system TST, you can import the latest changes by pulling the software component in the [Manage Software Components](#) app. See [How to Pull Software Components \[page 2597\]](#).

#### Create and Assign Business Roles

Before creating and assigning business roles, you have to make sure that business users are already available. They can be created manually or automatically. See [User Provisioning \[page 745\]](#).

To test the developed business services, as a test user, create business roles from the role templates in the test system and assign them to your user. See [Maintain Business Roles \(Deprecated\) \[page 2452\]](#).

#### Create Launchpad Space and Pages for Business Roles

To enable navigation to custom UIs via tiles, enable launchpad spaces and pages. Add spaces to the relevant business roles and add the needed SAP Fiori launchpad tiles to those spaces. Finally, enable spaces for business users in the system launchpad settings. See [How to Create Spaces and Pages for a Business Role \[page 2465\]](#).

#### Create Communication Arrangements

To test inbound and outbound communication, create communication arrangements in the test system TST based on the implemented communication scenarios. See [How to Create a Communication Arrangement \[page 2395\]](#).

#### Note

Depending on whether you want to use an authentication method for outbound communication that requires a business user context (Oauth2 SAML Bearer Assertion, Oauth2 User Token Exchange, JWT Principal Propagation), you need to configure a destination in a communication arrangement instead

of maintaining credentials by using an outbound communication user. See [Supported Protocols and Authentication Methods \[page 850\]](#) and [Create a Destination \[page 854\]](#).

You can integrate the test system TST with on-premise systems. See [Integrating On-Premise Systems \[page 1070\]](#).

In the subaccount of test system TST, the subaccount for testing, you can assign the Cloud Connector administrator role collection to the Cloud Connector administrator user to operate the data transmission tunnels used by the Cloud Connector. See [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\]](#).

### Create Business Configuration

As a test user, you can adjust business configuration objects in the *Maintain Business Configurations* app to change and influence the system behavior. See [Custom Business Configurations App \[page 2373\]](#).

### Configure Key User Extensibility

Key user extensibility that is enabled in the SaaS solution can be configured and consumed in test systems.

#### Note

Key user extensibility provided in a SaaS solution can only be configured in tenants of particular types, for testing purposes in tenants of type Partner Test.

These tenant types are provisioned in non-development systems, such as test system TST or quality assurance system QAS, where development is not allowed (`is_development_allowed = false`). The tenants are created independently from a subscription to the SaaS solution by using the *Landscape Portal* application. See [Manage Test Tenants \[page 1317\]](#).

As a test user in a Partner Test tenant (client  $\geq$  200), you configure key user extensibility in a test system.

- See [Custom Logic \(Deprecated\) \[page 2428\]](#) for guidance on how to use the *Custom Logic* app to create and maintain custom logic for business add-ins (BADIs).
- See [Configuring Predefined Custom Fields \[page 2434\]](#) for guidance on how to configure predefined custom fields to customize applications and their UIs.

## 4.2.11.1.5.4.2 Test in the ABAP Test Cockpit

With the ABAP Test Cockpit, you can run a set of checks (check variants) on software component or package level. See [Checking Quality of ABAP Code with ATC and ABAP Test Cockpit in the Cloud – What is already possible](#).

To fix and revalidate ABAP Test Cockpit findings, as a developer user, you can run ABAP Test Cockpit checks on developed software components explicitly via ABAP Development Tools in the DEV system. See [Launching ATC Check Run from the Project Explorer](#) and [Launching ATC Check Run Explicitly](#).

If transport blocking in case of ABAP Test Cockpit findings is configured (see [Set Up Add-On Development](#)), ABAP Test Cockpit checks are executed implicitly. See [Launching ATC Check Implicitly](#).

### ATC Exemptions

If you can't clear an ABAP Test Cockpit finding by correcting the underlying problem, you can still clear it by requesting an exemption. Exemptions are created as part of a specific software component. See [Working with ATC Exemptions](#).

## Continuous Testing using ABAP Environment Pipeline

### → Tip

For in-depth information about the ABAP environment pipeline used for continuous testing, see [ABAP Environment Pipeline \[page 1215\]](#).

To schedule a regular execution of ABAP Test Cockpit checks for a software component in the test system, you can use a CI server and pipeline to automate this process. You can reuse the previously described setup of a transport from development to test system using the ABAP environment pipeline. See [Set Up Transport from Development to Test System](#).

As a DevOps engineer, configure the ABAP environment pipeline by using a static and preconfigured system. With the pipeline, the following steps are then automated, triggered by the pipeline execution of a Jenkins administrator:

- Pulling the specified software components/Git repositories
- Running the configured ABAP Test Cockpit checks

The continuous testing scenario of the ABAP environment pipeline is described in detail in [Continuous Testing on SAP BTP ABAP Environment](#).

## 4.2.11.1.5.5 Build

As an add-on administrator, you have two options for triggering the add-on build process. The recommended approach is to use the Build Product Version app in the Landscape Portal to configure and execute an add-on build pipeline, leveraging the CI/CD service on SAP BTP. Alternatively, you can implement your own pipeline manually and run it on an existing CI/CD server. In both cases, a successful pipeline execution will result in a new product version that can be installed.

The add-on build pipeline runs through multiple steps:

- For the add-on assembly, an assembly system is created in the 03 Build/Assemble subaccount. All software components that are part of the add-on product are imported into the system.

### 📘 Note

The import in the assembly system is enabled by communication scenario [Integration \(SAP COM 0510\)](#).

- During the add-on build, delivery packages corresponding to included software component versions are created. For the add-on product version, a target vector is created and published in test scope. See [Target Vector](#).

### Note

The build process is enabled by communication scenario [Software Assembly Integration \(SAP COM 0582\)](#).

- To ensure that the add-on provisioning works correctly, an installation test system is provisioned in the 04 Build/Test subaccount. The new product version is installed using the target vector published in the build stage.

### Note

The installation test system uses the service plan `saas_oem`, enabling the add-on installation.

- Once the build and test installation have been completed successfully, the target vector is published in production scope.
- After a successful build, all ABAP systems used are deprovisioned (unless otherwise specified) and the add-on is technically available for deployment to the ABAP environment.

With any new add-on, it is required that you first register the add-on product and any global accounts you wish to use before building your initial product version.

### → Tip

For in-depth information about the ABAP environment pipeline used for add-on build, check out [ABAP Environment Pipeline](#).

## Prerequisites

- Using the Build Product Version app requires an existing CI/CD subscription in the same subaccount as the Landscape Portal subscription (recommended option)
- Using a custom pipeline configuration and Jenkins server requires the following (not recommended):
  - To execute the pipeline, you have to set up a Jenkins CI/CD server that is provisioned using the Cx server and you need an S-user in SAP One Support Launchpad with user management authorization. See [Jenkins](#), [Cx Server](#), and SAP note [1271482](#).
  - To configure the pipeline, you need to create a configuration repository and implement the add-on build scenario. See [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#).

### 4.2.11.1.5.5.1 Set Up Add-On Build

The following section explains how to build the initial version of the add-on product. The result is a delivery of type AOI (Add-on Installation) for the initial release 1.0.0 of both the software component and the add-on product.

The add-on build process is orchestrated by an automated pipeline. Before the pipeline can be configured, the following steps need to be performed.

## Add Technical Platform User to Space in Subaccount *03 Build/Assemble*

As an operator, assign a technical Cloud Foundry platform user as a space developer in subaccount 03 Build/Assemble. This technical user will be used to provision the assembly system. See [Creating New Space Members and Assigning Space Developer Roles to Them](#).

## Add Technical Platform User to Space in Subaccount *04 Build/Test*

As an operator, assign a technical Cloud Foundry platform user as a space developer in the space in subaccount 04 Build/Test. This technical user will be used to provision the installation test system. See [Creating New Space Members and Assigning Space Developer Roles to Them](#).

## Create a Technical Communication User for Access to AAKaaS

As part of the add-on build process, the Add-on Assembly Kit is used. With AAKaaS, the on-premise tooling is now available as a cloud service that is used by the build pipeline.

To access the service that is offered via SAP Support Launchpad, a technical communication user is used. See SAP note [2532813](#).

In the *Support User Management* app in SAP ONE Support Launchpad, as an S-user, request a new technical communication user. After the technical communication user has been generated, activate the user.

### Note

To create technical communication users in SAP Support Launchpad, you have to assign the user administrator function to the logged on user.

Make sure that this technical communication user is assigned to the customer number under which the ABAP environment tenants are licensed and for which the development namespace was reserved.

Ensure that this technical communication user is assigned to the customer number under which the ABAP environment tenants are licensed and for which the development namespace was reserved.

See SAP note [2174416](#) for more information on how to create and activate technical communication users.

## Add credentials to credential store

The credentials of the three technical communication users need to be maintained in the Build Product Version app. See [Maintain Credentials](#).

If you are using your own Jenkins server, the Jenkins administrator needs to add the credentials of the three technical communication users to the Jenkins Credentials store.

## Register Add-On Product for Installation in Global Accounts

The registration of a new add-on product is a manual step. Your add-on product should only be installed in ABAP systems in your global accounts for development and production. Therefore, the product needs to be created and global accounts need to be registered with SAP using Landscape Portal.

See [Register Product \[page 1318\]](#).

## Configure ABAP Environment Pipeline

As a DevOps engineer, you have the choice between using the Build Product Version app in the Landscape Portal or creating a pipeline configuration for the add-on build scenario from scratch.

We strongly recommend using the Build Product Version app, as it greatly reduces both the initial configuration and the maintenance effort:

- the user-friendly tooling hides the complexity of configuring a pipeline definition and removes the need for an external repository,
- the app automatically delegates the execution of the pipeline to the CI/CD service on SAP BTP, removing the need for a partner-owned Jenkins server.

Creating a custom pipeline configuration allows you to modify parameters of the ABAP Environment pipeline that are not exposed in the Build Product Version app; however, the app should cover all common use cases.

Currently there are two features available in the pipeline that the app does not support:

- It is not possible to define a manual confirmation step before the target vector is published productively. This option allows you to perform integration tests in the ATI system before your final release decision. The pipeline executed by the app will simply check if the new version was installed successfully and will then automatically proceed to the publishing step.
- It is not possible to work with a permanent build system. This option allows to save on execution time, as no new system has to be provisioned. The app will always provision a new build system.

### **Build Product Version app (recommended)**

The Build Product Version app allows you to configure the pipeline directly in a Fiori UI. See [Build Product Version](#).

As a Landscape Portal Administrator, configure the Release Delivery pipeline template to be able to build your initial version. You can also configure the Test Release Delivery template in case you wish to perform a test execution, without releasing the new version.

### **Manual Configuration**

As a Jenkins administrator, create a new pipeline in Jenkins pointing to the Jenkins file of the pipeline configuration for the add-on build scenario. See [Configuration](#) .

The add-on build scenario of the ABAP environment pipeline is described in detail in [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#) .

## **4.2.11.1.5.5.2 Build the First Add-On Version**

### **Create Maintenance Branch**

#### **→ Recommendation**

For each release and support package level, as an add-on admin, create a maintenance branch that is used for development of bug fixes and maintenance deliveries. See [Versioning and Branches \[page 1219\]](#).

In test system TST, create branch `v1.0.0` that is based on the main branch.

### **Build New Product Version**

Each version contains an add-on version number – 1.0.0 for the initial delivery – as well as the included software components, such as the corresponding names, branches, and software component versions to be used for the add-on build. You may also choose specific software component commit IDs (as seen in the

Manage Software Components app) and select which languages should be included in the new product version. Add-on version numbers may not be used more than once.

### Build Product Version app (recommended)

New product versions for your registered add-on products can be defined directly in the Build Product Version app. The initial product version will always be of type "Release Delivery". See [Create New Product Version](#).

The corresponding pipeline is executed automatically when the **Build Product Version** button is clicked on in the app. If the execution is successful, the initial version of the add-on will then be available for installation.

### Manual Configuration

If using a custom pipeline configuration and your own Jenkins server, create an add-on configuration file (`addon.yml`) in the corresponding Git repository. This file includes the metadata of the add-on product that is being built, such as versioning information and the included software component versions. Please follow the best practices on how to define the `addon.yml` file. See [Add-on Descriptor File](#).

Once the repository is updated, trigger the pipeline execution on your Jenkins server. If your pipeline includes manual confirmation steps, you will have to follow its progress and react accordingly. You may use the add-on installation test system ATI to confirm the success of the add-on installation before confirming its release. You can also use the system for additional tests, similar to the steps described in [Test in the ABAP Environment SAP Fiori Launchpad](#). For testing in a consumer-like environment, you can create tenants of type Partner Test using the Landscape Portal application. See [Use Test Tenants](#).

#### → Tip

For in-depth information about versioning and branches, check out [Versioning and Branches \[page 1219\]](#).

To learn how software lifecycle management in the ABAP environment works with software components, see [Basic Concepts and Terms \[page 660\]](#).

#### ⓘ Note

Please make sure that the add-on product version to be published is properly tested before confirming the release decision. This includes testing in SAP Fiori launchpad and the ABAP Test Cockpit. See [Test in the ABAP Environment SAP Fiori Launchpad \[page 1248\]](#) and [Test in the ABAP Test Cockpit \[page 1249\]](#).

### Check Add-on Build Result

Use the [Check Product Version](#) app in Landscape Portal to check whether the product version, its components, and respective packages are ready for delivery. See [Check Product Version \[page 1330\]](#).

## 4.2.11.1.6 Order and Provide

After the initial add-on version has been built, you must deploy and provide it as a SaaS solution so that the add-on can be consumed by customers via a subscription in the SAP BTP cockpit.

### 4.2.11.1.6.1 Deploy

A SaaS solution refers to a multitenant application that is deployed to the Cloud Foundry environment on SAP BTP and enabled for subscription. When consumers subscribe, multitenant-enabled SAP BTP ABAP environment instances which have an add-on installed are provisioned automatically and tenants are assigned to the consumers.

The configuration and deployment of such a project can be done in a few simple steps using the [Maintain Solution \[page 1333\]](#) app in the Landscape Portal. However, the app does not support some advanced scenarios, such as:

- customizing the application router
- the gCTS use case (see [Delivery via Add-On or gCTS \[page 1228\]](#))

In such a case, you can configure and deploy the multitenant application manually, which allows you to modify parameters that are not exposed in the *Maintain Solution* app. See [Multitenant Applications \[page 1259\]](#). This approach is not recommended unless it is strictly necessary for your scenario.

Once you've configured your multitenant application, you can deploy it once for testing purposes in the global account for development. After testing the subscription process in this provider subaccount, the multitenant application can be deployed to the global account for production. At that point, the SaaS solution is ready for commercialization.

Please note that you need certain entitlements to deploy your multitenant application to SAP BTP. These are assigned to the relevant subaccounts in the [Prepare \[page 1235\]](#) section of this guide.

#### 4.2.11.1.6.1.1 Sizing

A multitenant application has some central sizing properties that dictate the scope and metric of your offering, or in other words, how many resources will be available for each consumer.

**Tenant Limit:** Before deploying your application, you must decide on a tenant limit. Once that number of consumer tenants is reached in a system, a new system will be provisioned for the next consumer. If you choose a limit of 1, you will be defining a single tenant offering with one consumer per system.

#### → Tip

For in-depth information about multitenancy, see [this section](#).

Additionally, you need to define the sizing of each provisioned ABAP system. The sizing is defined by the number of ABAP compute units (runtime) and HANA compute units (persistence) each system is assigned. These values are reflected by the parameters `size_of_runtime` and `size_of_persistence`. For more information, see [Creating an ABAP System \[page 163\]](#).

For multitenancy offerings, there's no sizing/quota per customer. You must decide on an overall sizing depending on the expected load in a region. You can use the Technical Monitoring Cockpit to assist you in this.

#### Note

If the quota for a system is exceeded, you can request a resizing of the ABAP runtime or persistency depending on the needs of the SaaS application.

## 4.2.11.1.6.1.2 Using the Maintain Solution App

### Configure the solution

As a Landscape Portal administrator, you can implement the multitenant application using the *Maintain Solution* app in the Landscape Portal. Create a new solution using:

- the previously registered product,
- the product version that shall be installed initially ("latest" will always install the newest available product version),
- the usage mode "prod", unless you do not intend to deploy a productive application at the end,
- the consumer tenant limit and system sizing values that you have decided on.

For more information regarding solutions, see [Create Solution \[page 1335\]](#).

### Deploy the solution for test purposes

After creating the solution, it is recommended to perform a test deployment to validate the subscription process. Use the *Maintain Solution* app to create a deployment configuration for your solution:

- Target the Provide space in the 05 Provide subaccount in your global account for development. You need to specify the corresponding CF API Endpoint, CF Organization Name and CF Space Name.
- Choose the domain type "shared". Since this is not a productive deployment, it is sufficient to use one of the available app domains provided by SAP.
- Since you are deploying to a shared app domain, a unique route prefix is needed to uniquely identify your application endpoint.
- Maintain the subdomain of the subaccount where you intend to test the subscription process.

For more information regarding deployment configurations, see [Create Deployment Configuration \[page 1337\]](#).

### Test the solution

You can test the multitenant application by subscribing from a consumer subaccount created in the global account for development. See [Subscribe to Multitenant Applications Using the Cockpit](#).

Once the subscription is successful, you may also want to test the initial user onboarding process. First, assign the onboarding role collection, which includes the SolutionAdmin role, to your user. Afterwards, access the application via the consumer subaccount and trigger the user onboarding. For more details, please see the section on the productive tenant onboarding.

## Deploy the solution for production purposes

After successfully testing the subscription process you can proceed to a productive deployment of your solution. Use the [Maintain Solution](#) app to create a second deployment configuration for your solution:

- Target the Provide space in the O5 Provide subaccount in the global account for production. You need to specify the corresponding CF API Endpoint, CF Organization Name and CF Space Name.
- Choose the domain type "custom". It is recommended to use a custom domain for your productive application, such that consumers can access it via a recognizable URL.
- It is recommended to use a wildcard route in conjunction with custom domains. This will route all requests towards that domain to your application.

To set up a custom domain, please follow the steps outlined in [Configuring Custom Domains](#) or [Get Started with the Custom Domain Manager](#). After registering the custom domain in your provider subaccount, it becomes available as a private domain (see [Private domains](#)) for route creation in any of the Cloud Foundry spaces of the subaccount. Once you have created the production deployment configuration, you can trigger it using the [Deploy](#) action, see [Deploy Solution \[page 1339\]](#). Once deployed, your solution should appear in the service marketplace on SAP BTP Cockpit for subaccounts within your global account for production.

### 4.2.11.1.6.1.3 Configuring a Solution Manually

You can configure the multitenant application manually, which allows you to finetune your solution beyond the options offered in the [Maintain Solution](#) app. In this case, you must configure the individual project files and deploy the project using the corresponding command line tools.

In the following sections, the general steps are described. For a description of multitenant applications in general and more detailed configuration options, see [Multitenant Applications \[page 1259\]](#).

## Configure the solution

It is recommended that you initially configure your solution using the Maintain Solution app and then use the Download functionality to obtain the application descriptor file. Since the download is available on deployment configuration level, it is necessary to create both a solution and a deployment configuration.

Follow the steps detailed in Using the Maintain Solution app (see [Order and Provide \[page 1255\]](#)), creating both the solution and the deployment configuration for the test phase. Once configured, use the Download function to obtain the application descriptor. Finally, clone the reference solution linked below and replace the standard descriptor with the generated one. This results in a project that is already configured, making it the perfect starting point to implement your modifications.

The reference solution provided by SAP can be found here: [GitHub - sap-software/abap-saas-reference-solution: Template of an ABAP SaaS Reference Solution allowing the SAP Partner to deploy a solution containing approuter and XSUAA dependencies](#) .

### Note

gCTS Delivery: If you use gCTS instead of add-ons for the delivery of software components to production systems, the value for the add-on product name in the application descriptor has to be empty. See [Delivery via Add-On or gCTS \[page 1228\]](#).

## Deploy the solution for test purposes

After configuring the multitenant application, it is recommended to perform a test deployment to validate the subscription process.

Your project should already have the correct deployment configuration, as you maintained this in the Maintain Solution app before generating the application descriptor. As a result, you can directly build and deploy your project.

Use the [Cloud MTA Build Tool](#) and the [Cloud Foundry CLI](#) .

Once deployed, your solution should appear in the service marketplace on SAP BTP Cockpit for subaccounts within your global account for development.

## Test the solution

You can test the multitenant application by subscribing from a consumer subaccount created in the global account for development. See [Subscribe to Multitenant Applications Using the Cockpit](#).

Once the subscription is successful, you may also want to test the initial user onboarding process. First, assign the onboarding role collection, which includes the SolutionAdmin role, to your user. Afterwards, access the application via the consumer subaccount and trigger the user onboarding. For more details, please see the section on the [Initial User Onboarding \[page 1278\]](#).

## Deploy the solution for production purposes

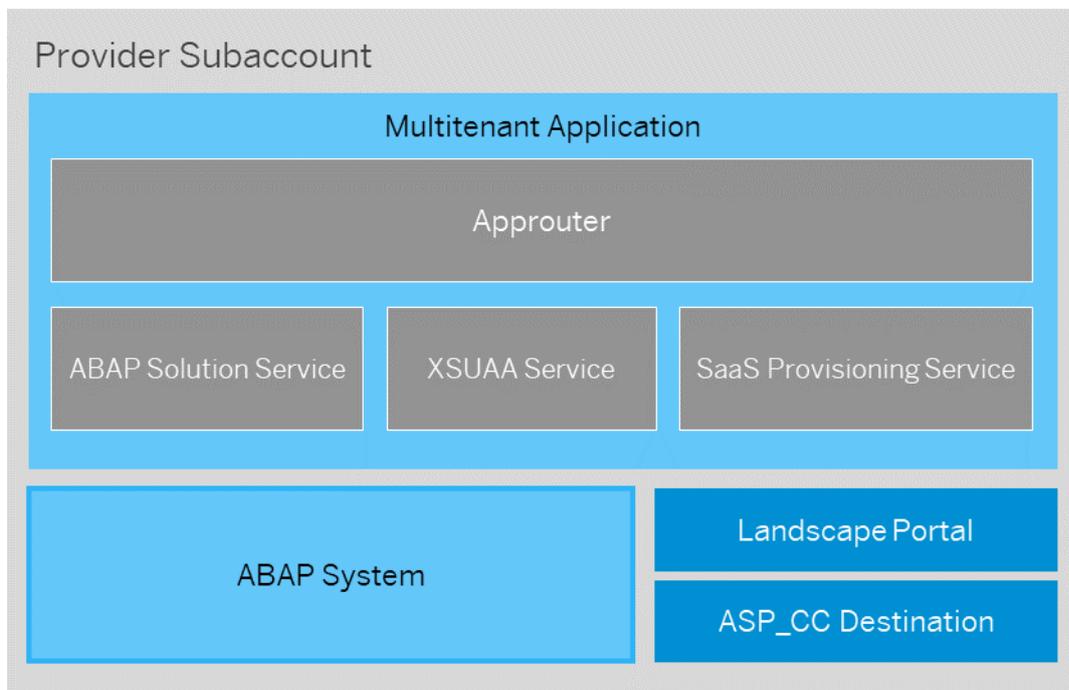

After successfully testing the subscription process, you can proceed to a production deployment of your solution.

You can use MTA extension descriptors to configure the required values for deployment to different targets. This allows you to deploy the same project to different subaccounts. See [Multitenant Applications \[page 1259\]](#).

Build and then deploy your project. Once deployed, your solution should appear in the service marketplace on SAP BTP Cockpit for subaccounts within your global account for production.

## 4.2.11.1.6.1.4 Multitenant Applications

To make the software components in the ABAP System available for multiple different consumers, a multitenant application is deployed into the provider subaccount. This application can then be accessed by different tenants through a dedicated URL.

For the multitenant application, different services and apps are used:

- **Approuter application:** The application router is the single point-of-entry for the multitenant application and used to forward tenant-specific requests to the corresponding tenant in the ABAP system. See [Application Router](#).
- **ABAP Solution Service:** ABAP Solution service is required to create multitenant-enabled, ABAP environment-based SaaS solutions. Instead of a service binding from the approuter application to the ABAP environment business service, the approuter is bound to an ABAP Solution service instance. The service orchestrates the creation of ABAP systems upon consumer subscription as well as tenant provisioning/decommissioning. Requests routed via the approuter application to the ABAP solution service instance are automatically proxied to the corresponding ABAP tenant.
- **SAP Authorization and Trust Management service (XSUAA):** The `xsuaa` service instance acts as an OAuth 2.0 client to the multitenant application, and to the `ABAP Solution` service instance. The SAP Authorization and Trust Management service lets you manage user authorizations and trust to identity providers used for the multitenant application. The service instance is created with a corresponding security configuration. See [SAP Authorization and Trust Management Service in the Cloud Foundry Environment](#).
- **SaaS Provisioning Service:** The `SaaS Provisioning` service allows application providers to register multitenant applications and services in the Cloud Foundry environment in SAP Business Technology Platform. After a SaaS Provisioning service instance is created, the multitenant application becomes available for subscription in a consumer subaccount.
- **ABAP System:** ABAP systems and tenants used to provide the multitenant application are not created manually but are managed by the ABAP Solution service: Upon first subscription the ABAP system is

created as well the consumer tenant in the system. To be able to create the system, the ABAP solution service uses credentials of a technical platform user that is defined in the ASP\_CC destination. Depending on the configuration of the ABAP solution, for every subsequent subscription either a new tenant is created in the same ABAP system (`consumer_tenant_limit > 1`) or a new system is created for every new subscription (`consumer_tenant_limit = 1`). A new ABAP system is also created if all the existing ones are "full" because the consumer tenant limit that you specified was reached. Note that an ABAP system can only be deleted if no consumer tenants exist.

Consumer subscription-based multitenancy is only possible in those systems in which you provide your software as a service (SaaS) solution to consumers, i.e. your production and test systems. It is not available in development systems.

See [Creating an ABAP System](#).

- **Landscape Portal:** The Landscape Portal acts as a central tool to allow service providers to perform lifecycle management operations such as add-on updates, provisioning new consumers as new tenants, and more. A subscription to the Landscape Portal in the globalaccount where the multitenant application is deployed is required for the subscription flow to work.  
See [Landscape Portal](#).
- **ASP\_CC Destination:** An `OAuth2Password` destination pointing to the Cloud Foundry Cloud Controller API is required for the ABAP Solution service to create and access ABAP service instances. Credentials of a technical platform user, that is assigned as a space developer in the space where the multitenant application is deployed, are maintained.

## Multitarget Application

The multitenant application is deployed as a multitarget application (MTA), which is logically a single application comprised of multiple parts created with different technologies.

The MTA describes the desired result in an `mta.yaml` file which may be extended with `mta` extensions (`.mtaext`) using the MTA model which contains MTA modules, MTA resources and interdependencies between them. Afterwards, the MTA deployment service validates, orchestrates, and automates the deployment of the MTA, which results in Cloud Foundry (CF) applications, services and SAP-specific contents. For more information about the Multitarget Application model, see the official [The Multitarget Application Model specification](#). For more details on how to use it in the CF Environment, which is the case here, see [Multitarget Applications in the Cloud Foundry Environment](#).

A complete reference example of the multitenant application MTA is provided in GitHub/SAPSamples: [ABAP SaaS Reference Solution for ABAP solution provider](#) 🐙

## MTA Parameters

Parameters are defined at the beginning of the `mta.yaml` file, so that the actual structure of the MTA model does not have to be changed but can be extended via extension files. The parameters are referenced in the subsequent sections of the MTA using the syntax `${parameter-name}`. For more details on parameters, see [Parameters and Properties](#).

- **Freely defined parameters:**
  - `app-domain`: The domain that should be used for the approuter and therefore the SaaS application. In our example, this is the `${default-domain}` (equals to the `cfapps-domain` of the current landscapes) for a development deployment; for production it should be the custom domain (so here: `mydomain.com`).
  - `appname`: The value that should be used as `xsappname` and solution name (here: `abap-saas-reference-solution`).
  - `route-prefix`: The value that should be used as a prefix in the route of the approuter, allowing it to deploy the same MTA to the same landscape multiple times using the default landscape domain.

- `addon-product-name`: Name of add-on product to be installed
- `provider-admin-email`: Provider administrator e-mail address used for provisioning of ABAP systems
- `saas-display-name`: Display name of SaaS application shown in subscription tile
- `saas-description`: Description of SaaS application shown in subscription tile
- `tenant-mode`: Whether to provide a 'single' or 'multi' tenancy solution
- **Parameter with semantics to MTA deployer:**
  - `enable-parallel-deployments`: If set to `true`, deploys multiple modules at the same time.

## MTA Extension Descriptors

The parameters defined in the MTA can be adapted for the corresponding landscape using MTA extension descriptor files. These files extend the original MTA descriptor file (`mta.yaml`) and provide certain deployment specific configurations/parameters/values. The descriptor files have the file extension `*.mtaext` and are used during the deployment using CF CLI with MultiApps plugin, see [MultiApps CF CLI Plugin](#) .

For more information on MTA extension descriptors, see: [Defining MTA Extension Descriptors](#).

The extension descriptor files are usually in the folder "extensions" next to the `mta.yaml` file.

Depending on the stage of implementation of the multitenant application, a different approuter configuration is used. This is controlled via different extension descriptor files used during MTA deployment:

- Configuration for **Development Phase**:  
For development, test and demo purposes, MTA deployment can be done using the `${default-domain}` as `app-domain` and a `route-prefix`, which will avoid collisions due to the default domain. Additionally, we suggest setting the property `XS_APP_LOG_LEVEL` on the approuter module to `debug` to ensure that there is more detailed logging output.
- Configuration for **Production Phase**:  
For purpose of providing a solution / solutions to applications consumers in a production scenario, the MTA deployment should be done using a custom domain configured with the `app-domain` parameter (`app-domain`) and an empty `route-prefix` (`route-prefix.`). Using the custom domain, a wildcard route for tenant access (`"*.${app-domain}"`) can be created.

## MTA Build and Deploy

Before MTA deployment, the MTA project is built using the [Cloud MTA Build Tool \(MBT\)](#) . Afterwards the deployment-ready multitarget application archive (`*.mtar` file) is deployed in combination with the corresponding MTA extension descriptor file using the Cloud Foundry CLI with the MultiApps plugin: `cf deploy <path to .mtar file> -e <path to MTA extension descriptor>`

## 4.2.11.1.6.1.4.1 ABAP Solution Service

### Sample Code

```
- name: abap-solution
  type: org.cloudfoundry.managed-service
  parameters:
    service: abap-solution
    service-plan: standard
    service-name: ${appname}-abap-solution
  config:
    name: ${appname}
    consumer_id_pattern: ${consumer-id-pattern}
  plans:
    - plan_name: ${plan-name}
      addon_product_name: ${addon-product-name}
      size_of_runtime: ${size-of-runtime}
      size_of_persistence: ${size-of-persistence}
      provider_admin_email: ${provider-admin-email}
      consumer_tenant_limit: ${consumer-tenant-limit}
      sap_system_name: ${sap-system-name}
      usage: ${usage-mode}
  xs-security:
    xsappname: xs-app-${appname}
```

ABAP Solution Service is used to enable multitenancy for ABAP Environment systems: Instead of creating the ABAP system manually it is created by the ABAP Solution service during the first subscription of an application consumer or once the consumer tenant limit for all viable systems has been reached.

Credentials provided in the ASP\_CC destination are used by ABAP Solution Service to authenticate at the Cloud Foundry Cloud Controller API endpoint and to create required ABAP service instances.

The service plan used for created ABAP service instances is depending on the `addon_product_name` parameter: `abap/standard` is used for a system without add-on, `abap/saas_oem` is used for a system with installed add-on. Provisioning parameters like `sap_system_name`, `provider_admin_email` and sizing-relevant parameters can be defined.

After a new system is created, a tenant for the application consumer is provisioned. The business type (see [Tenant Business Types](#)) used for provisioning of the tenant depends on the `usage` parameter: In case of `usage = test`, the tenant is created as `Partner Customer Test` tenant. Whereas with `usage = prod`, the tenant is created as `Partner Customer Production` tenant. Parameter `tenant_mode` controls if per subscription a new tenant is created in the same system and with `consumer_tenant_limit` the number of tenants per system is configured.

### ABAP System: saas\_oem plan

This service plan is like the standard service plan of the ABAP service (see [Create an ABAP System](#)), but it is used as "backing service" for a partner-provided SaaS solution. In comparison to a standard service plan of the ABAP service, there is one main differences: An add-on product (see [The Add-on product](#)) which is installed during system provisioning can be specified.

- Parameter: `addon_product_name`  
(specifies which ABAP add-on to install during provisioning)
- Parameter: `addon_product_version`  
(if - for testing purpose - another add-on version instead of the most recent released version shall be installed)

## ABAP Solution Service Parameters

Name	Data Type	Description	Purpose	Updateable
name	string	Name of the solution as defined by the provider. Must be unique in the scope of the Global Account (or globally if this information is not available)	Used to identify the solution and will be passed through to ABAP System (saas_oem plan)	No
sap_system_name (optional)	string	Name of the system as defined by the provider. If a value is supplied, the new system(s) will be created with this parameter.	Passed through ABAP System	No
addon_product_name (optional)	string	Registered name of the add-on product	Passed through ABAP System (saas_oem plan)	No
addon_product_version (optional)	string	Version of the add-on product to be installed. A released product version needs to be defined. If you do not specify the parameter, the latest released product version will be used during the add-on installation. If you specify other versions than allowed, the add-on installation and therefore also the system provisioning and consumer subscription will be unsuccessful.	Passed through ABAP System (saas_oem plan)	Yes (updated value applies for new systems only)

Name	Data Type	Description	Purpose	Updateable
consumer_tenant_limit	int	<p>Maximum number of consumer tenants in the multitenant ABAP system. If the consumer tenant limit is exceeded, a new multitenant system will be created.</p> <p>consumer_tenant_limit &gt;= 1</p> <div data-bbox="683 728 909 1198" style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>A recently deleted tenant will be counted towards the limit, in case it is restored during the grace period. After the 30-day grace period is up, it will no longer be considered for the limit.</p> </div>	Passed through ABAP System (saas_oem plan)	Yes
size_of_runtime	int	Default sizing (ABAP runtime) of abap system(s) created/provisioned by solution	Passed through to ABAP System	Yes (updated value applies for new systems only)
size_of_persistence	int	Default sizing (ABAP persistence [HANA]) of abap system(s) created/provisioned by solution	Passed through to ABAP System	Yes (updated value applies for new systems only)

Name	Data Type	Description	Purpose	Updateable
tenant_mode (deprecated)	enum (string): - single - multi	Tenant Mode of the solution	Decides whether a customer will have a tenant in  - a dedicated system (single)  - a shared system (multi)  <b>single:</b> will trigger a system creation and a tenant onboarding  <b>multi</b> will trigger a system creation (only if necessary) and a tenant onboarding  The parameter will be passed through to ABAP System (saas_oem plan).	No
consumer_id_pattern	string (regex)	String containing a regular expression with a capturing group. The <b>subdomain of the consumer</b> is matched against this regular expression. The value of the first capturing group is used as consumer id.	To allow the provider to group his consumer subaccounts based on a self-chosen consumer identifier: e.g. the subdomains of consumer subaccounts always include a static part that identifies the application consumer, then event if there are multiple test & production consumer subaccounts, the application consumer can be identified in Landscape Portal.	No
provider_admin_email	email	Email address of initial provider user	Passed through to ABAP System (saas_oem plan).	Yes

Name	Data Type	Description	Purpose	Updateable
xs-security/xsapp-name (optional)	tring	xsappname used for the OAuth clone during instance creation. Will be visible in the security section of SAP BTP Cockpit when assigning the initial on-boarder role. Will be the "Application Name" shown in the Roles UI.  <b>Default:</b> Service Instance GUID  <b>Recommendation:</b> Provide the same value as defined in the xs-security.json of the XSUAA Instance of your application	Allows providing a meaningful application name to assign the on-boarding roles.	No
usage	enum (string): - test - prod	Specifies whether it is a test or production solution.	In case of usage = test a Partner Customer Test tenant is created, whereas with usage = prod, a Partner Customer Production tenant is provisioned.	No

## 4.2.11.1.6.1.4.2 SAP Authorization and Trust Management Service

### Sample Code

```

- name: xsuaa
  type: com.sap.xs.uaa
  requires:
    - name: abap-solution
  parameters:
    service-plan: application
    service-name: xsuaa
  config:
    oauth2-configuration:
      redirect-uris:
        - "https://*.*${app-domain}/**"
    xsappname: ${appname}
    tenant-mode: shared
    scopes:
      - name: $XSAPPNAME.Callback
        description: With this scope set, the callbacks for tenant
onboarding, offboarding and getDependencies can be called.
        grant-as-authority-to-apps:

```

```

- $XSAPPNAME(application,sap-provisioning,tenant-onboarding)
foreign-scope-references:
- uaa.user
role-collections:
- name: ${appname}-admin
  role-template-references:
  - $XSSEVICENAME(${appname}-abap-solution).SolutionAdmin

```

The `xsuaa` service instance, acts as an OAuth 2.0 client to the multitenant application, and to the `ABAP Solution` service instance. It provides access to the SaaS Provisioning service for calling callbacks and getting the dependencies API by granting corresponding scopes.

A role collection is defined as part of the `xsuaa` configuration which provides authorization for the initial user onboarding in the new ABAP tenant after a subscription was done.

For this purpose, the “SolutionAdmin” role is referenced. See [Quick Start: Create Role Collections \(with Predefined Roles\)](#).

Finally, a foreign scope reference is defined to ensure a token exchange will be possible and the ABAP systems can be called.

## 4.2.11.1.6.1.4.3 SaaS Provisioning Service

### ↔ Sample Code

```

- name: saas-registry
  type: org.cloudfoundry.managed-service
  parameters:
    service: saas-registry
    service-plan: application
    service-name: saas-registry
    config:
      xsappname: ${appname}
      appName: ${appname}
      appUrls:
        getDependencies: https://cis${route-prefix}.${app-domain}/callback/v1.0/dependencies
        onSubscription: https://cis${route-prefix}.${app-domain}/callback/v1.0/tenants/{tenantId}
      displayName: ${saas-display-name}
      description: ${saas-description}

```

The `SaaS Provisioning` service allows application providers to register multitenant applications and services in the Cloud Foundry environment in SAP Business Technology Platform.

### SaaS Provisioning Service Parameters

<code>xsappname</code>	The <code>xsappname</code> configured in the security descriptor file used to create the XSUAA instance.
------------------------	--

getDependencies

**(Optional)** Any URL that the application exposes for GET dependencies. If the application does not have dependencies and the callback is not implemented, it should not be declared. **Note:** The JSON response of the callback must be encoded as either UTF8, UTF16, or UTF32, otherwise an error is returned. Important: You can either provide your own getDependencies Callback or use the default implementation of the AppRouter (recommended if no special logic is needed). **But:** If an own implementation is provided you have to make sure that the ABAP Solution instance is returned as a dependency.

The path is: /callback/v1.0/dependencies

---

onSubscription

Any URL that the application exposes via PUT and DELETE subscription. It must end with /{tenantId}. The tenant for the subscription is passed to this callback as a path parameter. You must keep {tenantId} as a parameter in the URL so that it is replaced at real time with the tenant calling the subscription. This callback URL is called when a subscription between a multitenant application and a consumer tenant is created (PUT) and when the subscription is removed (DELETE). **Important:** You can either provide your own onSubscription Callback or use the default implementation of the approuter (recommended if no special logic is needed).

The path is: /callback/v1.0/tenants/{tenantId}

---

displayName

**(Optional)** The display name of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's technical name.

---

description

**(Optional)** The description of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's display name.

---

category

**(Optional)** The category to which the application is grouped in the Subscriptions page in the cockpit. If left empty, gets assigned to the default category.

---

## Callback APIs

Callback URLs defined in parameters *getDependencies* and *onSubscription* are called during the subscription flow and need to be callable via a consumer-independent URL. For this purpose, a dedicated URL that matches the `TENANT_HOST_PATTERN` of the approuter application should be defined as part for the MTA project.

Depending on the phase of the multitenant application, a different `TENANT_HOST_PATTERN` is defined:

- **During development phase:**

`TENANT_HOST_PATTERN: ^(.*)-abap-saas-app.cfapps.eu10.hana.ondemand.com`

Define a route `cis-abap-saas-app.cfapps.eu10.hana.ondemand.com` for SaaS Provisioning service callback URLs

- **During production phase:**

`TENANT_HOST_PATTERN: ^(.*)\.mydomain.com`

Define a route `cis.mydomain.com` for SaaS Provisioning service callback URLs

## Subscription Management Dashboard

With Subscription Management Dashboard as the dashboard UI of SaaS Provisioning Service, the application provider can centrally manage subscriptions, e.g. unsubscribe existing application consumer subscriptions. See [Using the Subscription Management Dashboard](#).

## 4.2.11.1.6.1.4.4 Approuter Application

To authenticate business users of the application at runtime, a tenant-aware approuter application and the `xsuaa` service in SAP Business Technology Platform are used. This will also provide the necessary callbacks for the SaaS Provisioning Service.

The enhanced approuter application is as a logical part of the multitenant application and configured as an external access point of the application.

For more details on the application router, see [Application Router](#).

With the middleware `@sap/asp-middleware` component a library (npm module) is provided that enhances the approuter to also take care of automatically routing the consumer to their ABAP tenants. See [@sap/asp-middleware](#). 🐘

### Approuter Configuration

To make sure that the approuter routes all relevant requests to the ABAP Solution, a routing configuration is configured:

#### 🔗 Sample Code

```
{
  "authenticationMethod": "route",
  "welcomeFile": "/ui",
  "logout": {
    "logoutEndpoint": "/sap/public/bc/icf/logoff",
    "logoutPage": "/ui"
  },
  "routes": [
    {
      "source": "^/sap/(.*)$",
      "target": "/sap/$1",
      "authenticationType": "xsuaa",
      "service": "com.sap.cloud.abap.solution",
      "csrfProtection": false
    },
    {
      "source": "^/ui/(.*)$",
      "target": "/ui$1",
      "authenticationType": "xsuaa",
      "service": "com.sap.cloud.abap.solution",
      "csrfProtection": false
    }
  ]
}
```

- **Requests to the `.../sap/...` path** are backend requests and will be routed to the ABAP Solution service after successful authentication. CSRF token protection is disabled for this route as CSRF protection is already enforced via the underlying services in the ABAP system.
- **Requests to the `.../ui/...`** are requests to the Fiori Launchpad / End User UI and will be routed to the ABAP Solution service after successful authentication. CSRF token protection is disabled for this route as CSRF protection is already enforced via the underlying services in the ABAP system.

For more details on the parameters, see [Routing Configuration File](#).

## Approuter Multitenancy

The consumer accesses their multitenant application via the tenant-specific url which is resolved by the app router and "forwarded" (calls) to the corresponding abap tenant (client). The URL follows the same pattern for all application consumers and differs depending on the implementation phase of the multitenant application:

- **During development phase:**

```
<SUBSCRIBER_TENANT_SUBDOMAIN>-<APPROUTER_APPLICATION_HOST>.<SAP-PROVIDED_STANDARD_DOMAIN>
```

In each development landscape, SAP provides a different standard domain you can use to create URLs. Using that domain, and following the specified URL structure, an example for a created URL could be: `tenant1-myapprouter.cfapps.eu10.hana.ondemand.com`

Here `tenant1-myapprouter` is the hostname, and `cfapps.sap.hana.ondemand.com` is the SAP-provided standard domain for this development landscape. In this format, a new route must be created manually for each new tenant.

The common pattern identifying tenant-specific URLs is defined with `TENANT_HOST_PATTERN: ^(.*)->-<APPROUTER_APPLICATION_HOST>.<SAP-PROVIDED_STANDARD_DOMAIN>`

- **During production phase:**

```
*.<YOUR_CUSTOM_DOMAIN>
```

A custom domain is registered via the custom domain service, then a pattern with `*` as the wildcard hostname can be established.

In this format, since the wildcard is replaced by an actual tenant during runtime, there is no need to create a new route for each new tenant manually.

The common pattern identifying tenant-specific URLs is defined with `TENANT_HOST_PATTERN: ^(.*)-<YOUR_CUSTOM_DOMAIN>`

For more information, see [Using Custom Domains](#).

The application router derives the tenant from the URL and calls the tenant-aware XSUAA, which is responsible for the authentication of the business user. The UAA reads the tenant and gets the customer-specific identity provider (IdP) from the tenant-specific identity zone. Then, the XSUAA delegates the authentication to the configured IdP, and creates a JSON Web Token (JWT) that contains the tenant, the current user, and the authorization scopes of the user. The JWT is then sent back to the application router, and from there to the application.

To read and store tenant-specific data, the multitenant application needs to know the tenant ID. Using the Container Security API, the multitenant application is enabled to read the tenant, user, and scopes from the given JWT. The API also validates whether the JWT is valid. The tenant information is contained in the `identityZone` user attribute.

For more information, see:

[Web Access in the Cloud Foundry Environment](#)

[What Is Authorization and Trust Management](#)

## 4.2.11.1.6.1.4.5 Cloud Controller Access Destination

A destination called ASP\_CC needs to be created for ABAP Solution Service to be able to access the Cloud Foundry Cloud Controller API for creation and access to ABAP service instances.

### Prerequisites

- You've created a user in SAP ID service.
- The user has been added as a Cloud Foundry org member in the provider subaccount where the Cloud Foundry environment is enabled.
- The User has been added with the role of a Space Developer, in the space where the multitenant application (MTA) is deployed.

#### Note

Please note that you should never set personal credentials (e.g. for your account) in the User and Password fields. Always use a technical user instead.

### Process Steps

1. In the provider subaccount navigate to Connectivity -> Destinations
2. Create a new destination as follows:

Property	Value
Name	ASP_CC
Type	HTTP
Description	Access the Cloud Foundry Cloud Controller API
URL	< API Endpoint domain of Cloud Foundry landscape> You can find it under your subaccount > Overview.
Proxy Type	Internet
Authentication	OAuth2Password
User	<User ID/E-mail>
Password	<Password>
Client ID	cf
Client Secret	<needs to be left blank>

#### Example

`https://api.cf.eu10.hana.ondemand.com`

Property	Value
Token Service URL	http:// uaa.<landscape-host>/oauth/token

**Example**

https://uaa.cf.eu10.hana.ondemand.com/oauth/to-ken

For more information on landscapes/regions, see [Regions and API Endpoints for the ABAP Environment](#).

Instead of creating the ASP\_CC destination manually, you can also save the following as a text file instead and then import the destination as a template:

```

❏ Sample Code

Type=HTTP
                                clientId=cf
                                Authentication=OAuth2Password
                                Name=ASP_CC
                                tokenServiceURL=https\://
uaa.cf.eu10.hana.ondemand.com/oauth/token
                                ProxyType=Internet
                                URL=https\://api.cf.<e.g.eu10>.hana.ondemand.com

```

## 4.2.11.1.6.1.4.6 Regions

As a provider, you can deploy your SaaS solution in a subaccount that is located in one of the regions available for the ABAP environment, see [Regions and API Endpoints for the ABAP Environment \[page 33\]](#).

A consumer can then subscribe to and access your SaaS solution from a subaccount. The consumer subaccount needs to be located in the same region as the subaccount which you deployed the SaaS solution in.

Keep in mind that regions are chosen on the subaccount level: For each subaccount, you select exactly one region. This is done when creating the subaccount. The **Landscape Portal** can only be accessed from subaccounts located in region cf-eu10. You thus need to make sure that the subaccount from which you want to access the **Landscape Portal** has the region attribute cf-eu10. For more information on regions, see [Regions](#). and [Accessing the Landscape Portal \[page 1303\]](#).

## 4.2.11.1.6.1.4.7 Troubleshooting

### Multitenant application cannot be undeployed

- Always use MTA Undeployment (cf undeploy <MTA ID> --delete-services) instead of deleting service instances individually.
- Check if the saas-registry service instance still contains active subscriptions: the saas-registry instance can only be deleted once there are no more active subscriptions. Unsubscribe using the [Subscription](#)

[Management Dashboard](#) Note, however that if the subscription is forced to be deleted through any additional channel (using the Subscription Management Dashboard or by subaccount deletion), it will lead to an orphan tenant in the ABAP Solution. Providers need to be aware of this before deleting subscriptions with the 'force' option.

## Cannot create consumer-specific route according to `TENANT_HOST_PATTERN` (in the development phase)

### Sample Code

```
TENANT_HOST_PATTERN: (.*)-my-consumer-subdomain-productabcdefghijklmnpq-saas-  
solution-dev.cfapps.eu10.hana.ondemand.com  
Consumer Subaccount Subdomain: my-consumer-subdomain  
Route Domain: cfapps.eu10.hana.ondemand.com  
Route Hostname: my-consumer-subdomain-productabcdefghijklmnpq-saas-solution-  
dev (64 characters)
```

## After deployment of MTA for multitenant application, no abap system is created

- ABAP systems are automatically created by the ABAP Solution Provider (ASP) during the first subscription and not after the solution deployment.

## Issues with parameter `consumer_tenant_limit`

- Keep in mind that recently deleted consumer tenants are counted towards the tenant limit as long as they are still in retention time. Systems are automatically created. Non-consumer tenants (provider tenant, test tenants) do not count towards this limit.

## 4.2.11.1.6.1.4.8 Using a Custom Domain for the Multitenant Application

The SAP Custom Domain Service (see [SAP Custom Domain service](#)) lets you configure your own custom domain (see [What Is Custom Domain?](#)) to publicly expose your application instead of using an SAP-provided default/shared/standard domain like `cfapps.eu10.hana.ondemand.com` for your application URLs.

By using this service, subaccount owners can make their SAP BTP applications accessible via a custom domain that is different from the default one; for example, `myshop.com`.

In case of multitenant applications (see [Multitenant Applications \[page 1259\]](#)), using a custom domain comes with another advantage: For each subscription there needs to be a CF route (see [Routes](#)) that is mapped to the approuter module of the multitenant application, so that the application is accessible via a URL.

While using a default domain, a new route like `<SUBSCRIBER_TENANT_SUBDOMAIN>-<APPROUTER_APPLICATION_HOST>.<SAP-PROVIDED_STANDARD_DOMAIN>` must be created manually for each new tenant.

By configuring the multitenant application with a custom domain, a route with a wildcard hostname like `*.<YOUR_CUSTOM_DOMAIN>` can be mapped, so that there is no need to create a new route for each new tenant manually. For more information, refer to [Approuter Application \[page 1269\]](#).

It is recommended to use a custom domain for your multitenant application only during the production phase; during the development phase using a default domain is sufficient.

Please follow the steps outlined in [Configuring Custom Domains](#) or [Get Started with the Custom Domain Manager](#) (refer to PaaS-User) to register your custom domain in the provider subaccount's CF org (see [Multitenancy in the ABAP Environment \[page 1290\]](#)). After registering the custom domain successfully, the domain becomes available as private domain (see [Private domains](#)) for route creation in any space of the provider subaccount's CF org.

To create a multitenant application for use with a custom domain, following configurations are adjusted accordingly:

- `TENANT_HOST_PATTERN` configuration of the approuter application: String containing a regular expression with a capturing group. The request host is matched against this regular expression. The value of the first capturing group is used as tenant id. Please refer to [TENANT\\_HOST\\_PATTERN](#).
- SaaS Registry Callback URLs `getDependencies` and `onSubscription`. Please refer to [SaaS Provisioning Service \[page 1267\]](#).
- XSUAA OAuth 2.0 Client configuration `redirect-uris`. Please refer to [Listing Allowed Redirect URIs](#)
- [CF routes](#) assigned to approuter application

For the subscriptions to the multitenant application to work correctly, configured SaaS Registry callback URLs need to be reachable (cis... route). For Application Routing routing to work, the approuter needs to be able to resolve the application URL based on current `TENANT_HOST_PATTERN` configuration.

You can use the [Maintain Solution \[page 1333\]](#) app in the Landscape Portal to easily create such a multitenant application with custom domain, please refer to [Create Deployment Configuration \[page 1337\]](#) → **Step 3: Routing Information**.

Or, if you are following the MTA-based approach to create your multitenant application, in the [MTA Extension descriptor for production phase](#) these configurations are changed using following MTA parameters:

- `app-domain`: the registered custom domain, e.g. `mydomain.com`
- `route-prefix`: needs to be empty because application URLs are mapped using following structure:  
`*.<YOUR_CUSTOM_DOMAIN>` (dot separator) and therefore do not include a route prefix

A route with wildcard hostname for tenant access is added to the approuter module, on top of the route used for SaaS Registry callback URLs:

#### Sample Code

```
modules:
  - name: approuter
    parameters:
      routes:
```

```
- route: "cis${route-prefix}.${app-domain}"
- route: "*${route-prefix}.${app-domain}"
```

To reduce risks use [Blue-Green Deployment of Multitarget Applications](#) while deploying multitenant application MTA during production phase.

After MTA build and deployment, the approuter application is created with a route `cis.mydomain.com` that is used for the SaaS Registry callback URLs `getDependencies` and `onSubscription`. On top of that a route with wild card hostname `*.mydomain.com` is mapped to the approuter. In this format, since the wildcard is replaced by an actual tenant during runtime, there is no need to create a new route for each new tenant manually.

If you change the domain type of your multitenant application from shared to custom domain, you need to update the application URL of existing subscriptions. Please use the option to update the application URL of an active subscription in the [Subscription Management Dashboard](#). In such case, make sure to inform application consumers beforehand about temporary downtimes that might occur during this change.

## 4.2.11.1.6.2 Commercialize

To offer your SaaS solution to customers, register the SaaS solution in the SAP Store. See [SAP Store](#).

Additionally, you can request an SAP Extension Suite certification for your product so that it gets listed in the SAP Certified Solutions Directory. See [SAP Extension Suite Certification](#) and [SAP Certified Solutions Directory](#).

After finishing this process, your customers can order the SaaS solution, which is the preliminary step to actual subscription.

### Prerequisites

Before registering a SaaS solution in SAP Store or certifying the solution, you have to deploy the first add-on version and multitenant application. See [Multitenant Applications \[page 1259\]](#).

### 4.2.11.1.6.2.1 (Optional) Register SaaS Solution in SAP Store

SAP Store is the enterprise marketplace where we bring together customers and partners on a single, easy-to-use, global online platform. See [SAP Store](#).

To learn more about how you can offer your SaaS solution to SAP customers via SAP Store, see [Getting Started with SAP Store](#).

## 4.2.11.1.6.2.2 (Optional) Certification

With an SAP Extension Suite certification, your SaaS solution is featured in the SAP Certified Solution Directory, which allows for more growth and customer participation. See [SAP ICC Integration Scenario - SAP Extension Suite Certification](#) and [SAP Certified Solution Directory](#).

### Note

Certification of SaaS solutions is only available if you have used add-on build delivery.

## 4.2.11.1.6.3 Subscribe

Once the SaaS solution has been fully deployed and commercialized, customers can order the offered product. After the buying process has been completed, you, as a SaaS solution operator, are responsible for onboarding the customer.

### 4.2.11.1.6.3.1 Create Consumer Subaccount

Since your solution is only available within your global accounts for production, you as the solution operator must create a consumer subaccount for your customer. After a customer has ordered the SaaS solution, create a 06 Consume subaccount in the global account for production, which will be used to create the subscription. See [Set Up a Global Account for Production \[page 1239\]](#).

While creating the subaccount, you must provide the following details:

- **Name:** Give the subaccount a unique display name. This can be the name of the customer, a customer number or a specific naming pattern.
- **Provider:** Choose the IaaS provider according to the IaaS provider selected for the provider subaccount.
- **Region:** Choose the subaccount region according to the region where the provider subaccount was created. See [Regions and API Endpoints for the ABAP Environment](#).
- **Subdomain:** The subdomain plays an important role, as it becomes the consumer-specific part of the tenant-specific application URL.

### 4.2.11.1.6.3.2 Subscribe to SaaS Solution

After you as the solution operator have created the consumer subaccount, the subscription to the SaaS solution is enabled for the consumer.

In the consumer subaccount, navigate to the Service Marketplace. To subscribe to the SaaS solution, select the solution and the desired service plan and choose Create. The subscribed application is now displayed in Services Instances and Subscriptions.

The subscription process triggers the provisioning of:

- a new ABAP system in case all other systems have reached the consumer tenant limit.
- a new consumer tenant that is represented by an additional client in the ABAP system.

In both cases, a confirmation mail will be sent to the initial administrator maintained in the solution configuration. You can also monitor the provisioning using the [Systems Overview](#) and [Operations Dashboard](#) apps in the Landscape Portal.

The business type of the consumer tenant that is created depends on the usage parameter configured for your solution. If you have set `usage = prod`, a tenant of business type *Partner Customer Production Tenant* is created. If you have set `usage = test`, a tenant of business type *Partner Customer Test Tenant* is created. For more information, see [Tenant Business Types \[page 1292\]](#).

#### 📘 Note

gCTS Delivery: In case of delivery via gCTS, you, as a SaaS solution operator, can use a separate test subscription that is not related to a customer to trigger the creation of the system before the actual customer subscription. This initial system creation and import of the software components needs to be performed for each customer production system.

### 4.2.11.1.6.3.3 Configure Consumer Subaccount

Depending on the scope of the SaaS solution and customer requirements, you can make the following configurations in the consumer subaccount:

- Trust Configuration: You can configure a custom identity provider for the authentication of subscribed applications in the consumer subaccount. See [Trust and Federation with Identity Providers](#). To restrict access based on certain criteria, such as the IP address, use the SAP Cloud Identity Services - Identity Authentication.

#### 📘 Note

With new subaccounts created after September 24th 2020, [automatic creation of shadow users](#) is switched off by default for the default identity provider, SAP ID service. If the creation of shadow users is disabled, any additional business users need to be added manually to the users of the consumer subaccount so that authentication on subaccount level is possible. Business users can only log on to the ABAP tenant if there is an existing employee/business user in the ABAP system.

- Cloud Connector: Using Cloud Connector, you can create a link between SAP BTP applications and on-premise systems. See [Managing Subaccounts](#) on how to add and connect a consumer subaccount to Cloud Connector.
- Destination: Configure destinations, including technical information about the target resource, to connect your application to a remote service or system. See [Managing Destinations](#).

These configurations can be done directly by you, the SaaS solution operator, or by the customer. In the latter case you provide the necessary authorizations by assigning the role collection Subaccount Administrator to a consumer subaccount administrator. The consumer subaccount administrator can then access the consumer subaccount in the SAP BTP cockpit including subscriptions, trust configuration, Cloud Connectors and destinations without having access to other consumer subaccounts in the global account for production.

The consumer subaccount administrator can assign role collection Cloud Connector Administrator to a user to operate the data transmission tunnels used by the Cloud Connector. While adding the consumer subaccount in Cloud Connector, the same Cloud Connector administrator user is being configured.

See Role Collections and [Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\]](#) for more information on available role collections in the consumer subaccount.

## 4.2.11.1.6.3.4 Initial User Onboarding

In order to be able to start using the solution, your customer needs to receive an initial administrator user in their consumer tenant. This is done automatically via the initial tenant onboarding of your solution.

To trigger this onboarding process, you as the provider need to be assigned to the SolutionAdmin role collection in the consumer subaccount:

1. Log on to the consumer subaccount and navigate to Security Role Collections.
2. Select the role collection SolutionAdmin, choose Edit, scroll down to Users, and select +. Enter the email address of your user, select SAP ID Service as your identity provider or use your preferred custom identity provider, and save your changes.

Now you are ready to access the solution's new tenant, where you will see the initial onboarding screen. In the confirmation dialog, you must confirm details such as email, subdomain, and subaccount ID to onboard an initial user for the customer:

1. Open the URL your provider has sent you to get access to their SaaS application.
2. On the initial administrator onboarding screen, your email address, subdomain, and subaccount ID are displayed. Select Onboard User to start the onboarding process. This might take a few minutes. Once the process is finished, you are redirected to the system. This onboarding process only needs to be performed once.

You can also monitor the tenant user provisioning using the Systems Overview and Operations Dashboard apps in the Landscape Portal. Ongoing tenant user provisionings are displayed in the Requests section of the Systems Overview app. See [View the Request Log \[page 1306\]](#).

## 4.2.11.1.7 Configure and Implement a Customer Project

After you have set up the consumer subaccount, tenant, and tenant user, a remaining customer implementation project in the consumer tenant can start. This includes the setup of identity and authentication management, integration with other systems or services, and adjustment of business configuration.

Once you have configured and implemented the customer project, the SaaS solution matches the requirements of the customer and you can provide the SaaS application URL to the customer.

### → Tip

We recommend providing documentation for your solution that includes specific configuration steps, for example to describe which business roles users have to create. In the following, we only describe the generic configuration steps.

## gCTS Delivery

If you use gCTS for delivery to a customer production system AMT instead of add-ons, the system is initially created without application content. Therefore, you have to clone the required software components manually.

For the initial import of a software component, as a SaaS solution operator on the provider side, you have to clone the software component in the customer production system AMT. The system can be accessed via the *Landscape Portal* application. In the *Landscape Portal*, the *Systems Overview* app provides an overview about the provisioned systems. Open the system that has been created during subscription to the multitenant application. In the *Tenants Overview*, the production tenant (client 100) can then be opened for provider access.

In the *Manage Software Components* app, select a software component and clone the branch of the software component with the product version, for example v1.0.0.

See [Delivery via Add-On or gCTS \[page 1228\]](#).

## Prerequisites

To start with the customer project, you have to know the requirements of the customer, and need to have a consumer tenant subscription and a user for the initial consumer access. See [Subscribe to Multitenant Applications Using the Cockpit](#) and [Initial User Onboarding \[page 1278\]](#).

As the consumer subaccount administrator, access the SAP Fiori launchpad of the SaaS Solution subscription from the consumer subaccount account by navigating to ► [Services](#) ► [Instances and Subscriptions](#) ►.

## Set Up IAM

### Create and Assign Business Roles

Before creating and assigning business roles, you have to make sure that business users are already available. They can be created manually or automatically. See [User Provisioning \[page 745\]](#).

As a business user, you configure the authorization to access the applications that are part of the SaaS solution via business roles. With the *Maintain Business Roles* app, you define business roles by combining predefined business catalogs and, if necessary, define value help, read and write access by maintaining the allowed values for fields.

Instead of creating a business role from scratch, you can also use business role templates. See [How to Create a Business Role from a Template \[page 2455\]](#).

### Create Spaces and Pages for Business Roles

The spaces mode offers more flexibility to adjust the SAP Fiori launchpad layout for specific user groups.

As a business user, to create launchpad spaces and pages, see [How to Create Spaces and Pages for a Business Role \[page 2465\]](#).

## Integrate

### Create Communication Arrangements

A communication arrangement is a runtime description of a specific communication scenario created by you as a business user. It describes which communication partners communicate with each other in the scenario and how they communicate. See [How to Create a Communication Arrangement \[page 2395\]](#).

#### Note

Depending on whether you want to use an authentication method for outbound communication that requires a business user context (OAuth 2.0 SAML Bearer Assertion, OAuth 2.0 User Token Exchange, JWT Principal Propagation), you need to configure a destination for communication arrangements in the system instead of maintaining credentials by using an outbound communication user. See [Supported Protocols and Authentication Methods \[page 850\]](#) and [Create a Destination \[page 854\]](#).

See [Integrating On-Premise Systems \[page 1070\]](#) on how to integrate the SaaS solution with on-premise systems.

## Configure

### Create Business Configuration

As a business user, you can use the [Custom Business Configurations](#) app to adjust business configuration objects to change and influence the system behavior.

See [Custom Business Configurations App \[page 2373\]](#) on how to adjust configuration objects provided in the SaaS solution.

### Configure Key User Extensibility

Key user extensibility that is enabled in the SaaS solution can be configured and consumed in consumer tenants.

#### Note

Key user extensibility provided in a SaaS solution can only be configured in tenants of particular types, for consumption purposes in customer systems, such as AMT, in tenants of type [Partner Customer Test](#) or [Partner Customer Production](#) depending on parameter `usage` in the configuration of the ABAP solution. See [ABAP Solution Service \[page 1262\]](#).

These tenant types are provisioned in non-development systems, such as customer system AMT, where development is not allowed (`is_development_allowed = false`). The tenants are created dependent on a subscription to the SaaS solution. See [Subscribe to Multitenant Applications Using the Cockpit](#).

As a business user in a [Partner Customer Test](#) or [Partner Customer Production](#) tenant (`client >= 200`), you configure key user extensibility in a customer production system AMT.

- See [Custom Logic \(Deprecated\) \[page 2428\]](#) for guidance on how to use the [Custom Logic](#) app to create and maintain custom logic for business add-ins (BADIs).
- See [Configuring Predefined Custom Fields \[page 2434\]](#) for guidance on how to configure predefined custom fields to customize applications and their UIs.

- See [Adapting SAP Fiori UIs at Runtime - Key User Adaptation](#) for guidance on how to adapt the user interface of an app separately for specific user roles.

## 4.2.11.1.8 Maintain, Monitor, Support

After the go-live of the SaaS solution and the deployment of its updates, consumers using the solution might run into issues that you have to troubleshoot and debug.

### 4.2.11.1.8.1 Maintain

After the initial add-on release has been shipped as a SaaS solution offering, the development of maintenance patches, support packages, and consequent add-on releases comes into play.

Once everything is implemented, built, and the maintenance delivery is deployed, the corresponding changes become available in the customer production system AMT.

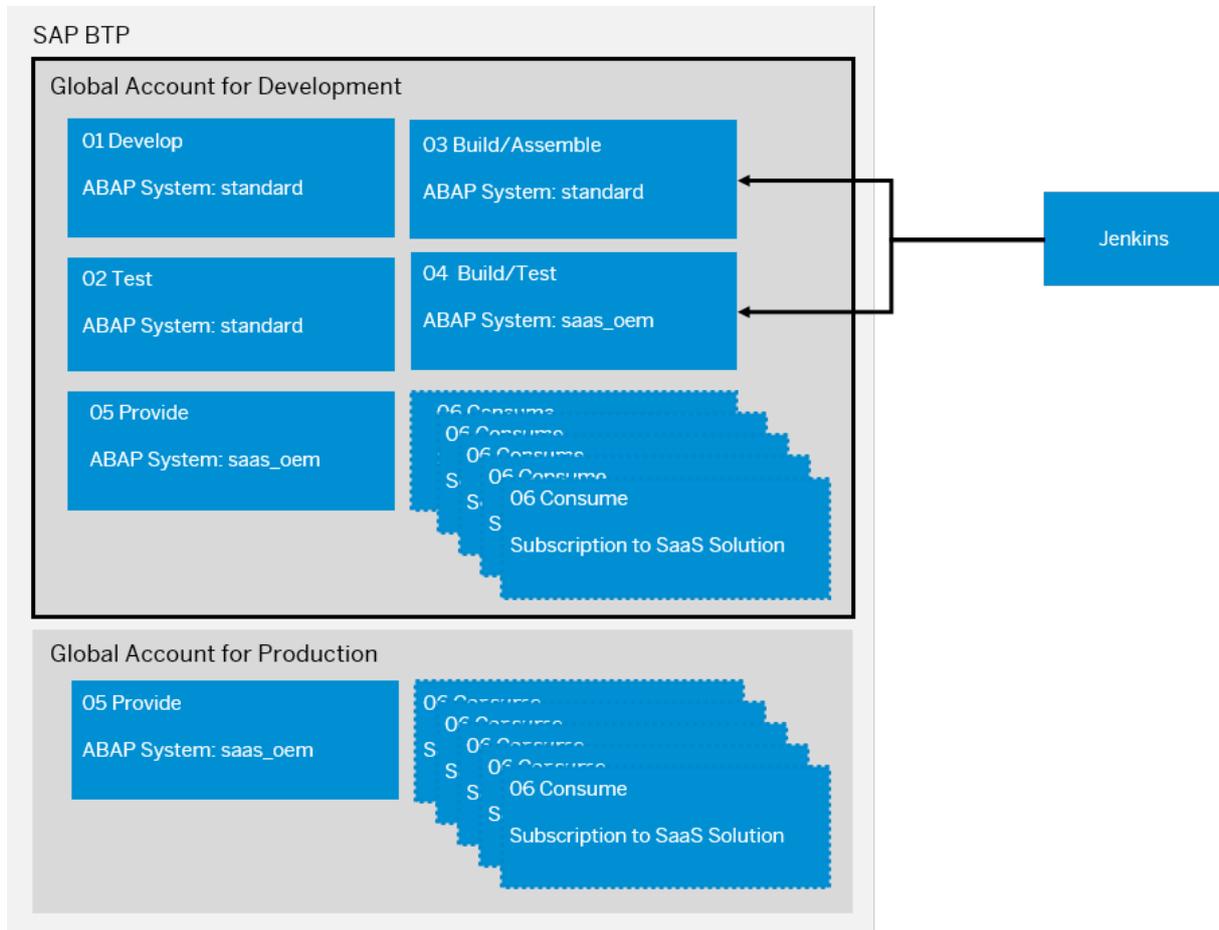

#### Note

New features are developed on different code lines (branches). If you create a so-called maintenance branch to implement patches while new features are implemented in the main branch of a software component, you can implement new features and provide bug fixes at the same time. For more information, see [Versioning and Branches](#).

## Prerequisites

- To set up the maintenance system landscape, you need the relevant entitlements in the global account for development. See [Entitlements and Quotas](#).
- When using a maintenance system landscape, you require business users with authorization to use the Manage Software Components app and developer users using ABAP Development Tools must be available in the systems. See [Manage Software Components \[page 2592\]](#) and [Getting Started as a Developer in the ABAP Environment \[page 198\]](#).
- To configure new add-on versions, you need the existing pipeline configuration for an add-on build pipeline. These can be the pipeline templates in the Build Product Version app or a manual configuration. See [Build Product Version](#) and [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#).
- If you have configured the add-on build pipeline manually, you need a Jenkins server where you can execute it.
- To use the Landscape Portal, you need a subscription to the Landscape Portal application and a user assigned to role collection `LandscapePortalAdminRoleCollection`.

## 4.2.11.1.8.1.1 Set Up Maintenance System Landscape

Bug fixes aren't implemented as part of the development code line, but in a separate correction code line. In this manner, corrections can be delivered to consumers even while regular development is ongoing.

We recommend setting up a maintenance system landscape that runs in parallel to the development system landscape. This maintenance landscape consists of:

- A correction system COR where corrections are developed. This system is provisioned in subaccount **01 Develop** in the development space. Set parameter `is_development_allowed = true`.
- A quality assurance system QAS for testing the corrections. This system is provisioned in subaccount **02 Test** in the test space. Set parameter `is_development_allowed = false`.

The required entitlements and system-related details are listed in the table below:

Global Account	Subaccount	Space	Entitlements	ABAP System
Global Account for Development	01 Develop	Develop	1x abap/standard	COR
			abap/hana_compute_unit (standard: 2)	
			abap/abap_compute_unit (standard: 1)	
	02 Test	Test	1x abap/standard	QAS
abap/hana_compute_unit (standard: 2)				
abap/abap_compute_unit (standard: 1)				

The Manage System Hibernation app in the Landscape Portal allows you to shut down the maintenance systems when no corrections are being developed, significantly reducing the costs incurred. See [Manage System Hibernation](#). For more information on working with two codelines, see [Use Case 2: One Development and Correction Codeline in a 5-System Landscape](#).

It is not strictly necessary to set up a separate maintenance system landscape. You can also implement corrections in the existing development and test systems to further reduce costs. In this case, ongoing development must be stopped while the release branch is checked out and worked on. See [Use Case 1: One Codeline in a 3-System Landscape](#).

## 4.2.11.1.8.1.2 Create Add-On Update

As an add-on administrator, you can provide different kinds of updates. The decision regarding which one to use depends on the motivation behind a given update.

- Small and urgent corrections are delivered as patches
- Collections of less urgent corrections and other functional enhancements should be delivered as support packages
- New release versions are released with updates containing significant enhancements and new features

### → Tip

Use the [Check Product Version \[page 1330\]](#) app in Landscape Portal to find out which product version has already been built.

### Create new patch version (emergency patch)

Patch versions are used to deliver unplanned and most likely urgent corrections that are required to keep the application up and running. These changes could be required for a service consumption model of an OData Client Proxy in case of changes to the structure of the underlying OData service. See [OData Client Proxies \[page 864\]](#).

Bug fixes are delivered as a new patch version of a software component and are implemented on the correction code line. Therefore, the dedicated ABAP correction system COR is used. For more information on the different software component version numbers, see [Software Component Version](#) .

### Note

While creating patch versions for the same support package level or release version, the same maintenance branch should be used.

To deliver a new patch version, see the following steps:

- **Develop**
  - As an add-on admin, check out the maintenance branch, which is the branch that is created for bug fixes and maintenance deliveries. See [How to Work with Branches \[page 2608\]](#).
  - Implement the bug fix in the ABAP correction system  
As a developer, implement the required changes to the software component in the ABAP correction system COR. These changes shouldn't introduce new features because patch versions should only contain small emergency corrections. Release the transport tasks and requests.
- **Test**
  - Import the maintenance branch in the ABAP quality assurance system  
You need to test the implemented corrections by importing the maintenance branch for the current support package level, where the transports for necessary bug fixes were released, in the dedicated test system, which is the ABAP quality assurance system QAS. See [How to Pull Software Components \[page 2597\]](#).
  - Test bugfix in ABAP quality assurance system  
As a tester, test the corrections in the QAS system to validate that the provided bug fixes are solving the problem and are working properly. Required testing can involve anything from maintaining business roles, creating communication arrangements to more complex testing scenarios where connectivity is involved.
- **Double maintenance of corrections into development**  
As a developer, you have to maintain the corrections that have been developed in the ABAP correction system COR as separate transports in development system DEV (so called double-maintenance). See [Double Maintenance of Corrections into Development \[page 701\]](#).
- **Configure new product version**  
As an add-on admin, you can use the Build Product Version app in the Landscape Portal to create new patches:
  - Make sure that the pipeline template for Patch Delivery is configured. If you want to validate the add-on build beforehand, configure the template for Test Patch Delivery as well. See [Configure Pipeline Template](#).
  - Choose the parent version that shall be patched and create a new product version of type Patch Delivery. See [Create a New Product Version](#).

If you are configuring the add-on build pipeline manually, adjust your add-on descriptor file to build the new patch version. See [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#) .

### Create new support package version (hotfix collection)

Support package versions are used to deliver planned functional enhancements outside of new major releases. They are often used to bundle multiple patch versions to a hotfix collection.

A support package version could be used for example to deliver a new simple business configuration UI. See [Business Configuration in SAP BTP ABAP Environment \(1\): Overview and BC Maintenance Apps](#) .

### Note

Support package deliveries aren't limited to changes to only one software component. But only software component support packages and patches should be included in a support package delivery. The software components that are part of an add-on product can only be changed as part of a release delivery.

### Note

If you use a quarterly delivery approach, new features are not delivered using support package versions. Instead, a new maintenance branch is created from the previous maintenance branch, using systems COR and QAS instead. See [Delivery Models](#).

To deliver a new support package stack, see the following steps:

- **Develop**
  - As a developer, implement the new feature in the main branch in the ABAP development system DEV. Bug fixes should be delivered via patch deliveries if they need to be available before the next support package delivery cycle. See [The Add-On Product](#) .
- **Test**

As an add-on admin, use the [Manage Software Components](#) app to import the changes in the main branch into test system TST.
- As a tester, test the new implemented features in the TST system to validate the functionality. Required testing can involve anything from maintaining business roles, creating communication arrangements to more complex testing scenarios where connectivity is involved.
- **Create maintenance branches**

As an add-on admin, create a new maintenance branch for each new support package level of a software component. These maintenance branches are used for developing bug fixes and maintaining deliveries. This assures that these bug fixes can be implemented in the correction code line to not block ongoing development on the main branch.

### Create new product version

As an add-on admin, you can use the Build Product Version app in the Landscape Portal to create new support package stacks:

1. Make sure that the pipeline template for Support Package Stack is configured. If you want to validate the add-on build beforehand, configure the template for Test Support Package Stack as well. See [Configure a Pipeline Template](#).
2. Choose the parent version that shall be patched and create a new product version of type Patch Delivery. See [Create a New Product Version](#).

If you are configuring the add-on build pipeline manually, adjust your add-on descriptor file to build the new patch version. See [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#) .

### Create new release version (product version)

Release versions are used to deliver new major, planned functional enhancements. Typically, they include multiple new implemented features. For example, multiple new apps could be introduced with such a major release.

### Note

Only with new release deliveries, you can change the software component version bundle in a new release.

To deliver a new release version, see the following steps:

- **Develop**  
As a developer, implement the new feature in the main branch in the ABAP development system DEV. Bug fixes should be delivered via patches or support packages instead. Release the transport tasks and requests.
- **Test**  
As an add-on admin, use the *Manage Software Components* app to import the main branch into the test system TST so that new developments can be tested.  
As a tester, test the new implemented features in system TST to validate the functionality. Required testing can involve anything from maintaining business roles, creating communication arrangements to more complex testing scenarios where connectivity is involved.
- **Create maintenance branches**  
As an add-on admin, create a new maintenance branch for each new release version of a software component. These maintenance branches are used for developing bug fixes and maintaining deliveries. This assures that these bug fixes can be implemented in the correction code line to not block ongoing development on the main branch.
- **Configure new product version**  
As an add-on admin, you can use the Build Product Version app in the Landscape Portal to create new release versions:
  - Make sure that the pipeline template for Release Delivery is configured. If you want to validate the add-on build beforehand, configure the template for Test Release Delivery as well. See [Configure Pipeline Template](#).
  - Choose the relevant add-on product and create a new product version of type Release Delivery. See [Create a New Product Version](#).

If you are configuring the add-on build pipeline manually, adjust your add-on descriptor file to build the new patch version. See [Build and Publish Add-on Products on SAP BTP, ABAP Environment](#) .

### gCTS Delivery

If you use gCTS for delivery, the process of creating an update for SaaS solutions is grouped into urgent corrections (patch version) and new releases (release version). See [Use Case 2: One Development and Correction Codeline in a 5-System Landscape](#) and [Delivery via Add-On or gCTS](#).

For delivering an emergency patch via gCTS, see section Urgent Corrections in [Use Case 2: One Development and Correction Codeline in a 5-System Landscape](#)

For delivering a new major version via gCTS instead of using add-ons, see section For Go Live/Development after Go Live (Including Deferrable Corrections) in [Use Case 2: One Development and Correction Codeline in a 5-System Landscape](#).

For general information regarding gCTS delivery, see [Delivery via Add-On or gCTS](#).

## 4.2.11.1.8.1.3 Trigger Add-On Build Pipeline

Similar to the build of the initial add-on version, as an add-on administrator, you need to trigger the execution of the configured ABAP environment pipeline for an add-on build. You can do this using the Build Product Version button in the corresponding app. After a successful build, the new add-on version is technically available for deployment to the ABAP environment. See [Create a New Product Version](#). If you are configuring the add-on build pipeline manually, then you need to trigger its execution in your Jenkins server. For in-depth information about the ABAP environment pipeline, check out [ABAP Environment Pipeline](#).

#### *gCTS Delivery*

If you are using gCTS instead of add-ons for delivering software components into production systems, an add-on build is not required.

#### **Note**

Please ensure that the add-on product version to be published is properly tested before confirming the release decision. This includes testing in SAP Fiori launchpad and the ABAP Test Cockpit. See [Test in the ABAP Environment SAP Fiori Launchpad \[page 1248\]](#) and [Test in the ABAP Test Cockpit \[page 1249\]](#).

### **4.2.11.1.8.1.4 Check Add-on Build Result**

Use the [Check Product Version](#) app in Landscape Portal to check whether the product version, its components, and respective packages are ready for delivery. See [Check Product Version \[page 1330\]](#).

### **4.2.11.1.8.1.5 Deploy Add-On Update**

As a SaaS solution operator, you can apply add-on updates to existing systems via the [Deploy Product \[page 1331\]](#) app in the Landscape Portal.

You can select the target add-on product and version for the update. Afterwards, you can select the systems where the update should be applied and schedule the update.

#### **gCTS Delivery**

If you are using gCTS instead of add-ons for delivering software components into production systems, you need to pull the changes of all relevant software components into all productive systems using the [Manage Software Components](#) app. An update deployment via the Landscape Portal is not required.

## **4.2.11.1.8.2 Manage Incidents**

### **Incident Management System**

As a provider of a SaaS solution, you should establish an incident management system, such as SAP Resolve, so that consumers can report issues.

If consumers of your SaaS solution run into problems, they need to be able to contact the provider of the software in a standardized way.

### Information to Identify ABAP System and Consumer Tenant for Incident Processing

To process an incident, you have to identify the ABAP system and tenant, where the consumer issue has occurred. Therefore, the following information is required:

- SAP Fiori launchpad URL  
In the SAP Fiori launchpad user actions menu, the SAP Fiori launchpad URL of a consumer tenant is displayed as *Server* in the *Settings* dialog. See [Settings](#).
- System Details  
In the user actions menu, information about the ABAP system and tenant is displayed in section *System* in the *About* dialog. See [About](#).  
The system name and description are of particular interest.

### Information to Reproduce the Customer Issue

To reproduce the consumer issue, the following information should be provided:

- Application details  
In the user actions menu, information about the SAP Fiori application is displayed in the *About* dialog in the *Application* section. See [About](#).  
The application title and technical component ID are of particular interest.
- Error details  
The error message is displayed in the SAP Fiori application or as a status code of the HTTP request that is failing.
- Business user details  
In the user actions menu, the name and email address identifying the business user of the consumer are displayed in the *Settings* dialog in the *User Account* section. See [Settings](#).
- Step-by-Step Description of the User Actions and Input  
To reproduce the customer issue, you need detailed information about the user actions that lead to the error, and, if possible, user input that was performed during these steps.

## 4.2.11.1.8.3 Troubleshoot and Debug

If a customer faces an issue, you have to provide troubleshooting based on a reported consumer incident. You can access the SAP Fiori launchpad of the consumer tenant or the backend using ABAP Development Tools to further analyze the issue.

### Identify ABAP System and Consumer Tenant

The ABAP system can be identified in the *Systems Overview* in the Landscape Portal application. See [View Tenants and Systems \[page 1305\]](#).

The system ID is defined in the ABAP Solution service via configuration parameter `sap_system_name`. If there are multiple solutions, the system description identifies the corresponding ABAP system as it always follows the same pattern: *ABAP Solution System for <parameter "name" in ABAP Solution service>*. See [ABAP Solution Service \[page 1262\]](#).

Based on the SAP Fiori launchpad URL of a consumer tenant, the consumer subaccount subdomain, that uniquely identifies the tenant, can be derived. The pattern to extract the subdomain is defined in

TENANT\_HOST\_PATTERN. This is defined as environment variable of the deployed approuter, which is part of the multitenant application. See [Approuter Application \[page 1269\]](#).

### ❁ Example

Identifying the subdomain with a multitenant application created based on the MTA-based approach, see [Multitenant Applications \[page 1259\]](#).

- `TENANT_HOST_PATTERN = (.*)${route-prefix}.${app-domain}`
- `${route-prefix} = <empty>`
- `${app-domain} = mydomain.com`
- `SAP Fiori Launchpad URL = myconsumer.mydomain.com`

In this example, `myconsumer` is the subdomain identifying the consumer tenant.

The subdomain is displayed in the *Tenants View* as *Subaccount Domain* when selecting the system in the Landscape Portal app and thus can be used to find the consumer tenant (business type *Partner Customer Test* and *Partner Customer Production*).

### Access the Consumer Tenant of the ABAP System

A consumer tenant in client  $\geq 200$  (business type *Partner Customer Test* or *Partner Customer Production*) can be accessed with a provider support user created in the Landscape Portal. See [Create Support Users \[page 1307\]](#).

- **Frontend Access to SAP Fiori launchpad**

The SAP Fiori launchpad of a consumer tenant in client  $\geq 200$  can be accessed via the link listed in the tenant overview in the Landscape Portal. A provider support user must be requested for the tenant beforehand. Such a user can only access a limited set of SAP-provided apps, for example for Identity and Access Management and Communication Management.

- **Backend Access using ABAP Development Tools**

Access to a consumer tenant in client  $\geq 200$  using ABAP Development Tools requires an adapted service key in the service instance in the SAP BTP cockpit: The service key `SAP_ASP` displayed in the cockpit needs to be adjusted with the GUID of the consumer tenant. See [Create Support Users \[page 1307\]](#).

ABAP Development Tools access with a provider support user created in the Landscape Portal grants access to troubleshooting capabilities, such as those granted with business role `Application Support Engineer - Development Support (BR_APPL_SUP_ENG_DEV_SUP)`.

### Troubleshoot

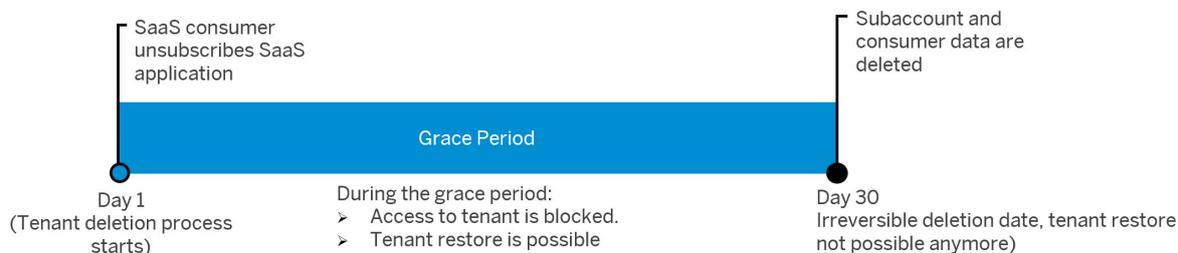

The most common use case for troubleshooting is to debug a business user or communication user executing the implemented business logic that is causing an issue in the consumer tenant. See [Troubleshoot Custom Apps \[page 2744\]](#).

With a provider support user, you need to connect with ABAP Development Tools to the system and consumer tenant, set a breakpoint in the logic, and afterwards the business user of the consumer must reproduce the error.

Apart from debugging, you can also use other troubleshooting tools in ABAP Development Tools to analyze issues in a consumer tenant. See [Troubleshooting Tools \[page 2747\]](#).

## 4.2.11.1.9 Dismantle

As soon as a consumer unsubscribes from the SaaS solution, an immediate tenant decommissioning process takes place while taking a “grace period” of 30 days into account, according to the following legal obligations:

During the grace period

- The tenant access is blocked for the consumer and for the SaaS provider as well in the support use case.
- The provider can restore the tenant in the *Landscape Portal*. See [Restore Consumer Tenants \[page 1316\]](#).

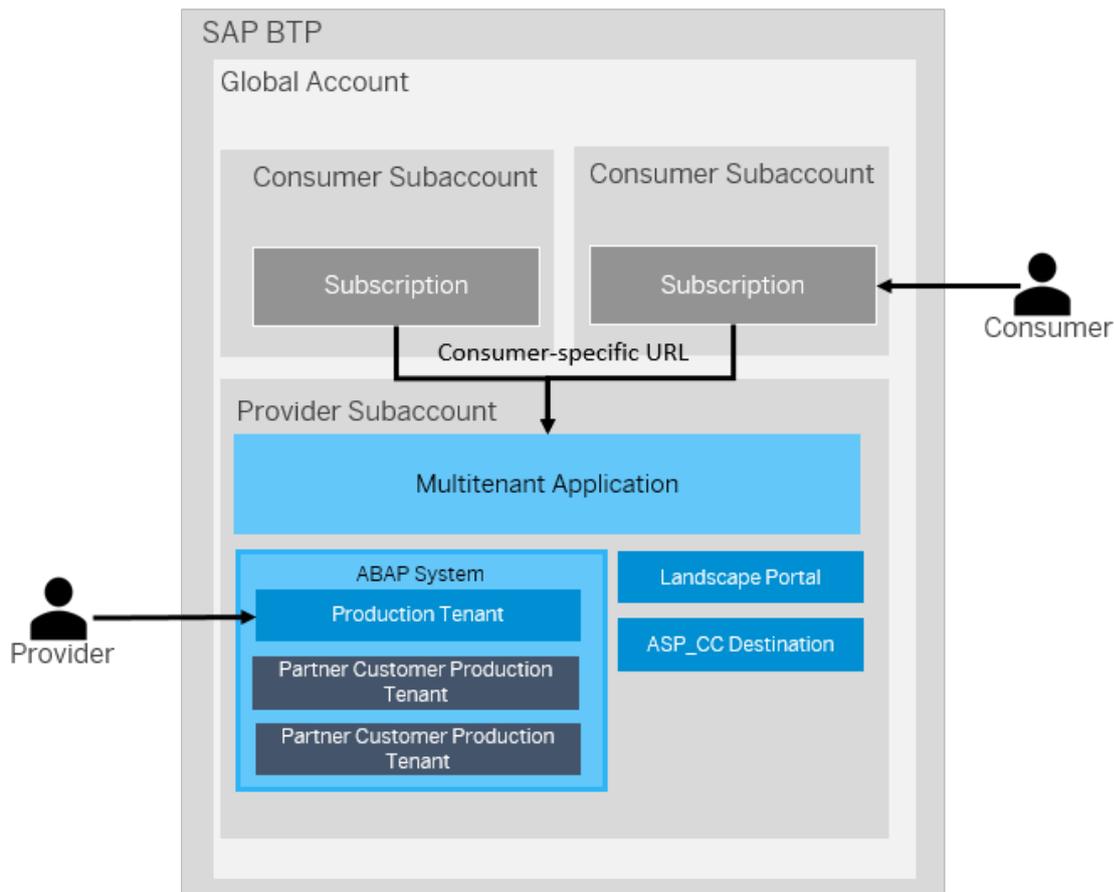

After the end of the grace period, the tenant and all related data are irreversibly deleted and cannot be restored anymore.

Once the last consumer unsubscribes from the SaaS solution, the provider needs to delete the empty system in the BTP cockpit.

Alternatively, as a SaaS solution operator, you can use the *Subscription Management Dashboard* in the provider subaccount to unsubscribe tenants centrally without triggering unsubscription in the consumer subaccount. See [Using the Subscription Management Dashboard](#).

## 4.2.11.2 Multitenancy in the ABAP Environment

Multitenancy defines the capability to host different customers (tenants) on a single, shared computing infrastructure in order to optimize administration and significantly reduce TCO. A tenant is an organizationally independent unit whose IT business is entirely or partly operated together with the businesses of other tenants by a hosting provider. Multitenancy is especially relevant in a “Software as a Service” (SaaS) business model where customers subscribe to hosted software solutions rather than buying and installing them. For hosting providers, the operation costs per user per tenant are a decisive factor - particularly in the SME market, where typically each tenant only has a small number of users (10 – 50) accessing the hosted solution. Hosting providers can only operate profitably if they succeed in keeping the administration and maintenance costs for the hosted solution as low as possible. This cost pressure also limits the degree of individualization and customization a hosting provider is willing to accept for a hosted solution provided to many tenants.

Multitenancy in the ABAP environment enables independent software vendors or partners (referred to as application **provider**) to develop and operate ABAP solutions as software as a service (SaaS) leveraging SAP BTP infrastructure while hosting several consumers on the same ABAP system. The resources on SAP BTP platform consumed by the solution are paid for by the application provider.

Application **consumers** (= end customers of the provider) subscribe to a provider's multitenant application and use it in a specific consumer subaccount (= tenant). Consumers access the provider's SaaS application via a consumer-specific URL. Consumers cannot see the data of other consumers and Identity and Access Management is kept isolated between different tenants.

The **Multitenant Application** is deployed to the provider subaccount and serves as the entry point for the consumer-specific URLs, so that requests are routed to the corresponding consumer tenant in the ABAP system. Only after the multitenant application has been deployed, the application will be available for subscription to consumers. See [Multitenant Applications \[page 1259\]](#).

The **ABAP system** used to serve the application to the consumers is provisioned in the provider subaccount during the first subscription as abap/standard or abap/saas\_oem system (depending on whether add-on is used for delivery). See [Creating an ABAP System \[page 163\]](#). Different tenants are created as separate clients in the system. Tenants in the ABAP system have different capabilities represented by the tenant business type and a lifecycle status. The ABAP system contains by default a tenant used by the application provider (client 100) for system-level operations like the import of software components to the system. For each subscription to the multitenant application, a tenant used by the consumer (client  $\geq 200$ ) is created. If any consumer tenants still exist in the ABAP system, the system cannot be deleted.

The **Landscape Portal** functions as a central plane for tenant management that allows providers to perform lifecycle management operations such as add-on updates, creating test tenants or support users and more. For more information on how to access and use the Landscape Portal, see [Landscape Portal \[page 1302\]](#).

The **ASP\_CC Destination** is a destination created on subaccount-level in the provider subaccounts. It points to the Cloud Foundry Cloud Controller API and is utilized by the multitenant application to create the ABAP system in the Cloud Foundry space/org where the multitenant application is deployed. See [Cloud Controller Access Destination \[page 1271\]](#).

#### Note

When building tenant-aware applications on top of the ABAP environment, providers need to follow specific ABAP implementation rules to ensure a content separation between different consumers. To view these guidelines, see [Multitenancy Development Guideline \[page 1295\]](#).

## 4.2.11.2.1 Tenant Business Types

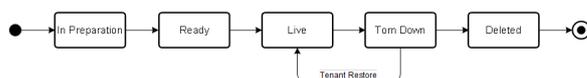

The capabilities of a tenant used by the application provider or application consumer depend on the tenant business type. Business types of tenants that reflect how the tenant is used are derived from the system business type (partner development or production system via parameter `is_development_allowed`).

- **Target Group:** Whether the tenant is primarily used by the application provider or application consumer.
- **ABAP System Client:** Consumer/Provider tenants are created as a different ABAP system client for content separation.
- **Business User Logon:** Business users are authenticated in an ABAP tenant using trusted identity providers configured in either the provider subaccount or consumer subaccount. See [Trust and Federation with Identity Providers](#).
- **Provider Support Access:** In the Landscape Portal the application provider can request support user access for certain tenants in the ABAP system to troubleshoot & debug issues. See [Create Support Users \[page 1307\]](#).
- **Key-User Extensibility Configuration:** Key-user extensibility features of a solution like custom logic and predefined custom fields can only be configured in tenants of particular types. See [Providing Business Add-Ins \[page 1342\]](#) and [Configuring Predefined Custom Fields \[page 1348\]](#).
- **Software Component Import:** The Manage Software Components app is only available in tenants of particular type. See [Manage Software Components \[page 2592\]](#).
- **Tenant Onboarding:** When and how tenants are created differs depending on the business type. See [Subscribe to Multitenant Applications Using the Cockpit](#).
- **Initial Administrator Onboarding:** In each tenant an initial user is created based on an e-mail address to get access to the tenant after it has been created.
- **Tenant Offboarding:** When and how tenants are deleted differs depending on the business type. See [Dismantle \[page 1290\]](#).
- **Tenant Restore:** Only tenants of particular types can be restored during the retention period. See [Restore Consumer Tenants \[page 1316\]](#).

	Partner Development System		Production System			
	Partner Development Tenant	Partner Test Tenant	Production Tenant	Partner Test	Partner Customer Test Tenant	Partner Customer Production Tenant
<b>Target Group</b>	Application Provider	Application Provider	Application Provider	Application Provider	Application Consumer	Application Consumer
<b>ABAP System Client</b>	100	>=200	100	>=200	>=200	>=200

## 4.2.11.2.2 Tenant Lifecycle

Each consumer tenant goes through a certain lifecycle starting from the provisioning to the deprovisioning of the tenant and possibly tenant restoration. The current lifecycle status of a tenant in the ABAP system is shown in the Landscape Portal.

Request Type in Landscape Portal	Changes to Lifecycle Status	Description
New Tenant	In Preparation	The creation of a new tenant starts with status <b>In Preparation</b> . After the creation of the new tenant in the system, the registration of client and tenant in the system, and the import of initial tenant data, the tenant is <b>Ready</b> . Finally, after preparation of logon to the new tenant, technical configuration, business configuration, activation of tenant features, setup of monitoring, the tenant is finalized, and the lifecycle status is set to <b>Live</b> .
	Ready	
	Live	
Delete Tenant	Live	Tenant deletion is triggered when the consumer subscription is deleted. The deletion request changes the tenant lifecycle status from <b>Live</b> to <b>Torn Down</b> . During a retention period of 30 days, the tenant remains in status <b>Torn Down</b> , reflecting the deletion in progress. After 30 days, and if the tenant is not restored, the tenant deletion is automatically completed, and the status is changed to <b>Deleted</b> .
	Torn Down	
	Deleted	
Restore Tenant	Live	After a tenant deletion was requested by deleting the corresponding consumer subscription, the tenant can be restored in the Landscape Portal during a retention period of 30 days. Doing so, the lifecycle status is changed back from <b>Torn Down</b> during the retention period, to <b>Live</b> after the completed tenant restoration.
	Torn Down	
	Live	

## 4.2.11.2.3 Multitenancy Development Guideline

Multitenancy is required if you want to run several customers on the same ABAP system. When building tenant-aware applications on top of the ABAP environment, you must follow dedicated rules to ensure, for example, a content separation between different customers.

### Architecture Overview and Basic Concept

The following sections explain how to host multiple tenants in one ABAP system by building a multitenant enabled solution. We use multiple clients in the ABAP environment as a technical means to implement multitenancy.

There are the following basic principles regarding multitenancy:

- for the **tenant**: Strict data isolation is guaranteed between tenants on all levels of the system. It must be ensured that the tenants' data as well as their tenant-specific application extensions are under no circumstances mingled with the data or applications of any other tenant being operated in the same system.
- for the **hosting provider**: The costs for operating multiple tenants in the same system must be significantly lower compared to single tenant systems. Multitenant systems must reduce the TCO of a hosted solution in such a way that the business case is met.

#### Note

Multitenancy is only one means to reduce the marginal costs of operations addressing system and hardware costs.

To some extent, these principles are contradictory. The first principle could be most easily fulfilled by single tenant systems, whereas the second principle imposes the need for sharing resources on each system level, for example, hardware, database, application server. Multitenancy can thus be described as sharing as much system resources as possible without violating the principle of tenant data isolation.

#### Note

Tenant isolation isn't completely ensured by the ABAP environment infrastructure. However, the following sections describe the design principles how multitenancy can be achieved in the ABAP environment by an evolution of the present multiclient capability of an ABAP system.

The ABAP environment is a Platform as a Service (PaaS) offering for ABAP. In a typical scenario, an independent software vendor (ISV) develops and runs a Software as a Service (SaaS) application in the ABAP environment and sells this application to end-customers. In order to avoid confusion with the term "customer", as the ISV is also a customer of the ABAP environment, the following terminology is used in this document:

- The **service provider** of the SaaS application is responsible for developing, maintaining, and operating the application on top of the ABAP environment. The service provider is typically an ISV or a development partner.
- The **provider system** is an ABAP system in the ABAP environment that runs the SaaS application. The provider system is operated by the service provider and offers multitenancy capabilities.
- The **service consumer** of the SaaS application is an end-customer of the service provider who has subscribed a tenant in a provider system.

## Assumptions and Limitations

- Multitenancy is only supported in provider systems operated by the same service provider to run a single SaaS application.
- Multitenancy isn't supported for the development scenario using the ABAP Development Tools (ADT). This means that several service providers can't share the same system for development. Furthermore, a consumer can't further develop or extend the provider's SaaS application using ADT.
- You as a service provider can build a multitenancy application following the respective guidelines.
- Transport of objects isn't supported in a multitenant environment.  
Business configuration content is usually transported to a productive environment by using the transport API `IF_A4C_BC_HANDLER`, in this case, the user interface doesn't have to be implemented. To transport business configurations between systems, you can use the download/upload functionality, see [Upload Business Configuration \[page 2377\]](#).
- There is no system-controlled process to ensure that you as a service provider build your application in a multitenancy-compliant way. If strict data isolation is a legal requirement, we propose an external audit to ensure that your code doesn't break data isolation.
- There are options to share data between tenants. Furthermore, native SAP HANA database access via ABAP-managed database procedures (AMDP) requires special considerations. It's only documented which functionality does have which impact on client isolation. There is no check ensuring that you as a service provider use these features in a multitenancy-compliant way.
- To ensure tenant lifecycle procedures, the applications must be built in such a way that the procedures for tenant copy, tenant move, and tenant delete can deal with it.

### Note

If you don't comply with these aspects of the guideline, this causes issues where SAP, you as a provider, and the consumer are involved.

- Security and system logs store data in a cross-client persistence together.
- Any multitenancy-specific certifications from SAP in addition to the already existing ABAP environment product certifications are out of scope.

## Guidelines for Multitenancy Applications in the ABAP environment

The following sections cover the relevant guidelines for content separation in multiclient systems. We use the multiclient architecture of the ABAP system for multitenancy enablement and list the design principles to reach multitenancy.

## Prerequisites

- Store tenant-related data in client-dependent tables of type A, C, or L.
- Store system-related data in client-independent tables of type S.
- Always add the selection of the client to ABAP database procedures (AMDPs).

Make sure consumers cannot modify the client parameter or any other part of the AMDP using the application or by tampering requests.

- Don't generate development objects or other client-independent data system-locally in the provider system.
- Don't evaluate the actual value of the 3-digit client field (IF sy-mandt = 'nnn'. .... ENDIF).

## Database Table Design

You have to classify database tables according to their content. There are the following types:

- Tenant Content (client-dependent)
  - Tenant configuration data – tables with delivery class “C”
  - Tenant application data – tables with delivery class “A”
  - Tenant temporary data – tables with delivery class “L”

Database tables for tenant content must be client-dependent. This means that the first field of the table must be of datatype “CLNT”. We recommend using the inline declaration „abap.clnt“.

Only the content of client-dependent “C” and “A” tables is considered during tenant copy and tenant move. Content of client-independent tables which are not delivered from the development system and “L” tables are lost during tenant lifecycle processes such as tenant move.

During tenant delete, the content of all client-dependent tables is removed.

The delivery class must be “C”, “A”, or “L”.

The delivery classes “E”, “G” and “W” are not supported in the ABAP environment at all.

- System Content (client-independent)
  - System configuration data – tables with delivery class “S”

Store data that is defined by the service provider and not specific for any tenant in a client-independent “S” table. Define the content in the respective development system and export it as TABU entries via a development transport request. The content is considered as code and imported like other development artifacts into subsequent systems such as the provider system.

## Database Table Access

- Read Access Using ABAP SQL  
Whenever you access table content, ensure that you don't violate tenant isolation. ABAP SQL does not support additions such as CLIENT SPECIFIED or USING CLIENT in the ABAP environment. As a result, access to other clients than SY-MANDT is technically not possible. But you have to define client-dependent tables properly so that the ABAP runtime applies this role accordingly.
- Write Access Using ABAP SQL  
Do not write “S” tables in the provider system.

### Note

If you write “S” tables in the provider system, this content is not considered during tenant lifecycle management events, such as tenant move, and you lose content. Furthermore, you violate tenant isolation, since every tenant has immediately access to the changes.

- Access Using AMDP  
Access to SAP HANA database using AMDP is not controlled via the ABAP database interface. The client is just handed over as a parameter. This can easily violate the content separation and access a table data for another client. Make sure that the client is always passed via SY-MANDT.  
Consumers must never be able to modify the client parameter or any other part of the AMDP using the application or by tampering requests.

## Code Generation

Development artifacts such as Data Dictionary objects, classes, or interfaces, which are typically created via ABAP Development Tools (ADT), are always client-independent. Changes are always recorded in transport requests.

### Note

It is not allowed to generate development artifacts in a non-development system, such as a provider system. This generation violates the content separation and is not be considered during tenant move and copy procedures. You are only allowed to generate development artifacts in **development systems** in the ABAP environment. You can use the XCO library for that purpose. If you generate development artifacts, the service provider is responsible for ensuring that the generated artifacts are transported into all required provider systems. Standard lifecycle events such as a tenant move don't consider such client-independent artifacts.

## Multitenant-Aware Programming

- Cross-Client Locking (Enqueue)  
Lock Objects are associated to database tables or structures. The runtime API in the ABAP environment is `CL_ABAP_LOCK_OBJECT_FACTORY` and the returned instance of type `IF_ABAP_LOCK_OBJECT`.

### Note

Only lock client-dependent database tables or structures having a `CLIENT` field.

- `CL_ABAP_CONTEXT_INFO=>GET_SYSTEM_DATE` and `TIME`  
The system date/time (methods `CL_ABAP_CONTEXT_INFO=>GET_SYSTEM_DATE`, `CL_ABAP_CONTEXT_INFO=>GET_SYSTEM_TIME`) is always based on UTC time zone. The system time zone can't be changed tenant-specifically. As a usual approach in cloud environments, it needs to be considered in your code, as it gives the same date and time for all tenants.
- Usage of System Information (`sy-sysid` and `sy-mandt`)

Storing SY-SYSID and SY-MANDT explicitly in database tables is not allowed. This would lead to issues after tenant copy or tenant move, because both values are not unique and not stable in the system landscape. A dedicated API is provided to get a unique and stable identifier for the tenant. See [Tenant \[page 1694\]](#).

## Connectivity

Outbound communication management in the ABAP environment differs from the on-premise usage of SM59 destinations. See [Developing External Service Consumption \(Outbound Communication\) \[page 852\]](#). Destinations are configured in a Cloud Foundry destination service and the ABAP consumer API references these destinations.

### ⚠ Restriction

The ABAP environment only supports one communication configuration layer that is intended for the consumer. It is currently not possible to enforce a communication configuration exclusively managed by the service provider within the consumer tenant.

With regard to inbound communication, inbound RFC is not entirely supported.

## Limitations

There might be some use cases where the guidelines provided are not applicable, for example, when sharing data across tenants or sharing aggregated customer data.

For such use cases, the operations concept needs to be documented and an alignment with SAP is required. We recommend checking the operational impact on tenant move and tenant copy procedures. In addition, we recommend a review for multiclient content separation.

## Usage of SAP-Delivered SAP Fiori Apps

SAP has delivered several SAP Fiori apps for the administration of an ABAP environment system. These SAP Fiori apps are targeting different roles, such as administrator, project manager, and developer. Regarding multitenancy, some of these apps are covering client-independent objects and configuration according to their purpose. For example, the SAP Fiori app Manage Software Components allows you to import software components, which has an immediate impact on all tenants. Therefore, you need to carefully choose which SAP-delivered business catalogs to include in the business roles of your SaaS application.

## 4.2.11.2.4 Troubleshooting

Find out which steps you can take to identify and resolve specific issues that may come up when developing a multitenant application.

### SaaS subscription error

- The *Landscape Portal* subscription might be missing. Make sure the *Landscape Portal* is subscribed to in the provider subaccount. This needs to be done before the SaaS subscription.
- The ASP\_CC (CF Cloud Controller) destination might have failed: An ASP\_CC destination with the correct credentials/URLs must exist in the provider subaccount (see [Cloud Controller Access Destination \[page 1271\]](#)). You can use a connection check in the destination for a basic connectivity test. You can also test if the user that was used in the ASP\_CC destination is able to authenticate with the following cf command: `cf login -a <cf-api-endpoint e.g. https://api.cf.eu10.hana.ondemand.com> -u <destination-user-name> -p <password> -s <provider-space> -o <provider-org>`. Make sure the following is the case:
  - You have the credentials you require (space developer user). This user is a CF Platform User, i.e. it is either an S-User or a P-User, usually created using a distribution list so that it is a non-personalized e-mail address. A technical communication user that can also be created similar to normal S-Users cannot be used here.
  - You are using the correct URL: the URL needs to be the same as the CF API URL in the provider subaccount, depending on the region, see [Region](#).
  - You are using the right Token Service URL for the region.
  - You are using a technical user as recommended, not a personal user. Personal user accounts can cause issues due to password changes etc.
- The space developer user might be missing: The user used in the credentials of the ASP\_CC destination must be added as space developer in the space of the multitenant application.
- There might be missing entitlements for ABAP systems: During the subscription, the multitenant application/ASP automatically provisions ABAP systems. Make sure that the necessary entitlements are added to the provider subaccount:
  - `abap/standard` (for delivery via gCTS) or `abap/saas_oem` (for add-on based delivery), depending on the configuration of ASP parameter `addon_product_name`. See [Multitenancy in the ABAP Environment \[page 1290\]](#) and [ABAP Solution Service \[page 1262\]](#).
  - `abap_compute_unit` and `hana_compute_unit` depending on the configuration of ASP parameter `size_of_runtime` and `size_of_persistence`. See [Multitenancy in the ABAP Environment \[page 1290\]](#) and [ABAP Solution Service \[page 1262\]](#).
- There might be missing entitlements for multitenant app deployment. Make sure that the necessary entitlements are added to the provider subaccount:
  - Cloud Foundry Runtime entitlement for the approuter in the multitenant app.
  - ABAP Solution Service.
- In case of error "Illegal given domain name" during subscription:
  - The subscription fails because in the `saas-registry` service instance the URL defined for `onSubscription` and `getDependencies` callbacks does not match the pattern of the `cis-...` route assigned to the approuter application. Please make sure that the route defined in your `saas-registry` configuration for callbacks has the same pattern as defined in the `cis-...` route.

## Cannot delete ABAP service instance

- If you cannot delete an ABAP service instance, the ABAP service instance might still contain *Partner Test*, *Partner Customer Test*, or *Partner Customer Production* tenants. Make sure you delete these tenants first by unsubscribing from them (for tenants created via consumer subscription) or deleting the tenants in the *Landscape Portal* (for test tenants created directly in the *Landscape Portal*).
- The ABAP service instance might still contain a SAP\_ASP service key: The service key needs to be deleted before the service instance can be deleted.

## Multitenant application cannot be undeployed

- Always use MTA Undeployment (`cf undeploy <MTA ID> --delete-services`) instead of deleting service instances individually.
- Check if the `saas-registry` service instance still contains active subscriptions: the `saas-registry` instance can only be deleted once there are no more active subscriptions. Unsubscribe using the [Subscription Management Dashboard](#).

## Cannot create consumer-specific route according to `TENANT_HOST_PATTERN` (in the development phase)

### Sample Code

```
TENANT_HOST_PATTERN: (.*)-my-consumer-subdomain-productabcdefghijklmnopq-saas-  
solution-dev.cfapps.eu10.hana.ondemand.com  
Consumer Subaccount Subdomain: my-consumer-subdomain  
Route Domain: cfapps.eu10.hana.ondemand.com  
Route Hostname: my-consumer-subdomain-productabcdefghijklmnopq-saas-solution-  
dev (64 characters)
```

- Keep in mind that the hostname of the route in CF is limited to 63 characters.
- In the development phase, the hostname part of the route should consist of the consumer subdomain, separator ("-"), and the appName.
- Either shorten the subdomain of the consumer subaccount or shorten the appName used in `TENANT_HOST_PATTERN`.

## After deployment of MTA for multitenant application, no abap system is created

- ABAP systems are automatically created by the ABAP Solution Provider (ASP) during the first subscription.

## Issues with parameter `consumer_tenant_limit`

- Keep in mind that recently deleted consumer tenants are counted towards the tenant limit. Systems are automatically created.

## First consumer tenant is missing application content after subscription

- Only in case of delivery via add-on, the application content is installed before the consumer tenant is accessible. In case of delivery via gCTS, the software components need to be imported manually using the [Manage Software Components](#) app in client 100 of the system.

## 4.2.11.3 Landscape Portal

### Context

Multitenancy allows providers to host different consumers (tenants) on a single shared system. But how do you, as a provider, keep track of all your tenants and systems? This is where the [Landscape Portal](#) comes in. The [Landscape Portal](#) acts as a central tool to allow service providers to perform lifecycle management operations such as building and updating product versions, configuring and deploying multitenant SaaS solutions, managing system hibernations, and more.

### Key Features

You can currently use the [Landscape Portal](#) to do the following:

- get an overview of all your ABAP systems and tenants
- create new namespaces and install them in your ABAP system
- schedule (regularly occurring) system hibernation periods for specific systems
- register specific ABAP systems for a pre-upgrade
- restore deleted consumer tenants that are still in retention time
- create test tenants
- create support users to access consumer tenants
- create a new product and register your product for your global accounts
- build a product version via pipelines based on templates for different use cases (e.g. new release deliveries, support packages, patches)
- check a product version to see if it's ready for delivery
- deploy or update a product version in specific systems
- configure and deploy your solution
- monitor your operations in the Landscape Portal

### Note

Keep in mind that a consumer subscription-based multitenancy is only possible in those systems in which you provide your software as a service (SaaS) solution to consumers, i.e. your production and test systems that are created via the ABAP Solution service on first subscription. It is not available in development systems. However, in development systems, in addition to your development tenant, you can create further test tenants within the *Landscape Portal* if required, see [Manage Test Tenants \[page 1317\]](#).

## Related Information

[Accessing the Landscape Portal \[page 1303\]](#)

### 4.2.11.3.1 Accessing the Landscape Portal

The Landscape Portal itself is part of SAP BTP ABAP environment and requires no additional license. To build and deploy products (see [Build Product Version \[page 1319\]](#) and [Maintain Solution \[page 1333\]](#)) a subscription to the SAP Continuous Integration and Delivery service is needed, which requires a separate license, see [SAP Continuous Integration and Delivery](#). To set up access to the Landscape Portal, you just need to add the Landscape Portal as entitlement to your subaccount, subscribe to it, and assign the necessary role collections to your user. Once you have done this, you can easily access the Landscape Portal by clicking on its tile in the Service Marketplace.

### Note

The Landscape Portal authorization is handled by the SAP ID Service (accounts.sap.com) for SAP BTP only. No other identity providers, such as custom IDPs, are supported. For more information on how to proceed, see [Default Identity Provider](#).

### Note

**Important:** The Landscape Portal can only be accessed from subaccounts located in region cf-eu10. Please use a subaccount located in this region to add the entitlement and to subscribe to and access the Landscape Portal.

You can manage systems for (and deploy your SaaS solution to) all regions within the same global account using the same Landscape Portal instance. Only the subaccount used for Landscape Portal access must be located in cf-eu10.

## Adding the *Landscape Portal* as Entitlement

The *Landscape Portal* needs to be assigned to your subaccount as an entitlement.

1. Sign into your account in the [SAP BTP Cockpit](#).

2. On global account level, navigate to [Entity Assignments](#) in the Entitlements menu tree.
3. Open the value help for [Select Entities](#) and choose the subaccount (located in cf-eu10) to which the [Landscape Portal](#) entitlement shall be added. Click [Select](#).
4. Click the button [Configure Entitlements](#) and then [Add Service Plans](#).
5. Select [Landscape Portal](#) from the list and choose the service plan [standard](#), then click [Add 1 Service Plan](#).
6. Click [Save](#) to add the service plan to your selected subaccount.

## Subscribing to the [Landscape Portal](#) in the SAP BTP cockpit

To enable the [Landscape Portal](#), you need to subscribe to it in the SAP BTP cockpit. Here's how:

1. Sign into your account in the [SAP BTP Cockpit](#).
2. Select your global account, then navigate to [Subaccounts](#) and select your production subaccount (located in cf-eu10).
3. Navigate to [Service Marketplace](#).
4. The [Landscape Portal](#) tile is now visible and says "Not subscribed".
5. Click the tile to subscribe to it. The subscription process might take a few minutes. When everything is ready, the tile will say [Subscribed](#). From now on, you can open the [Landscape Portal](#) simply by navigating to the tile and clicking on [Go to application](#).

## Assigning the Landscape Portal Role Collections

In order to log into the [Landscape Portal](#), a user first needs to be assigned the necessary role collection. This is done by the security administrators of your production subaccount in the SAP BTP cockpit. For more information on how to add security administrators, see [Add Security Administrators to Your Subaccount \[Feature Set A\]](#). For more information on how to assign role collections, see [Assign Users to Role Collections](#).

### → Remember

You need to be a security administrator in your production subaccount in order to assign the role collections.

There are four different role collections available for the [Landscape Portal](#):

- Landscape Portal Admin ("LandscapePortalAdminRoleCollection"): Full functionality of the [Landscape Portal](#).
- Landscape Portal User ("LandscapePortalUserRoleCollection"): Read-only view of the [Landscape Portal](#) and the right to create Support Users.

### 📘 Note

If you have subscribed to the [Landscape Portal](#) from multiple subaccounts, you have to adjust the role collection assignment consistently, that is you need to assign the same role collections to the same user in every subaccount you are accessing the [Landscape Portal](#) from.

## 4.2.11.3.2 Systems Overview

The [Systems Overview](#) app helps you keep track of your tenants and systems.

### Key Features

- Get an overview of your systems and tenants.
- See which version a system software is currently on.
- Create support users.
- Perform add-on updates.
- View the request log.
- Create a ticket with support context.

### 4.2.11.3.2.1 View Tenants and Systems

#### Context

You can use the Landscape Portal to get an overview of your systems and tenants.

#### Procedure

1. Sign in to the [Landscape Portal](#) and click on the tile [Systems Overview](#).
2. You can view a table listing all of your systems. You can see their lifecycle status, business type, and more.
3. To get more information on one of the systems, click on that list entry. This will open the details view for that system.
4. Scroll down to [Software](#) to see which software and which of your add-ons are currently installed in this system.
5. Scroll down to [Tenants](#) to display a list of all tenants that are currently on this system, as well as their current lifecycle status, their business type and more. Via the client link you can login to the ABAP FLP of each of the clients. Prerequisite for access is a user in the tenant. For [Partner Customer Test](#) and [Partner Customer Production](#) tenants, request a support user in the [Landscape Portal](#). For [Partner Test](#) tenants, the initial admin user is created during the test tenant creation. For [Partner Tenant](#) tenants, login using the initial administrator user created according to ABAP Solution service parameter provider\_admin\_email.

## 4.2.11.3.2 View the Request Log

### Context

You can view a log of every action that was requested for a system in the Landscape Portal.

### Procedure

1. Sign in to the [Landscape Portal](#) and click on the tile [Systems Overview](#).
2. Select one of the systems to open the details view.
3. Scroll to [Requests](#) to view a log of every action that was requested for this system in the [Landscape Portal](#). The table displays when each action was scheduled, who it was scheduled by, and for what time it was scheduled. You can also see whether an action was successful or, if it wasn't, which error occurred.

## 4.2.11.3.2.3 Perform Add-on Updates

### Context

You can use the Landscape Portal to update add-ons on your systems.

#### ⓘ Note

Keep in mind that the target version of the update cannot be selected. The latest released version (target vector for add-on product published with productive scope) is automatically determined. The target vector is created as part of the add-on build process and is published in productive scope after the release decision; see [The Add-on Product](#) .

### Procedure

1. Log in to the [Landscape Portal](#) and click on the tile [Systems Overview](#) to see an overview of all your systems.
2. Select the system for which you would like to update the add-on.
3. Click on [Add-On Update](#).

- (Optional) You can check the [Requests](#) tab in your system to track the execution status of your action.

#### ⓘ Note

- The [Add-On Update](#) button is visible regardless of whether there is an add-on installed in the system. If no add-on is installed and you click the button, you will later see an error in the request log. Add-on updates can only be performed in a SaaS Provider Production System.
- It is not possible to start a new add-on update if an add-on update is already running on the system or is in status error.

## 4.2.11.3.2.4 Create Support Users

### Context

You can create a support user to access a consumer tenant.

#### ⓘ Note

Support users can only be created in tenants that are live and are of type "Partner Customer Production Tenant" or type "Partner Customer Test Tenant", i.e. the tenant must have been created through a subscription (see [Tenant Business Types \[page 1292\]](#)). For test tenants created in the Landscape Portal, support users cannot be created.

### Procedure

- Log in to the [Landscape Portal](#) and click the tile [Systems Overview](#) to see an overview of all your systems.
- Select the system that contains the tenant for which you would like to create a support user.
- Navigate to the tenant for which you would like to create a support user.
- Click on the [Request Support User](#) button in the upper right corner of the page.
- (Optional) Check the [Requests](#) tab in your system to track the execution status of your action ("New support user").
- Afterwards, you can log on to the Fiori Launchpad of the tenant via the link in the tenants overview. Note that you need to subscribe to Web Access for ABAP in order to gain access, see [Subscribing to the Web Access for ABAP](#).

You can connect to the system via ADT.

- Retrieve the service key for the targeted ABAP System:
  - Navigate to the provider accounts' service instances.
  - Select the ABAP service instance.
  - Open and copy the SAP\_ASP service key.

2. Retrieve the tenant GUID of the targeted ABAP tenant:
  1. Sign in to the [Landscape Portal](#).
  2. Copy the link of the client column of the target tenant.
  3. Extract the tenant GUID from the URL.
3. Create a tenant-specific service key
  1. Replace the GUID in the url field of the service key from step 1.c with the tenant GUID.
4. Use the created service key to login to the target system using an ABAP Cloud Project in ABAP Development Tools.

## 4.2.11.3.2.5 Create Support Tickets

### Context

In the [Landscape Portal](#), you can create a support ticket containing meaningful collected context information via SAP One Support Launchpad.

### Procedure

1. Log in to the [Landscape Portal](#) and click the tile [Systems Overview](#).
2. Click on a system and navigate to the [Requests](#) tab.
3. Click on the request for which you want to create a ticket.
4. Click the [Create Ticket](#) button on the top right. The context information will be collected for the request.
5. Copy the context for the ticket. Open the displayed link and paste the context into the description field (select the icon for "Paste as Text", then press Ctrl+V).
6. Fill in the remaining information and submit your ticket.

### Results

Your support ticket has been created under component BC-CP-ABA.

## 4.2.11.3.3 Maintain Namespaces

With the [Maintain Namespaces](#) app, you can now both create new namespaces and install the namespaces in your ABAP system.

When you provision a new system or when you upgrade it, all your namespaces are automatically installed in that system as well. However, you might have created a new namespace after the system has been provisioned and you need it installed in your system before the next system upgrade. This is where the [Maintain Namespaces](#) app comes in.

The [Maintain Namespaces](#) app enables you, as a provider, to:

- create new namespaces
- see which namespaces are installed in which of your systems
- install new namespaces in already provisioned systems.

## Prerequisites

You need to have the “LandscapePortalAdmin” user role assigned to your user account to access this app.

## Request Namespaces

1. Log into the `Landscape Portal`.
2. In the `Systems` section, click on the [Maintain Namespaces](#) tile to open the app.
3. The `Namespaces` tab shows you the list of your provider namespaces and their description checked against all existing SAP provider namespaces.
4. To create a new namespace, click the [Request Namespace](#) button.
  - Type in a namespace name as well as a description according to the listed set of rules. Since the namespace is supposed to be globally unique, the check is made against all namespaces available.
  - For the mandatory field `User ID`, the following checks are carried out in the background:
    - The user ID namespace needs to inherit authority.
    - The user ID needs to belong to the customer or the conglomerate.
    - The namespace requested fulfills all requirements of a valid namespace.
    - The namespace needs to be available.
  - If the check has been successful and you confirmed that you read the notice regarding namespaces, click the [Request Namespace](#) button.
  - Find the newly created namespace displayed in the list.

## Maintain Namespaces

1. Log into the `Landscape Portal` from your provider subaccount.
2. In the `Systems` section, click on the [Maintain Namespaces](#) tile to open the app.
3. A list of all your systems, including their system number, system ID, description and instance name, is displayed. Select a system to view more details.
4. You can now see more detailed information on the system as well as a list of all your namespaces and whether they are installed in this system (highlighted in green) or not (highlighted in orange).

5. Click the [Install Namespaces](#) button in the top right corner to install all your namespaces in this system. Note that the [Install Namespaces](#) button is only visible if the following is the case:
  - There are one or more customer namespaces that have not already been installed in the system.
  - The system in which you want to install namespaces is in lifecycle status [Live](#).

#### Note

All new namespaces will be installed in the system. It's not possible to select only a specific namespace to be installed.

## 4.2.11.3.4 Register Systems for Pre-Upgrade

You have an upgrade planned for your systems. The [Register Systems for Pre-Upgrade](#) app allows you to select specific test- or development systems for an early upgrade: These systems will be upgraded two weeks before the official roll-out, giving you ample time to test your solution prior to the actual upgrade.

### Prerequisites

You need to have the "LandscapePortalAdmin" user role assigned to your user account to access this app.

### Working in the Register Systems for Pre-Upgrade app

1. Log into the Landscape Portal.
2. Under [Systems](#), click on the [Register Systems for Pre-Upgrade](#) tile to open the app.
3. Select the system that you want to register for a pre-upgrade.
4. Click the [Register System](#) button.

#### Note

The button is only active if the current date is within the registration period.

5. Refresh the page by clicking on the [Refresh](#) button. The status of your system has changed from "Not registered for pre-upgrade" to "Registered for pre-upgrade".
6. If you change your mind and want to undo the registration of a system for pre-upgrade, simply select the system and click the [Un-Register System](#) button.

#### Caution

Make sure not to register your Add-on Build systems for pre-upgrade because product versions assembled on them cannot be installed into other systems until the target systems were updated as well. For production systems, this would be the regular update weeks later.

For more information, see [Pre-Upgrade Option for Release 2402](#) .

## 4.2.11.3.5 Manage System Hibernation

As a provider, you might not always need all your systems to be live at all times. Deleting a system, however, is only an option if the data within the systems database is not needed anymore. But what if you want to temporarily stop a currently unused system?

The *Manage System Hibernation* app allows you to put systems into hibernation (i.e. “stop” them), and (re-)start them without deletion of the systems data. You can stop systems immediately or schedule a planned stop for a specific time. You can also schedule regularly recurring stops for a system, e.g. on a weekly or monthly basis. This might be useful for example in the following situations:

- to stop development systems outside of working hours or during the weekend
- to stop correction systems outside of correction activities
- to stop test systems outside of test activities
- to stop a custom code analysis system when the analysis is finished
- to stop production systems before go-live.

In case you have a consumption-based contract, stopping a system allows you to reduce resource usage and thus operating costs. For more information, see [Blog Post: SAP BTP ABAP Environment – Manage System Hibernation](#).

### Note

As a provider, you can still trigger lifecycle events for stopped systems. Stopped systems will automatically be (re-)started for lifecycle events (e.g. product version updates, SAP upgrades). Once the event is complete, the system will automatically be stopped again.

## Key Features

You can use the *Manage System Hibernation* app to:

- Put a system into hibernation (i.e. „stop” it).
- Bring a stopped system back into live status (i.e. “start” it again).
- Schedule a stop and a start at specific times, choosing when a system will be stopped and when it will be started again.
- Schedule regularly recurring stops and starts for a system, e.g. on a weekly or monthly basis.
- See which systems are currently live and which ones are stopped.
- View past and current stops in a calendar.

### Note

Planned stops that were scheduled beforehand (see [Schedule a \(Recurring\) Stop/Start \[page 1313\]](#)) are not displayed in the calendar.

### 📘 Note

Note that systems based on the deprecated service plan [16\\_abap\\_64\\_db](#) need to be migrated to the service plan [standard](#) in order to use the app. For more information on how to do this, see [SAP BTP ABAP Environment – Migration of Service Plan 16\\_abap\\_64\\_db](#).

## 4.2.11.3.5.1 Stop a System

You want to put a system into hibernation immediately. This will cause the system to shut down all connection, remove the application servers and halt the database. Users that are currently logged in will have their sessions be closed.

Here's how it's done.

1. Log into the [Landscape Portal](#).
2. In the [Systems](#) section, click on the [Manage System Hibernation](#) tile to open the app.
3. On the left side, under [Systems](#), you can see a list of all your systems, as well as their current status ([Live](#) or [Stopped](#)). [Live](#) systems are currently active, [Stopped](#) systems are in hibernation. You can also see if a system is currently in the process of [Stopping](#) or [Starting](#).
4. Select one or more systems with status [Live](#) that you want to put into hibernation, then click the [Stop](#) button at the top.

### 📘 Note

The button will only be enabled if all selected systems can be stopped.

5. A pop-up window will open, asking you to confirm your choice. Confirm your choice by clicking [OK](#).

The selected system(s) will now be put into hibernation.

### 📘 Note

Note that it might take a few minutes for the system to stop.

Note that a stopped system doesn't process any regular or event-driven business tasks. The system must explicitly be started again to process these tasks.

## 4.2.11.3.5.2 Start a System

You want to bring a system out of hibernation and start it again.

Here's how it's done.

1. Log into the [Landscape Portal](#).
2. In the [Systems](#) section, click on the [Manage System Hibernation](#) tile to open the app.
3. On the left side, under [Systems](#), you can see a list of all your systems, as well as their current status ([Live](#) or [Stopped](#)). [Live](#) systems are currently active, [Stopped](#) systems are in hibernation. You can also see if a system is currently in the process of [Stopping](#) or [Starting](#).

4. Select one or more systems with status *Stopped* that you want to bring out of hibernation, then click the *Start* button at the top.

#### Note

The button will only be enabled if all selected systems can be started.

5. A pop-up window will open, asking you to confirm your choice. Confirm your choice by clicking *OK*.  
The selected system(s) will now start again.

#### Note

Note that it might take a few minutes for the system to be live again.

## 4.2.11.3.5.3 Schedule a (Recurring) Stop/Start

You want to put a system into hibernation at a specific time, choosing at what time it will be stopped, and when it will be started again. This planned hibernation can be scheduled to happen once, or it can be set up to recur regularly, e.g. on a daily or weekly basis. Here's how to schedule a planned or recurring stop (= recurrence).

#### Note

Note that it is not possible to schedule recurrences for free-tier systems.

1. Log into the *Landscape Portal*.
2. In the *Systems* section, click on the *Manage System Hibernation* tile to open the app.
3. On the left side, under *Systems*, you can see a list of all your systems, as well as their current status (*Live* or *Stopped*). *Live* systems are currently active, *Stopped* systems are in hibernation. Select one or more systems for which you want to schedule a planned stop, then click *Schedule Stop/Start* at the top.
4. Fill in the information in the pop-up window, then click *Save*.
5. Your scheduled stop will be added under *Scheduled Stops/Starts*. Click the arrow on the left to expand the panel and view more information on it.
6. (Optional) You can delete a planned stop by clicking the respective icon to the right of it. This can be done as soon as the planned stop is active (a few minutes after its creation).

### Example 1

Let's say you want a system to only be live from 6:00 to 20:00 on Mondays through Fridays. It should be stopped outside of working hours as well as on the weekends.

Here's how you can set up this scenario in the app:

Create two recurrences. Recurrence 1 stops the system on weekdays over night (from 20:00 to 6:00). Recurrence 2 stops the system on the weekends (from Friday night 20:00 until Monday morning 06:00).

Settings for Recurrence 1:

**Schedule Stop/Start**

Title: \*

System:

Time Zone:

From: \*  today (weekday)  stop is triggered at 20:00

To: \*  the following day  start is triggered at 06:00

Recur Every: \*

Day(s)

Week(s)

On: \*

End Recurrence:  on date

after a specific number of recurrences

never

end date (e.g. end of year)

Starting today, the system will stop over night from Mondays to Fridays until the end of the year. Now let's set the recurrence for the weekend stops.

Settings for Recurrence 2:

**Schedule Stop/Start**

Title: \* Weekend Stop

System: SAS (000347246)

Time Zone: UTC+02

From: \* 2023-08-18 upcoming Friday 20:00 stop is triggered at 20:00 on Friday

To: \* 2023-08-21 following Monday 06:00 start is triggered at 6:00 on Monday

Recur Every: \* 1

Day(s)

Week(s)

On: \* Friday

End Recurrence:  on date

after a specific number of recurrences

never

2023-12-31 end date (e.g. end of year)

Save Cancel

With this recurrence, the system will stop every Friday night until Monday morning.

The two recurrences (R1: daily overnight stop in yellow; R2: weekend stop in blue) will make sure your system is only live from Mondays through Fridays from 06:00 to 20:00.

	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
06:00	Start (R2)	Start (R1)	Start (R1)	Start (R1)	Start (R1)		
	system is live Mondays - Fridays from 06:00 - 20:00					R1 = daily overnight stop R2 = weekend stop	
20:00	Stop (R1)	Stop (R1)	Stop (R1)	Stop (R1)	Stop (R2)		

**Note**

Note that the end time you select (06:00 in our example) specifies when the system (re)start will be triggered. It might take a few minutes for the system to be available again.

## Example 2

Keep in mind that the date you specify in the *From* field is the start date of your scheduled recurrence but not necessarily the start of your stop event: If you schedule a stop/start that recurs on a weekly basis, the day of the week you specify in the *On* field determines the start date of your system stop.

Let's look at an example.

If you enter the following settings, the system stop will not be triggered on August 22nd (a Tuesday) , but on the first Friday after this date (August 25th) and every following Friday. The stop will be triggered on Fridays at 14:00 and the start will be triggered two hours later, at 16:00.

**Schedule Stop/Start**

Title: \*

System: SAS (000347246)

Time Zone: UTC+02

From: \* 2023-08-22 Tuesday 14:00 stop event: 2 hours

To: \* 2023-08-22 16:00

Recur Every: \* 1

Day(s)

Week(s)

On: \* Friday stop event will take place every Friday

End Recurrence:  on date

after a specific number of recurrences

never

### 4.2.11.3.6 Restore Consumer Tenants

*Partner Customer Production* tenants and *Partner Customer Test* tenants in status *Torn Down* (i.e. they are currently being deleted) can be restored while they are still in retention time. You, as a provider, can restore these tenants in the *Landscape Portal*.

## Context

When a consumer unsubscribes from a provider's SaaS production or test solution, a tenant decommissioning process will take place taking a grace period of 30 days into account (see [Dismantle \[page 1290\]](#)). During the grace period, the tenant is in what is referred to as retention time and can no longer be accessed by you as the

provider, nor by your consumer. If the consumer decides to re-subscribe to the SaaS solution during this time, or if the consumer requests important data before the tenant will be deleted, you, as a provider, can trigger the tenant recovery directly in the [Landscape Portal](#).

#### ⓘ Note

Tenant recovery is only possible for tenants which were created via consumer subscription. Tenants which can be created and deleted directly in the [Landscape Portal](#) for test purposes can't be restored.

If a consumer provisions a tenant but doesn't complete the onboarding process by signing in as initial administrator, then the tenant can't be restored after it has been deleted.

## Procedure

1. Check the BTP Cockpit to make sure that the concerned consumer is unsubscribed from the SaaS solution in their subaccount.
2. Sign in to the [Landscape Portal](#) and click on the tile [Restore Consumer Tenant](#) to see a list of tenants that are currently in retention time.
3. Select the tenant you would like to restore for the consumer and click [Restore](#). Confirm your selection with [OK](#).
4. **(Optional)** You can track the status of the tenant restore process in the request log.
5. Once the tenant has been restored, the consumer can (re)subscribe to the SaaS solution from their subaccount. The restored tenant will be immediately accessible for the consumer and can be used again.

### 4.2.11.3.7 Manage Test Tenants

As a provider, you might want to test your solution on a test tenant. While you could create a new subaccount and provision a new tenant for yourself for test purposes, the [Landscape Portal](#) offers a much simpler and faster way for you to create a test tenant.

With the [Manage Test Tenant](#) app, you can easily create or delete test tenants, and view their status history.

#### ⓘ Note

The business type of the test tenant depends on the system type. In a development system, a tenant of type "Partner Test Tenant" is created. In non-development systems, a tenant of type "Test Tenant" is created. Unlike consumer tenants, created via subscription, test tenants can be created in any type of system. For more information, see [Tenant Business Types \[page 1292\]](#).

## Creating / Deleting a Test Tenant:

1. Sign in to the [Landscape Portal](#) and click on the [Manage Test Tenant](#) tile to open the app.

2. In the *Available Systems* list, select a system. The *Available Tenants* list on the right will now display all tenants in this system. Use the filter in the top right-hand corner to view all tenants or only test tenants.
3. a) *To delete a test tenant*: select it, and click the *Delete* button. Note that only test tenants can be deleted in the app. Keep in mind that there is no retention time: once the test tenant is deleted, it cannot be restored.  
b) *To create a new test tenant*: click the *Create Tenant* button. Enter the email address for the initial tenant admin. This is the user who will be the first to sign into the test tenant. Use a provider's email address that is contained in the provider IDP. Click *OK*. A request to create the tenant is now scheduled. Once the tenant has been created, a request to provision the initial tenant admin will be triggered automatically.
4. Track the progress of your action in the status list below.

## Accessing a Test Tenant

You can log on to the Fiori Launchpad of the tenant via the link in the *Available Tenants* list. Note that you need to subscribe to Web Access for ABAP in order to gain access, see [Subscribing to the Web Access for ABAP \[page 168\]](#).

1. Once the test tenant and the initial tenant admin have been provisioned, the test tenant is added to the list of *Available Tenants* with *Lifecycle Status "Live"*. You can now click on the tenant's client number to open the test tenant.
2. Use the initial tenant admin's credentials to sign into the test tenant for the first time.

### Note

Note that you cannot access a test tenant via ADT with a support user.

## 4.2.11.3.8 Register Product

The *Register Product* app provides information about which global accounts are already registered for an available product and enables you, as a provider, to:

- create new products
- register your global accounts for your existing products.

## Prerequisites

You need to have the "LandscapePortalAdmin" user role assigned to your user account to access this app.

## Creating a product in the Register Product app

1. Log into the *Landscape Portal*.

2. In the *Product* section, click on the *Register Product* tile to open the app.
3. A list of all your products, including their product ID, namespace and registration status, is displayed. The registration status indicates whether a product has already been registered to the global account you are currently logged in to.  
Possible registration statuses:
  - Current global account already registered. (green indicator)
  - Current global account can be registered. (orange indicator)
  - Pending... (orange indicator)
  - Registration not triggered (orange indicator)
  - Error (red indicator)
4. Click the *Create* button in the top right corner.
5. Enter the name of the product you want to create and confirm with *Create*. Your request for creation has been sent and the registration status of the product changes to "Pending...". The namespace is automatically determined from the product name you entered, and the product ID is generated as part of the creation process.
6. Refresh the page to view the progress. Once the creation is complete, the registration status of the product changes to "Current global account can be registered". Your product has now been created and you can register your global account for it.

#### Note

If the registration status changes to "Error" or "Registration not triggered", or if it remains in status "Pending..." over a longer period of time, please restart the creation process using the same product name. The process will start again; namespace and product ID will stay the same. Should the error remain, please open a ticket.

## Registering a global account for a product using the Register Product app

1. In the *Register Product* app, select the product that you want to register your global account for.
2. Under *Global Accounts*, you can see a list of all your global accounts. The global account that you are currently logged in to will be displayed at the top of the list. Different colored bars indicate which global accounts are already registered for the product (green), are not yet registered for the product (red), or can now be registered for the product (orange). It is only possible to register the global account that you are currently logged in to.
3. To register the global account you are currently logged in to, click the *Register* button in the top right corner. Once the registration is complete, the registration status changes to "Current global account already registered" (green) and the list of accounts will display who the account was registered by (email address) as well as the date of registration.

### 4.2.11.3.9 Build Product Version

You can use the *Build Product Version* app to easily trigger the build of new product versions via pipelines based on templates that you can configure for different use cases such as new (test) release deliveries, (test) support packages or (test) hotfixes/patch deliveries.

The app guides you through the creation of runs for your product versions and provisions an integration test system.

Since technical users are needed in various steps, the app can also be used to add and maintain credentials that can be reused in multiple products, see [Maintain Credentials \[page 1321\]](#).

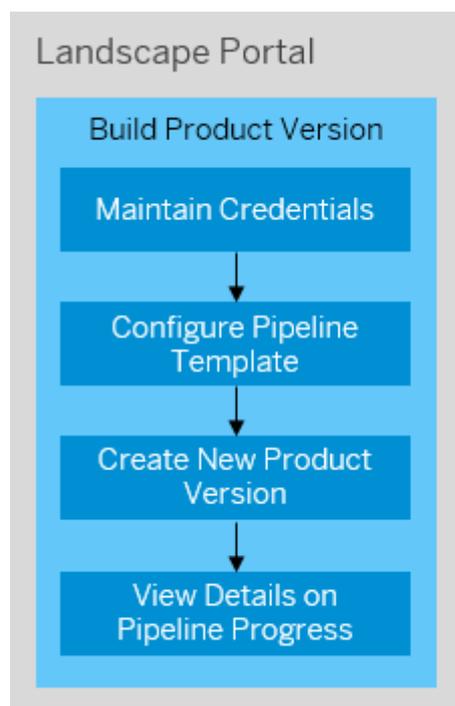

Previously, the scenario was described in project "Piper", see [Build and Publish Add-On Products on SAP BTP, ABAP Environment](#). 🐼 We recommend using the *Build Product Version* app that enables the 'Build Add-On Products' scenario for you without the need to set up a Jenkins server.

## Key Features

You can use the *Build Product Version* app to:

- Choose prepared pipeline templates depending on your use case and configure them to create different types of pipelines for your product versions:
  - Release Deliveries / Test Release Deliveries
  - Support Package Stacks / Test Support Package Stacks
  - Patch Deliveries / Test Patch Deliveries
- View details on a product version's pipeline progress
- Maintain credentials for users that can be reused for different products

The standard user flow is described in the following diagram. Hover over the different steps to display additional information.

- [Maintain Credentials \[page 1321\]](#)
- [Configure a Pipeline Template \[page 1322\]](#)
- [Create a New Product Version \[page 1328\]](#)
- [View Details on a Product Version's Pipeline Progress \[page 1329\]](#)

## Prerequisites

- Users need to have the "LandscapePortalAdmin" user role assigned to their user account to access this app.
- Users need an active subscription for the SAP Continuous Integration and Delivery service in the BTP subaccount of the Landscape Portal subscription to be able to use the *Build Product Version* app. If this subscription is not maintained, the following error will occur: 'No subscription to CI/CD service found for this subaccount. Please see the note below for more information on how to add the CI/CD service as entitlement and how to subscribe to it.

### Note

Follow these steps to add the CI/CD service as entitlement and to subscribe to it.

#### Adding the CI/CD Service as Entitlement

1. Sign into your account in the *SAP BTP Cockpit*.
2. On global account level, navigate to *Entity Assignments* in the Entitlements menu tree.
3. Open the value help for *Select Entities* and choose the subaccount to which the *Continuous Integration & Delivery app/application* entitlement shall be added. Click *Select*.
4. Click the button *Configure Entitlements* and then *Add Service Plans*.
5. Select *Continuous Integration & Delivery* from the list and choose the service plan *default (Application)*, then click *Add 1 Service Plan*.
6. Click *Save* to add the service plan to your selected subaccount.

#### Subscribing to the CI/CD Service in the SAP BTP Cockpit

1. Sign into your account in the *SAP BTP Cockpit*.
2. Select your global account, then navigate to *Subaccounts* and select your production subaccount.
3. Navigate to *Service Marketplace*.
4. Select *Continuous Integration & Delivery* tile.
5. Click *Create*.
6. Select the plan *default (Subscription)* and click the *Create* button.  
The subscription process might take a few minutes. After the CI/CD service is subscribed, you can use the *Build Product Version* app from this subaccount.

## 4.2.11.3.9.1 Maintain Credentials

You can use the *Build Product Version* app to add and edit credentials that are used in various stages of the build process. These credentials can be reused for different products.

1. Log in to the [Landscape Portal](#) and click on the tile [Build Product Version](#).
2. Switch to the tab [Credentials](#).
3. In the [Credentials](#) table, you can view all of your existing credentials. To edit an existing credential, select it and click the [Edit](#) button. To create a new user, click the [Create](#) button and fill in the required information. [Save](#) your changes.
4. (Optional) To delete an existing credential, select it and click the [Delete](#) button.

## 4.2.11.3.9.2 Configure a Pipeline Template

The [Build Product Version](#) app offers templates based on the [ABAP Environment Pipeline](#) that you can configure for the following types of pipelines:

Type	Description
Release Delivery	Release versions of the product usually include new deliveries of software components that are planned and used for new functionalities and feature enhancements. In case of multiple software components, release deliveries may also include new support package- or patch deliveries of software components. Not yet included software components can only be added with a new release delivery version of the product. The template can be executed using a transient build system or to create a new permanent build system which can be reused to create patches or support packages. Additionally, the integration test stage should be performed.
Support Package Stack	Support package stack deliveries of the product usually include new support package deliveries of software components that are planned and used for smaller functional enhancements. Support package deliveries of software components are created based on a delta comparison in regard to the previous support package level in the same release. In case of multiple software components, support package stacks may also include new patch deliveries of software components. The template can be executed using a transient build system or to create a new permanent build system which can be reused to create patches. Additionally, an installation test should be performed.
Patch Delivery	Patch delivery versions of the product should only include new patch deliveries of software components that contain unplanned, urgent and small corrections. Patch deliveries of software components are created based on a delta comparison in regard to the previous patch level on the same support package, in the same release. The template should be executed using a permanent build system and an update test should be performed.

Type	Description
Test Release Delivery	<p>Release versions of the product usually include new deliveries of software components that are planned and used for new functionalities and feature enhancements. <i>Test Release Delivery</i> is part of the continuous testing in the development process. The run performs static code checks and builds the next release delivery locally (no upload to the product framework) to detect findings early that might delay a productive build later on. It should be executed using a permanent build system. Execution of an integration test stage is not possible as no package is uploaded to the product framework.</p> <p>The generated product versions in the test run are not released, thus the versioning of the build runs can be reused for multiple runs, hence reducing the consumption of product version numbers.</p>
Test Support Package Stack	<p>Support package stack deliveries of the product usually include new support package deliveries of software components that are planned and used for smaller functional enhancements. <i>Test Support Package</i> is part of the continuous testing in the development branch. The run performs static code checks and builds the next support package locally (no upload to the product framework) to detect findings early that might delay a productive build. It should be executed using a permanent build or test system dedicated to the development branch. An add-on update test is not possible as no package is uploaded to the product framework.</p> <p>The generated product versions in the test run mode are not released, thus the versioning of the build runs can be reused for multiple runs, hence reducing the consumption of product version numbers.</p>
Test Patch Delivery	<p>Patch delivery versions of the product should only include new patch deliveries of software components that contain unplanned, urgent and small corrections. <i>Test Patch Delivery</i> is part of the continuous testing in the development branch. The run performs static code checks and builds the next patch delivery locally (no upload to the product framework) to detect findings early that might delay a productive build. It should be executed using a permanent build or test system dedicated to the development branch. An add-on update test is not possible as no package is uploaded to the product framework.</p> <p>The generated product versions in the test run mode are not released, thus the versioning of the build runs can be reused for multiple runs, hence reducing the consumption of product version numbers.</p>

These different pipeline templates need to be configured for each of your products. For each template you add information on the credentials that should be used, the clone strategy, software components, tests, and more. Once you've configured the templates for a product, you can easily trigger the build of new versions (be it release deliveries, support package stacks or patch deliveries) of this product based on the information given in the templates. For more information on add-on product/software component versioning, see [The Add-On Product](#). 🗨️

Let's take a closer look at how to configure a pipeline template for a product:

1. Log in to the [Landscape Portal](#) and click on the tile [Build Product Version](#).
2. Select one of your products from the list and navigate to the [Templates](#) tab. The templates table displays whether the templates have already been configured for this product. Select the template type that you would like to configure.  
You will now be guided through a series of steps. Please be aware that fields marked with a red asterisk are mandatory and need to be filled out.

### 3. Prepare System:

In this section you can configure a job that will build your product. A system is prepared for the product version build. Per default, the system will be deprovisioned after a successful build has been completed. You can, however, override this in order to perform checks in that system (check [Keep System](#)).

Group	Field	Explanation	Remarks
Cloud Foundry	API Endpoint	The Cloud Foundry API endpoint specific to the region of the Cloud Foundry Environment where your integration test system is located. See <a href="#">Regions and API Endpoints for the ABAP Environment</a> .	Can be retrieved from Sub-account Overview in BTP Cockpit → Cloud Foundry Environment → API Endpoint
	Credential Name	The credentials for the space developer user to authenticate to the Cloud Foundry API. See <a href="#">Creating New Space Members and Assigning Space Developer Roles to Them</a> .	User needs to be org member and assigned to space with space developer role
	Organization	The Cloud Foundry org used to create the . See <a href="#">Managing Orgs</a> .	Can be retrieved from Sub-account Overview in BTP Cockpit → Cloud Foundry Environment → Org Name
	Space	The Cloud Foundry space used to create the . See <a href="#">Managing Spaces</a> .	

Group	Field	Explanation	Remarks
ABAP Build System	Service Instance Name	The name of the ABAP Service instance for the assembly of the product version. See <a href="#">Creating an ABAP System</a> .  The installation test system is created with service plan <code>abap/standard</code> .	The service instance name can be used to identify systems in the Systems Overview application
	System ID	The three-character name of the ABAP Build System. This maps to <code>sap_system_name</code> service instance parameter.	The system ID can be used to identify systems in Systems Overview application
	System Admin E-Mail	The email-address for the initial administrator in the ABAP Build System. This administrator can be used to access the system in case of errors if the "Keep System" flag has been selected and the system was created from scratch. See <a href="#">Creating an ABAP System</a> .	
	Keep System	Check this box if the system should be kept after the build is complete to allow debugging. Please be aware that the system occurs in costs and you are responsible for deleting the system manually once you have finished.	

Proceed to the next step.

#### 4. Clone Repositories:

Here, you can select the clone strategy ([CheckoutPull](#), [Clone](#), [Pull](#)) for software components that are relevant for the build of the product version. This influences which steps will be executed to import the repositories. For more information, see [Clone Repositories](#) .

Select the desired clone strategy from the drop-down menu and proceed to the next step. If you unsure which strategy to use or don't have a specific requirement, we recommend selecting clone.

#### 5. ATC:

The ABAP Test Cockpit (ATC) can check the software components which will be assembled as part of the product version build. Select whether the ATC stage should be executed and enter the ATC check variant that should be used to check the configured software. Then proceed to the next step.

Without Run ATC Stage enabled, you risk a defective product version being built.

#### Caution

Created delivery packages for an add-on product version are final, so to fix any errors in these packages, another add-on product version would have to be built. ATC findings should be resolved

during development as early as possible, e.g. [during transport release](#) and by using an additional pipeline configured for the [Continuous Testing on SAP BTP, ABAP Environment scenario](#). 

6. **Build:**

Enter the information needed for the build of the product version.

Group	Field	Explanation	Remarks
AAKaaS	Credential Name	The credential name refers to a technical communication user used to access Add-on Assembly Kit as a Service, see <a href="#">2174416</a> 	

Proceed to the next step.

7. **Integration Tests**

In this stage a system is prepared for the product version test installation. The system will be deprovisioned after successful testing has been completed.

 **Caution**

This step is necessary for a secure deployment in production. If you disable the integration tests, you risk defective add-ons being installed onto the production system. The possibility to disable the integration tests might be turned off at a future date without further notice from SAP.

 **Note**

The pipeline step 'Integration Tests' is inactive when you are configuring a test template.

Fill in the information.

Group	Field	Explanation	Remarks
	Run Integration Test Stage	Check this box if the integration test stage should be executed.	The Run Integration Test Stage prevents defective add-ons from being installed in the production system.
Cloud Foundry	API Endpoint	The Cloud foundry API endpoint specific to the region of Cloud Foundry Environment to be used. See <a href="#">Regions and API Endpoints for the ABAP Environment</a> .	Can be retrieved from Sub-account Overview in BTP Cockpit → Cloud Foundry Environment → API Endpoint

Group	Field	Explanation	Remarks
	Credential Name	The credentials for the space developer user to authenticate to the Cloud Foundry API. See <a href="#">Creating New Space Members and Assigning Space Developer Roles to Them</a> .	User needs to be org member and assigned to space with space developer role
	Organization	The Cloud Foundry org used to create the integration test system. See <a href="#">Managing Orgs</a> .	Can be retrieved from Sub-account Overview in BTP Cockpit → Cloud Foundry Environment → Org Name
	Space	The Cloud Foundry space used to create the integration test system. See <a href="#">Managing Spaces</a> .	
	Service Instance Name	The name of the ABAP Service instance for the installation test of the product version. See <a href="#">Creating an ABAP System</a> .  The installation test system is created with service plan <code>abap/saas_oem</code> .	The service instance name can be used to identify systems in Systems Overview application
Installation Test System	System ID	The three-character name of the integration system. This maps to <code>sap_system_name</code> service instance parameter.	The system ID can be used to identify systems in Systems Overview application
	System Admin E-Mail	The email-address for the initial administrator of the integration test system. This user can be used to access the system for error analysis purposes. See <a href="#">Creating an ABAP System</a> .	
	Keep System	Check this box if the system should be kept after the build is complete to allow debugging. Please be aware that the system occurs in costs and you are responsible for deleting the system manually once you have finished.	

Click on *Finish* to complete the template configuration.

## 4.2.11.3.9.3 Create a New Product Version

The *Build Product Version* app lets you create new product versions from scratch in case of new releases or based on parent ones if you are creating a patch delivery or support package stack.

### Note

You need to have configured the templates for a product to create new product versions using this app. See [Configure a Pipeline Template \[page 1322\]](#).

Find out how to create a new product version:

1. Log in to the *Landscape Portal* and click on the tile *Build Product Version*.
2. Select one of your products from the list. You will be forwarded to the *Product Versions* tab. Here, you can see a table listing all the existing versions of this product, their type (see a table overview of the types [here](#), or read more about [The Add-On Product](#) ), when they were created, as well as their delivery status:
  - **Not ready:** The product version is currently being built and is not available for test or production use yet.
  - **Ready for test:** The product version has been build but has not yet been released for production use. However, the version may be used for (automated) testing.
  - **Ready for production:** The product version is ready for production use. An ABAP environment production system can now be updated to this product version.
3. To create a new product version, click the *Create* button, choose *Delivery* or *Test* and select the desired type. The resulting product version will be calculated automatically.

### Note

Note that if you begin configuring a new product version but cancel before finishing the process, the new product version will still be displayed in the overview list in status “not yet triggered”. To continue working on it, simply select it from the list.

4. Select software components to be included in your new product version. To add additional software components, click the *Add* button on the right. For each software component, define a component version, enter the desired branch and commit ID as seen in the *Manage Software Components* app, and select in which languages your product version should be built. You can change the order of how the software components are imported via drag and drop in the table or by selecting a component and moving it using the arrows on the right. For more information, see [Manage Software Components](#).

### Note

The leading software component is the software component that is, as opposed to a reuse software component, exclusively used as part of one add-on product. The reuse software component should be the first, whereas a leading software component would be the last in order. This is to make sure that that the software components are imported in the correct order, making sure to adhere to dependencies.

5. Click the *Build Product Version* button to trigger the build of the pipeline for your new product version.
6. (Optional): You can use the *Cancel* button on the lower right to leave the screen. Please be aware that after confirming the cancellation, all changes will be lost.
7. You will be redirected to the Pipeline Status screen, where you can track the progress of your build. See [View Details on a Product Version's Pipeline Progress \[page 1329\]](#).

### ⓘ Note

Product versions can only be deleted if their status is '*In Configuration*' because then the build was not yet started. In this case, the delete button will be enabled once the product version is selected. Please be aware that the deletion cannot be reversed.

### ⓘ Note

The column Log Availability can have the following status:

Log Availability	Definition
Not built in LP	The product version you built did not originate from the Build Product Version app.
Not yet triggered	The configuration for your build has been set in the Build Product Version app.
Wrong Subaccount	The subaccount you want to use is not the one in which the current build has been started.
Log expired	Your product version log expired and is not available anymore.
Unknown	
Build running	There is currently a running build assembling your product version.
Build failed	Your recent build ran into an error and failed.
Build success	Your recent build ran successfully and is finished now.

## 4.2.11.3.9.4 View Details on a Product Version's Pipeline Progress

After you've used the *Build Product Version* app to trigger the build of a pipeline for your new product version, you can also view details on a version's pipeline progress directly in the app.

Here's how this is done:

1. Log in to the Landscape Portal and click on the tile *Build Product Version*.
2. Select one of your products from the list. You will be forwarded to the *Product Versions* tab. Here, you can see a table listing all the existing versions of this product, their type, when they were created, as well as their delivery status (for more information on the delivery status, see [Create a New Product Version \[page 1328\]](#)).
3. Click on the product version for which you would like to see the pipeline progress. You will be redirected to a screen showing the *Pipeline Status* for that product version.
4. You can now click on the different stages in the pipeline to view the logs of each step. The stages that you switched off in the underlying template will not be selectable.

Stage	Description
Init	

Stage	Description
Initial Checks	This stage runs preliminary checks for the Build stage, validating add-on product/software component versions. See <a href="#">Initial Checks</a> . 🖱️
Prepare System	At this stage, the ABAP environment system for Add-On assembly is created (service plan abap/standard). SAP_COM_0510 (SAP BTP, ABAP Environment - Software Component Test Integration) is created via a service key. With the creation of the communication arrangement, a user and password are created on the ABAP environment system for the APIs that are used in the following stages. See <a href="#">Prepare System</a> . 🖱️
Clone Repositories	This stage pulls/clones the specified software components (repositories) to the ABAP environment system that are relevant for the Add-On build. <a href="#">Clone Repositories</a> . 🖱️
ATC	Check software components to be assembled as part of the add-on build via ABAP Test Cockpit. See <a href="#">ATC</a> . 🖱️
Build	This stage is responsible for building the product version for the ABAP environment. The build process of the product version is done in the Add-On assembly system, with the help of the SAP Add-On Assembly Kit as a Service (AAKaaS). After this stage has been executed successfully, the product version is ready to be tested. See <a href="#">Build</a> . 🖱️
Integration Tests	This stage creates an ABAP environment system (service plan abap/saas_oem) and installs the add-on product, that was built in the Build stage. See <a href="#">Integration Tests</a> . 🖱️
Publish	At this stage, the new product version for the ABAP environment is published. After publishing the new product version it becomes available for add-on installation/update. See <a href="#">Publish</a> . 🖱️

If a stage has successfully been completed, its icon will be blue; in case of errors it will be red. All stages that are still due are shown in grey and the stages that have been switched off in the template cannot be selected at all.

If the pipeline is still running, you can update the view using the [Refresh](#) button in the upper right corner.

#### 📌 Note

**Important:** The logs will be deleted after 28 days. Up to 99 builds can be saved within this period. In case of further builds, the oldest ones will be deleted.

## 4.2.11.3.10 Check Product Version

The [Check Product Version](#) app lets you view the results of product version delivery infrastructure checks to see if your product version is ready for delivery. The app shows results for checks of the product version, its components and respective packages.

## Prerequisites

You need to have the “LandscapePortalAdmin” user role assigned to your user account to access this app.

## Working in the Check Product Version app

1. Log into the [Landscape Portal](#).
2. In the [Product](#) section, click on the [Check Product Version](#) tile to open the app.
3. A list of all your products is displayed. Select one of the products from the list.
4. You can now see general details on the product (product name, namespace) as well as a list of all its product versions and their current delivery status:
  - G (Not ready): The product version is currently being built and is not available for test or production use yet.
  - T (Ready for test): The product version has been build but has not yet been released for production use. However, the version may be used for (automated) testing.
  - P (Ready for production): The product version is ready for production use. An ABAP environment production system can now be updated to this product version.
5. Select a version to see more detailed information on the check results:
  - **Delivery Requirements:** During the build process and depending on the integrated software components and involved objects in the dedicated product version, calculations are automatically made and mark whether the delivery of a product version can be done online or requires a downtime.
  - **Components:** View whether a system downtime is required when your software components are imported. This information is calculated automatically by the infrastructure. Click one of the components to view its attributes (package, delivery status, branch, commit ID) and its import conditions. The import conditions describe which components and packages must be installed into the system as a prerequisite to install the particular software component version. They are calculated automatically during the build of a product version based on the software in the build system. The following conditions exist:
    - Installed: The package/component needs to be installed in this exact version.
    - At least: The package/component needs to be installed in this version or a newer version.
    - Not installed: This version of the package/component must not be installed.All of the import conditions mentioned need to be fulfilled.
  - **Checks:** View whether the delivery check for the product version was successful.
  - **Object Lists:** View a complete list of all objects.
6. If the checks were successful and your product version is ready for delivery (i.e. has the delivery status P), you can click the [Schedule Update](#) button in the top right corner to navigate to the [Update Product Version](#) app.

## 4.2.11.3.11 Deploy Product

As a provider, you can use the [Deploy Product](#) app to update the version of your product on specific systems.

## Prerequisites

You need to have the "LandscapePortalAdmin" user role assigned to your user account to access this app.

## Working in the Deploy Product App

1. Sign in to the *Landscape Portal*.
2. Scroll down to *Product Lifecycle Management* and click on the *Deploy Product* tile to open the app.
3. On the right side of the screen, you can find the *Planning Calendar*.

The planning calendar gives an overview of planned and unplanned downtimes of service-relevant infrastructure as well as already scheduled product version updates.

Calendar legend:

You can use the calendar to help you find a fitting time slot for your product version update so as to make sure that it doesn't conflict with other downtimes.

4. On the left side, under *Product and Product Version Selection*, select which product and version you want to update from the drop-down menu.

### Note

The product version can only be updated to a higher version. It is not possible to update the product version to a lower version.

5. In the *Available Systems* section, select at least one system in which you want to update the product version. You can also select multiple systems at once. For each selected system, the app automatically calculates whether the delivery of a product version can be done online or whether it requires a downtime.

### Note

Whether or not downtime is required will only be displayed once you select a product and version from the drop-down menu.

6. Click the *Update* button. A dialog box will open. Fill in the remaining details:
  - **Title:** Choose a title for your update.
  - **From:** Select the time the update can begin.
  - **To:** The estimated time at which the product version update will be completed. The information you enter here will be added to the planning calendar. After the product version update has been successfully completed, the 'To' value will be automatically updated according to the actual duration of the update.

Confirm with *Schedule*.

7. Check the list under *Product Version Update Status*. Here, all update requests as well as their current status and progress are displayed. The update you just scheduled has been added to the list.
  - As long as an update is in status "scheduled" or "error", you can still cancel it using the rollback request icon.

- If the update process is stuck with an error, you can cancel it using the rollback request icon. In this case, the process is technically aborted and an automatic cleanup is performed to execute a revoke or a rollback behind the scenes.
- Only in case a SPAM import error has occurred, you can choose the then appearing icon [Show errorlog](#) on the right side. This will open a window with an error log. Here, error messages are listed and can further be inspected by a click as well.

### Note

The product version update status list is refreshed automatically every 30 seconds. The planning calendar as well as the systems list can be refreshed manually by clicking the reload button.

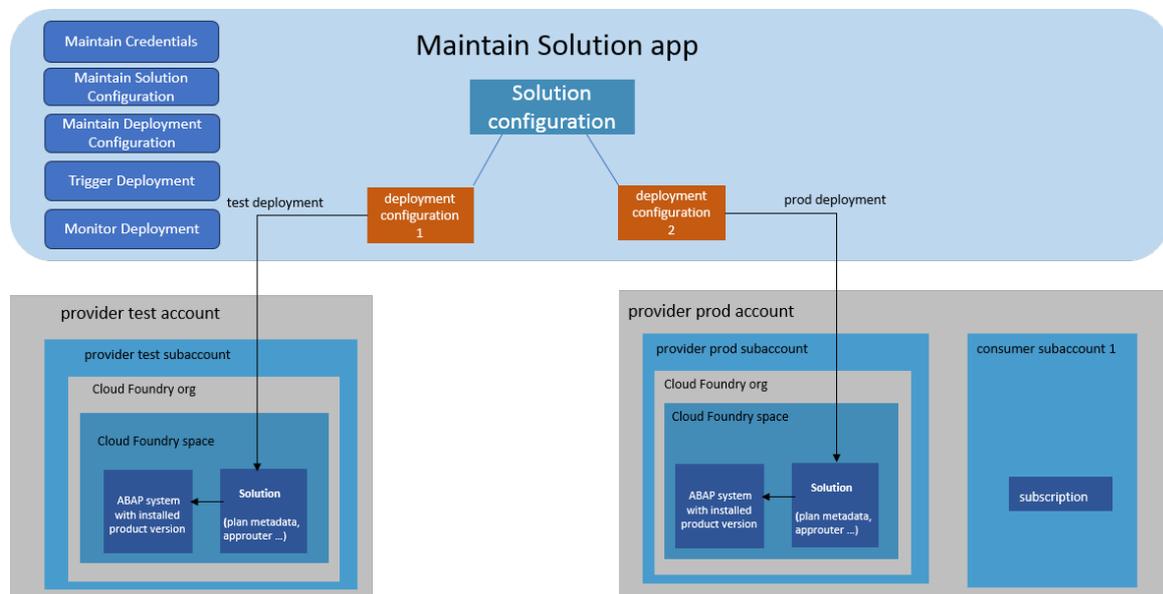

## 4.2.11.3.12 Maintain Solution

The purpose of the Maintain Solution app is to comfortably guide you, as provider, through the SaaS solution configuration process, and to enable you to trigger and monitor the deployment of your SaaS solution.

At the end of this process, your consumers will be able to subscribe to your SaaS solution.

### Note

Specific implementations for the approuter are not supported in the Maintain Solution app. Providers that need such enhancements need to configure and deploy the solution manually. See [Approuter Application \[page 1269\]](#).

## Introduction

Once you have created your product and built a new product version using the [Build Product Version](#) app, you can use the [Maintain Solution](#) app to create and maintain the necessary configuration settings for your SaaS

solution, its deployment and to trigger the deployment of your solution to SAP BTP Cloud Foundry so that your consumers can subscribe to it.

The app supports you in defining what your SaaS solution should technically look like. For this purpose, the app guides you through the creation and configuration of a 'solution plan', which is required for the subscription in SAP BTP Cloud Foundry. A plan contains technical parameters on how the ABAP system containing your solution will be set up.

The app also lets you create different deployment configurations for the same SaaS solution. Since the settings for each subaccount vary, you may also need to create different deployment configurations (e.g. one for a subaccount used for testing, another for the production subaccount).

Once you have defined a deployment configuration, you can trigger your solution deployment and monitor the progress in the app.

The ABAP system with the plan (that you specified when configuring your solution) will be created within the CF space into which you deployed your solution and which is part of the CF organisation (both of which you specified in the deployment configuration) that your provider account belongs to.

When your solution has successfully been deployed, your consumers will be able to subscribe to it.

## Process Description

After creating the credentials necessary to access the provider subaccounts where the solution is to be deployed (see [Maintain Credentials \[page 1335\]](#)), you use the step-by-step guide to create a new solution (step 1), configure a solution plan (step 2), and specify some advanced settings (step 3) (see [Create Solution \[page 1335\]](#)). Then, you create a deployment configuration using another step-by-step guide (see [Create Deployment Configuration \[page 1337\]](#)). Afterwards, you can deploy your solution with the respective deployment configuration (see [Deploy Solution \[page 1339\]](#)). You can then monitor the progress of the deployment in the app (see [Monitor Deployment \[page 1339\]](#)).

- [Maintain Credentials \[page 1335\]](#)
- [Create Solution \[page 1335\]](#)
- [Create Deployment Configuration \[page 1337\]](#)
- [Deploy Solution \[page 1339\]](#)
- [Monitor Deployment \[page 1339\]](#)

## Prerequisites

- You have created a space in your provider subaccount. This is the space that your solution will be deployed to.

- You have created a technical user (email address) that has the Space Developer role assigned to it. This technical user needs to be available in SAP ID provider. This user will be used for the deployment.

### 4.2.11.3.12.1 Maintain Credentials

Before you configure and deploy your SaaS solution, you need to maintain the necessary credentials for the user that will be used in the deployment. You have already created a technical user that is available in SAP ID service, and have assigned it the Space Developer role in the Cloud Foundry space that you want to deploy your SaaS solution to. Now you need to add this user in the *Maintain Solution* app.

1. Log in to the *Landscape Portal*.
2. Under *Solution*, click on the *Maintain Solution* tile to open the app.
3. Switch to the tab *Credentials*.
4. In the *Credentials* table, you can view all of your existing credentials. To edit an existing credential, select it and click the *Edit* button. To create a new user, click the *Create* button and fill in the required information. *Save* your changes.
5. (Optional) To delete an existing credential, select it and click the *Delete* button.

Now that you've added your technical user, you are ready to create your solution, see [Create Solution \[page 1335\]](#).

### 4.2.11.3.12.2 Create Solution

You want to prepare a new solution for delivery to your consumers. Since a solution can be deployed to more than one subaccount, the creation of the solution has been separated from the creation of its deployment configurations (see [Create Deployment Configuration \[page 1337\]](#)).

Here's how to create a new solution.

1. Log in to the *Landscape Portal*.
2. Under *Solution*, click on the *Maintain Solution* tile to open the app.
3. In the *Solutions* tab, click the *Create* button. You are now guided through the process of setting all necessary parameter values. Please fill in the data.

There are three steps to this process:

#### *Step 1: General Settings*

This step covers the visual representation of your solution. Title and description will be visible to your consumers on the corresponding tile in SAP BTP Service Marketplace. The ID uniquely identifies your solution.

#### **Note**

Note that the ID cannot be changed once the solution has been saved.

#### *Step 2: Solution Plan*

Here, you specify the technical parameters on how the ABAP system containing your solution will be set up.

Provider Admin Email	The provider admin email is not only the email address of the initial provider user and owner of the system, but also enables the access to it, functioning as the login email address.
Usage Mode	The usage mode specifies whether you create a test or production solution. It will be passed on to the ABAP system during the creation request.
ABAP System Name	It is mandatory for you as a provider to name your ABAP system. When a value has been supplied, the new system(s) will be created with this parameter. <div data-bbox="826 656 1398 846" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>To avoid using forbidden SIDs, read more about <a href="#">Reserved SAP System Identifiers (SAPSID) with Software Provisioning Manager</a>.</p> </div>
Size of Runtime	The size of runtime describes the default sizing for your solution and is passed on to your ABAP system during the creation request.
Size of Persistence	The size of persistence describes the default amount of resources available for your solution and is passed on to your ABAP system during the creation request.
Consumer Tenant Limit	The consumer tenant limit describes the maximum number of tenants in the multitenant ABAP system. If the consumer tenant limit is exceeded, a new multitenant system will be created. <div data-bbox="826 1249 1398 1469" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>Note: A recently deleted tenant will be counted towards the limit in case it is restored during the grace period. After the 30-day grace period is up, it will no longer be considered for the limit. See <a href="#">Dismantle</a></p> </div>

### Step 3: Advanced Settings

ABAP Timeout (ms)	The ABAP endpoint timeout is a timeout for requests issued by the approuter to the ABAP backend. It consists of a positive integer, stated in milliseconds. If you do not enter a value, the system will use the default value.
Application Log Level	The application log level defines how much detail the approuter writes into the log. Since a longer log is performance-intensive and harder to read, you can choose to only write errors or warning messages for example.

## Enable IFrame Integration

The IFrame integration enables you to incorporate your solution into the Fiori Launchpad Build Work Zone. Keep in mind that enabling the IFrame integration might reduce security. The shell header and the application UI are decoupled from each other, and each can point to a different domain. If the two frames each point to different domains, it can lead to issues with the browser and cookie policies. See [Security Guidelines for Content Providers](#)

4. Click [Save](#) to save your solution.  
You are now forwarded to the objects page of your newly created solution. Now you can continue by creating a deployment configuration, see Step 4 in [Create Deployment Configuration \[page 1337\]](#).

### 4.2.11.3.12.3 Create Deployment Configuration

You have created a solution (see [Create Solution \[page 1335\]](#)). Now you want to create a deployment configuration. Here's how it's done.

1. Log in to the [Landscape Portal](#) from your provider subaccount.
2. Under [Solution](#), click on the [Maintain Solution](#) tile to open the app.
3. Select a solution from the list to go to its object page.
4. At the bottom of the solution object page, you can see the [Deployment Configurations](#) table. Click the Create button on the right. You are now guided through the process of setting all necessary parameter values. Please fill in the necessary data.

There are three steps to this process:

#### [Step 1 General Settings:](#)

ID	The deployment ID references this particular deployment. It will be reflected in the name of the deployed application, as well as in that of provisioned service instances created during SaaS deployment.
Description	(Optional) You can add a description.

#### [Step 2 Target:](#)

Specify where your solution shall be deployed.

Note that a technical user with Space Developer rights in the targeted Cloud Foundry space is required. You should have already created this user in the start page of the app (Credentials tab).

CF API Endpoint	Cloud Foundry endpoint of the landscape the solution should be deployed to. You can find this information in the SAP BTP Cockpit, in your provider subaccount under Overview > General tab> Cloud Foundry Environment section> API Endpoint.
CF Organization Name	Name of the organization your solution gets deployed to. You can find this information in the SAP BTP Cockpit, in your provider subaccount under Overview > General tab> Cloud Foundry Environment section> Org Name.

CF Space Name	Name of the space your solution gets deployed to. You can find this information in the SAP BTP Cockpit, in your provider subaccount under Overview > General tab> Cloud Foundry Environment section> Spaces.
---------------	--

### Step 3: Routing Information

In this step you specify the routing information for your solution. This defines the endpoints that consumers will use to access the solution.

You have the choice between using a *custom domain*, which is owned by yourself, or a *shared domain*, which is provided by SAP and shared by many users. Custom domains are managed using the [SAP Custom Domain](#) service.

Each subscription to your solution will be assigned an endpoint, which will follow one of two patterns.

- When using a custom domain: <subdomain>.<custom domain> | consumer-a.mycompany.com
- When using a shared domain provided by SAP: <subdomain>-<route prefix>.<shared domain> | consumer-a.cfapps.eu10.hana.ondemand.com

Here, <subdomain> is the subdomain of the subscribing subaccount. In order to route these endpoints to your solution, corresponding Cloud Foundry routes must be created and mapped in the subaccount where the solution is deployed. This is done automatically by the Maintain Solution app during deployment. You can always add or modify routes manually using the SAP BTP Cockpit, see [About Routes in the Cockpit](#). Please note that routes have a maximum length of 64 characters.

Setting	Shared Domain Type	Custom Domain Type
Domain Type	Shared	Custom
App Domain	You can select an app domain from the list of the available SAP domains.	You can enter a custom domain that is registered for your company. For example, company.com.
Route Prefix	The route prefix is used to ensure the uniqueness of your routes, as shared domains are used by many customers simultaneously. It needs to be unique and is defaulted to the solution ID.	The route prefix field is disabled. To provide multiple solutions within the same top-level custom domain, you need to define multiple private domains using the SAP Custom Domain service (for example, "sales-solution.mycompany.com" and "tax-solution.mycompany.com").
Use wildcard route	A wildcard route cannot be used with a shared domain. The checkbox is unchecked and set to read-only.	A wildcard route can be used. This route maps all requests towards endpoints of the form "*.mycompany.com" to your solution. In this case, it is not necessary to create a route for each consumer.
Subdomains	At least one subdomain needs to be maintained. A route will be created for each subdomain that is maintained.	If a wildcard route is not used, at least one subdomain needs to be maintained.

5. Click on [Save](#) to complete the process.

You are now ready to deploy your solution. See [Deploy Solution \[page 1339\]](#).

#### Note

[Editing a Deployment Configuration](#)

You want to make changes to an existing deployment configuration? Please keep the following in mind.

- Editing a deployment configuration when a solution has already been successfully deployed: Only the user, description and subdomains can be edited.
- Editing a deployment configuration when a solution is in the process of being deployed: Only the user, description and subdomains can be edited.
- Editing a deployment configuration when a solution was saved but not deployed yet: Only the user, description and subdomains can be edited.
- Editing a deployment configuration when a solution was not successfully deployed because of an error: everything can be edited.

## 4.2.11.3.12.4 Deploy Solution

You've created a solution (see [Create Solution \[page 1335\]](#)) and specified the deployment configurations (see [Create Deployment Configuration \[page 1337\]](#)). Now you're ready to deploy your solution to your provider subaccount. Here's how that's done.

1. Log in to the [Landscape Portal](#).
2. Under [Solution](#), click on the [Maintain Solution](#) tile to open the app.
3. Select a solution from the list to go to its object page.
4. Under [Deployment Configurations](#), select a deployment configuration and click the [Deploy](#) button on the right. The deployment is now triggered and you will be forwarded to the [Deployment Status](#) view.
5. You can monitor the pipeline status for your deployment.

### Note

Note that you can only deploy one solution per space.

## 4.2.11.3.12.5 Monitor Deployment

You've triggered the deployment of a solution with a specific deployment configuration. Now you want to monitor the pipeline status and see whether the deployment was successful.

1. Log in to the [Landscape Portal](#).
2. Under [Solution](#), click on the [Maintain Solution](#) tile to open the app.
3. Select the solution from the list to go to its object page.
4. Under [Deployment Configurations](#), select a deployment configuration to view more details.
5. Scroll to "Deployment History" to see the status of your deployment. Click on an entry to view the logs for this deployment. Click on the icons (Init, Build, Publish) to jump to the respective sections of the log.
  - If an icon is grey: There is no information available.
  - If an icon is yellow: The step is currently in progress.
  - If the icon is red: There is an error. Scan the log to find more information on the error.
  - If the icon is blue: The step was completed successfully.

### ⓘ Note

*Important:* The logs will be deleted after 28 days.

## 4.2.11.3.12.6 Download File Containing Configurations

In the case that you have extended your approuter with additional logic, you cannot use the Maintain Solution app to deploy your SaaS solution directly, since specific implementations for the approuter are not supported in the app. However, you can use the app to download an mta.yaml file containing all the configurations for the solution and deployment that you specified in the app. Once you've downloaded the file, you can make the changes you need in it, and build and deploy it manually, see [Multitenant Applications \[page 1259\]](#) and [Build the First Add-On Version \[page 1253\]](#).

You have already created a solution (see [Create Solution \[page 1335\]](#)) and a deployment configuration (see [Create Deployment Configuration \[page 1337\]](#)). Now you can download your mta.yaml file. Here's how:

1. Log in to the [Landscape Portal](#).
2. Under [Solution](#), click on the [Maintain Solution](#) tile to open the app.
3. Select a solution from the list to go to its object page.
4. Under [Deployment Configurations](#), select a deployment configuration to go to its object page.
5. Click the [Download](#) button in the top right corner.  
An mta.yaml file containing your configurations will be downloaded to your computer. You can now adapt the file and use it for manual deployment.

### ⓘ Note

The content of the generated file is in JSON. It is compatible with YAML and can thus be used for deployment without needing to be converted first.

### → Tip

**Approuter Sizing Recommendations:** The application router process should run with at least 256MB memory. This is sufficient for smaller test scenarios. In all other cases, more memory (at least 1GB) may be required. Please consult the [Sizing Guide](#).

## 4.2.11.3.13 Operations Dashboard

The [Operations Dashboard](#) gives an overview of all processes that have been triggered in the [Landscape Portal](#) to help you monitor your operations.

### Prerequisites

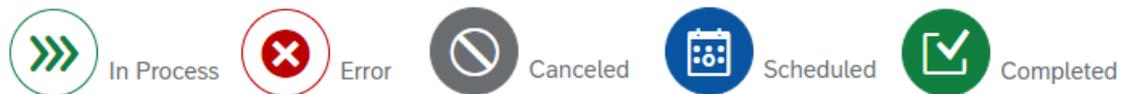

You need to have the "LandscapePortalAdmin" user role assigned to your user account to access this app.

## Working in the Operations Dashboard

1. Log into the [Landscape Portal](#).
2. Click on the [Operations Dashboard](#) tile to open the app.
3. Use the drop-down menu in the [Available Systems](#) section to choose for which systems to display the information. In case no system is selected the information is displayed for all systems.
4. In the [Downtimes](#) section on the left-hand side of the screen, you can see a calendar that displays on which days downtimes are scheduled. Select a date to view more information on the downtimes.  
Calendar legend:

5. The [Requests](#) section displays a list of all requests triggered for your systems as well as their current status. You can filter for different statuses by clicking the respective icons:

6. In the [Active Requests](#) section, you can view all active processes, their request IDs, execution date, systems, and their progress bars.

### 4.2.11.3.14 Troubleshooting

Find out which steps you can take to identify and resolve specific issues in the [Landscape Portal](#).

#### [Add-on Update](#) button is not enabled

- Check if you have the necessary role collection assigned to your user. This feature requires role collection "LandscapePortalAdminRoleCollection".
- To use this feature, an add-on product needs to be installed. Make sure the add-on product is shown in the [Software](#) section of the system.
- Make sure there are no ongoing add-on update processes.

#### Version number does not change after add-on update

- If the version number does not change after an add-on update, a new add-on version might have already been installed in the system.
- The software component version may already be installed in the system or the add-on configuration might not match the required settings. Please see [Add-on descriptor file](#). ➔

## 4.2.11.4 Extending SaaS Applications

Learn more about extending SaaS applications.

[Providing Business Add-Ins \[page 1342\]](#)

You, as an SAP partner, want to provide your customers with business add-ins (hereafter called BAdIs) so that customers can add their own business logic to your business processes by using the *Custom Logic* app.

[Configuring Predefined Custom Fields \[page 1348\]](#)

### 4.2.11.4.1 Providing Business Add-Ins

You, as an SAP partner, want to provide your customers with business add-ins (hereafter called BAdIs) so that customers can add their own business logic to your business processes by using the *Custom Logic* app.

This document describes the steps required for releasing a BAdI that can be used by key users of the *Custom Logic* app. The following steps are required:

- Create an enhancement spot for your BAdIs.
- Create the BAdI definition. This includes the interface definition and filter definitions.
- Release the BAdI definition.
- Provide an example implementation for your BAdI.
- Register the BAdI definition for the *Custom Logic* app.

After following these steps, your customers will be able to create BAdI implementations using the *Custom Logic* app.

#### 4.2.11.4.1.1 Creating an Enhancement Spot for BAdIs

##### Context

Creating an enhancement spot for your BAdIs allows you to group BAdI definitions that you want to register for the *Custom Logic* app together in one place.

##### Procedure

Create a BAdI enhancement spot in ABAP Development Tools (ADT) using the creation wizard, as described in [Creating BAdI Enhancement Spots](#).

## 4.2.11.4.1.2 Creating the BAdI Definition

Create a BAdI definition to provide your business add-in to the customer.

When creating a BAdI definition, please pay attention that some features may not be used, as indicated in the table below. When registering your BAdI for use within the *Custom Logic* app, make sure to perform a compatibility check to verify that all restrictions are met.

### BAdI Option Restrictions

Option	Description	Restriction	Comment
Description	The short description of the BAdI definition	Mandatory	Please keep the short description clear and intuitive for frontend display.
Instantiation	BAdI implementations are objects that may contain a state. Therefore, it's important whether subsequent similar requests for BAdI instances return the same or different instances of the BAdI implementation. For the instantiation of BAdIs, three different modes are supported.	Set to <code>Creating New Instances</code>	This option simplifies the instantiation process.
Multiple Use Indicator	If this indicator is set, several BAdI implementations can be active at the same time.	Set to <code>TRUE</code>	
Use Fallback Indicator	If this indicator is set, the fallback class will be executed in case no other implementation is called.	No restrictions	
Limited Filter Use Indicator	If this checkbox is marked, at most only one filter must be defined in the BAdI definition.	Set to <code>FALSE</code>	It's not allowed to prevent interference with the mandatory filter <code>TENANT_PREFIX</code> .
AMDP BAdI	Option to use a BAdI definition in an ABAP-Managed Database Procedure (AMDP)	Set to <code>FALSE</code>	This option can't be set due to the limitations of our app.
Example Classes	In order to demonstrate how to implement the BAdI method, you may use implementation example classes to provide a template for your customers.	Mandatory	Exactly one example class must be implemented for your customers to refer to. The class should contain meaningful restricted ABAP coding.
BAdI Interface	Defines the methods for this BAdI.	For restrictions, see the next section below	

## Naming Conventions

The description of the BAdI should relate to, or be, a noun. For example, the description of the BAdI that converts A to B should rather be “A To B Conversion” than “Convert A To B”. The technical (ABAP) name should be derived from the description (shortened to 30 characters maximum, upper case only). The description and the technical name of the BAdI are visible to the customer.

Do not use technical terms like “Enhancement Spot”, “Extensibility”, or “Customer” in the description and in the technical name.

For the interface parameter names, use the following naming convention: Use `BUSINESSPARTNER` as importing parameter instead of `IV_BP_ID`. Do not use technical names, abbreviations, or the hungarian notation.

## BAdI Interface

Define the method for the BAdI. Note that the BAdI interface must include the interface `IF_BADI_INTERFACE`, and no other interfaces should be included. Choose a name for the method, and remember to use exactly one method for the interface. Note the following restrictions for the interface **method signature**:

- Use only `IMPORTING` and `CHANGING` parameters. Use `CHANGING` parameters only for the output. This requirement is due to the BAdI framework and limitations of the app.
- Consider `CHANGING` parameters as returning parameters from the key users' point of view, which means that you shouldn't pass values through the parameters.
- Use `TYPE` as the typing method.
- The use of released CDS entities as parameters is allowed.
- The method must have the exception `CX_BLE_RUNTIME_ERROR` in its `RAISING` clause. No other exceptions must be raised. The framework catches all catchable exceptions, logs them and re-throws them as `CX_BLE_RUNTIME_ERROR`.
- The table type is allowed for `IMPORTING` and `CHANGING` parameters. Please use a limited number of fields to reduce the complexity.
- Nested tables are technically allowed for both `IMPORTING` and `CHANGING` parameters, but they should only be used in exceptional cases where their usage simplifies the process.
- Please use only a limited number of `IMPORTING` or `CHANGING` parameters.

### Note

Whenever possible, make the method signatures self-contained by using parameter types which you define directly in ABAP within the BAdI interface. Example: `TYPES ty_name TYPE c LENGTH 30.`

## Additional Notes

All ABAP Dictionary types that are used in the parameter typing must be C1-released with the visibility *Use in Key User Apps*. It's often useful to create wrapper classes to control the set of released data types. Furthermore, any catchable exception raised from the key user coding (directly or indirectly by called methods) will be caught and re-raised in the previous field of `CX_BLE_RUNTIME_ERROR`. This is done by a try-catch

statement that is automatically wrapped around the key user's coding. Variable `IMPLEMENTATION_NAME` of exception `CX_BLE_RUNTIME_ERROR` contains the name of the implementation where the error occurred. If you show messages to the user, remember to always mention this implementation, so that the key user has a chance to find the error and fix it. Adding to that, non-catchable exceptions will still cause a backend dump, as in for example:

`ITAB_DUPLICATE_KEY`: Updating the unique table key `PRIMARY_KEY` resulted in a duplicate entry.

## BAdI Filter Definition

Define a filter for your BAdI definition. Note that filter usage in BAdI implementations is restricted: Filters shouldn't overlap. To make sure that this is not the case, the filters of two distinct implementations of the same BAdI definition should not be `true` at the same time. See the table below for more restrictions and requirements when defining filters:

Filter Definitions

Option	Description	Recommendation/Restriction
Type	Data type of BAdI filter attribute.	The following types are available: <ul style="list-style-type: none"> <li>• I - Integers</li> <li>• C - Character type</li> <li>• S - String</li> <li>• N - Numeric</li> <li>• P - Packed (not allowed)</li> </ul>
Description	The short description of the filter.	This field is mandatory. Please keep the short description clear and intuitive for frontend display.
Only constant filter values	The field indicates filters which must be specified as constants when calling them. Therefore, you can already make sure during the compilation of your BAdI whether or not a corresponding BAdI implementation is called. This improves the runtime.	This option can be set depending on business use case. The default is that the indicator is not set.
Value check	It's possible to check the filter values maintained for BAdI implementations.	Set the value check to <code>FALSE</code> . Note that filter value checks are not supported.

### Note

When implementing the BAdI, the key user maintains filter values to specify under which conditions the implementation will be called at runtime. The *Custom Logic* app only allows the definition of conditions in disjunctive normal form, and only allows comparisons containing a single operator. For example: `(area = 1 AND category > 0 AND volume > 0 AND volume <= 100) OR (area = 1 AND category > 1 AND volume > 100 AND volume <= 199) OR ...`

Key users can maintain the conditions in a form-based editor. At runtime, at most one customer-provided implementation will be executed

## Tenant Prefix Filter

Add a filter called `TENANT_PREFIX` with the type `CHARACTER` to your BAdI definition. This filter ensures that only BAdI implementations for the current tenant are executed at runtime. In your code, obtain the current tenant's prefix by using the ABAP API `cl_ble_api_mt_tenant`. The method `GET_PREFIX` returns the tenant prefix.

```
CLASS zcl_badi_demo DEFINITION PUBLIC FINAL CREATE PUBLIC.
  PUBLIC SECTION.
    METHODS:
      my_method.
ENDCLASS.

CLASS zcl_badi_demo IMPLEMENTATION.
  METHOD my_method.
    DATA(lo_tenant_api) = cl_ble_api_mt_tenant=>create_instance( ).
    DATA(lv_tenant_prefix) = lo_tenant_api->get_prefix( ).

    DATA lo_badi TYPE REF TO z_badi.

    GET BADI lo_badi FILTERS tenant_prefix = lv_tenant_prefix.

    TRY.
      CALL BADI lo_badi->execute.
      CATCH cx_ble_runtime_error INTO DATA(lx_ble_runtime_error).
        " Handle exception.
    ENDTRY.
  ENDMETHOD.
ENDCLASS.
```

### 4.2.11.4.1.3 Releasing the BAdI Definition

#### Context

Maintain the release status for development objects.

#### Procedure

1. Right-click the development object in the *Project Explorer* and choose *API State*. Select *Add Use System-Internally (Contract C1)*.
2. Set the visibility to *Use in Key User Apps*.
3. Maintain the release status in a similar way for the BAdI definition, the BAdI interface, and for all data types that are used in the BAdI method signature.

## 4.2.11.4.1.4 Providing an Example Implementation

Provide an example implementation of your BAdI for your customers. Note that only one example implementation is allowed. The example code must be written in restricted ABAP because this is the template for the key users, and the key users are only allowed to write restricted ABAP code.

As you can only use the ABAP language version *ABAP for Cloud Development* in your example class, it could happen that you write code that isn't allowed to be used by key users. To prevent this from happening, please create an implementation of your BAdI in the *Custom Logic* app on your test system. If you don't see syntax errors on the UI, your example code is written in restricted ABAP. Have a look at the code reference for key users here: [Statements in ABAP for Key Users \[page 2430\]](#).

## 4.2.11.4.1.5 Registering the BAdI Definition

### Context

To make your BAdI available in the *Custom Logic* app, follow the steps below.

### Procedure

1. Right-click on your BAdI definition in the enhancement spot detail screen and choose *Custom Logic*.
2. Select *Check* to verify that your BAdI was implemented correctly. In case error messages appear, fix the root cause of the errors. Then, select *Register*.
3. Choose a transport request and select *Finish*. Your BAdI definition has now been registered.
4. To deregister your BAdI, right-click on the BAdI definition and select *Custom Logic*. Then, choose *Deregister*. Click *Next*, choose a transport request and select *Finish*. Now, the BAdI has been deregistered.

#### Note

Do not deregister a BAdI that was already shipped to customers. There could be existing implementations that are no longer visible when the BAdI is gone.

Remember to deregister the BAdI that is registered for *Custom Logic* first before deleting it. If you delete the BAdI without deregistering it, you'll receive an error message preventing you from saving the enhancement spot. You can go back to the last active version by closing the enhancement spot without saving.

## 4.2.11.4.2 Configuring Predefined Custom Fields

The predefined extension field framework allows you, as an SAP partner, to equip your SaaS applications with the support of customer-specific extension fields. Customers can extend partner applications with customer-specific extension fields once the application has been deployed on SAP BTP ABAP Environment Multitenancy.

An extensible partner application contains fields which are marked as predefined extension fields. Those fields are part of application but invisible in OData Services by default. You can enable the predefined custom fields in ABAP Developer Tools (ADT) and configure the extension fields using the Fiori app [Configure Predefined Custom Fields](#).

### Related Information

[Working with Predefined Field Enablings](#)

[Configure Predefined Custom Fields \[page 2433\]](#)

[Manage API Snapshots \[page 2355\]](#)

## 4.2.12 Released Components and Objects

To establish lifecycle independence of SAP code and your own applications as well as extensions built in the ABAP environment, you can only use released components and reuse services, together with a cloud-optimized scope of the ABAP language. Those components and reuse services form the public, upgrade-stable interface of the ABAP environment. Any other object or service that is not released can't be used for your own development.

In this chapter, you can learn more about released APIs from the ABAP language, technical APIs, and released services.

### 4.2.12.1 ABAP Language

Get an overview of all the objects and services of the ABAP programming language that were released for use in the ABAP environment.

You can use them for basic programming techniques such as data handling and database access. Note that not all objects and services that you know from the ABAP on-premise environment are available (or available in the same way).

## More Information and Help

For more detailed information about the objects and services listed here, go to the [ABAP Keyword Documentation](#) (ABAP language help) or, in the relevant development object in ABAP Development Tools (ADT), directly to ABAP Doc.

To access the ABAP language help from the source code editor, position your cursor on an ABAP statement for which you need help, and press `F1`.

### 4.2.12.1.1 ADT Class Execution

Easily execute ABAP classes directly in ABAP Development Tools (ADT) without having to launch a service.

#### Sample Code

```
CLASS zcl_example_class DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .

  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.

CLASS zcl_example_class IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    out->write( 'Hello World!' ).
  ENDMETHOD.
ENDCLASS.
```

For more information, see the ABAP Doc comments of the `IF_OO_ADT_CLASSRUN` interface in ABAP Development Tools (ADT).

### 4.2.12.1.2 ABAP Managed Database Procedures (AMDP)

Use this class-based framework for managing and calling stored procedures or database procedures as AMDP procedures.

For more information, see the [ABAP Keyword Documentation](#).

### 4.2.12.1.3 Arithmetic

Get an overview of the service classes that support arithmetic features such as conversions and random number generators.

For more information about numeric calculations, see the [ABAP Keyword Documentation](#).

## 4.2.12.1.4 Compression/Decompression

You can compress and decompress data using the `gzip` format.

For more information, see the ABAP Doc comments of the classes in package `SABP_GZIP` in ABAP Development Tools (ADT).

## 4.2.12.1.5 Database Access

You can use locators and streams to access large binary or large character objects (BLOB and CLOB) in the database.

For more information, see the [ABAP Keyword Documentation](#).

## 4.2.12.1.6 Date/Time and Time Stamp Processing

To handle and convert time stamps, use the following classes:

- `CL_ABAP_DTFM`
- `CL_ABAP_TIMEFM`
- `CL_ABAP_UTCLONG`
- `CL_ABAP_TSTMP`

For more information, see the ABAP Doc comments for these classes.

For more information about handling time stamps, see [System Class for Time Stamps in Packed Numbers](#) and [System Class for Time Stamp Fields](#) in the ABAP Keyword Documentation.

## 4.2.12.1.7 Parallel Processing

To start parallel tasks, use class `CL_ABAP_PARALLEL`.

### Context

In an ABAP system, dialog processes are intended for processing dialog requests. In most cases, a large number of dialog processes is unused and you want to assign these free processes to parallel processing.

## Procedure

Specify how many and which of the free dialog processes are used for parallel tasks when you create an instance of `CL_ABAP_PARALLEL`:

### Note

Keep in mind that two of the free dialog processes on a server are always retained by the system for dialog requests.

- If you set the parameter `P_LOCAL_SERVER` to the value 'X', only processes of the current server are used. By default, the dialog processes of all servers of the current SAP system are used.
- With parameter `P_PERCENTAGE`, you can set the maximum percentage of free dialog processes to be used. If nothing is specified here, a value of 50 percent is used.

Transporting the data into a free dialog process may take some time. Therefore, it's not efficient to parallelize very short-running operations. The time limit is around 200 milliseconds.

### → Recommendation

Shorter operations should be bundled, that is, several short operations should be executed in one task.

## Error Handling

When the framework is called, an internal table with the information on the tasks to be executed is transferred for each variant.

The result is a table that has the same number of entries as the input table, regardless of whether the tasks were actually executed. The output table also has the same order. A structure is returned as the result for each task. If the task was successful, the results of the processing are returned. In the case of the `RUNT_INST` method, for example, a result instance is returned in the `INST` component. If the processing was not successful for any reason, a message is returned instead. The corresponding field is the `MESSAGE` component in the result structure.

Messages from the framework are returned in this message field. For example, if a task is canceled due to a timeout, the following message is returned:

```
Time limit exceeded
```

If a task was aborted with a runtime error, the short text of the corresponding runtime error is provided as a message.

## Related Information

For more information, see the ABAP Doc comments of the `CL_ABAP_PARALLEL` class in ABAP Development Tools (ADT).

## 4.2.12.1.8 Runtime Type Information

Implement the Runtime Type Services (RTTS) using a hierarchy of type description classes that contain the methods for Runtime Type Creation (RTTC) and Runtime Type Identification (RTTI).

Using these system classes, you can do the following:

- Determine type information of existing instances and type names in the ABAP type system at runtime.
- Define new data types at runtime.

For more information, see the ABAP Doc comments of class `CL_ABAP_TYPEDESCR` and its subclasses in the ABAP Development Tools (ADT).

## 4.2.12.1.9 Security

To support secure dynamic programming in ABAP, use class `CL_ABAP_DYN_PRG`.

For more information, see the ABAP Doc comments of this class in ABAP Development Tools (ADT).

## 4.2.12.1.10 String Processing

Use the following classes to process strings:

- `CL_ABAP_[STRING|CHAR]_UTILITIES`  
Provides auxiliary functions for string/character processing
- `CL_ABAP_CONV_CODEPAGE`  
For code page conversion of strings/characters
- `CL_ABAP_[REGEX|MATCHER]`  
For regular expression processing  
For more information about regular expressions, see the [ABAP Keyword Documentation](#).

For more information about these classes, see their ABAP Doc comments in ABAP Development Tools (ADT).

## 4.2.12.1.11 Structure Processing

You can use the system class `CL_ABAP_CORRESPONDING` to assign components between structures or between internal tables with dynamically specified mapping rules. Methods are available for simple assignments, assignments of default values, and for using a lookup table.

For more information, see the [ABAP Keyword Documentation](#).

## 4.2.12.112 System Information

To get technical information such as the current user, language, or time zone, use class `CL_ABAP_CONTEXT_INFO`.

To query for released objects, use the CDS view `I_APIsForSAPCloudPlatform`.

For more information, see the relevant ABAP Doc comments in ABAP Development Tools (ADT).

## 4.2.12.113 XML/XSLT/ST

You can handle and process XML data using XSLT or ST programs.

For more information about how XML data can be created and read in ABAP, see the [ABAP Keyword Documentation](#).

## 4.2.12.114 Access to System Structure SY

Access to the system structure `SY` is restricted to read access to the following components:

`BATCH`, `DBCNT`, `FDPOS`, `INDEX`, `LANGU`, `MSGID`, `MSGNO`, `MSGTY`, `MSGV1`, `MSGV2`, `MSGV3`, `MSGV4`, `SUBRC`, `TABIX`, and `UNAME`.

### Note

Access to all other components is **not** allowed because they are related to either obsolete or unsupported features.

For more information, see [ABAP System Fields](#) in the ABAP Keyword Documentation.

You can use class `CL_ABAP_CONTEXT_INFO` to retrieve information about the user session, for example, technical user name, business user name, time zone, and so on. The built-in function `utclong_current` generates a UTC time stamp from the current system time and the current system date in accordance with POSIX standards.

## 4.2.12.2 Change Document Solution

You can document changes made to a commercial object, such as the time, the content and the way changes are made, by logging these changes in a change document.

### Example

You can use the change document to simplify the change history analysis for auditing in [Financial Accounting](#).

Every application object type has its own change document object type, which is called the *Change Document Object*. To log changes to a commercial object in a change document, you must define the *Change Document Object* for the commercial object type. The *Change Document Object* definition contains the tables which represent a commercial object in the system.

### Note

- Specify for each table, whether a commercial object contains only one (single case) or several (multiple case) records. For example, an order contains an order header and several order items. In general, one record for the order header and several records for the order items are passed to the change document creation when an order is changed.
- If a table contains fields with values referring to units and currency fields, the associated table, containing these units and currencies, can also be specified.
- The object ID identifies a given commercial object. You can retrieve all changes made to a commercial object using this key.

### Change Document Structure

- **Change Document Header**  
The change document header is the part of the change document which contains general information about the changes made. The document header is identified by object class name, the object ID and a change document number (automatically provided by the runtime system). The change document header contains information about who made the changes, when they were made, what type of changes were made (update, insert or delete operation) and if they were real or planned changes. Starting with Release 6.20 information about the system language and the length of the table key of the documented table are saved here as well. The header data is stored in table CDHDR.
- **Change Document Item**  
The change document item contains the old and new values of a field for a particular change, and a change flag, that presents the kind of change. The change flag can take the following values:
  - **U = Update**  
Changed data. (Log entry for each changed field which was flagged in the Dictionary as *change document relevant*.)
  - **I = Insert**  
Data Inserted.  
Changes: Log entry for the whole table record.  
Planned changes: Log entry for each table record field.
  - **D = Delete**  
Data were deleted (log entry for the whole table record).
  - **E = Individual field documentation at Delete**  
Delete a table record with field documentation.  
One log entry per field of the deleted table entry.
  - **J = Individual field documentation at Insert**  
Insert a table record with field documentation.  
One log entry per field of the inserted table entry.

## 4.2.12.2.1 Authorization Checks

### Authorization Check for Change Document Object Maintenance

There is an authority check during all methods of Change Document Object Maintenance. Use method `IF_CHDO_OBJECT_TOOLS_REL~CHECK_AUTHORIZATION` to run the authorization check separately.

Use method `IF_CHDO_OBJECT_TOOLS_REL~CHECK_AUTHORIZATION` to run an additional authorization check. `IV_OBJECT`, `IV_DEVCLASS` and `IV_ACTIVITY` get passed as import parameters. The return parameter `RV_IS_AUTHORIZED` must be set to `ABAP_TRUE` if the check is successful.

Import Parameters

Parameter Name	Field Name	Value Help
IV_OBJECT		Name of Change Document Object
IV_ACTIVITY		Activity to be checked. Existing values: <ul style="list-style-type: none"><li>'01' – Create</li><li>'02' – Change</li><li>'03' – Read</li><li>'06' = delete</li></ul>
IV_DEVCLASS		

Return Parameters

Parameter Name	Field Name	Value Help
RV_IS_AUTHORIZED		ABAP_TRUE if the authority check was successfully

#### Sample Code

```
CLASS zcl_chdo_test_auth DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.
CLASS zcl_chdo_test_auth IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    DATA: lv_is_authorized type abap_bool.
    TRY.
      " iv_object : Change document object name
      " it_activity : Activity to be checked. Possible values '01' = create,
      "                                                    '02' = change,
      "                                                    '03' = read,
      "                                                    '06' = delete
      " it_devclass : development class of change document object
      cl_chdo_object_tools_rel=>if_chdo_object_tools_rel~check_authorization(
```

```

EXPORTING
  iv_object      = 'ZCHDO_TEST'
  iv_activity    = '03'
  iv_devclass    = 'ZLOCAL'
RECEIVING
  rv_is_authorized = lv_is_authorized
).
ENDTRY.
IF lv_is_authorized IS INITIAL.
  out->write( |Exception occurred: authorization error.| ).
ELSE.
  out->write( |Activity can be performed on the change document
object.| ).
ENDIF.
ENDMETHOD.
ENDCLASS.

```

## Authorization Check for Reading Change Documents

When a change document object is generated, you receive the <name space>CL\_<change document object name>\_CHDO class with method IF\_CHDO\_ENHANCEMENTS~AUTHORITY\_CHECK without implementation. You can create your own authority check for reading change documents written for this change document object. The authority check for reading change documents are successful if parameter RV\_IS\_AUTHORIZED = 'X' is returned.

### 4.2.12.2.2 Managing Change Document Objects

To maintain a change document object during design time, the ABAP Development Tools UI editor for change document objects can be used. For more information, see [Working with Change Document Objects](#).

Use class CL\_CHDO\_OBJECT\_TOOLS\_REL to maintain change document objects.

For more information, see

- [Creating a Change Document Object \[page 1357\]](#)
- [Updating a Change Document Object \[page 1362\]](#)
- [Deleting a Change Document Object \[page 1366\]](#)
- [Reading a Change Document Object Definition \[page 1368\]](#)

## Related Information

[Working with Change Document Objects](#)

## 4.2.12.2.1 Creating a Change Document Object

When creating a change document object, the following naming-rules apply:

- For customer objects, start the name with a 'Z' or a 'Y'. For more information, see SAP Note 16466.
- If a name space is requested, use an object starting with namespace as object name.
- Keep in mind that the change document object name including the name space has a maximum length of 15 characters. That means that if the name space has 10 characters, only 5 characters are left for the change document object name.

### Process

Use method `IF_CHDO_OBJECT_TOOLS_REL~CREATE_AND_GENERATE_OBJECT` to create and generate change document objects.

The name of the object is assigned using the import parameter `IV_OBJECT`. Object details and generation information are passed using the internal tables `IT_CD_OBJECT_DEF` (the object definition), `IT_CDOBJECT_TEXT` (object texts) and `IS_CD_OBJECT_GEN` (generation information).

Once generated, the class (`<name space>CL_<change document object name>_CHDO`) with methods `WRITE` and `IF_CHDO_ENHANCEMENTS~AUTHORITY_CHECK` are created. `IV_CL_OVERWRITE` can be used to specify whether an existing class with the specified name can be overwritten or not. If a class already exists and can't be overwritten, no changes will be made. Changes are saved in the transport request (`IV_CORRNR`).

Method `AUTHORITY_CHECK` of interface '`IF_CHDO_ENHANCEMENTS`' must be implemented later on in order to enable an authorization check for reading change documents.

The export parameter `ET_ERRORS` is used to return all generation messages (messages from message class `CD`). Any syntax errors in the generated class are provided using `ET_SYNT_ERROR` (with long text if applicable (`ET_SYNT_ERROR_LONG`)).

Import Parameters

Parameter Name	Field Name	Value Help
<code>IV_OBJECT</code>		Name of change document object
<code>IT_CD_OBJECT_DEF</code>		Change document object definition
	<code>TABNAME</code>	Name of the table as defined in the dictionary
	<code>MULTCASE</code>	If more than one record for a particular table is to be documented during a single <code>CREATE/UPDATE/DELETE</code> operation, the value <code>MULTCASE</code> should be ' <code>ABAP_TRUE</code> ' or ' <code>X</code> ' (multiple case). If no value is provided a single record can be documented and passed in a work area (single case).

Parameter Name	Field Name	Value Help
	DOCUDEL	<p>DOCUDEL = SPACE</p> <p>The deletion of a table entry will be documented in one change document item using the table key to identify the table entry deleted. ## 4.2.12.2.2 Updating a Change Document Object

Use method `IF_CHDO_OBJECT_TOOLS_REL~UPDATE_OBJECT` to modify and regenerate change document objects.

The name of the object is assigned using the import parameter `IV_OBJECT`. The object details and generation information are passed using the internal tables `IT_CD_OBJECT_DEF` (the object definition), `IT_CD_OBJECT_TEXT` (the object texts) and `IS_CD_OBJECT_GEN` (the generation information).

If the internal tables are not filled, the object definition is read directly from the database tables `TCDOB` and `TADIR` and the generation information is read directly from database table `TCDRP`. If only parameter `IS_CD_OBJECT_GEN` is passed, the change document object will be newly generated without changing the change document object definition. Use this method when the structure of a table, that belongs to the change document object, was changed.

Once generated, a class (`<name space>CL_<change document object name>_CHDO`) with methods `WRITE` and `IF_CHDO_ENHANCEMENTS~AUTHORITY_CHECK` are created. You can use `IV_CL_OVERWRITE` to specify whether an existing class can be overwritten with the specified name or not. If a class already exists and can't be overwritten, no changes will be made. Changes made to the class are saved in the transport request (`IV_CORRNR`).

Method `AUTHORITY_CHECK` of interface '`IF_CHDO_ENHANCEMENTS`' must be implemented later on in order to enable an authorization check for reading change documents.

The export parameter `ET_ERRORS` is used to return all generation messages (messages from message class `CD`). Any syntax errors in the generated class are provided using `ET_SYNT_ERROR` (with long text if applicable (`ET_SYNT_ERROR_LONG`)).

Import Parameters

Parameter Name	Field Name	Value Help
<code>IV_OBJECT</code>		Name of change document object
<code>IT_CD_OBJECT_DEF</code>		Change document object definition
	<code>TABNAME</code>	Name of the table as defined in the dictionary
	<code>MULTCASE</code>	If more than one record for a particular table is to be documented during a single <code>CREATE/UPDATE/DELETE</code> operation, the value <code>MULTICASE</code> should be ' <code>ABAP_TRUE</code> ' or ' <code>X</code> ' (multiple case). If no value is provided a single record can be documented and passed in a work area (single case).

Parameter Name	Field Name	Value Help
	DOCUDEL	<p>DOCUDEL = SPACE</p> <p>The deletion of a table entry will be documented in one change document item using the table key to identify the table entry deleted. The field FNAME will be filled with 'KEY'.</p> <p>DOCUDEL = 'X'</p> <p>Each change document relevant field value of the table entry will be documented individually in its own change document item.</p> <p>The change indicator is 'E' instead of 'D'.</p>
	DOCUINS	<p>DOCUINS = SPACE</p> <p>The insert of a table entry will be documented in one change document item using the table key to identify the inserted table entry. The field FNAME will be filled with 'KEY'.</p> <p>DOCUINS = 'X'</p> <p>Each change document relevant field value of the table entry will be documented individually in its own change document item.</p> <p>The change indicator is 'J' instead of 'I'.</p>
	REFNAME	<p>If fields of table TABNAME reference unit or currency field values from another table, the name of that table has to be passed here to document its values as well.</p> <p>Only one reference table can be used for table TABNAME.</p> <p>In single case, the referenced entry from table REFNAME is passed as two additional work areas (old, new). In multiple case, the import tables (old, new) are enhanced to include the referenced structure of table REFNAME.</p>

Parameter Name	Field Name	Value Help
	DOCUD_IF	<p>If you want to document the value of a field even though it is initial when data is deleted, mark this field. ```

### 4.2.12.2.2.3 Deleting a Change Document Object

Use method IF\_CHDO\_OBJECT\_TOOLS\_REL~DELETE\_OBJECT to delete change document objects. The name of the object is assigned using the import parameter IV\_OBJECT.

Furthermore, the import parameter `IV_DEL_CL_WHEN_USED` determines, if the class of the change document object should be deleted (if value passed is `ABAP_TRUE`) or not (value `ABAP_FALSE`) when it is still being used. The changes made to the class are saved in the transport request (`IV_CORRNR`).

The export parameter `ET_ERRORS` is used to return all deletion messages (messages from message class `CD`).

The object will be deleted if no exception and no error messages of kind 'E-' were raised.

#### Import Parameters

Parameter Name	Field Name	Value Help
<code>IV_OBJECT</code>		Change document object name
<code>IV_CORRNR</code>		Transport request where deletion should be logged
<code>IV_DEL_CL_WHEN_USED</code>		Delete generated class "CL_<change document object name>_CHDO" even if it is currently used.

#### Export Parameters

Parameter Name	Field Name	Value Help
<code>ET_ERRORS</code>		
	<code>kind</code>	Message type (empty means information message, 'E-', means error)
	<code>msgid</code>	Message class (CD)
	<code>msgnr</code>	Message ID
	<code>v1</code>	Variable to message
	<code>v2</code>	Variable to message
	<code>v3</code>	Variable to message
	<code>v4</code>	Variable to message
	<code>text</code>	Short text of the message

## 4.2.12.2.2.4 Reading a Change Document Object Definition

Use method `IF_CHDO_OBJECT_TOOLS_REL~READ_OBJECT` to read a change document object definition.

The name of the object is assigned using the import parameter `IV_OBJECT`. The information is returned using the export parameter `ET_OBJECT_INFO`.

Import Parameter

Parameter Name	Field Name	Value Help
IV_OBJECT		Change document object name

Export Parameters

Parameter Name	Field Name	Value Help
ET_OBJECT_INFO		
	ET_OBJECT_INFO	Name of the change document object
	ET_OBJECT_INFO	Generation information counter for field <code>gen_type</code>

Parameter Name	Field Name	Value Help
	ET_OBJECT_INFO	Generation information type technical name (DEFINITION, GENERATION, CLASS)
	ET_OBJECT_INFO	Generation information type text (Definition, Generate, Class details)
	ET_OBJECT_INFO	Line counter for field name
	ET_OBJECT_INFO	Information long text
	ET_OBJECT_INFO	Information technical name
	ET_OBJECT_INFO	Value of the change document object
	OBJECTCLASS	Name of the change document object
	GNR	Generation information counter for field gen_type
	GEN_TYPE	Generation information type technical name (DEFINITION, GENERATION, CLASS)
	GROUP	Generation information type text (Definition, Generate, Class details)
	ZNR	Line counter
	INFOTEXT	Information long text
	OBJ_TYPE	Information technical name
	NAME	Information value (e.g. table name, package, user name, class name)

### Sample Code

```

CLASS zcl_chdo_read_object DEFINITION

IMPORTING
        et_object_info = pt_object_info    " change document object details
    ).
    CATCH cx_chdo_generation_error INTO lr_err.
        out->write( |Exception occurred: { lr_err->get_text( ) }| ).
    ENDTRY.
    ENDMETHOD.
ENDCLASS.

```

## 4.2.12.2.3 Writing Change Documents

Write change documents

The `WRITE` method in the generated class `CL_<change document object name>_CHDO` creates change documents from the object-specific update for an object ID.

Import Parameters

Parameter Name	Value Help
OBJECTID	Identifier of the changed application object
UTIME	Time of change
UDATE	Date of change
USERNAME	User name of the person responsible in change document
PLANNED_CHANGE_NUMBER	Planned change number (only for writing planned changes)
OBJECT_CHANGE_INDICATOR	Type of Change to Application Object. Possible values are: <ul style="list-style-type: none"> <li>• U - Change</li> <li>• I - Insert</li> <li>• D - Delete</li> </ul>
PLANNED_OR_REAL_CHANGES	You can use this parameter to control whether the changes to be logged are actual or planned changes. Available values: <ul style="list-style-type: none"> <li>• "R" actual (real) changes -"P" planned changes</li> <li>• if there is no plan number: actual change if there is a plan number: planned change</li> </ul>
NO_CHANGE_POINTERS	'X': no change pointers will be written. Change pointers are used for Application Link Enabling (ALE) master data scenarios. Currently, this parameter is obsolete for SAP Business Technology Platform (SAP BTP), ABAP Environment.

Parameter Name	Value Help
ICDXTX_<change document object name>	<p>In this structure, the change document-relevant texts are collected with the corresponding specifications:</p> <ul style="list-style-type: none"> <li>• TEILOBJID: Key of changed table row</li> <li>• TEXTART: Text type of changed text</li> <li>• TEXTSPR: Language Key</li> <li>• UPDKZ: Change flag for table row: D(elete), I(nsert) or U(pdate)</li> </ul>
UPD_ICDXTX_<change document object name>	<p>Change flag for text table:</p> <ul style="list-style-type: none"> <li>• " " (Space): Table is not considered.</li> <li>• "U": Table is considered</li> </ul>
O_<table name>	<p>Object-specific parameter for single case tables with the same table structure as &lt;table name&gt;. The workarea must contain the original data.</p>
N_<table name>	<p>Object-specific parameter for single case tables with the same table structure as &lt;table name&gt;. The workarea must contain the original data.</p>
Y<table name>	<p>Object-specific parameter for multiple case tables.</p> <p>The table must contain the original version of the changed or deleted records. The structure consists of the table, as specified in the change document object definition under table name, a processing flag (TYPE C, length 1)</p>
X<table name>	<p>The table must contain the current version of the changed or created records. The structure is the same as Y&lt;table name&gt; (see above). It is not necessary to set the processing flag to values &lt;&gt; space for standard behavior. The following values for the processing flag exist:</p> <ul style="list-style-type: none"> <li>• "I" (INSERT)Records were created, or table records were deleted, then a record with the same key was created in the same transaction, and this is to be documented as "Delete" and "Create" (special case), not as "Change".</li> <li>• "U" or " " (space) (UPDATE)</li> </ul> <p>The parameter UPD_&lt;table name &gt; (see below) initially determines whether the record is new or changed. The processing flag is only checked when - with the parameter value "U" - the following key comparison between the two tables x&lt;table name&gt; and y&lt;table name&gt; finds two records with the same key.</p>

Parameter Name	Value Help
UPD_<table name >	<p>With this flag, you determine the processing logic. The following values exist:</p> <ul style="list-style-type: none"> <li>"D" (DELETE) A change document item is to be created for each record in Y&lt;table name &gt;. X&lt;table name&gt; is not processed.</li> <li>"I" (INSERT) A change document item is to be created for each record in X&lt;table name&gt;. Y&lt;table name&gt; is not processed.</li> <li>"U" (UPDATE) The keys of Y&lt;table name&gt; and X&lt;table name&gt; are compared. The following cases are distinguished: <ul style="list-style-type: none"> <li>Record exists in Y&lt;table name&gt; but not in X&lt;table name&gt;: Change document items are to be created for the record in Y&lt;table name&gt; which is to be deleted.</li> <li>Record exists in X&lt;table name&gt; but not in Y&lt;table name&gt;: A change document item is to be created for the records in X&lt;table name&gt; which are to be flagged as created.</li> <li>Record exists in both Y&lt;table name&gt; and X&lt;table name&gt; and processing flag in X&lt;table name&gt; record is "U" or space: A change document item is created for each changed field which is defined as change document-relevant in the dictionary.</li> <li>Record exists in both Y&lt;table name&gt; and X&lt;table name&gt; and processing flag in X&lt;table name&gt; record is "I": Change document item is to be created for the record in Y&lt;table name&gt; which is to be deleted and change document item is to be created for the record in X&lt;table name&gt; which is to be flagged as created.</li> <li>" " (space, no processing) X&lt;table name&gt; and Y&lt;table name&gt; are not processed by the <code>WRITE</code> method. (If no changes have been made, the processing can be skipped to save time.)</li> </ul> </li> </ul>

## 4.2.12.2.4 Deleting Change Documents

Use class CL\_CHDO\_DELETE\_TOOLS to delete change documents.

First use GET\_INSTANCE method to create an instance for the interface IF\_CHDO\_DELETE\_TOOLS.

Parameter Name	Field Name	Value Help
RO_INSTANCE		Return parameter for instance creation

Method IF\_CHDO\_DELETE\_TOOLS~CHANGEDOCUMENT\_DELETE deletes the change documents for one change document object. You can restrict the selection by various parameters (such as date, change number or time).

Import Parameters

Parameter Name	Field Name	Value Help
I_OBJECTCLASS		Name of change document object
I_OBJECTID		Parameter of application objects IDs
I_UP_TO_DATE		Date by which the change documents are to be deleted  All change documents until the specified date are deleted.
I_CHANGENUMBER		Change Number of Document  If only one specific change document number is to be deleted, it can be transferred here.

Parameter Name	Field Name	Value Help
I_WITH_COMMIT		<p>Flag whether there should be a COMMIT WORK in the method.</p> <p>The flag determines whether a COMMIT WORK should be called in the method. This can be necessary when a lot is to be deleted. In this case the delete operations are divided up to avoid Roll-back segment overflow. The division is by clusters, so that no inconsistencies occur in the case of cancellation.</p>
COMMIT_COUNTER		<p>The parameter is only effective when a COMMIT WORK should be performed in the method (see parameter I_WITH_COMMIT).</p> <p>In the method, as many object change documents are read as are passed in COMMIT_COUNTER. These change documents are then deleted, and COMMIT WORK called. This procedure is repeated until there are no more change documents for the object before the until date.</p>

Export Parameter

Parameter Name	Field Name	Value Help
E_NUMBER_OF_DELETED_HEADERS		<p>Number of deleted change document headers</p> <p>This parameter contains the number of deleted change document headers</p>
E_NUMBER_OF_DELETED_POSITIONS		<p>Number of deleted change document items</p> <p>This parameter contains the number of deleted change document items.</p>
E_NUMBER_OF_DELETED_UIDS		<p>Number of deleted change document item GUIDs</p>
E_NUMBER_OF_DELETED_STRINGS		<p>Number of deleted change document item STRINGS</p> <p>This parameter contains the number of deleted change document items with STRINGS.</p>

## Sample Code

```
DATA lv_objectclass TYPE if_chdo_object_tools_rel=>ty_cdobjectcl VALUE

```

## 4.2.12.2.5 Reading Change Documents

Use class `CL_CHDO_READ_TOOLS` to read change documents.

Method `CHANGEDOCUMENT_READ` reads the change documents for one change document object. You can restrict the search by various parameters (such as changed by, date, or time).

Import Parameters

Parameter Name	Field Name	Value Help
ET_CDREDADD_TAB		Table type for structure CDREDADD, change documents return table
I_OBJECTCLAS		Name of change document object
IT_OBJECTID		Range table of application object IDs
I_DATE_OF_CHANGE		From-change date for search. All change documents are selected written on the specified date or later are found.
I_TIME_OF_CHANGE		From-change time for search. If no change time is specified, a selection is made from the time '000000'.

Parameter Name	Field Name	Value Help
I_DATE_UNTIL		Change date up to which you want to search. All change documents are selected written up to and including this date.
I_TIME_UNTIL		Latest change time in search. Time to which change documents are read on the "To" change date. If no time is passed, all change documents on the "To" change date are read.
IT_USERNAME		Username of the person responsible in change document. Only those change documents are selected that document changes made by this user. If no user name is passed, change documents are read for all users.
IS_READ_OPTIONS		
	local_time	If it is set, the date and time information in the formatted change documents is displayed in the local time of the user.
	time_zone	<p>It contains the time zone in which the change documents were written. If it's not set UTC applies.</p> <p>If it contains a time zone, this zone is used as the time zone in which the change documents were saved.</p> <p>If the change documents were saved in CET, the parameter must be set to CET.</p>

Parameter Name	Field Name	Value Help
	it_changenr	Range table for change document number. Change document numbers were created internally as part of key of change documents. The key of change document is represented by Object name, Object ID of the application object and a change number. During creation of change documents using the write method of class <name space>CL_<change document object name>_CHDO  Change documents numbers were received by export parameter CHANGENUMBER.
	only_headers	Only return the change document header information without the position
IV_READ_ARCHIVE		Control the interface to read change documents from the archive, too

Export Parameter

Parameter Name	Field Name	Value Help
	OBJECTCLAS	Name of Change Document Object
	OBJECTID	Object ID of application object
	OBJECTID_DB	Object value
	CHANGENR	Change Number of Document
	OBJECTTXT	Object Description
	USERNAME	Username of the person responsible in change document
	USERNAME_DB	Username of the person responsible in change document
	UDATE	Creation date of the change document
	UDATE_DB	Creation date of the change document
	UTIME	Time changed
	UTIME_DB	Time changed

Parameter Name	Field Name	Value Help
	TCODE	Transaction in which a change was made
	APPLNAME	Application Object
	APPLTYPE	Application Type
	TABNAME	Change document creation: Table name
	TABNAME_DB	Change document creation: Table name
	TABKEY	Key of Changed Table Line
	TABKEY_DB	Key of Changed Table Line
	KEYLEN	Table key length
	CHNGIND	Type of Change
	FNAME	Field Name
	FNAME_DB	Field Name
	FTEXT	Explanatory Short Text
	TEXTART	Create change document: Text type
	SPRACHE	Language Key
	TEXT_CASE	Text change flag ('X')
	OUTLEN	Output length of the old and new value
	F_OLD	Old contents of changed field
	F_NEW	New contents of changed field
	F_NEW_DB	New contents of changed field
	VALUE_OLD	Old Extended Value (Long)
	VALUE_OLD_DB	Old Extended Value (Long)
	VALUE_NEW	New Extended Value (Long)
	VALUE_NEW_DB	New Extended Value (Long)
	VALUE_RAWSTR_OLD	Old Change Document Value for RAW-STRING Variable

Parameter Name	Field Name	Value Help
	VALUE_RAWSTR_OLD_DB	Old Change Document Value for RAW-STRING Variable
	VALUE_RAWSTR_NEW	New Change Document Value for RAW-STRING Variable
	VALUE_RAWSTR_NEW_DB	New Change Document Value for RAW-STRING Variable
	VALUE_SHSTR_OLD	Old Extended Value (Short)
	VALUE_SHSTR_OLD_DB	Old Extended Value (Short)
	VALUE_SHSTR_NEW	New Extended Value (Short)
	VALUE_SHSTR_NEW_DB	New Extended Value (Short)
	KEYGUID	KEYGUID for Link to CDPOS_UID
	TABKEY254	Key of Modified Table Row
	TABKEY254_DB	Key of Modified Table Row
	EXT_KEYLEN	Table key length
	KEYGUID_STR	KEYGUID for Link to CDPOS_STR
	VERSION	3-Byte field

### Sample Code

Read all change documents for object class ZCHDO\_TEST

```

CLASS zcl_chdo_read DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.

                out->write( |Exception occurred: { ls_read_err-
>get_text( ) }| ).
            ENDMETHOD.
            APPEND LINES OF lt_cd TO lt_cdredadd.
        ENDDO.
    ENDMETHOD.
ENDCLASS.

```

```
        lo_read->close( ).
    CATCH cx_arch_api INTO DATA(lx_error).
        out->write( |Exception occurred: { lx_error->get_text( ) }| ).
    ENDTRY.
ENDMETHOD.
```

## 4.2.12.2.6 Archiving Change Documents

You can archive change documents together with their application documents.

### Prerequisites

1. A change document object is available (see [Working with Change Document Objects](#)) and it's implemented to create change documents (see [Writing Change Documents \[page 1370\]](#)).
2. There is an archiving object to archive current application documents (see [Working with Archiving Objects](#)).

### Procedure

1. Add the archiving class `CHANGEDOCU` to the archiving classes of your archiving object using `ABAP Development Tools (ADT)`:

## Archiving Object: CDTESTLV5

**Attributes**

Write Class:

Delete Class:

Reload Class:

Storage Class:

**Tables to be Archived**

Name

**Archiving Classes**

Name
CHANGEDOCU

- Update the write class of your archiving object to archive change documents.

### Sample Code

```
CLASS ZCL_<YOUR_ARCH_OBJECT>_WRI IMPLEMENTATION.  
METHOD if_apj_rt_exec_object~execute.  
...  
TRY.  
DATA(lo_write) = cl_arch_write_api=>get_instance( iv_archiving_object =  
<YOUR_ARCH_OBJECT> iv_testmode = lv_test ).  
LOOP AT lt_keys_tab ASSIGNING FIELD-SYMBOL(<fs_keys>).  
lo_write->open_data_object( ).  
cl_changedocu_archive=>get_instance( )-  
>if_changedocu_archive~changedocu_archive_object( iv_objectclass  
= <YOUR_CD_OBJECTCLASS>  
iv_objectid = <fs_keys>-objectid  
iv_write_instance = lo_write ).  
lo_write->close_data_object( ).  
ENDLOOP.  
lo_write->finalize( ).  
CATCH cx_arch_api INTO DATA(lx_error).  
CATCH cx_chdo_archive_error INTO DATA(lx_error2).  
ENDTRY.  
ENDMETHOD.
```

### Note

String <YOUR\_ARCH\_OBJECT> is for your archiving object. String <YOUR\_CD\_OBJECTCLASS> is for your change document object.

### Note

To read change documents from the archive, consider [Reading Change Documents \[page 1376\]](#).

## 4.2.12.2.7 How to Use the Fiori Reuse Library for Change Document Solution

You can use the *Reuse Library* to implement a reusable component that can display change documents.

### Context

To be able to use the reusable components, you need to adapt the code that can be found in your `manifest.json` file.

### Procedure

1. Adapt your `<manifest.json>` file and add the `sap.nw.core.changedocs.lib.reuse` library under the `sap.ui5` section:

#### Sample Code

```
"sap.ui5": {
  "resources": {
    "js": [],
    "css": []
  },
  "componentUsages": {
    "ChangedocReuseComponent": {
      "name":
"sap.nw.core.changedocs.lib.reuse.changedocscomponent"
    }
  },
  "dependencies": {
    "minUI5Version": "1.65.0",
    "libs": {
      "sap.ui.core": {
        "lazy": false
      },
      "sap.ui.generic.app": {
        "lazy": false
      },
      "sap.suite.ui.generic.template": {
```

```

        "lazy": false
      },
      "sap.ui.comp": {
        "lazy": false
      }
    },
    "components": {
      "sap.nw.core.changedocs.lib.reuse": {
        "lazy": true
      }
    }
  },
}

```

2. Adapt your `<manifest.json>` file and add the component as section on your page:

### Sample Code

```

"pages": {
  "ObjectPage|TravelProcessor": {
    "entitySet": "TravelProcessor",
    "defaultLayoutTypeIfExternalNavigation": "MidColumnFullScreen",
    "component": {
      "name": "sap.suite.ui.generic.template.ObjectPage"
    },
    "embeddedComponents": {
      "changedoccomponent": {
        "id": "changedoccomponent",
        "componentUsage": "ChangedocReuseComponent",
        "title": "{{reuseTitle}}",
        "settings": {
          "objectClass": [
            "<MY_CHANGE_DOC>"
          ],
          "objectId": "{parts:
[{{path: '<MY_OBJECTID>'}], formatter:
'sap.nw.core.changedocs.lib.reuse.changedocscomponent.arrayFormatter'",
          "startDate": "1900-01-01T00:00:00"
        }
      }
    }
  }
}

```

### Note

Make sure to replace strings `<MY_CHANGE_DOC>` with your own change document object and `<MY_OBJECTID>` with your own Object id which were also used to create change documents.

3. Adapt your `<i18n.properties>` file and add:

### Sample Code

```

...
#XTIT: Reuse component title
reuseTitle =Change Documents
...

```

### Note

Manual tests of the reuse library using *SAP Business Application Studio* is not possible. Create and test your app finally before implementing the reuse app. Test the reuse app after deployment.

After your app was deployed successfully to an SAP Business Technology Platform system, the updated BSP application and the SAP Fiori Launchpad app descriptor item will appear under your created package in Eclipse.

4. Update your IAM App. For more information, see [Defining an IAM App for the Business Service \[page 768\]](#).
5. Once created, maintain the *Change Document OData Service*. Go to the *Service* tab and add the *Change Document Log OData Service* by naming the *OData V2* service type and add the following service name: `APS_CHANGE_DOCUMENTS_SRV 0001` (**Note: make sure to add all 11 spaces in between 'SRV' and '0001'**).
6. Create a new Business Catalog. For more information, see [Creating a Business Catalog \[page 769\]](#)  
Having created the business catalog, you have successfully implemented a reusable component to display your change documents.

## 4.2.12.3 Currency Conversion

The ABAP Core Data Services (CDS) provide the built-in function `CURRENCY_CONVERSION` to convert different currencies to a common target currency.

For more information, see [CDS DDL - CDS View Entity, Unit and Currency Conversion Functions](#) in the [ABAP Keyword Documentation](#).

To customize this conversion function, you can use API class `CL_EXCHANGE_RATES` to load the current exchange rates into your system for a correct conversion. Class `CL_EXCHANGE_RATES` is based on the business API function modules `BAPI_EXCHRATE_CREATEMULTIPLE` and `BAPI_EXCHANGERATE_SAVEREPLICA`.

API class `CL_EXCHANGE_RATES` provides PUT methods to write exchange rates to the corresponding customizing persistence. For more information, see the ABAP Doc comments in the class implementation.

Note that aside from use in CDS, the class additionally provides two methods to convert currencies.

### Example

To learn how to obtain and store exchange rates from an official source, see the detailed example at <https://github.com/SAP-samples/cloud-abap-exchange-rates>.

#### Sample Code

```
@EndUserText.label: 'Price (in US American Dollars)'  
currency_conversion(  
  client => client,  
  amount => amount,  
  round => '',  
  source_currency => currency,
```

```
target_currency => cast('USD' as abap.cuky),
exchange_rate_type => cast('M' as abap.char(4)),
exchange_rate_date => cast($session.system_date as abap.dats)
) as PriceInUSD
```

## 4.2.12.4 Factory Calendar

Get an overview of the ABAP classes, interfaces, and methods you can use to access calendar-related information.

The calendar system comprises the definition of the following categories:

- Public holidays
- Holiday calendars (a collection of public holidays)
- Factory calendars

A factory calendar is based on a country-specific holiday calendar and defines which days are working days, for example, Monday to Friday, and location-specific rules.

Read on to learn about the set of data we deliver for these categories.

### Note

Class `CL_SCAL_API` is still available, but deprecated. We recommend that you use class `CL_FHC_CALENDAR_RUNTIME` and the related interfaces `IF_FHC_FCAL_RUNTIME`, `IF_FHC_HCAL_RUNTIME` and `IF_FHC_HOLIDAY_RUNTIME` instead. Furthermore, the CDS views from the section [Accessing Holiday and Factory Calendar Tables Using VDM-Compliant CDS Views \[page 1391\]](#) can be used to get an overview of existing factory- and holiday calendars. For information about the mapping between SCAL-relevant IDs and FHC-relevant IDs, see the corresponding section below.

## Creating a Runtime to Access Calendar-Related Information

Use class `CL_FHC_CALENDAR_RUNTIME` that contains the following list of methods to create a runtime for holidays, holiday calendars, and factory calendar:

Method	Description
<code>create_factorycalendar_runtime</code>	Provides a factory calendar runtime
<code>create_holidaycalendar_runtime</code>	Provides a holiday calendar runtime
<code>create_holiday_runtime</code>	Provides a holiday runtime

### Sample Code

```
try.
  data(lo_fcal_run) =
    cl_fhc_calendar_runtime=>create_factorycalendar_runtime (
```

```

        iv_factorycalendar_id = 'ExampleID' ).
    catch cx_fhc_runtime into data(lx_err).
        "exception handling
endtry.

```

## Reading Factory Calendar-Related Information

Use the before created runtime to access the following list of methods provided in the interface IF\_FHC\_FCAL\_RUNTIME to get information about the factory calendar:

Method	Description
convert_date_to_factorydate	Converts a date to a factory date
convert_factorydate_to_date	Converts a factory date to a date
get_last_factorydate	Provides the last factory date of the calendar
calc_workingdays_between_dates	Calculates the number of working days between two dates
add_workingdays_to_date	Adds working days to a date
subtract_workingdays_from_date	Subtracts working days to a date
get_validity_start	Provides the first valid date
get_validity_end	Provides the last valid date
is_date_workingday	Check if a weekday is a working day
is_holiday_workingday	Check if holiday is a working day
get_description	Provides the description of the calendar
get_hcal_assignment	Provides the assigned holiday calendar runtime
get_id	Provides the ID of the factory calendar

### Sample Code

```

try.
    data(lv_date) = lo_fcal_run->convert_factorydate_to_date(
        iv_factorydate = '123' ).
    catch cx_fhc_runtime into data(lx_run_err).
        "exception handling
endtry.

```

## Reading Holiday Calendar-Related Information

Use the before created runtime to access the following list of methods provided in the interface `IF_FHC_HCAL_RUNTIME` to get information about the holiday calendar:

Method	Description
<code>is_holiday</code>	Check if a date is a holiday
<code>get_holiday</code>	Provides the assigned holiday for a date
<code>calc_holidays_between_dates</code>	Calculates the number of holidays between two dates
<code>get_validity_start</code>	Provides the first valid date
<code>get_validity_end</code>	Provides the last valid date
<code>get_description</code>	Provides the description of the calendar
<code>get_holiday_assignments</code>	Get the assigned holidays from current holiday calendar
<code>get_id</code>	Provides the ID of the holiday calendar

## Reading Holiday-Related Information

Use the before created runtime to access the following list of methods provided in the interface `IF_FHC_HOLIDAY_RUNTIME` to get information about the holidays:

Method	Description
<code>get_holiday_id</code>	Provides the ID of the holiday
<code>get_type</code>	Provides the type of the holiday
<code>get_class</code>	Provides the class of the holiday
<code>get_confession</code>	Provides the confession of the holiday
<code>get_text</code>	Provides the title and description of the holiday in a specific language

## Mapping between SCAL-relevant IDs and FHC-relevant IDs

Class `CL_FHC_CALENDAR_RUNTIME` uses longer IDs (32 digits) than the deprecated class `CL_SCAL_API`, which had only two-digit IDs for the factory calendars and holiday calendars, and three-digit IDs for the public holidays (also referred to as legacy IDs). The longer IDs make it easier to categorize calendar data.

To enable the use of the above mentioned runtimes, it may be necessary that an application establishes a connection between a legacy two-digit ID (as formerly used with `CL_SCAL_API`) and a longer ID that the newer class `CL_FHC_CALENDAR_RUNTIME` uses.

You can do such a mapping using the interface `IF_FHC_ID_MAPPER` and class `CL_FHC_CALENDAR_ID_MAPPER`. The mapping is available for holidays, holiday calendars, and factory calendars.

The `CL_FHC_CALENDAR_ID_MAPPER` class returns an ID mapper instance. Subsequently, you can use the methods provided by the interface `IF_FHC_ID_MAPPER` to perform the desired mappings.

### ⚠ Caution

It can't be guaranteed that the 2-digit legacy ID will point to the same calendar on each system. The 2-digit legacy ID should only be used if applications have already used `CL_SCAL_API`, stored the 2-digit legacy ID and have not yet migrated to the new APIs and IDs. The 2-digit legacy IDs are only intended for the transition phase.

We recommend using and saving the new 32-digit IDs on the application side. The whole functionality is optimized for using the new 32-digit ID.

## Creating an ID Mapper Instance

Method	Description
<code>create_id_mapper</code>	Provides an ID mapper instance

### ↗ Sample Code

```
data(lo_id_mapper) = cl_fhc_calendar_id_mapper=>create_id_mapper( ).
```

## Mapping the IDs

Method	Description
<code>mapping_fcal_legacyid_to_id</code>	Provides the 32-digit factory calendar ID for a two-digit SCAL factory calendar ID
<code>mapping_hcal_legacyid_to_id</code>	Provides the 32-digit holiday calendar ID for a two-digit SCAL holiday calendar ID
<code>mapping_hol_legacyid_to_id</code>	Provides the 32-digit holiday ID for a three-digit SCAL holiday ID
<code>mapping_fcal_id_to_legacyid</code>	Provides the two-digit SCAL factory calendar ID for a 32-digit factory calendar ID
<code>mapping_hcal_id_to_legacyid</code>	Provides the two-digit SCAL holiday calendar ID for a 32-digit holiday calendar ID
<code>mapping_hol_id_to_legacyid</code>	Provides the three-digit SCAL holiday calendar ID for a 32-digit holiday ID

### ↗ Sample Code

```
try.
```

```

    data(lv_new_id) = lo_id_mapper->mapping_fcal_legacyid_to_id( iv_legacy_id
= '01' ).
    catch cx_fhc_runtime into data(lx_err).
        "exception handling
endtry.

"another example

try.
    data(lv_legacy_id) = lo_id_mapper-
>mapping_fcal_id_to_legacyid( iv_factorycalendar_id = 'ExampleID' ).
    catch cx_fhc_runtime into lx_err.
        "exception handling
endtry.

```

## Reading Additional Factory Calendar-Related Information

Independently from the above factory calendar information, you can use class `CL_SCAL_UTILS`, which contains the following methods:

Method	Description
MONTH_NAMES_GET	Provides the names of the months
WEEK_GET_FIRST_DAY	Provides the first day of a week
DATE_GET_WEEK	Provides the year and week of a date
DATE_COMPUTE_DAY	Provides the name and number of the weekday for a specified date

### Sample Code

```

try.
    cl_scal_utils=>date_get_week(
        exporting
            iv_date = '20201001'
        importing
            ev_year = data(lv_year)
            ev_week = data(lv_week) ).
    catch cx_scal into data(lx_scal).
        "exception handling
endtry.

```

## 4.2.12.4.1 Accessing Holiday and Factory Calendar Tables Using VDM-Compliant CDS Views

You can access the factory calendar and holiday calendar tables using VDM-compliant CDS views.

The VDM-compliant CDS views used here are CDS views that were created in `SAP_BASIS` and belong to the component `BC-SRV-ASF-CAL`.

## Note

The CDS views mentioned here should be differentiated from the C1-released VDM CDS views created by SAP S/4HANA. An example for a C1-released CDS view is `I_FactoryCalendar`. C1-released VDM CDS views refer to the tables of the factory- and holiday calendar used previously. They don't belong to component `BC-SRV-ASF-CAL`. For this reason, the name addition `BASIC` was introduced for the new version of the CDS views, as can be seen below.

The following CDS views access the factory- and holiday calendar tables:

CDS View	Description
<code>I_PublicHolidayCalendarBasic</code>	General information about holiday calendars
<code>I_PublHolidayCalendarBasicText</code>	Maintained description for holiday calendars
<code>I_PublicHolidayCalendarVH</code>	Value help for holiday calendars containing the holiday calendar ID, legacy holiday calendar ID, the validity start and end date and description
<code>I_FactoryCalendarBasic</code>	General information about a factory calendar
<code>I_FactoryCalendarBasicText</code>	Maintained description for factory calendars
<code>I_FactoryCalendarValueHelp</code>	Value help for factory calendars containing the factory calendar ID, legacy factory calendar ID, the validity start and end date and description

## 4.2.12.5 Lock Objects

When you activate a lock object in the ABAP Dictionary, the system automatically creates function modules for setting locks (`ENQUEUE_<lock object name>`) and releasing locks (`DEQUEUE_<lock object name>`).

### Using Lock Objects

Since the direct usage of these function modules is not permitted, the function module calls are wrapped in a generic API to set and release locks.

- Use class `CL_ABAP_LOCK_OBJECT_FACTORY` to do the following:
  - Create a lock object instance using method `GET_INSTANCE`
  - Release all locks of the current LUW using method `DEQUEUE_ALL`
- Use the created lock object instance to do the following:
  - Set a lock using method `ENQUEUE`
  - Release a lock using method `DEQUEUE`

For more information, see the ABAP Doc comments of class `CL_ABAP_LOCK_OBJECT_FACTORY` and interface `IF_ABAP_LOCK_OBJECT`. The interface `IF_ABAP_LOCK_OBJECT` also contains constants to be used for parameterization of lock methods.

## Sample Code

```
data lv_value type <type of lock object parameter 1>.
lv_value = <value for lock parameter 1>.
data(lr_lock_object) = cl_abap_lock_object_factory=>get_instance(
    exporting iv_name = <name of lock object> ).
try.
    lr_lock_object->enqueue(
        it_parameter = value #( ( name = <name of lock parameter 1> value =
ref #( lv_value ) ) )
        it_table_mode = value #( ( table_name = <table name> mode =
if_abap_lock_object=>cs_mode-<constant for lock mode> ) ) ).
    catch cx_abap_lock_failure into data(lr_exc).
        <exception handling code>
    endtry.
<application code>
try.
    lr_lock_object->dequeue( ).
    catch cx_abap_lock_failure into lr_exc.
        <exception handling code>
    endtry.
```

## 4.2.12.6 Number Range Solution

Many business applications require unique numbers, for example, to complete the keys of data records. In order to get numbers from an interval, a number range object must be defined which can contain different properties. In addition, intervals containing the numbers, must be assigned to the number range object. Numbers can be generated from existing number range intervals.

### Note

Creation, change, and deletion of number range objects and intervals require developer role authorization. Changes to objects and intervals can only be performed in the same software layer.

### 4.2.12.6.1 Maintaining Number Range Objects

To maintain a number range object during design time, the ABAP development tools for Eclipse UI editor for number range objects can be used. For more information, see [Working with Number Range Objects](#).

Class `CL_NUMBERRANGE_OBJECTS` provides methods for maintaining number range objects.

For more information, see

- [Creating Number Range Objects \[page 1394\]](#)
- [Changing Number Range Objects \[page 1396\]](#)
- [Deleting Number Range Objects \[page 1397\]](#)
- [Reading Number Range Objects \[page 1397\]](#)

## Related Information

[Working with Number Range Objects](#)

### 4.2.12.6.1.1 Creating Number Range Objects

Use method `CREATE` to create number range objects.

When creating a number range object, the following naming-rules apply:

- For customer objects, the name must start with a 'Z' or a 'Y'.
- The maximum length of a number range object is 10 characters.

Import Parameters

Parameter Name	Field Name	Value Help
ATTRIBUTES		Number Range Object Definition.
	OBJECT	Name Range Object.
	DTELSOBJ	Data element for sub-object.
	YEARIND	Flag, whether number range object is to- year relevant.
	DOMLEN	Domain, which determines the length of the numbers.
	PERCENTAGE	Percentage of numbers remaining in an interval after having identified in which number assignment a warning is given.
	CODE	Transaction code to call interval maintenance (obsolete for ABAP CP).
	BUFFER	Buffering type for number assignment.
	NOIVBUFFER	Number of numbers in the buffer.
	NRSWAP	Selecting the flag prevents the intervals from automatically starting from the beginning at the upper limit.
	NRCHECKASCII	
	DEVCLASS	Development class of the object.
OBJ_TEXT	CORRNR	Correction number for transport.

Parameter Name	Field Name	Value Help
		Texts for objects for change document object creation.
	LANGU	Language.
	TXT	Description of object, long text.
	TXTSHORT	Description of object, short text.

#### Export Parameters

Parameter Name	Field Name	Value Help
ERRORS		
	MSGID	Message class (NR)
	MSGTYPE	Message type
	MSGNUMBER	Message number
	MSGVAR1	Variable to message
	MSGVAR2	Variable to message
	MSGVAR3	Variable to message
	MSGVAR4	Variable to message
	TABlename	Table
	FIELDNAME	Field
	CRITCHANGE	Critical change
RETURNCODE		Space: no error E: error W: warning

#### Sample Code

```

CLASS zcl_nr_object_create DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.
CLASS zcl_nr_object_create IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
  DATA:
    lv_object TYPE cl_numberrange_objects=>nr_attributes-object,

```

```

lv_devclass TYPE cl_numberrange_objects=>nr_attributes-devclass,
lv_corrnr   TYPE cl_numberrange_objects=>nr_attributes-corrnr.
lv_object   = 'Z_TEST_03'.
lv_devclass = 'Z_SNUM'.
lv_corrnr   = 'SIDK123456'.
TRY.
cl_numberrange_objects=>create(
  EXPORTING
    attributes = VALUE #( object      = lv_object
                           domlen     = 'CHAR8'
                           percentage = 5
                           buffer     = abap_true
                           noiivbuffer = 10
                           devclass   = lv_devclass
                           corrnr     = lv_corrnr )
    obj_text   = VALUE #( object      = lv_object
                           langu     = 'E'
                           txt       = 'Create object'
                           txtshort  = 'Test create' )

  IMPORTING
    errors      = DATA(lt_errors)
    returncode = DATA(lv_returncode)
  ).
CATCH.
  ...
ENDTRY.
...
ENDMETHOD.
ENDCLASS.

```

## 4.2.12.6.1.2 Changing Number Range Objects

Use method `CHANGE` to update number range objects.

Import and export parameters are the same as in the `CREATE` method.

### Sample Code

```

...
lv_object   = 'Z_TEST_03'.
lv_devclass = 'Z_SNUM'.
lv_corrnr   = 'SIDK123456'.
...
cl_numberrange_objects=>update(
  EXPORTING
    attributes = VALUE #( object      = lv_object
                           domlen     = 'CHAR8'
                           percentage = 9
                           buffer     = 'S'
                           noiivbuffer = 12
                           devclass   = lv_devclass
                           corrnr     = lv_corrnr )
    obj_text   = VALUE #( object      = lv_object
                           langu     = 'E'
                           txt       = 'Update object'
                           txtshort  = 'Test update' )

  IMPORTING
    errors      = DATA(lt_errors)
    returncode = DATA(lv_returncode)
  ).
...

```

### 4.2.12.6.1.3 Deleting Number Range Objects

Use method `DELETE` to delete number range objects.

Import Parameters

Parameter Name	Field Name	Value Help
OBJECT		Number Range Object
CORRNR		Correction number for transport

#### Sample Code

```
...
lv_object = 'Z_TEST_03'.
lv_corrnr = 'SIDK123456'.
...
cl_numberrange_objects=>delete(
  EXPORTING
    object = lv_object
    corrnr = lv_corrnr
  ).
...
```

### 4.2.12.6.1.4 Reading Number Range Objects

Use the `READ` method to read the attributes of a number range object.

Import Parameters

Parameter Name	Field Name	Value Help
LANGUAGE		Language for the object texts
OBJECT		Number Range Object

Export Parameters

Parameter Name	Field Name	Value Help
ATTRIBUTES		Number Range Object Definition.
	OBJECT	Number Range Object.
	DTELSOBJ	Data element for sub-object.

Parameter Name	Field Name	Value Help
	YEARIND	Flag, whether number range object is to-year relevant.
	DOMLEN	Domain, which determines the length of the numbers.
	PERCENTAGE	Percentage of numbers remaining in an interval after having identified in which number assignment a warning is given.
	CODE	Transaction code to call interval maintenance (obsolete for ABAP CP).
	BUFFER	Buffering type for number assignment.
	NOIVBUFFER	Number of numbers in the buffer.
	NRSWAP	Selecting the flag prevents intervals from automatically starting from the beginning at the upper limit.
	NRCHECKASCII	
INTERVAL_EXISTS		
OBJ_TEXT		Texts for objects for change document object creation.
	LANGU	Language.
	TXT	Description of object, long text.
	TXTSHORT	Description of object, short text.

#### Sample Code

```

...
lv_object = 'Z_TEST_03'
...
cl_numberrange_objects=>read(
    EXPORTING
        language      = sy-langu
        object         = lv_object
    IMPORTING
        attributes    = DATA(ls_attributes)
        interval_exists = DATA(lv_interval_exists)
        obj_text      = DATA(obj_text)
    ).
...

```

## 4.2.12.6.2 Maintaining Intervals of Number Range Objects

The class `CL_NUMBERRANGE_INTERVALS` provides methods for maintaining intervals of number range objects. Will the APIs be used by a business user, assign the `SAP_CA_BC_IC_LND_NUM_PC` (Number Range Management – Configuration) business catalog to a proper business role and - if required - restrict it to specific number range objects.

For more information, see

- [Creating Intervals of Number Range Objects \[page 1399\]](#)
- [Changing Intervals of Number Range Objects \[page 1401\]](#)
- [Deleting Intervals of Number Range Objects \[page 1402\]](#)
- [Reading Intervals of Number Range Objects \[page 1402\]](#)

### 4.2.12.6.2.1 Creating Intervals of Number Range Objects

Use the `CREATE` method to create number range intervals.

Import Parameters

Parameter Name	Field Name	Value Help
INTERVAL		Interval Table
	SUBOBJECT	Number Range Object Sub-object Value
	NRRANGENR	Number Range Number
	TOYEAR	To Fiscal Year
	FROMNUMBER	From Number
	TONUMBER	To Number
	NRLEVEL	Number Range Level
	EXTERNIND	Internal ('I') or external ('X') number range flag
	PROCIND	Processing flag (I=Insert, D=Delete, U=Update, ' '=no changes)
OBJECT		Number Range Object
SUBOBJECT		Sub-object

## Export Parameters

Parameter Name	Field Name	Value Help
ERROR		Flag showing that an error occurred during testing
ERROR_INF		Error Information
	MSGNR	Message Number
	TABlename	Parameter Name
	FIELDNAME	Field Name
	TABIX	Index of Row with Error
ERROR_IV		Intervals with errors
	SUBOBJECT	Number range object subobject value
	NRRANGENR	Number range number
	TOYEAR	To fiscal year
	FROMNUMBER	From number
	TONUMBER	To number
	NRLEVEL	Number range level
	EXTERNIND	Internal ('I') or external ('X') number range flag
	PROCIND	Processing flag (I=Insert, D=Delete, U=Update, '='=no changes)
WARNING		Flag: Warning after check?

## Sample Code

```

...
CLASS zcl_nr_test_intervals_create DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC.
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.
CLASS zcl_nr_test_intervals_create IMPLEMENTATION.
METHOD if_oo_adt_classrun~main.
DATA: lv_object TYPE cl_numberrange_objects=>nr_attributes-object,
      lt_interval TYPE cl_numberrange_intervals=>nr_interval,
      ls_interval TYPE cl_numberrange_intervals=>nr_nriv_line.
      lv_object = 'Z_TEST_03'.
* intervals

```

```

ls_interval-nrrangenr = '01'.
ls_interval-fromnumber = '00000001'.
ls_interval-tonumber = '19999999'.
ls_interval-procind = 'I'.
APPEND ls_interval TO lt_interval.
ls_interval-nrrangenr = '02'.
ls_interval-fromnumber = '20000000'.
ls_interval-tonumber = '29999999'.
APPEND ls_interval TO lt_interval.
*
create intervals
TRY.
    out->write( |Create Intervals for Object: { lv_object } | ).
    CALL METHOD cl_numberrange_intervals=>create
        EXPORTING
            interval = lt_interval
            object = lv_object
            subobject = ' '
        IMPORTING
            error = DATA(lv_error)
            error_inf = DATA(ls_error)
            error_iv = DATA(lt_error_iv)
            warning = DATA(lv_warning).
    ENDMETHOD.
ENDMETHOD.
ENDCLASS.
...

```

## 4.2.12.6.2.2 Changing Intervals of Number Range Objects

Use the `UPDATE` method to change number range intervals.

Import and export parameters are the same as in the `CREATE` method.

### Sample Code

```

...
lv_object = 'Z_TEST_03'.
*
intervals
ls_interval-nrrangenr = '01'.
ls_interval-fromnumber = '00000002'.
ls_interval-tonumber = '19999998'.
ls_interval-procind = 'U'.
APPEND ls_interval TO lt_interval.
ls_interval-nrrangenr = '02'.
ls_interval-fromnumber = '20000002'.
ls_interval-tonumber = '29999997'.
APPEND ls_interval TO lt_interval.
...
CALL METHOD cl_numberrange_intervals=>update
    EXPORTING
        interval = lt_interval
        object = lv_object
        subobject = ' '
    IMPORTING
        error = DATA(lv_error)
        error_inf = DATA(ls_error)
        error_iv = DATA(lt_error_iv)
        warning = DATA(lv_warning)
...

```

## 4.2.12.6.2.3 Deleting Intervals of Number Range Objects

Use the `DELETE` method to delete number range intervals.

Import and export parameters are the same as in the `CREATE` method.

### Sample Code

```
...
lv_object = 'Z_TEST_03'
*
intervals
ls_interval-nrrangenr = '01'.
ls_interval-fromnumber = '00000001'.
ls_interval-tonumber   = '19999999'.
ls_interval-procind    = 'D'.
APPEND ls_interval TO lt_interval.
ls_interval-nrrangenr = '02'.
ls_interval-fromnumber = '20000000'.
ls_interval-tonumber   = '29999999'.
APPEND ls_interval TO lt_interval.
...
CALL METHOD cl_numberrange_intervals=>delete
  EXPORTING
    interval = lt_interval
    object   = lv_object
    subobject = ' '
  IMPORTING
    error      = DATA(lv_error)
    error_inf  = DATA(ls_error)
    error_iv   = DATA(lt_error_iv)
    warning    = DATA(lv_warning).
...
```

## 4.2.12.6.2.4 Reading Intervals of Number Range Objects

Use the `READ` method to get the properties of number range intervals.

Import Parameters

Parameter Name	Field Name	Value Help
NR_RANGE_NR1		Interval Number (internal interval)
NR_RANGE_NR2		Interval Number (external interval)
OBJECT		Number Range Object
SUBOBJECT		Sub-object

### Sample Code

```
...
lv_object = 'Z_TEST_03'.
...
CALL METHOD cl_numberrange_intervals=>read
```

```
EXPORTING
  object      = lv_object
  nr_range_nr1 = ' '
  nr_range_nr2 = ' '
  subobject   = ' '
IMPORTING
  interval    = lt_interval.
...
```

## 4.2.12.6.2.5 How to Create a Fiori App for a single Number Range Object

You can maintain files in the SAP Fiori Launchpad to launch the Number Range app with the help of a custom app.

### Prerequisites

The business user will need to be assigned with suitable authorization in the Steampunk system:

- the SAP\_CA\_BC\_IC\_LND\_NUM\_PC catalog is needed, as it grants access to the Maintain Number Ranges app
- the SAP\_CA\_BC\_IC\_LND\_PC catalog is needed, as it grants access to the customizing changes
- if the targeted business configuration instance is protected, the relevant custom business catalog must also be assigned to the business user

### Procedure

A custom tile that navigates directly to the Number Range Object app has been created. This is done by using the parameter `Technical_Identifier` in the intent-based navigation .

The implementation contains a creation and deployment of an empty freestyle UI5 app that redirects to the `NumberRangeInterval-manage` (manage number range intervals) with the required parameter. When clicking the tile, the launchpad will first navigate to the intent of the custom app (which is maintained in the app descriptor) and will then automatically be rerouted to the intent of the Maintain Business Configurations app. This rerouting is quite simple to implement after generating an empty app in Business Application Studio (BAS).

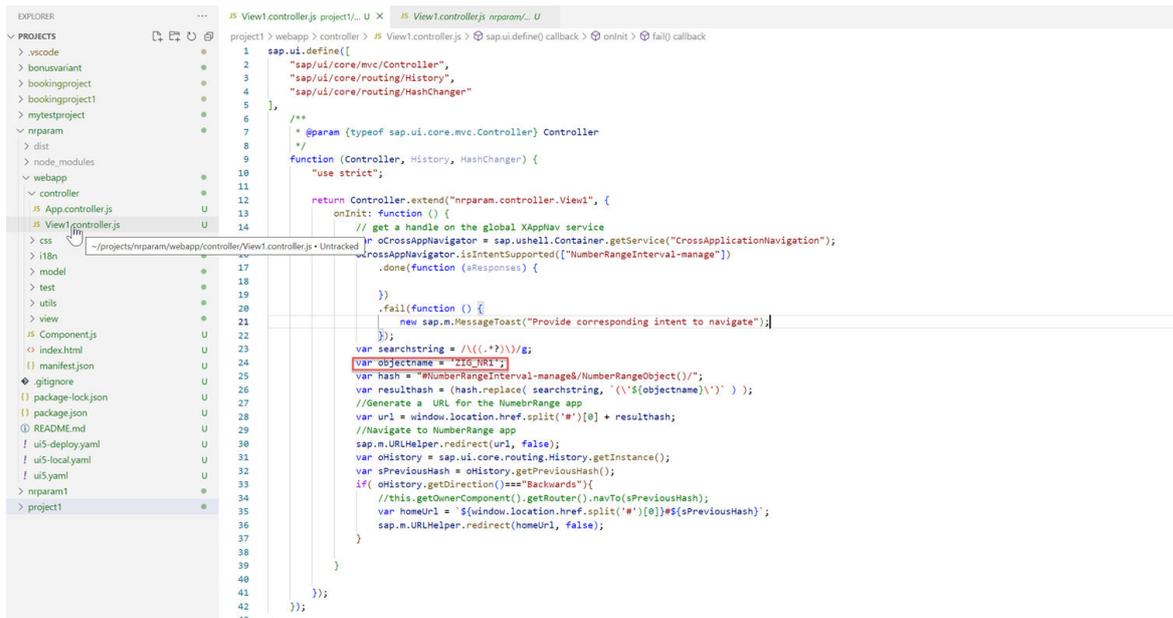

In terms of authorization control, a custom business catalog and business role needs to be created in the Steampunk system and assigned to the business user.

## Reproduce

A development package and a transport request are needed to implement the solution.

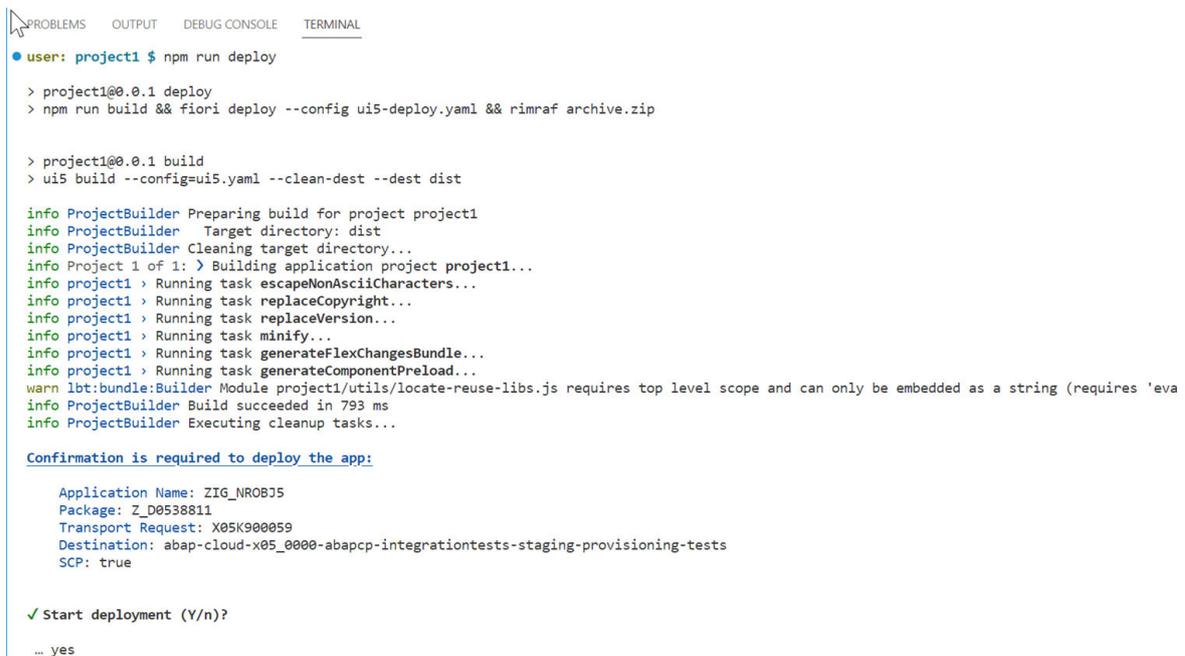

### Create a new SAP Fiori application in BAS

1. Log on to the Business Application Studio (BAS) Development Space to create a new *SAP Fiori application* in BAS and press *Start*.
2. Choose SAPUI5 freestyle from the drop-down menu *Application Type* and press *Next*.

```
1 sap.ui.define([
2   "sap/ui/core/mvc/Controller",
3   "sap/ui/core/routing/History",
4   "sap/ui/core/routing/HashChanger"
5 ],
6 ,
7 /**
8  * @param {typeof sap.ui.core.mvc.Controller} Controller
9  */
10 function (Controller, History, HashChanger) {
11   "use strict";
12
13   return Controller.extend("nrparam.controller.View1", {
14     onInit: function () {
15       // get a handle on the global XAppNav service
16       oCrossAppNavigator = sap.usHELL.Container.getService("CrossApplicationNavigation");
17       oCrossAppNavigator.isIntentSupported(["NumberRangeInterval-manage"]);
18     },
19     .done(function (sResponses) {
20     })
21     .fail(function () {
22       new sap.m.MessageToast("Provide corresponding intent to navigate");
23     });
24
25     var searchstring = /\{\{.*?\}\}/g;
26     var oObjectName = "ZIG_NROBJS";
27     var hash = "#NumberRangeInterval-manage&NumberRangeObject()";
28     var resulthash = (hash.replace(searchstring, '\\${ObjectName}'));
29     //Generate a URL for the NumberRange app
30     var url = window.location.href.split("#")[0] + resulthash;
31     //Navigate to NumberRange app
32     sap.m.URLHelper.redirect(url, false);
33     var oHistory = sap.ui.core.routing.History.getInstance();
34     var sPreviousHash = oHistory.getPreviousHash();
35     if (oHistory.getDirection() === "Backwards"){
36       //this.getOwnerComponent().getRouter().navTo(sPreviousHash);
37       var homeurl = $(window.location.href.split("#")[0]) + sPreviousHash;
38       sap.m.URLHelper.redirect(homeurl, false);
39     }
40   });
41 };
42
43 });
```

3. For *Data source* choose *None* out of the drop-down menu and press *Next*. You can use the proposed view name in the next step or rename it. Press *Next*.

```
user: project1 $ npm run deploy
> project1@0.0.1 deploy
> npm run build && fiori deploy --config ui5-deploy.yaml && rimraf archive.zip

> project1@0.0.1 build
> ui5 build --config=ui5.yaml --clean-dest --dest dist

warn lbt:bundle:Builder Module project1/utills/locate-reuse-libs.js requires top level scope and can only be embedded as a string (requires 'eva
info ProjectBuilder Build succeeded in 793 ms
info ProjectBuilder Executing cleanup tasks...

Confirmation is required to deploy the app:

Application Name: ZIG_NROBJS
Package: Z_D0538811
Transport Request: X05K900059
Destination: abap-cloud-x05_0000-abapcp-integrationtests-staging-provisioning-tests
SCP: true

✓ Start deployment (Y/n)?
... yes
```

4. After filling in the mandatory fields of the project attributes, add your deployment configuration as well as your FLP configuration by choosing *Yes*.

### Note

This configuration can also be added later via the terminal by running the command

```
npx fiori add flp-config
```

Press *Next*.

1. Add a target repository name and a target package, then create a workbench transport request or choose an already existing one. Press *Next*.
6. Finally, adjust the Fiori Launchpad Configuration information:
  - Choose a semantic object that represents a business entity such as a customer, a sales order or a product.
  - Choose an action that describes which operation (such as `display` or `manage`) is intended to be performed on a semantic object.
  - Choose a title that will represent the tile name.

Press *Finish*.

After creating a new SAP Fiori application in BAS, you can deploy it.

### Deploy your SAP Fiori application

1. In the project folder open the created project in the integrated terminal.
2. Go to the `controller` folder which you will find in the folder `webapps` of the project. Open `view1.controller.js`. Insert the code snippet into the view. Adopt the value of the `objectname` variable to the object which you would like to call in Fiori.
3. Deploy your application by means of running the terminal command: `npm run deploy`.
4. After successful deployment a note will appear that is required for the identity application manager.

### Sample Code

```
info builder:custom deploy-to-abap Fiori Launchpad App Descr Item  
ZIG_NROBJ5_UI5R was created
```

5. Now, a successfully deployed application will appear in ABAP Development Tool in the BSP library folder of the deployment package.

To publish the business catalog to the system and pin your final product to the home screen of your Fiori Launchpad, continue reading the next topic called [IAM App Creation and Settings](#).

## 4.2.12.6.2.5.1 IAM App Creation and Settings

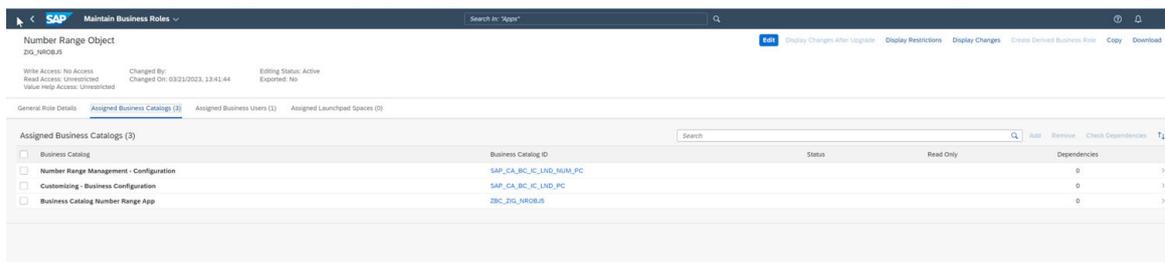

To publish a business catalog, you need to create a new IAM app first in case you do not use an already existing one.

1. Create a new IAM app under the Cloud Identity and Access Management folder.
2. Add an IAM app name as well as a description and press *Next*.
3. Choose a corresponding transport request and press *Finish*.
4. Open the created IAM app and add the previously deployed Business Application Studio app as *Fiori Launchpad Descr Item ID*. Finally, press *Publish Locally*.

- Now assign the IAM app to a new or already existing business catalog and an according description. Press *Finish*.
- Complete the process by publishing the business catalog to the system. Press *Publish Locally*.

## Business Role Settings

- Log onto the staging landscape of the Steampunk system and create a new business role or use an existing one.
- Assign the previously published business catalog to the business role and press *Save*.
- In order to run your application properly, your business role should contain the following business catalogs:

- Go back to the Fiori Launchpad Home view and find your application by searching via App Finder in the drop-down menu of your account icon on the upper right corner of the screen. Now you can also pin the app on your home screen.

## 4.2.12.6.3 Getting Numbers from an Interval

The `CL_NUMBERRANGE_RUNTIME` class provides methods for getting numbers from an interval at runtime.

### Checking Numbers for External Intervals

Use the `NUMBER_CHECK` method to check whether a number is within an external interval.

Import Parameters

Parameter Name	Field Name	Value Help
NR_RANGE_NR		Interval number
NUMBER		Number to be checked
NUMERIC_CHECK		Numeric check (for numeric intervals only)
OBJECT		Number range object
SUBOBJECT		Sub-object
TOYEAR		To fiscal year

Parameter Name	Field Name	Value Help
NUMBER_ALPHA		Obsolete. Please use the parameter NUMBER
LENGTH_CHECK		Check of number length

Export Parameter

Parameter Name	Field Name	Value Help
RETURNCODE		Return code

## Getting Numbers for Internal Intervals

Use the `NUMBER_GET` method to determine the next number of a number range interval.

Import Parameters

Parameter Name	Field Name	Value Help
IGNORE_BUFFER		Ignore Buffer
NR_RANGE_NR		Interval Number
OBJECT		Number Range Object
QUANTITY		Number of Numbers in Buffer
SUBOBJECT		Sub-object
TOYEAR		To Fiscal Year

Export Parameters

Parameter Name	Field Name	Value Help
NUMBER		Returned number
RETURNCODE		Return code
RETURNED_QUANTITY		Number of returned numbers

### Sample Code

```

...
lv_object = 'Z_TEST_03'.
...
CALL METHOD cl_numberrange_runtime=>number_get
  EXPORTING
    nr_range_nr = '01'
    object      = lv_object
  IMPORTING
    number      = DATA(lv_number)

```

```
returncode = DATA(lv_rcode).  
...
```

## Getting the Number Status of an Interval

Use the `NUMBER_STATUS` method to determine the number status of a number range interval.

Import Parameters

Parameter Name	Field Name	Value Help
NR_RANGE_NR		Interval number
OBJECT		Number range object
SUBOBJECT		Sub-object
TOYEAR		To Fiscal Year

Export parameter

Parameter Name	Field Name	Value Help
NUMBER		Number status of the interval

### 4.2.12.6.4 Getting Numbers from an Interval in RAP environment

The `CL_NUMBERRANGE_BUFFER` class provides methods for getting numbers from an interval at runtime. Each method is called based on the buffer type setting of the object. In case the method caller calls a method, which doesn't coincide with the buffer type of the object, an exception `CX_NUMBER_RANGES` will be raised.

## Getting Numbers for Internal Intervals

Based on the buffering settings of the object, you can call a specific API method.

### Getting Numbers for the Object with main Memory Buffering

Use the `NUMBER_GET_MAIN_MEMORY` method to determine the next number of a number range interval.

Import Parameters

Parameter Name	Value Help
IV_OBJECT	Number Range Object

Export Parameters

Parameter Name	Value Help
EV_NUMBER	Returned Number
EV_RETURNCODE	Return Code

Sample Code

```
lv_object = 'ZIG_NR2'.
lv_interval = '01'.
TRY.
DATA(lo_get_number) = cl_numberrange_buffer=>get_instance( ).
lo_get_number->if_numberrange_buffer~number_get_parallel( EXPORTING
lv_object      = lv_object
lv_interval    = lv_interval
lv_subobject   =
lv_year       =
IMPORTING
ev_number     = iv_number ).
CATCH cx_number_ranges INTO DATA(lr_error).
ENDTRY.
```

**Getting Numbers for the Object without Buffering**

Use the NUMBER\_GET\_NO\_BUFFER method to determine the next number of a number range interval.

Export Parameters

Parameter Name	Value Help
EV_NUMBER	Returned Number
EV_RETURNCODE	Return Code
EV_RETURNED_QUANTITY	Number of Returned Numbers

Sample Code

```
lv_object = 'ZIG_NR9'.
lv_interval = '01'.
lv_quantity = 10.
TRY.
DATA(lo_get_number) = cl_numberrange_buffer=>get_instance( ).
lo_get_number->if_numberrange_buffer~number_get_no_buffer( EXPORTING
lv_object      = lv_object
lv_subobject   =
lv_interval    =
lv_year       =
lv_quantity    =
lv_ignore_buffer =
IMPORTING
ev_number     = lv_number
ev_returned_quantity = lv_returned_quantity).
CATCH cx_number_ranges INTO DATA(lr_error).
```

## 4.2.12.7 Customer Data Browser

With this app, you can view SAP BTP ABAP environment data owned by the customer.

### Key Features

You can use this app as a self-service to:

- View business data owned by customers.
- View the data of custom fields.
- View the technical names and business names of fields.
- Configure filter criteria and sort data.
- Configure display columns.
- Get the total number of records.
- Export data visible in the application to a spreadsheet.
- Provide controlled and restricted access to users (Admin user feature).

### Component for Customer Incidents

If you need support or experience issues, please report an incident under component `BC-SRV-APS-CDB`.

### Supported Device Types

- Desktop
- Tablet

### Related Information

[Security Audit Log \[page 1413\]](#)

[Getting Started \[page 1414\]](#)

[Restrictions and App Behavior \[page 1415\]](#)

[Using the App \[page 1419\]](#)

[FAQs \[page 1420\]](#)

## 4.2.12.7.1 Application Overview

Customer Data Browser is a self-service application that you can use to view data that belongs to CDS views and database tables allowed for user access by SAP or by the customer.

The CDS views and database tables allowed for user access by SAP in the Customer Data Browser app are called Customer Data Browser objects.

You can create Customer Data Browser objects using the ABAP Development Tools (ADT). For more information, see [Working with Customer Data Browser Objects](#).

### CDS View Coverage

In keeping with the SAP BTP ABAP Environment guidelines, the Customer Data Browser application primarily displays data using published CDS views (of the type contract C1) that are relevant to this environment.

For application areas which do not have good coverage of published CDS views, SAP may provide database tables as a temporary solution to display the data. After the relevant CDS views are published, SAP may disable the corresponding tables.

As part of continuous review and update of application content, the number of allowed Customer Data Browser objects available in the application are projected to increase with every upcoming release.

#### Disclaimer

The use of the Customer Data Browser application may conflict with the data protection policies of your organization. The authorization concept does not support any filtering by the Data Controller or by typical attributes reflecting the purposes of processing. In addition, a download of the data is a transfer in a software/ environment that is potentially not secured. Hence, before using the Customer Data Browser application, please ensure that you follow the data protection Policies in your organization.

### Related Information

[Customer Data Browser \[page 1411\]](#)

[Read Access Logging \[page 1413\]](#)

## 4.2.12.7.2 Read Access Logging

### Use

In Read Access Logging (RAL), you can configure which read-access information to log and under which conditions.

SAP delivers sample configurations for applications.

The **BC/BC-SRV-APS-CDB/Template for Preview Access** captures information related to viewing and accessing data.

In the following configurations, fields are logged in combination with additional fields, in the following business contexts:

Channel	Configuration	Fields Logged	Business Context
SAP Gateway (OData)	BC/BC-SRV-APS-CDB/ Template for Preview Access	Username (SY-UNAME) Request URL (:Request URL)>	Log viewing and accessing data along with the search fil- ter criteria

#### Note

See SAP Note [3351781](#) for information about the template RAL configuration file for Customer Data Browser.

### Related Information

[Customer Data Browser \[page 1411\]](#)

[Security Audit Log \[page 1413\]](#)

## 4.2.12.7.3 Security Audit Log

In Security Audit Log (SAL), you can get information about user access to the *Customer Data Browser* application.

You can check the security audit logs for the Customer Data Browser app using the [Display Security Audit Log \[page 2560\]](#) app. In the *Display Security Audit Log* app, choose the audit event FU5.

For more information about security audit logs, see: [Security Audit Log](#).

## Related Information

[Customer Data Browser \[page 1411\]](#)

[Getting Started \[page 1414\]](#)

### 4.2.12.7.4 Getting Started

Customer Data Browser is a self-service application that you can use to view data that belongs to specific CDS views and database tables that are allowed for user access by SAP or by the customer.

#### Note

The CDS views and database tables that are allowed for user access by SAP or by the customer in the Customer Data Browser app are called Customer Data Browser objects.

## Viewing Fiori Tiles

This application is available on the SAP Fiori launchpad screen as a customer self-service.

Based on your assigned business role catalog, you can view the SAP Fiori launchpad tile [Customer Data Browser](#).

## Required Users

The required user and the respective business catalog role and business role template for the **Customer Data Browser** app are described below.

Required User	User Task	Business Catalog Role	Business Role Template	Application
Business User	Access application	SAP_CORE_BC_CDB_PC	SAP_BR_ADMINISTRATOR_DANA  (Administrator - Data Analysis)	Customer Data Browser
Admin User	Maintain authorization restrictions	Not relevant	SAP_BR_ADMINISTRATOR  (Administrator)	Maintain Business Roles

## Role Purpose

The roles are used for the following purposes:

- **SAP\_BR\_ADMINISTRATOR** (Administrator): With this role, you can maintain authorization restrictions using the [https://help.sap.com/docs/SAP\\_S4HANA\\_CLOUD/a630d57fc5004c6383e7a81efee7a8bb/365b0d6fe67d4cecbfe11cc8344264cc.html](https://help.sap.com/docs/SAP_S4HANA_CLOUD/a630d57fc5004c6383e7a81efee7a8bb/365b0d6fe67d4cecbfe11cc8344264cc.html) app.  
For more information about maintaining restrictions for Customer Data Browser, see [How to Define Authorizations Based on Restrictions \[page 2459\]](#).  
For more information about restriction fields for Customer Data Browser, see [Restrictions and App Behavior \[page 1415\]](#).
- **SAP\_BR\_ADMINISTRATOR\_DANA** (Administrator – Data Analysis): With this role, you can access Customer Data Browser application.

## Role Assignment Recommendations

- Assign the **SAP\_BR\_ADMINISTRATOR\_DANA** role to a business user who does not have the **SAP\_BR\_ADMINISTRATOR** role.
- Make sure that the user with the **SAP\_BR\_ADMINISTRATOR\_DANA** role is assigned to a single copy of the **SAP\_BR\_ADMINISTRATOR\_DANA** role. Assigning the user to multiple copies of the **SAP\_BR\_ADMINISTRATOR\_DANA** role may cause authorization issues when you access the Customer Data Browser app.

## Related Information

[Customer Data Browser \[page 1411\]](#)

[Restrictions and App Behavior \[page 1415\]](#)

### 4.2.12.75 Restrictions and App Behavior

#### Restrictions Required to Be Maintained by the Administrative User

The *Read/Value Help* restriction type for the Customer Data Browser app consists of the following restriction fields:

Restriction Field	Description
Object Group	Logically groups Customer Data Browser objects.  Note that this field is not active.
Object Name	Displays a list of Customer Data Browser objects and their descriptions.
Object Fields	Provides access to the following categories of fields in Customer Data Browser objects: <ul style="list-style-type: none"> <li>• GE: General fields that do not contain sensitive personal information</li> <li>• SP: Sensitive personal information fields that contain key fields and fields with sensitive personal information</li> <li>• Unrestricted: All fields containing general and sensitive personal information</li> </ul> <p>Note that the field categories are determined by internal SAP classifications.</p>
Object Records	Provides access to the following categories of data records in Customer Data Browser objects: <ul style="list-style-type: none"> <li>• OV: Records with bypassed access controls (privileged access)</li> <li>• AC: Records that fulfill access controls (unprivileged access)</li> <li>• Unrestricted: Records that fulfill access controls (unprivileged access)</li> </ul>

### Note

When maintaining restrictions, set the *Write, Read, Value Help* restriction to **No Access**.

## App Behavior in Response to Administrative Restrictions

Refer to the restriction matrix below to understand the expected behavior of the application.

Restrictions Set By the Administrator			Display Behavior in Customer Data Browser App				
For Object Name	For Object Field	For Object Record	Objects	CDS Views	Database Tables	Fields	Records

**Restrictions Set By the Administrator      Display Behavior in Customer Data Browser App**

Unrestricted access	Unrestricted	Unrestricted	Displays all objects	Displays data that is authorized for the user. Note that the user is explicitly required to obtain the necessary authorizations.	No data displayed	Displays general (GE) and sensitive personal (SP) fields	Displays records that fulfill access controls (AC)
Restrictions not maintained	Restrictions not maintained	Restrictions not maintained	Displays no objects	No data displayed	No data displayed	No data displayed	No data displayed
Restricted access	Access to general fields (GE)	Access to records that fulfill access controls (AC)	Displays objects with access	Displays data that is authorized for the user. Note that the user is explicitly required to obtain the necessary authorizations.	No data displayed	Displays general fields (GE)	Displays records that fulfill access controls (AC)
Restricted access	Access to sensitive personal fields (SP)	Access to records that fulfill access controls (AC)	Displays objects with access	Displays data that is authorized for the user. Note that the user is explicitly required to obtain the necessary authorizations.	No data displayed	Displays sensitive personal fields (SP)	Displays records that fulfill access controls (AC)
	Access to general (GE) and sensitive personal (SP) fields	Access to records that fulfill access controls (AC)	Displays objects with access	Displays data that is authorized for the user. Note that the user is explicitly required to obtain the necessary authorizations.	No data displayed	Displays general (GE) and sensitive personal (SP) fields	Displays records that fulfill access controls (AC)

Restrictions Set By the Administrator		Display Behavior in Customer Data Browser App					
	Access to general fields (GE)	Access to records with bypassed access controls (OV)	Displays objects with access	Displays all data	Displays all data	Displays general fields (GE)	Displays all records
Restricted Read Access	Access to sensitive personal fields (SP)	Access to records with bypassed access controls (OV)	Displays objects with access	Displays all data	Displays all data	Displays sensitive personal fields (SP)	Displays all records
Restricted access	Access to general (GE) and sensitive personal (SP) fields	Access to records with bypassed access controls (OV)	Displays objects with access	Displays all data	Displays all data	Displays general (GE) and sensitive personal (SP) fields	Displays all records

## Summary of User Access

### Business Users

You can access...	If...	Even if...
Data in CDS views	You have the required CDS view-specific access controls	You have Customer Data Browser-specific access to bypass access controls (Object Records: OV)
Data in database tables	You have Customer Data Browser-specific access to bypass access controls (Object Records: OV)	

### Administrators

You can restrict access to Customer Data Browser objects by providing a list of object names in the *Object Name* restriction field.:

## Related Information

[Customer Data Browser \[page 1411\]](#)

[Using the App \[page 1419\]](#)

## 4.2.12.76 Using the App

When you choose the **Customer Data Browser** tile, you can see a list of Customer Data Browser objects that you are authorized to view.

The list of Customer Data Browser objects includes:

- CDS views, including custom CDS views
- Database tables

### Working with the App

#### Navigating to the Data Details Screen

Choose a row to navigate to the *Customer Data Browser – Data Details* screen where you can view the data relevant to the object. You can sort the data and configure filter criteria to view a subset of data.

#### Entering Parameter Values for CDS Views

If you choose a CDS view that requires you to enter parameter values before previewing data, you can enter the values in the Maintain Parameters dialog box.

#### Customer Data Browser - Data Details Screen

You can see the following options on the *Customer Data Browser – Data Details* screen

- **Total Records**: Choose to display the total number of records in the selected Customer Data Browser object.

#### Note

If you set filters, the total number of records is calculated based on the filter criteria.

- **View Technical Name/View Business Name**: Choose this toggle button to display the technical names or the business names of the columns.
- **Parameters**: Choose this button to change parameter values for CDS views that require parameters.

#### Note

This button is visible if the CDS view requires parameter values before preview.

- **Maximum Rows to Be Displayed**: Enter the maximum number of rows to be displayed on the screen. By default, this value is set to 100. This means that the first 100 entries that match the filter criteria are displayed on the screen. You can reset this value to display a different maximum number.
- **Adapt Filters**: Choose this button to select additional filters or deselect existing filters.
- **Export**: From the *Export* icon, choose the export option to download data displayed on the screen to your local machine as a spreadsheet.
- **Settings**: Choose this button to select columns you want to view or deselect columns you no longer want to view.

## Related Information

[Customer Data Browser \[page 1411\]](#)

[FAQs \[page 1420\]](#)

### 4.2.12.7.7 FAQs

#### Business Users

##### 1. Why can't I see any Customer Data Browser objects in the app?

**Answer:** You do not have the authorization to view the objects. Please contact your administrator and ask them to grant the authorization you need to view the objects. For more information, see [Restrictions and App Behavior \[page 1415\]](#).

##### 2: How can I see the complete list of Customer Data Browser objects available with the app?

**Answer:** You can view the complete list of Customer Data Browser objects if you have admin-level authorization. Contact your administrator to get the complete set of authorizations. Please ask the administrator to select all values in the *Object Name* restriction field.

##### 3. Why can't I find a particular CDS view or table in the list of Customer Data Browser objects?

**Answer:** Here are some possible reasons:

- Your administrator has not granted you authorization to access this object, or
- The particular object is not yet enabled for Customer Data Browser

Contact your administrator for the exact reason.

##### 4. When trying to view the CDS view data, why do I get the message "You either do not have the required authorization or there is no data to be displayed"?

**Answer:** You get this message because:

- Your administrator has not granted the required CDS view-specific authorizations (business catalogs) to your user. This means you cannot view the data of this CDS view.
- Alternatively, your administrator has granted the required CDS view-specific authorizations (business catalogs) to your user, but there is no data to be displayed. So, the system displays the error message.

Contact your administrator to obtain the required CDS view-specific authorizations.

##### 5. When trying to view the data of a table, why do I get the message "No authorization to view object data"?

**Answer:** You see this message when your administrator has not granted the Customer Data Browser-specific authorizations to your user to view the data of database tables.

Contact your administrator to obtain the required authorizations.

For more information, see [Restrictions and App Behavior \[page 1415\]](#).

## **6. My administrator has maintained the required restrictions to view data of relevant tables or CDS views. However, I keep getting a message in the app that I am not authorized to view the data.**

**Answer:** Inform your administrator that you do not have the authorization to view the specific tables or CDS views.

- The user with the `SAP_BR_ADMINISTRATOR_DANA` role is assigned to a single copy of the `SAP_BR_ADMINISTRATOR_DANA` role (either the original or a copy of original, we recommend creating a copy). You can check the assignment in the [Maintain Business Users \[page 2444\]](#) app.
- The *Write, Read, Value Help* restriction is maintained as **No Access**

To validate the values provided in the restrictions, see [Restrictions and App Behavior \[page 1415\]](#).

## **Administrators**

### **1. As an administrator, how can I maintain restrictions for the Customer Data Browser app?**

**Answer:** For detailed information about restrictions, see [Restrictions and App Behavior \[page 1415\]](#).

### **2. As an administrator, how can I identify the CDS view-specific authorizations so that the user can view the data of a specific CDS view?**

**Answer:** In the [SAP Business Accelerator Hub](#), choose *CDS Views* to see detailed information about published interface (I\_) CDS views.

If you have any issues identifying the necessary CDS view-specific authorizations, report an incident under the application component relevant to the CDS view.

### **3 I have maintained the required restrictions for the business user to view data of relevant tables or CDS views. However, the business user keeps getting a message in the app that there is no authorization to view the data.**

**Answer**

- Ensure that the user with the `SAP_BR_ADMINISTRATOR_DANA` role is assigned to a single copy of the `SAP_BR_ADMINISTRATOR_DANA` role (either the original or a copy of original, we recommend creating a copy). You can check the assignment in the [Maintain Business Users \[page 2444\]](#) app.
- Ensure that the *Write, Read, Value Help* restriction is maintained as **No Access**

To validate the values provided in the restrictions, see [Restrictions and App Behavior \[page 1415\]](#).

### **4: How can I grant authorization to the business user to view the complete set of Customer Data Browser objects available with the app?**

**Answer:** You can provide unrestricted access to the business user by choosing the *Unrestricted Access* buttons in the *Object Name* window.

## 4.2.12.8 Application Jobs

You can use this app to schedule and monitor application-related jobs. If you have manual activities that you often need to do at a specific time, the *Application Jobs* app can reduce your workload by running these tasks smoothly in the background. You can plan regular jobs which keeps you free to concentrate on other tasks.

### Key Features

You can use this app to:

- Schedule jobs based on a job template: Select a job template, define the description, start date, start time and recurrence of the job, and enter job-specific selection criteria and parameters
- Work with personalized job templates: Create and personalize a job template, save personalized job template for later use, and share personalized template

#### Note

The parameters under *Scheduling Information* can't be saved as part of a template.

- Schedule jobs with a custom factory calendar: In the *Application Jobs* app, define the scheduling information, change an existing calendar, create a new one, and define execution days
- Arrange job series that take different time zones into account
- Monitor jobs
- Display logs and results: You can navigate to job logs and job results by clicking on the icon in the *Log* or the *Results* column
- Copy a job
- Cancel a job
- Restart job chains
- Navigate to the *Application Logs* reuse library. You can do this by selecting the corresponding icon in the log on the initial screen of the app.

## Supported Device Types

- Desktop
- Tablet

## Component for Customer Incidents

If you need support or experience issues, please report an incident under component `BC-SRV-APS-APJ`.

### 4.2.12.8.1 Creating a Job Catalog Entry and a Job Template in ADT

Follow these steps to create a job catalog entry and a job template in ADT.

#### Procedure

1. Implement the business logic. You need to create a class which implements certain interfaces so that it's usable in an application job. For more information, see [Implementing the Business Logic \[page 1424\]](#).
2. Define the job catalog entry. With a method of a certain framework class, you create a job catalog entry which refers to the class of step 1. For more information, see [Creating the Job Catalog Entry \[page 1426\]](#).
3. Define the job template. With another method of the framework class, you create a job template which refers to the job catalog entry of step 2. For more information, see [Creating the Job Template \[page 1426\]](#).

For more information on how to create a job catalog entry and a job template in ADT, see [Working with Application Job Objects](#).

If you want to implement a simple RAP (ABAP RESTful application programming model) business object, see [Code Sample: How to Schedule Application Jobs from a RAP-based Business Object](#) . This code sample allows you to schedule a class as an application job that takes the semantic key of the selected entity as a parameter.

### 4.2.12.8.1.1 Implementing the Business Logic

Business logic is ABAP coding that you want to be run within an application job. Usually this coding also defines selection fields. In this context, business logic is implemented in a class. The following development steps require a user with the development role.

Create a class which implements the two interfaces:

- **IF\_APJ\_DT\_EXEC\_OBJECT**
- **IF\_APJ\_RT\_EXEC\_OBJECT**

This class is considered the main class per application job. This class needs to be part of a customer-defined software component (not ZLOCAL) in order to be able to transport the class into subsequent systems.

The first interface, IF\_APJ\_DT\_EXEC\_OBJECT, contains design-time related methods. Method **GET\_PARAMETERS( )** is called by the application jobs framework to get all supported selection parameters.

The method GET\_PARAMETERS( ) returns two internal tables:

- The content of the table **ET\_PARAMETER\_DEF** determines the parameter section for the job catalog entry, which will refer to this main class.
- The content of the table **ET\_PARAMETER\_VAL** determines the default values for these parameters in the job template, which will refer to the job catalog entry mentioned above.

The second interface, IF\_APJ\_RT\_EXEC\_OBJECT, contains runtime related methods. Method **EXECUTE()** is called by the application jobs framework if a scheduled job will actually be executed. It receives an internal table as parameter. This table is of the same type as the table ET\_PARAMETER\_VAL of method GET\_PARAMETERS(). The method EXECUTE() simply receives the parameters and values, which were stored in the template and which were originally delivered by the method GET\_PARAMETERS().

Please refer to the example code for an application jobs main class. Literals are used instead of language-dependent texts in order to simplify the example. For writing application log entries, please refer to [Runtime API](#)

#### Sample Code

```
CLASS zcl_test_apj_simple DEFINITION

[Application Logs \[page 1433\]](#)

### 4.2.12.8.1.2 Creating the Job Catalog Entry

An application job catalog entry contains the information that is needed for scheduling and running an application job. The application job catalog entry contains the name of the class that implements the business logic, and the information on how selection fields are rendered in the job scheduling dialog in the app.

To create a job catalog entry, use the `ABAP Development Tools` (ADT) editor. For more information, see [Working with Application Job Objects](#). Alternatively, you could still also create job catalog entries and job templates via a released API. This API is called from within a console application. The console application is only required in the development system.

Job catalog entries and job templates are created with a package assignment and the objects are assigned to a transport request. You need to make sure that the package and transport request fit together (regarding the transport layer) and that possible naming conventions are obeyed.

The job catalog entry mainly contains the reference to the implementation class of the business logic.

#### Example

A code example of a console application that generates the minimal number of required development objects: One job catalog entry and one related job template is shown in [Creating the Job Template](#) (see [Related Links](#) below).

## Related Information

[Creating the Job Template \[page 1426\]](#)

[Setting up the Authorizations \[page 1428\]](#)

### 4.2.12.8.1.3 Creating the Job Template

An [Application Job Template](#) refers to an application job catalog entry and contains values for some or all selection fields. It can be thought of as a variant of an application job catalog. In the simplest case, a job template doesn't contain any values for the selection fields. In this case, the selection fields are prefilled with their initial values (such as 0 if the selection field is of type integer). An application job catalog entry can have more than one application job template. The job template is the entity that can be scheduled in the [Application](#)

*Jobs* app. In the scheduling dialog, the selection fields appear and are prefilled with the values defined in the template. They can be overwritten by the user. Scheduling an application job template then results in an application job.

The creation of a job template follows the same technical rules as a *Job Catalog Entry* as described in [Creating the Job Catalog Entry \[page 1426\]](#).

The following code example shows a console application that generates the minimal number of required development objects: One *Job Catalog* entry and one related *Job Template*.

### Sample Code

[Setting up the Authorizations \[page 1428\]](#)

### 4.2.12.8.1.4 Setting up the Authorizations

Some further activities in ADT and in the administrator's launchpad are necessary to be able to schedule the job template in the Fiori app *Application Jobs*.

1. Create an Identity and Access Management (IAM) Business Catalog.  
When you create a job catalog entry and a job template as explained in [Creating a Job Catalog Entry and a Job Template in ADT \[page 1423\]](#), an object of the type **IAM App** is created automatically. It has the name **<job catalog entry name>\_SAJC**. This IAM app contains the start authorization for all job templates that refer to this job catalog entry.

Create an IAM business catalog via ADT:

1. Right-click the package where the objects are located that have already been created.
2. Select *New > Other ABAP Repository Object*.
3. Expand *Cloud Identity and Access Management*.
4. Double-click *Business Catalog*.
5. Enter a name (e.g. ZTEST\_MY\_SIMPLE\_JOBS) and a description.
6. Select *Save* and choose the appropriate transport request.
7. Select the tab *Apps* below.
8. Press *Add ...* on the top right corner of the screen.
9. Enter the name of the IAM app mentioned in step **e** (ZTEST\_MY\_SIMPLE\_JOB\_SAJC).
10. Select *Save*.
11. Press *Publish Locally* on the top right corner of the screen.

2. If the business logic performs own authorization checks, remember to add the required authorizations to a separate IAM app of type `EXT`. The following steps explain how to do this:
  1. Right-click the package that contains the objects that have already been created.
  2. Select *New* and then choose *Other ABAP Repository Object*.
  3. Expand *Cloud Identity and Access Management*.
  4. Choose *IAM App*.
  5. Enter a name and a description. Choose *EXT - External App* as application type.
  6. Select an appropriate transport request and click *Save*.
  7. Select the *Authorizations* tab.
  8. Select *Insert*. Now, you can specify an authorization object and assign values to the authorization fields.
  9. Repeat step 8 for each authorization that is necessary to run the business logic.
  10. Add the IAM app to the business catalog that you've created as described in step 1.
3. Create a business role.
 

Open the Fiori App *Maintain Business Roles* in the Fiori Launchpad of the administrator and perform the following steps:

  1. Click *New*.
  2. Choose a name (e.g. `ZTEST_MY_SIMPLE_JOBS`) and a description.
  3. Click on *Assigned Business Catalogs*.
  4. Select *Add*.
  5. Select the business catalog created in the previous step (e.g. `ZTEST_MY_SIMPLE_JOBS`).

#### Note

A business user who shall be able to schedule application jobs needs to have access to the *Application Jobs* tile. This tile is provided by the business catalog `SAP_CORE_BC_APJ_JCE`, which is contained in the business role `SAP_BR_ADMINISTRATOR`. It doesn't only provide the *Application Jobs* app, but also contains restriction types to configure the authorization on other users' jobs and to schedule jobs for other users (for more information, see the section *Assigning Further Authorizations* below).

Add the business catalog `SAP_CORE_BC_APJ_JCE` to the business role created following the steps above, or assign it to a separate business role.

6. Select *Save*.
4. Assign the business role to a user.
 

For more information, see [How to Maintain Business Users \[page 2445\]](#).

## Assigning Further Authorizations

You can access only your own jobs in the *Application Jobs* app. In order to grant access to other users' objects used in the *Application Jobs* app, create a new business role assigning the business catalog `SAP_CORE_BC_APJ_JCE` to it. You can modify the provided restriction types according to your needs.

1. Create a new business role assigning the business catalog `SAP_CORE_BC_APJ_JCE` to it. The restriction type `Job Catalog Entry/Application Job Part` contains the two fields `Application Job Catalog Entry` and `Application Job Part`. For more information, see [Maintain Business Roles \[page 2472\]](#).

### Note

With this restriction type you'll be able to provide the necessary authorizations for certain actions on other users' application jobs, which are based on a specified job catalog entry. With this, you can display the logs of other users' jobs, which are based on this specified job catalog entry.

Alternatively, you can also create a display only-role using this restriction type.

2. The business catalog `SAP_CORE_BC_APJ_JCE` has another restriction type: `Create Application Jobs for Other Users`. It has the restriction field `Application Job Catalog Entry`.

### Note

With this restriction type you'll be able to grant a business user the authorization to schedule an application job for any other business user, based on the job catalog entry selected. This feature is supported by the parameter `iv_username` of the method `cl_apj_rt_api=>schedule_job`. For more information, see [Maintaining Application Jobs Using an API \[page 1431\]](#).

3. Next, define your business role with the above-mentioned restriction fields `Application Job Catalog Entry` and `Application Job Part`. To do so, select [Maintain Restrictions](#). In the `Application Job Catalog Entry` field, you can choose the job catalog entries, and in the `Application Job Part` field, you can choose for which part of a job access should be granted. You can choose the values `JOB` (Job Details), `SPOOL` (Result List), and `APPROG` (Log) by clicking the [Edit](#) icon next to the fields.
4. Go back and select [Save](#). Now, you've maintained your business role, and you can assign the role to a business user.

## 4.2.12.8.15 Deleting the Job Catalog Entry and the Job Template

Find out how to delete a job catalog entry and a related job template.

To delete a job catalog entry, you must first delete the related job template. You can delete the job template using the method `DELETE_JOB_TEMPLATE_ENTRY` of the class `CL_APJ_DT_CREATE_CONTENT`.

In order to delete a job catalog entry, if you don't want to create a job catalog entry with the same name anymore and if you enabled the job scheduling via the app, you need to manually undo all actions that were performed after the creation of the job catalog entry in reverse order. Undo the actions in the following order:

- Remove the business role from the business user in the Fiori app [Maintain Business Users](#)
- Delete the business role in the Fiori app [Maintain Business Roles](#)
- Unassign the IAM app from the IAM business catalog in ADT
- Delete the IAM business catalog in ADT

Then, call the method `DELETE_JOB_CAT_ENTRY` of the class `CL_APJ_DT_CREATE_CONTENT`.

If you do want to create a job catalog entry with the same name as the job catalog entry you want to delete, it's sufficient to remove the IAM app assignment from the IAM business catalog(s) to which you've assigned it before. After the creation of the new job catalog entry, assign the new IAM app again to the IAM business catalog.

## 4.2.12.8.2 Maintaining Application Jobs Using an API

You can use the `CL_APJ_RT_API` class to maintain application jobs. You can do the following:

- schedule an application job
- retrieve the status of an application job
- cancel an application job
- delete an application job

## 4.2.12.9 Application Logs

You can use the [Application Logs](#) to display and check if any errors occurred during runtime.

The [Application Logs](#) are a reuse library that is mainly used within the [Application Jobs](#) app, but can also be used in other apps. This reuse library gives you a clearly structured overview of all errors that might have occurred during runtime.

## Key Features

You can use this reuse library to:

- view application log details
- filter the logs by severity
- search for message texts
- display the message details

## Component for Customer Incidents

BC-SRV-APS-APL

For more information, see

- [Design Time API \[page 1434\]](#)
- [Runtime API \[page 1438\]](#)
- [How to Use the Fiori Reuse Library \[page 1493\]](#)

## Related Information

[Working with Application Log Objects](#)

### 4.2.12.9.1 Design Time API

You can use the *Application Log Design Time API* if you want to create, change, or delete an application log object or subobject during the development process of an application.

For information on how to create an application log object in ADT, see [Working with Application Log Objects](#).

The *Application Log Design Time API* provides the following design time operations:

- Create a new application log object, optionally with subobjects
- Delete an application log object and all of its subobjects
- Add a new subobject to an existing application log object
- Delete a subobject from an application log object
- Read an application log object and all of its subobjects

## Create a New Application Log Object, Optionally with Subobjects

Once you have created an instance of the `CL_BALI_OBJECT_HANDLER` API class using method `CREATE_OBJECT`, a new application log object is created.

### Sample Code

```
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->create_object( EXPORTING iv_object = 'MYOBJECT'
                                iv_object_text = 'My Application
Log Object'
                                iv_package = 'MYPACKAGE'
                                iv_transport_request =
'MYTRANSPORT' ).
    CATCH cx_bali_objects INTO DATA(lx_exception).
        WRITE lx_exception->get_text( ).
ENDTRY.
```

In case the new application log object has subobjects, you can create these too, using the `CREATE_OBJECT` method.

### Sample Code

```
DATA: ls_subobject TYPE LINE OF if_bali_object_handler=>ty_tab_subobject,
      lt_subobject TYPE if_bali_object_handler=>ty_tab_subobject.
ls_subobject-subobject = 'MYSUBOBJECT'.
ls_subobject-subobject_text = 'My Application Log Sub-Object'.
APPEND ls_subobject TO lt_subobject.
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->create_object( EXPORTING iv_object = 'MYOBJECT'
                                iv_object_text = 'My Application
Log Object'
                                it_subobjects = lt_subobject
                                iv_package = 'MYPACKAGE'
                                iv_transport_request =
'MYTRANSPORT' ).
    CATCH cx_bali_objects INTO DATA(lx_exception).
        WRITE lx_exception->get_text( ).
ENDTRY.
```

## Delete an Application Log Object and all of its Subobjects

Use method `DELETE_OBJECT` to delete an application log object and all of its subobjects.

### Sample Code

```
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->delete_object( EXPORTING iv_object = 'MYOBJECT'
                                iv_transport_request =
'MYTRANSPORT' ).
    CATCH cx_bali_objects INTO DATA(lx_exception).
        WRITE lx_exception->get_text( ).
```

```
ENDTRY.
```

## Add a New Subobject to an Existing Application Log Object

Use method `ADD_SUBOBJECT` if you want to add a new subobject to an existing application log object.

### Sample Code

```
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->add_subobject( EXPORTING iv_object = 'MYOBJECT'
                                iv_subobject = 'MYSUBOBJECT'
                                iv_subobject_text = 'My
Application Log Sub-Object'
                                iv_transport_request =
'MYTRANSPORT' ).
    CATCH cx_bali_objects INTO DATA(lx_exception).
        WRITE lx_exception->get_text( ).
ENDTRY.
```

## Delete a Subobject from an Application Log Object

You can delete a subobject using method `DELETE_SUBOBJECT`.

### Sample Code

```
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->delete_subobject( EXPORTING iv_object = 'MYOBJECT'
                                    iv_subobject = 'MYSUBOBJECT'
                                    iv_transport_request =
'MYTRANSPORT' ).
    CATCH cx_bali_objects INTO DATA(lx_exception).
        WRITE lx_exception->get_text( ).
ENDTRY.
```

## Read an Application Log Object and all of its Subobjects

Use method `READ_OBJECT` to read an application log object with its subobjects.

### Sample Code

```
DATA(lo_log_object) = cl_bali_object_handler=>get_instance( ).
TRY.
    lo_log_object->read_object( EXPORTING iv_object = 'MYOBJECT'
                               IMPORTING et_subobjects = DATA(lt_subobjects)
                               ev_object_text =
DATA(lv_object_text) ).
```

```
CATCH cx_bali_objects INTO DATA(lx_exception).
WRITE lx_exception->get_text( ).
ENDTRY.
```

## 4.2.12.9.1.1 Classes and Interfaces of the Design Time API

You can use the `CL_BALI_OBJECT_HANDLER` class as *Application Log Design Time API* to create, change, read, or delete application log objects or subobjects. It uses the public interface `IF_BALI_OBJECT_HANDLER`.

### Public Methods

GET\_INSTANCE (static)

Parameter	Type	Description
RO_OBJ_HANDLER	Returning	Create, change or delete application log objects

Create a new application log object, optionally with subobjects.

IF\_BALI\_OBJECT\_HANDLER~CREATE\_OBJECT

Parameter	Type	Description
IV_OBJECT	Importing	New application log object
IV_OBJECT_TEXT	Importing	Description for new application log object
IT_SUBOBJECTS	Importing	Table of new application log subobjects
IV_PACKAGE	Importing	Package
IV_TRANSPORT_REQUEST	Importing	Transport request

### Note

The input of a table of subobjects for parameter `IT_SUBOBJECTS` is optional. If parameters `IV_PACKAGE` and `IV_TRANSPORT_REQUEST` are not provided, it is assumed that a local object shall be created.

Delete an application log object and all of its subobjects.

IF\_BALI\_OBJECT\_HANDLER~DELETE\_OBJECT

Parameter	Type	Description
IV_OBJECT	Importing	Application log object
IV_TRANSPORT_REQUEST	Importing	Transport request

Add a new subobject to an existing application log object.

IF\_BALI\_OBJECT\_HANDLER~ADD\_SUBOBJECT

Parameter	Type	Description
IV_OBJECT	Importing	Application log object
IV_SUBOBJECT	Importing	New application log subobject
IV_SUBOBJECT_TEXT	Importing	Description for new application log sub-object
IV_TRANSPORT_REQUEST	Importing	Transport request

Delete a subobject from an application log object.

IF\_BALI\_OBJECT\_HANDLER~DELETE\_SUBOBJECT

Parameter	Type	Description
IV_OBJECT	Importing	Application log object
IV_SUBOBJECT	Importing	Application log subobject
IV_TRANSPORT_REQUEST	Importing	Transport request

Read an application log object and all of its subobjects

IF\_BALI\_OBJECT\_HANDLER~READ\_OBJECT

Parameter	Type	Description
IV_OBJECT	Importing	Application log object
EV_OBJECT_TEXT	Importing	Description for an application log object
ET_SUBOBJECTS	Importing	Table of application log subobjects

#### Note

For all methods, IV\_TRANSPORT\_REQUEST is not required for local objects.

All methods of IF\_BALI\_OBJECT\_HANDLER include exception CX\_BALI\_OBJECTS.

## 4.2.12.9.2 Runtime API

Use a class-based API to create and read application logs.

You can use a class-based API to create and read application logs. The application log is a tool for collecting messages or exceptions which are stored in a log. You can save this log in the database or read and delete it from there.

If an application wants to collect messages and exceptions which occur during runtime of an application program, the following steps are required:

- [Create a New Application Log \[page 1439\]](#)
- [Set Header Information \[page 1442\]](#)
- [Add Items \[page 1443\]](#)
- [Writing Application Logs to the Database \[page 1447\]](#)

If an application wants to read the content of an application log from the database, for example, to display its content, the following steps are required:

- [Define a Filter \[page 1450\]](#)
- [Read Application Logs from the Database \[page 1451\]](#)
- [Get Header Information from the Log \[page 1454\]](#)
- [Get Items from the Log \[page 1455\]](#)

## 4.2.12.9.2.1 Creating an Application Log

If an application wants to collect messages and exceptions which occur during runtime of an application program, the following steps are required:

- [Create a New Application Log \[page 1439\]](#)
- [Set Header Information \[page 1442\]](#)
- [Add Items \[page 1443\]](#)
- [Writing Application Logs to the Database \[page 1447\]](#)

### 4.2.12.9.2.1.1 Create a New Application Log

If you want to create a new application log, you must first create an object of class `CL_BALI_LOG`. This object manages a single application log and allows to get and set the log header and all log items, such as messages or exceptions.

To create an object of class `CL_BALI_LOG`, the class provides two methods:

- If the header information of the log, for example the external identifier, is already known when the application log is created, you can use the `CREATE_WITH_HEADER` method. In this case, you can set the log header during the call. For more information, see [Set Header Information \[page 1442\]](#).

#### Example

##### Sample Code

```
CLASS zcl_test_write DEFINITION
PUBLIC
FINAL
CREATE PUBLIC .
PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
PROTECTED SECTION.
PRIVATE SECTION.
ENDCLASS.
```

```

CLASS zcl_test_write IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    TRY.
      " Create a new Application Log
      DATA(l_log) = cl_bali_log=>create( ).
      " Add a header to the log
      l_log->set_header( header = cl_bali_header_setter=>create( object =
'ZOBJECT'

subobject = 'ZSUBOBJECT'

external_id = 'External ID' ) ).
      " Add a message as item to the log
      DATA(l_message) = cl_bali_message_setter=>create( severity =
if_bali_constants=>c_severity_error
                                                    id = 'PO'
                                                    number = '000' ).

      l_log->add_item( item = l_message ).
      " Add a second message, this time from system fields SY-MSGID, ...
      MESSAGE ID 'ZTEST' TYPE 'S' NUMBER '058' INTO DATA(l_text).
      l_log->add_item( item = cl_bali_message_setter=>create_from_sy( ) ).
      " Add a free text to the log
      DATA(l_free_text) = cl_bali_free_text_setter=>create( severity =
if_bali_constants=>c_severity_error
                                                    text = 'Some
Error Text' ).
      l_log->add_item( item = l_free_text ).
      " Add an exception to the log
      DATA: i TYPE i.
      TRY.
        i = 1 / 0.
        CATCH cx_sy_zerodivide INTO DATA(l_ref).
      ENDTRY.
      DATA(l_exception) = cl_bali_exception_setter=>create( severity =
if_bali_constants=>c_severity_error
                                                    exception =
l_ref ).
      l_log->add_item( item = l_exception ).
      " Save the log into the database
      cl_bali_log_db=>get_instance( )->save_log( log = l_log ).
      CATCH cx_bali_runtime INTO DATA(l_runtime_exception).
      out->write( l_runtime_exception->get_text( ) ).
    ENDTRY.
  ENDMETHOD.
ENDCLASS.

```

## Sample Code

```

...
  TRY.
    DATA(l_log) = cl_bali_log=>create_with_header(
      header = cl_bali_header_setter=>create( object =
'ZOBJECT'
subobject =
'ZSUBOBJECT'
external_id =
'External ID' ) ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
    out->write( l_exception->get_text( ) ).
  ENDTRY.
...

```

If the header information is not known when the application log is created, you can use the `CREATE` method. It creates an empty application log. In this case, the header should be set later using the `SET_HEADER` method.

If no subobjects were defined for the application log object, an empty string should be used at the parameter SUBOBJECT.

#### Sample Code

```
...
  TRY.
    DATA(l_log) = cl_bali_log=>create( ).
    ...
    l_log->set_header( header = cl_bali_header_setter=>create( object =
'ZOBJECT'
                                     subobject
= 'ZSUBOBJECT'
external_id = 'External ID' ) ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
...
```

If the application log is no longer needed in the memory, for example because it was saved into the database, it's possible to release its memory. This can be done using the method `RELEASE_MEMORY`.

After calling the method `RELEASE_MEMORY`, the log object is invalidated and can no longer be used. The method `IS_INVALIDATED` can be used to check whether the memory of the log object was already released by a previous call of the method `RELEASE_MEMORY`.

#### Sample Code

```
...
  TRY.
    DATA(l_log) = cl_bali_log=>create( ).
    ...
    " Add items to the log and e.g. write the log to the database
    ...
    " Release the memory of the log
    l_log->release_memory( ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
...
```

#### Sample Code

```
...
  TRY.
    DATA(l_log) = cl_bali_log=>create( ).
    ...
    " Check whether the log was already invalidated
    IF l_log->is_invalidated( ) = abap_true.
      " Start some error handling
    ENDIF.
    ...
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
...
```

## 4.2.12.9.2.1.2 Set Header Information

An application log contains header information and attributes to identify the log. During log creation, the following header information can be set:

- Log Object (required): Identifies the application to which the log belongs.
- Log Subobject: An application can define subcategories of its log object. These subcategories are called subobjects and must be set if the application defined them. If no subobjects were defined for the log object, the field should remain empty.
- External Identifier: We recommend to enter your preferred identifier containing, for example, the application document number.
- Expiry Date: It defines the date when the log expires and can be deleted from the database. The default value is the creation date of the log + 7 days.
- A flag defining whether it should not be allowed to delete the log before the expiry date by a standard report. The application is still able to delete the log before this date.

To define the log header, an instance of the `IF_BALI_HEADER_SETTER` interface is required. To create this instance, you can use method `CREATE` of class `CL_BALI_HEADER_SETTER`. It allows to set the object, subobject and the external identifier of the application log.

Interface `IF_BALI_HEADER_SETTER` contains the following methods to set or change the header attributes:

- `SET_DESCRIPTOR`: Changes the object, subobject and external identifier.
- `SET_EXPIRY`: Sets the expiry date and the *keep until expiry* flag.

### Note

You have two options to transfer the header to the application log object:

- Using method `CREATE_WITH_HEADER` of class `CL_BALI_LOG` when the log object is created.
- Using method `SET_HEADER` of interface `IF_BAL_LOG`.

If the header was already written to the log (for example, using method `SET_HEADER` of interface `IF_BAL_LOG`) and if the header object is changed afterwards (for example, using method `SET_DESCRIPTOR`), you must call method `SET_HEADER` to make these changes visible in the log.

### Sample Code

```
...
TRY.
    DATA(l_header) = cl_bali_header_setter=>create( object = 'ZOBJECT'
                                                    subobject = 'ZSUBOBJECT'
                                                    external_id = 'External
ID' ).
    l_header->set_expiry( expiry_date = CONV
#( cl_abap_context_info=>get_system_date( ) + 5 )
                           keep_until_expiry = abap_true ).
    CATCH cx_bali_runtime INTO DATA(l_runtime_exception).
        out->write( l_runtime_exception->get_text( ) ).
ENDTRY.
...
```

## 4.2.12.9.2.1.3 Add Items

To write items, such as messages or exceptions, to the log during runtime, the application requires an item object which contains all attributes of the item, such as the message number or the reference to the exception object.

The following categories of log items are provided:

- Message (for example, a message is displayed using ABAP command **MESSAGE**). For more information, see [Create a Message \[page 1445\]](#).
- Free Text (a text with a maximum length of 200 characters). For more information, see [Create a Free Text \[page 1446\]](#).
- Exception (for example, an exception is raised using ABAP command **RAISE EXCEPTION** and can be caught using ABAP command **CATCH**). For more information, see [Create an Exception \[page 1447\]](#).

To add a log item to an application log, the `IF_BALI_LOG` interface provides the following methods:

- `ADD_ITEM`: Append an item to the application log
- `CUMULATE_ITEM`: If the item is a message, it's checked whether the log already contains a message with the same message attributes (severity, message ID, message number and variables). If yes, the counter of the message is increased by 1. In all other cases, it works the same way as `ADD_ITEM`.
- `ADD_MESSAGES_FROM_BAPIRETTAB`: Append several messages to the application log. The message attributes are stored in an internal table of type `BAPIRETTAB`.
- `ADD_ABAP_BEHAVIOR_MESSAGE`: Append an ABAP behavior message, which uses the interface `IF_ABAP_BEHV_MESSAGE`, to the log.
- `ADD_ALL_ITEMS_FROM_OTHER_LOG`: Read all items from another application log and append them to this log. This method can be used if the items of different application logs are merged into one log. Sometimes it's required to filter items which are put into an application log by using the method `ADD_ITEM`. For example, there may be an encapsulated application class which writes error and status messages into an application log, and the caller of this application class only requires the error messages. In this case, the caller can define an item filter (see [Define a Filter \[page 1450\]](#)). The caller can then add this item filter to the log using the method `SET_FILTER_FOR_ADD_ITEM`. If an item filter is set for a log object, only those items that pass this filter are added to the log object.

### Note

If an item was already added to the application log, its attributes can't be changed any more. Therefore, if the attributes of the item object are changed after the item was added to the log, these changes are not transferred to the log.

When an item is added to the application log, it can probably be converted internally. For example, an exception which is based on a message (which contains a message ID and message number) is internally converted into a message.

### Sample Code

```
...
TRY.
    DATA(l_log) = cl_bali_log=>create( ).

    MESSAGE ID 'ZTEST' TYPE 'W' NUMBER '002' INTO DATA(l_text).
    l_log->add_item( item = cl_bali_message_setter=>create_from_sy( ) ).
```

```

l_log->cumulate_item( item = cl_bali_message_setter=>create_from_sy( ) ).
DATA: i TYPE i.
TRY.
    i = 1 / 0.
    CATCH cx_sy_zerodivide INTO DATA(l_ref).
ENDTRY.
l_log->add_item( item = cl_bali_exception_setter=>create( exception =
l_ref ) ).
DATA(l_bapirettab) = VALUE bapirettab( ( id = 'BL' type = 'I' number =
'315'
                                     message_v1 = 'A' message_v2 =
'B' message_v3 = 'C' message_v4 = 'D' )
                                     ( id = 'BL' type = 'E' number =
'319' ) ).
l_log->add_messages_from_bapirettab( message_table = l_bapirettab ).
CATCH cx_bali_runtime INTO DATA(l_exception).
out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

### Sample Code

```

...
TRY.
    DATA(l_log_target) = cl_bali_log=>create( ).

    MESSAGE ID 'ZTEST' TYPE 'W' NUMBER '002' INTO DATA(l_text).
    l_log_target->add_item( item =
cl_bali_message_setter=>create_from_sy( ) ).
    DATA(l_log_source) = cl_bali_log=>create( ).
    DATA: i TYPE i.
    TRY.
        i = 1 / 0.
        CATCH cx_sy_zerodivide INTO DATA(l_ref).
    ENDTRY.
    l_log_source->add_item( item =
cl_bali_exception_setter=>create( exception = l_ref ) ).
    " add all items of l_log_source to l_log_target
    l_log_target->add_all_items_from_other_log( source_log = l_log_source ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
    out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

### Sample Code

```

...
TRY.
    DATA(l_log) = cl_bali_log=>create( ).

    " Add item filter to the log which only allows error messages
    DATA(l_filter) = cl_bali_item_filter=>create( )-
>set_severity( severity_table = VALUE #( ( 'E' ) ) ).
    l_log->set_filter_for_add_item( filter = l_filter ).
    MESSAGE ID 'ZTEST' TYPE 'W' NUMBER '002' INTO DATA(l_text).
    l_log->add_item( item = cl_bali_message_setter=>create_from_sy( ) ). "
Message is not added, because it is a warning
    MESSAGE ID 'ZTEST' TYPE 'E' NUMBER '002' INTO l_text.
    l_log->add_item( item = cl_bali_message_setter=>create_from_sy( ) ). "
Message is added, because it is an error
    " Get the current item filter
    data(l_item_filter) = l_log->get_filter_for_add_item( ).

    " Clear the current item filter

```

```

l_log->set_filter_for_add_item( filter = value #( ) ).
CATCH cx_bali_runtime INTO DATA(l_exception).
  out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

## 4.2.12.9.2.1.3.1 Create a Message

One item category, which can be written into an application log, is a message. A message is identified by the message ID and the message number.

When an application log message is defined, you can set the following attributes:

- Severity, such as 'Error', 'Warning', 'Information'. Values of the severity are defined as constants in interface `IF_BALI_CONSTANTS`.
- Message ID
- Message Number
- Variables 1 - 4 of the message
- Detail Level of the item: If the application displays the items of the application log, the detail level can be used to define at which level of detail the item shall be displayed.

To add a message to an application log, an instance of interface `IF_BALI_MESSAGE_SETTER` is required. To create this instance, class `CL_BALI_MESSAGE_SETTER` provides the following methods:

- `CREATE`: It allows to set the severity, message ID, message number and the variables of the message.
- `CREATE_FROM_SY`: You can use this method to create an application log message from the system fields in the list below. These system fields are filled, for example, by ABAP command `MESSAGE`. The following system fields are available:
  - SY-MSGTY
  - SY-MSGID
  - SY-MSGNO
  - SY-MSGV1
  - SY-MSGV2
  - SY-MSGV3
  - SY-MSGV4
- `CREATE_FROM_BAPIRET2`: It allows to set all message parameters via structure `BAPIRET2`.

Interface `IF_BALI_MESSAGE_SETTER` contains the following methods to set or change the attributes of the message:

- `SET_ATTRIBUTES`: Changes the severity, message ID, message number and the variables of the message.
- `SET_FROM_SY`: Changes the severity, message ID, message number and the variables of the message to the values of the system fields, such as SY-MSGTY.
- `SET_FROM_BAPIRET2`: Changes the severity, message ID, message number and the variables of the message to the values of structure `BAPIRET2`.
- `SET_DETAIL_LEVEL`: Sets the detail level.

## Sample Code

```
...
DATA(l_ref) = cl_bali_message_setter=>create(
    severity = if_bali_constants=>c_severity_error
    id = 'BL'
    number = '315'
    variable_1 = 'A'
    variable_2 = 'B'
    variable_3 = 'C'
    variable_4 = 'D' ).
l_ref->set_detail_level( detail_level = '7' ).
...
MESSAGE ID 'ZTEST' TYPE 'I' NUMBER '315' WITH 'E' 'F' 'G' 'H' INTO
DATA(l_message).
l_ref = cl_bali_message_setter=>create_from_sy(
    )->set_detail_level( detail_level = '3' ).
...
DATA(l_bapiret2) = VALUE bapiret2( id = 'BL' type = 'I' number = '315'
    message_v1 = 'A' message_v2 = 'B'
    message_v3 = 'C' message_v4 = 'D' ).
l_ref = cl_bali_message_setter=>create_from_bapiret2( message_data =
l_bapiret2 ).
...
```

## 4.2.12.9.2.1.3.2 Create a Free Text

One item category, which can be written into an application log, is *Free Text*. It is any text with up to 200 characters.

The following attributes can be set when an application log free text is defined:

- Severity, such as 'Error', 'Warning', 'Information'. Possible values of the severity are defined as constants in interface `IF_BALI_CONSTANTS`.
- Text content
- Detail level of the item: If the application displays the items of the application log, the detail level can be used to define at which level of detail the item shall be visible.

To add a free text to an application log, an instance of interface `IF_BALI_FREE_TEXT_SETTER` is required. To create this instance, you can use method `CREATE` of class `CL_BALI_FREE_TEXT_SETTER`. It allows to set the severity and the text content.

To set or change the attributes of the free text, interface `IF_BALI_FREE_TEXT_SETTER` contains the following methods:

- `SET_TEXT`: Changes the text content and severity.
- `SET_DETAIL_LEVEL`: Sets the detail level.

## Sample Code

```
...
DATA(l_ref) = cl_bali_free_text_setter=>create(
    severity = if_bali_constants=>c_severity_error
    text = 'Some Error Text' ).
l_ref->set_detail_level( detail_level = '4' ).
...
```

```

l_ref = cl_bali_free_text_setter=>create( text = 'Some Other Text'
                                         )->set_detail_level( detail_level = '1' ).
...

```

### 4.2.12.9.2.1.3.3 Create an Exception

One item category, which can be written into an application log, is an *Exception*. An exception is raised by the application using ABAP command **RAISE EXCEPTION** and can be caught by ABAP command **CATCH**.

To define an application log exception, you can set the following attributes:

- Severity, such as 'Error', 'Warning', 'Information'. Possible values of the severity are defined as constants in interface `IF_BALI_CONSTANTS`.
- Reference to the exception object
- Detail Level of the item: If the application displays the items of the application log, the detail level can be used to define at which level of detail the item shall be displayed.

To add an exception to an application log, an instance of interface `IF_BALI_EXCEPTION_SETTER` is required. To create this instance, method `CREATE` of class `CL_BALI_EXCEPTION_SETTER` can be used. It allows to set the severity and the reference to the exception object.

If you want to set or change the attributes of the exception, you can use interface `IF_BALI_EXCEPTION_SETTER`. It contains the following methods:

- `SET_EXCEPTION`: Changes the reference to the exception object and the severity.
- `SET_DETAIL_LEVEL`: Sets the detail level.

#### Sample Code

```

...
DATA: i TYPE i.
TRY.
    i = 1 / 0.
    CATCH cx_sy_zerodivide INTO DATA(l_exception_ref).
ENDTRY.
DATA(l_ref) = cl_bali_exception_setter=>create( severity =
if_bali_constants=>c_severity_error
                                              exception =
l_exception_ref ).
l_ref->set_detail_level( detail_level = '2' ).
...

```

### 4.2.12.9.2.1.4 Writing Application Logs to the Database

You can use interface `IF_BALI_LOG_DB` to write an application log to the database or to delete database entries. To get an instance of the interface, method `GET_INSTANCE` of class `CL_BALI_LOG_DB` is available.

To change the logs in the database, interface `IF_BALI_LOG_DB` contains the following methods:

- **SAVE\_LOG / SAVE\_LOG\_2ND\_DB\_CONNECTION:** Save an application log in the database. The log is identified by the log object (which uses interface `IF_BAL_LOG`). It may be required to commit the saving of the log immediately after the saving. It ensures that the log is stored, even if the application calls *ROLLBACK WORK* later on. Whether it is required depends on the application. Some applications want to keep the log entries after the rollback, others want to remove everything by the *ROLLBACK WORK*, including the log entries.

Therefore, there are two different methods to save an application log:

- **SAVE\_LOG** uses the default database connection. This means that the changes of the log are only committed if the application calls `COMMIT_WORK`.
- **SAVE\_LOG\_2ND\_DB\_CONNECTION** uses a service connection to the database for the saving, and it immediately commits the saving of the log.

In addition, the optional parameter `ASSIGN_TO_CURRENT_APPL_JOB` is available. If this parameter is set, and if the application runs in an application job, the connection between the application log and an application job is established. The application log is visible in the application job display.

- **DELETE\_LOG:** Deletes an application log from the database. The log is identified by the log object (which uses interface `IF_BAL_LOG`).
- **ENQUEUE:** If there is a parallel processing of the same application report, it may happen - depending on the application - that several reports try to change the same application log at the same time. In this case, one report overwrites the application log data of the other report. To avoid this, method `ENQUEUE` can be used to set an enqueue on the application log. The log is identified by the log object (which uses interface `IF_BAL_LOG`).
- **DEQUEUE:** Clear the enqueue which was set via method `ENQUEUE`. The log is identified by the log object (which uses interface `IF_BAL_LOG`).

## Note

You can quickly access a log stored in the database using the log handle. The log handle is the UUID of the log. To enable the application to store the log handle in one of the application tables, interface `IF_BAL_LOG` offers method `GET_HANDLE` which returns the log handle.

## Example

Save a log in the database:

### Sample Code

```

...
    TRY.
        DATA(l_log) =
cl_bali_log=>create_with_header( cl_bali_header_setter=>create( object =
'ZOBJECT'

                subobject = 'ZSUBOBJECT'

                external_id = 'External ID' ) ).
        MESSAGE ID 'ZTEST' TYPE 'I' NUMBER '315' WITH 'A' 'B' 'C' 'D' INTO
DATA(l_text).
        l_log->add_item( cl_bali_message_setter=>create_from_sy( ) ).
        cl_bali_log_db=>get_instance( )->save_log( log = l_log ).
        CATCH cx_bali_runtime INTO DATA(l_exception).
            out->write( l_exception->get_text( ) ).
        ENDTRY.
...

```

Save the same log using the second database connection:

#### Sample Code

```
...
  TRY.
    cl_bali_log_db=>get_instance( )->save_log_2nd_db_connection( log =
l_log ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
  ...
```

Delete the same log from the database:

#### Sample Code

```
...
  TRY.
    cl_bali_log_db=>get_instance( )->delete_log( log = l_log ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
  ...
```

Delete a log from the database which uses the handle l\_handle.

:

#### Sample Code

```
...
  DATA l_handle TYPE if_bali_log=>ty_handle.
  l_handle = ...
  TRY.
    DATA(l_log_db) = cl_bali_log_db=>get_instance( ).
    DATA(l_log) = l_log_db->load_log( handle = l_handle
      read_only_header = abap_true ).
    l_log_db->delete_log( log = l_log ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
      out->write( l_exception->get_text( ) ).
    ENDTRY.
  ...
```

The following authorization is checked before a log is deleted from the database:

Authorization object: S\_APPL\_LOG, with

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 06

## 4.2.12.9.2.2 Reading an Application Log

If an application wants to read the content of an application log from the database, for example, to display its content, the following steps are required:

- [Define a Filter \[page 1450\]](#)
- [Read Application Logs from the Database \[page 1451\]](#)
- [Get Header Information from the Log \[page 1454\]](#)
- [Get Items from the Log \[page 1455\]](#)

### 4.2.12.9.2.2.1 Define a Filter

If one or more application logs shall be read from the database and if the log handles are not known, you can identify the logs by defining a filter.

To create a filter, an instance of interface `IF_BALI_LOG_FILTER` is required. To create this instance, you can use method `CREATE` of class `CL_BALI_LOG_FILTER`. It creates an empty filter.

#### Note

Due to performance reasons, we recommend to set at least the object and subobject in the filter.

Interface `IF_BALI_LOG_FILTER` contains the following methods to set the filter parameters:

- `SET_DESCRIPTOR`: Set a filter for the log object, subobject and external identifier. It offers the following parameters:
  - Select a single object
  - Select a single subobject (wildcards allowed)
  - Select a table of subobjects (wildcards allowed)
  - Select a single external identifier (wildcards allowed)
  - Select a table of external identifiers (wildcards allowed)
- `SET_CREATE_INFO`: Set a filter for the attribute which identifies the creator of the log. It offers the following parameters:
  - Select a single user (wildcards allowed)
  - Select a table of users (wildcards allowed)
- `SET_TIME_INTERVAL`: Set a time interval for the creation date and time of the log. The start and end time of the interval are set using UTC time stamps.
- `SET_MAXIMUM_LOG_NUMBER`: Set the maximum number of logs which shall be read from the database. If the parameter is not set, all logs are read (which fulfill the other filter criteria).

#### Example

Set a filter which selects up to 5 logs which were created in the last hour by the current user:

#### Sample Code

...

```

TRY.
  DATA(l_filter) = cl_bali_log_filter=>create( ).
  l_filter->set_create_info( user = sy-uname ).

  DATA(l_timestamp_now) = utclong_current( ).
  DATA(l_timestamp_minus_1_hour) = utclong_add( val = l_timestamp_now
                                                hours = '1-' ).
  l_filter->set_time_interval( start_time = l_timestamp_minus_1_hour
                             end_time = l_timestamp_now ).
  l_filter->set_maximum_log_number( max_log_number = 5 ).
CATCH cx_bali_runtime INTO DATA(l_exception).
  out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

Set a filter which reads all logs of the current user with object ZOBJECT, subobject ZSUBOBJECT and an external identifier which starts with an 'E':

#### Sample Code

```

...
TRY.
  DATA(l_filter) = cl_bali_log_filter=>create(
                                )->set_create_info( user = sy-
uname
                                )->set_descriptor( object =
'ZOBJECT'
                                                subobject =
'ZSUBOBJECT'
                                                external_id =
'E*' ).
  CATCH cx_bali_runtime INTO DATA(l_exception).
    out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

## 4.2.12.9.2.2.2 Read Application Logs from the Database

You can use interface `IF_BALI_LOG_DB` to read one or more application logs from the database. To get an instance of the interface, method `GET_INSTANCE` of class `CL_BALI_LOG_DB` is available.

Interface `IF_BALI_LOG_DB` contains the following methods which can be used to read the logs from the database:

- `LOAD_LOG / LOAD_LOG_WITH_ITEMS`: Load one application log from the database.
  - The log is identified by the log handle.
  - The method returns an object of interface `IF_BALI_LOG`.
  - With method `LOAD_LOG_WITH_ITEMS`, the complete log including all items is read from the database. If you use method `LOAD_LOG` and set the optional parameter `READ_ONLY_HEADER`, only the log header is read from the database. The log items are not read yet.
- `LOAD_LOGS_VIA_FILTER / LOAD_LOGS_W_ITEMS_VIA_FILTER`: Load one or more logs from the database.
  - The logs are identified by a filter object of interface `IF_BALI_LOG_FILTER`.

- The method returns an internal table of objects of interface IF\_BALI\_LOG.
- With method LOAD\_LOG\_W\_ITEMS\_VIA\_FILTER, the complete logs including all items are read from the database. If you use method LOAD\_LOGS\_VIA\_FILTER and set the optional parameter READ\_ONLY\_HEADER, only the log headers are read from the database. The log items are not read yet.

The following authorization is checked before a log is read from the database:

Authorization object: S\_APPL\_LOG, with

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 03

## ❖ Example

Load a log from the database, generic code example:

### ↔ Sample Code

```

CLASS zcl_test_read DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.
CLASS zcl_test_read IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    TRY.
      " Create a filter which selects all logs of the current user from
the last hour
      DATA(l_filter) = cl_bali_log_filter=>create( ).
      l_filter->set_create_info( user = sy-uname ).
      DATA(l_timestamp_now) = utclong_current( ).
      DATA(l_timestamp_minus_1_hour) = utclong_add( val = l_timestamp_now
                                                    hours = '1-' ).
      l_filter->set_time_interval( start_time = l_timestamp_minus_1_hour
                                end_time = l_timestamp_now ).
      " Read all Application Logs from the database which fit to the
filter
      DATA(log_table) = cl_bali_log_db=>get_instance( )-
>load_logs_w_items_via_filter( filter = l_filter ).
      LOOP AT log_table INTO DATA(l_log).
        " Output log handle
        out->write( |Handle: { l_log->get_handle( ) }| ).
        " Get log header and output attributes of the header
        DATA(l_header) = l_log->get_header( ).
        out->write( |{ l_header->object } { l_header->subobject }
{ l_header->external_id } { l_header->log_user }| ).
        " Get all items and output some data which exist in all item
categories
        DATA(l_item_table) = l_log->get_all_items( ).
        LOOP AT l_item_table INTO DATA(l_item_entry).
          out->write( |{ l_item_entry-log_item_number } { l_item_entry-
item->get_message_text( ) }| ).
          " Output attributes which are specific for messages and
exceptions
          IF l_item_entry-item->category =
if_bali_constants=>c_category_message.
            DATA(l_message_ref) = CAST
if_bali_message_getter( l_item_entry-item ).

```

```

        out->write( |{ l_message_ref->id } { l_message_ref-
>number }| ).
        ELSEIF l_item_entry-item->category =
if_bali_constants=>c_category_exception.
            DATA(l_exception_ref) = CAST
if_bali_exception_getter( l_item_entry-item ).
            out->write( |{ l_exception_ref->exception_class }
{ l_exception_ref->exception_id_name }| ).
        ENDIF.
    ENDMETHOD.
ENDLOOP.
ENDLOOP.
CATCH cx_bali_runtime INTO DATA(l_runtime_exception).
    out->write( l_runtime_exception->get_text( ) ).
ENDTRY.
ENDMETHOD.
ENDCLASS.

```

## ❁ Example

Load a single log from the database which uses log handle l\_handle; only read the log header:

### ↔ Sample Code

```

...
DATA l_handle TYPE if_bali_log=>ty_handle.
...
TRY.
    DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle
read_only_header = abap_true ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
        out->write( l_exception->get_text( ) ).
    ENDTRY.
...

```

Load all logs from the database which were created by the current user:

### ↔ Sample Code

```

...
TRY.
    DATA(l_filter) = cl_bali_log_filter=>create( )-
>set_create_info( user = sy-uname ).
    DATA(log_table) = cl_bali_log_db=>get_instance( )-
>load_logs_w_items_via_filter( filter = l_filter ).
    CATCH cx_bali_runtime INTO DATA(l_exception).
        out->write( l_exception->get_text( ) ).
    ENDTRY.
...

```

## 4.2.12.9.2.2.3 Get Header Information from the Log

An application log contains header information and several attributes which identify the log. To read the header from a log, method `GET_HEADER` of interface `IF_BALI_LOG` can be used. It returns an object which uses interface `IF_BALI_HEADER_GETTER`.

Interface `IF_BALI_HEADER_GETTER` contains the following attributes:

- `OBJECT`: Log object which identifies the application to which the log belongs.
- `SUBOBJECT`: Log subobject which is the subcategory of an application log object.
- `EXTERNAL_ID`: A free text which is usually used by the application to identify the log. It contains, for example, the application document number.
- `LOG_TIMESTAMP`: UTC time stamp of the log (usually the creation time).
- `LOG_USER`: Log user (usually the user who created the log).
- `EXPIRY_DATE`: It defines the date when the log expires and can be deleted from the database.
- `KEEP_UNTIL_EXPIRY`: A flag which defines whether or not it is allowed to delete the log before the expiry date. If the flag is set, the standard reports which delete application logs do not delete the log before the expiry date. The application is still able to delete the log before this date.
- `NUMBER_ALL_ITEMS`: Total number of items which are stored in the log.
- `NUMBER_ABORT_ITEMS`: Number of abort items which are stored in the log.
- `NUMBER_ERROR_ITEMS`: Number of error items which are stored in the log.
- `NUMBER_WARNING_ITEMS`: Number of warning items which are stored in the log.
- `NUMBER_INFORMATION_ITEMS`: Number of information items which are stored in the log.
- `NUMBER_STATUS_ITEMS`: Number of status items which are stored in the log.

Interface `IF_BALI_HEADER_GETTER` contains the following methods:

- `GET_OBJECT_DESCRIPTION`: Returns the description text of the log object in the logon language.
- `GET_SUBOBJECT_DESCRIPTION`: Returns the description text of the log subobject in the logon language.

### Note

The header object contains the header attributes that were valid when the method `GET_HEADER` was called. If the log is changed after this call (for example, when new items are added to the log), these changes are not automatically visible in the header object. To refresh the header object it's necessary to call the method `GET_HEADER` again.

### Example

Load a single log from the database which uses log handle `l_handle`, and output some fields of the log header:

#### Sample Code

```
...
DATA l_handle TYPE if_bali_log=>ty_handle.
...
TRY.
  DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle ).
  DATA(l_header) = l_log->get_header( ).
```

```

out->write( |{ l_header->object } { l_header-
>get_object_description( ) } {
      l_header->subobject } { l_header->external_id }
{ l_header->log_user }| ).
CATCH cx_bali_runtime INTO DATA(l_exception).
out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

## 4.2.12.9.2.2.4 Get Items from the Log

After an application log was read from the database, the items stored in the log must be accessed. To read one or more items from an application log, interface `IF_BALI_LOG` provides the following methods:

- `GET_ITEM`: Read a single item from the application log.
  - The item is identified by the *Log Item Number* which is a serial number containing the position of the item in the log.
  - The method returns the reference to the item object.
- `GET_ALL_ITEMS`: Read all items from the application log.
  - The method returns an internal table with the following structure:
    - The *Log Item Number* of the item
    - The reference to the item object

The item object contains all attributes of the item, for example the severity. Each item object uses interface `IF_BALI_ITEM_GETTER`.

Public attributes of all log items:

- `CATEGORY`: Identifies the category of the item (see below).
- `LOG_ITEM_NUMBER`: The log item number which is the position of the item in the log.
- `SEVERITY`: Severity, such as 'Error', 'Warning', 'Information'. Possible values of the severity are defined as constants in interface `IF_BALI_CONSTANTS`.
- `DETAIL_LEVEL`: If the application outputs the items of the application log, the detail level can be used to define at which level of detail the item shall be visible.
- `TIMESTAMP`: A UTC timestamp which contains the creation time of the item.

Method of all log items is `GET_MESSAGE_TEXT`: It returns the message text of the item.

- The output of ABAP command `MESSAGE` for a message item
- The text of a free text item
- The output of method `GET_TEXT` of the exception object for an exception item

The category of the item restricts which other attributes of the item are available. For example, the message number is only available for a message, because a free text does not have a message number. To get additional attributes, a down cast to the more specific interface of the item category is required. The following item categories are supported:

- Message
  - Attribute `CATEGORY` contains the value `IF_BALI_CONSTANTS=>C_CATEGORY_MESSAGE`.

- Interface of a message is IF\_BALI\_MESSAGE\_GETTER.  
For more information, see [Get a Message \[page 1457\]](#).
- Free Text
  - Attribute CATEGORY contains the value IF\_BALI\_CONSTANTS=>C\_CATEGORY\_FREE\_TEXT.
  - Interface of a free text is IF\_BALI\_FREE\_TEXT\_GETTER.  
For more information, see [Get a Free Text \[page 1456\]](#).
- Exception
  - Attribute CATEGORY contains the value IF\_BALI\_CONSTANTS=>C\_CATEGORY\_EXCEPTION.
  - Interface of an exception is IF\_BALI\_EXCEPTION\_GETTER.  
For more information, see [Get an Exception \[page 1458\]](#).

### Example

Load a single log from the database which uses log handle l\_handle and output all items of the log:

#### Sample Code

```

...
DATA l_handle TYPE if_bali_log=>ty_handle.
...
TRY.
  DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle ).
  DATA(l_item_table) = l_log->get_all_items( ).
  LOOP AT l_item_table INTO DATA(l_item_entry).
    out->write( |{ l_item_entry-log_item_number } { l_item_entry-item-
>get_message_text( ) }| ).
    IF l_item_entry-item->category =
if_bali_constants=>c_category_message.
      DATA(l_message_ref) = CAST if_bali_message_getter( l_item_entry-
item ).
      out->write( |{ l_message_ref->id } { l_message_ref->number }| ).
    ELSEIF l_item_entry-item->category =
if_bali_constants=>c_category_exception.
      DATA(l_exception_ref) = CAST
if_bali_exception_getter( l_item_entry-item ).
      out->write( |{ l_exception_ref->exception_class }
{ l_exception_ref->exception_id_name }| ).
    ENDIF.
  ENDLLOOP.
  CATCH cx_bali_runtime INTO DATA(l_exception).
    out->write( l_exception->get_text( ) ).
  ENDTRY.
...

```

## 4.2.12.9.2.2.4.1 Get a Free Text

Similar to all other items, a free text can be read from the application log using methods GET\_ITEM and GET\_ALL\_ITEMS of interface IF\_BALI\_LOG. The free text object, which is returned by these methods, uses interface IF\_BALI\_FREE\_TEXT\_GETTER.

The interface supports all attributes and methods of interface IF\_BALI\_ITEM\_GETTER.

Interface `IF_BALI_FREE_TEXT_GETTER` contains no additional attributes.

### ❖ Example

Load a single log from the database which uses log handle `l_handle` and output the text of the first item:

#### ↔ Sample Code

```
...
DATA l_handle TYPE if_bali_log=>ty_handle.
...
TRY.
  DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle ).
  DATA(l_item) = l_log->get_item( log_item_number = '1' ).
  out->write( ||{ l_item->get_message_text( ) }| ).
  CATCH cx_bali_runtime INTO DATA(l_exception).
  out->write( l_exception->get_text( ) ).
ENDTRY.
...
```

## 4.2.12.9.2.2.4.2 Get a Message

Similar to all other items, a message can be read from the application log using methods `GET_ITEM` and `GET_ALL_ITEMS` of interface `IF_BALI_LOG`. The message object, which is returned by these methods, uses interface `IF_BALI_MESSAGE_GETTER`.

The interface supports all attributes and methods of interface `IF_BALI_ITEM_GETTER`.

Interface `IF_BALI_MESSAGE_GETTER` contains the following additional attributes:

- ID: Message ID
- NUMBER: Message Number
- VARIABLE\_1: Variable 1 of the message
- VARIABLE\_2: Variable 2 of the message
- VARIABLE\_3: Variable 3 of the message
- VARIABLE\_4: Variable 4 of the message
- COUNT: The count of the message. It is increased, if method `CUMULATE_ITEM` of interface `IF_BALI_LOG` is used to add a message to the log and if the log already contains a message with the same message attributes (severity, message ID, message number and variables).

### ❖ Example

Load a single log from the database which uses log handle `l_handle` and output some attributes of the first item, if it is a message:

#### ↔ Sample Code

```
...
DATA l_handle TYPE if_bali_log=>ty_handle.
...
TRY.
```

```

DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle ).
DATA(l_item) = l_log->get_item( log_item_number = '1' ).
IF l_item->category = if_bali_constants=>c_category_message.
  DATA(l_message_ref) = CAST if_bali_message_getter( l_item ).
  out->write( |{ l_message_ref->id } { l_message_ref->number }| ).
ENDIF.
CATCH cx_bali_runtime INTO DATA(l_exception).
  out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

## 4.2.12.9.2.2.4.3 Get an Exception

Similar to all other items, an exception can be read from the application log using methods `GET_ITEM` and `GET_ALL_ITEMS` of interface `IF_BALI_LOG`. The exception object, which is returned by these methods, uses interface `IF_BALI_EXCEPTION_GETTER`.

The interface supports all attributes and methods of interface `IF_BALI_ITEM_GETTER`.

Interface `IF_BALI_EXCEPTION_GETTER` contains the following additional attributes:

- `EXCEPTION_CLASS`: The name of the exception class.
- `EXCEPTION_ID_NAME`: Name of the text ID of the ABAP exception.

### Example

Load a single log from the database which uses log handle `l_handle` and output some attributes of the first item, if it is an exception:

#### Sample Code

```

...
DATA l_handle TYPE if_bali_log=>ty_handle.
TRY.
  DATA(l_log) = cl_bali_log_db=>get_instance( )->load_log( handle =
l_handle ).
  DATA(l_item) = l_log->get_item( log_item_number = '1' ).
  IF l_item->category = if_bali_constants=>c_category_exception.
    DATA(l_exception_ref) = CAST if_bali_exception_getter( l_item ).
    out->write( |{ l_exception_ref->exception_class } { l_exception_ref-
>exception_id_name }| ).
  ENDIF.
  CATCH cx_bali_runtime INTO DATA(l_exception).
    out->write( l_exception->get_text( ) ).
ENDTRY.
...

```

## 4.2.12.9.2.3 Classes and Interfaces of the Application Log API

The following classes and interfaces are available:

Access the Database

Class Name	Public Interface	Description
CL_BALI_LOG_DB	IF_BALI_LOG_DB	Handles database access like reading or writing of logs in the database.
CL_BALI_LOG_FILTER	IF_BALI_LOG_FILTER	Defines a filter for reading of logs from the database.

Access the Content of a Log

Class Name	Public Interface	Description
CL_BALI_LOG	IF_BALI_LOG	Reads and writes the header and items of a log

Writing the Log Header

Class Name	Public Interface	Description
CL_BALI_HEADER_SETTER	IF_BALI_HEADER_SETTER	Log header which can be put into a log

Reading the Log Header

Class Name	Public Interface	Description
	IF_BALI_HEADER_GETTER	Log header which was read from the log

Writing a Log Item

Class Name	Public Interface	Description
	IF_BALI_ITEM_SETTER	Each item contains this interface
CL_BALI_MESSAGE_SETTER	IF_BALI_MESSAGE_SETTER	Message which can be put into a log
CL_BALI_FREE_TEXT_SETTER	IF_BALI_FREE_TEXT_SETTER	Free text which can be put into a log
CL_BALI_EXCEPTION_SETTER	IF_BALI_EXCEPTION_SETTER	Exception which can be put into a log

Reading a Log Item

Class Name	Public Interface	Description
	IF_BALI_ITEM_GETTER	Each item contains this interface
	IF_BALI_MESSAGE_GETTER	Message which was read from the log

Class Name	Public Interface	Description
	IF_BALI_FREE_TEXT_GETTER	Free text which was read from the log
	IF_BALI_EXCEPTION_GETTER	Exception which was read from the log

Other Classes and Interfaces

Class Name	Public Interface	Description
	IF_BALI_CONSTANTS	Some constants, such as available item categories and severities
CL_BALI_ITEM_FILTER	IF_BALI_ITEM_FILTER	Define an item filter for adding items to a log

If one of the class methods can't be processed or can't return the requested results, an exception is raised. The following exceptions are possible, each of them inherit from exception class `CX_BALI_RUNTIME`:

Exception Classes

Class Name	Description
<code>CX_BALI_INVALID_PARAMETER</code>	An input parameter of the method is invalid (e.g. the log object doesn't exist).
<code>CX_BALI_NOT_FOUND</code>	The entry which shall be read or changed was not found.
<code>CX_BALI_NOT_POSSIBLE</code>	<p>The requested processing is not possible.</p> <p>Possible values of class attribute <code>ERROR_CODE</code>:</p> <ul style="list-style-type: none"> <li><code>CX_BALI_NOT_POSSIBLE=&gt;NO_AUTHORIZATION</code>: No authorization to access the log</li> <li><code>CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED</code>: Access to the log object is not allowed</li> <li><code>CX_BALI_NOT_POSSIBLE=&gt;TOO_MANY_ITEMS</code>: The maximum number 999999 of items was reached</li> <li><code>CX_BALI_NOT_POSSIBLE=&gt;SAVE_NOT_ALLOWED</code>: Error during saving to the database (e.g. database error or object is empty)</li> <li><code>CX_BALI_NOT_POSSIBLE=&gt;ENTRY_IS_LOCKED</code>: The enqueue cannot be set, because the log is already locked</li> </ul>
<code>CX_BALI_INTERNAL_ERROR</code>	Internal error during processing

### Note

Find more information about classes and interfaces of the [Application Log API](#) in the ABAB Development Tools (ADT).

## 4.2.12.9.2.3.1 CL\_BALI\_LOG\_DB (Interface IF\_BALI\_LOG\_DB)

Class `CL_BALI_LOG_DB` handles all database accesses of the application logs. This includes the reading of one or several logs from the database, writing a log to the database and deleting a log from the database. In addition, it offers methods to set and clear an SAP enqueue on a log. The public interface of the instance methods is `IF_BALI_LOG_DB`.

### Public Methods

Get an Instance of the Database Handler:

`GET_INSTANCE` (static)

Name	Description
<b>Returning parameter</b>	
<code>DB_HANDLER</code>	Database handler object: A reference to interface <code>IF_BALI_LOG_DB</code>

Load a single log from the database into the memory:

`LOAD_LOG`

Name	Description
<b>Importing parameters</b>	
<code>HANDLE</code>	Handle of the Application Log which shall be read
<code>READ_ONLY_HEADER</code>	(Optional): If set, only the header of the log is read (no items) Default: Not set
<b>Returning parameter</b>	
<code>LOG</code>	Log which was read from the database: Reference to interface <code>IF_BALI_LOG</code>
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
<code>CX_BALI_NOT_FOUND</code>	<ul style="list-style-type: none"><li>The log handle is initial</li><li>The log was not found in the database</li></ul>
<code>CX_BALI_NOT_POSSIBLE</code>	<ul style="list-style-type: none"><li><code>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED:</code> Access to the log object is not allowed</li><li><code>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;NO_AUTHORIZATION:</code> No authorization to access the log</li></ul>
<code>CX_BALI_INTERNAL_ERROR</code>	Internal error during processing

### Note

It is recommended to use method `LOAD_LOG_WITH_ITEMS` if all items should be loaded.

The following authorization is checked:

Authorization Object: S\_APPL\_LOG with:

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 03

Load a single log including all items from the database into the memory:

LOAD\_LOG\_WITH\_ITEMS

Name	Description
<b>Importing parameters</b>	
HANDLE	Handle of the application log that should be read
<b>Returning parameter</b>	
LOG	Log that was read from the database: Reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_FOUND	<ul style="list-style-type: none"><li>• The log handle is initial</li><li>• The log was not found in the database</li></ul>
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"><li>• ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li><li>• ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;NO_AUTHORIZATION: No authorization to access the log</li></ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

The following authorization is checked:

Authorization Object: S\_APPL\_LOG with:

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 03

Load several logs via a filter from the database into the memory:

LOAD\_LOGS\_VIA\_FILTER

Name	Description
<b>Importing parameters</b>	
FILTER	Log filter object: Reference to interface IF_BALI_LOG_FILTER

Name	Description
READ_ONLY_HEADER	(Optional): If set, only the headers of the logs are read (no items)  Default: Not set
<b>Returning parameter</b>	
LOG_TABLE	Table of logs which were read from the database: Table of references to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_FOUND	No log can be returned which fits to the filter criteria
CX_BALI_INVALID_PARAMETERS	<ul style="list-style-type: none"> <li>The filter contains invalid values</li> <li>The filter is initial or empty</li> </ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

It is recommended to use method `LOAD_LOGS_W_ITEMS_VIA_FILTER` if all items should be loaded.

The following authorization is checked:

Authorization Object: S\_APPL\_LOG with:

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 03

If the object of a log is not allowed or if the log doesn't pass the authorization check, it is removed from the table of logs which is returned. An exception is only raised if the final table is empty.

Load several logs including all items via a filter from the database into the memory:

`LOAD_LOGS_W_ITEMS_VIA_FILTER`

Name	Description
<b>Importing parameters</b>	
FILTER	Log filter object: Reference to interface IF_BALI_LOG_FILTER
<b>Returning parameter</b>	
LOG_TABLE	Table of logs which were read from the database: Table of references to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_FOUND	No log can be returned that fits to the filter criteria

Name	Description
CX_BALI_INVALID_PARAMETERS	<ul style="list-style-type: none"> <li>The filter contains invalid values</li> <li>The filter is initial or empty</li> </ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

The following authorization is checked:

Authorization Object: S\_APPL\_LOG with:

- ALG\_OBJECT: Object name of the application log
- ALG\_SUBOBJ: Subobject of the application log
- ACTVT: 03

If the object of a log is not allowed or if the log doesn't pass the authorization check, it's removed from the table of logs that is returned. An exception is only raised if the final table is empty.

Save a single log to the database using the default database connection:

```
SAVE_LOG
```

Name	Description
<b>Importing parameters</b>	
LOG	Log that should be saved: Reference to interface IF_BALI_LOG
USE_2ND_DB_CONNECTION	Deprecated: Please use method SAVE_LOG_2ND_DB_CONNECTION instead
ASSIGN_TO_CURRENT_APPL_JOB	(Optional): If set, and if the application runs in an application job, a connection between the application log and an application job is established  Default: Not set
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	

Name	Description
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;SAVE_NOT_ALLOWED: <ul style="list-style-type: none"> <li>Log object and log subobject are empty</li> <li>Locking of the log is not possible</li> <li>Error during saving into the database</li> </ul> </li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

If parameter LOG is initial, the method returns without exception.

Save a single log to the database using a service connection to the database:

SAVE\_LOG\_2ND\_DB\_CONNECTION

Name	Description
<b>Importing parameters</b>	
LOG	Log that should be saved: Reference to interface IF_BALI_LOG
ASSIGN_TO_CURRENT_APPL_JOB	(Optional): If set, and if the application runs in an application job, a connection between the application log and an application job is established  Default: Not set

### Exceptions (inherit from CX\_BALI\_RUNTIME)

Name	Description
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;SAVE_NOT_ALLOWED: <ul style="list-style-type: none"> <li>Log object and log subobject are empty</li> <li>Locking of the log is not possible</li> <li>Error during saving into the database</li> </ul> </li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

A commit is executed on the service connection after the saving.  
If parameter LOG is initial, the method returns without exception.

Delete a single log from the database:

DELETE\_LOG

Name	Description
<b>Importing parameters</b>	
LOG	Log which shall be saved: Reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;NO_AUTHORIZATION: No authorization to access the log</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_NOT_FOUND	The log was not found in the database
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

- If parameter LOG is initial, the method returns without exception.
- The following authorization is checked:  
Authorization Object: S\_APPL\_LOG with:
  - ALG\_OBJECT: Object name of the application log
  - ALG\_SUBOBJ: Subobject of the application log
  - ACTVT: 06

Set an SAP enqueue on a log:

ENQUEUE

Name	Description
<b>Importing parameters</b>	
LOG	Log which shall be saved: Reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"><li>• ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li><li>• ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;ENTRY_IS_LOCKED: The enqueue can't be set, because the log is already locked</li><li>• ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li></ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

If parameter LOG is initial, the method returns without exception.

Clear an SAP enqueue from a log:

DEQUEUE

Name	Description
<b>Importing parameters</b>	
LOG	Log which shall be saved: Reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	

Name	Description
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

If parameter LOG is initial, the method returns without exception.

## 4.2.12.9.2.3.2 CL\_BALI\_LOG\_FILTER (Interface IF\_BALI\_LOG\_FILTER)

Class `CL_BALI_LOG_FILTER` allows to define a filter which can be used if logs shall be read from the database and if the log handles are not known. The public interface of the instance methods is `IF_BALI_LOG_FILTER`.

### Public Methods

Create an instance of the filter class:

CREATE (static)

Name	Description
<b>Returning parameter</b>	
FILTER	Filter object: A reference to interface <code>IF_BALI_LOG_FILTER</code>

Set object, subobject and external identifier of the log. It overwrites all previous filter settings of object, subobject and external identifier:

SET\_DESCRIPTOR

Name	Description
<b>Importing parameters</b>	
OBJECT	(Optional): Object of the log (no wildcards)
SUBOBJECT	(Optional): Subobject of the log (wildcards allowed)
SUBOBJECT_TABLE	(Optional): Table with subobjects (wildcards allowed)

Name	Description
EXTERNAL_ID	(Optional): External identifier of the log (wildcards allowed)
EXTERNAL_ID_TABLE	(Optional): Table with external identifiers (wildcards allowed)
<b>Returning parameter</b>	
NEW_FILTER	Reference to current filter object
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>OBJECT_NOT_ALLOWED: Access to the log object is not allowed

### Note

If parameter EXTERNAL\_ID is supplied and empty, the filter searches for logs with empty external identifier.  
If parameters OBJECT, SUBOBJECT, SUBOBJECT\_TABLE, or EXTERNAL\_ID\_TABLE are supplied and empty, they are ignored

Set information about the log creation like the user. It overwrites all previous filter settings about the log creation:

SET\_CREATE\_INFO

Name	Description
<b>Importing parameters</b>	
USER	(Optional): Log user (wildcards allowed)
USER_TABLE	(Optional): Table with log users (wildcards allowed)
<b>Returning parameter</b>	
NEW_FILTER	Reference to current filter object

### Note

If parameters USER or USER\_TABLE are supplied and empty, they are ignored.

Set the date and time interval of the log creation. It overwrites all previous filter settings of the time interval:

SET\_TIME\_INTERVAL

Name	Description
<b>Importing parameters</b>	
START_TIME	UTC time stamp of the start time of the time interval

Name	Description
END_TIME	UTC time stamp of the end time of the time interval

**Returning parameter**

NEW_FILTER	Reference to current filter object
------------	------------------------------------

Set the maximum number of logs which are processed:

SET\_MAXIMUM\_LOG\_NUMBER

Name	Description
------	-------------

**Importing parameters**

MAX_LOG_NUMBER	Maximum number of logs which are processed (0 = all logs are processed which is the default)
----------------	--

**Returning parameter**

NEW_FILTER	Reference to current filter object
------------	------------------------------------

Get all filter values:

GET\_ALL\_VALUES

Name	Description
------	-------------

**Exporting parameters**

OBJECT_TABLE	Table of objects (no wildcards)
SUBOBJECT_TABLE	Table of subobjects (wildcards allowed)
EXTERNAL_ID_TABLE	Table of external identifiers (wildcards allowed)
USER_TABLE	
TIME_INTERVAL	Date and time interval
MAX_LOG_NUMBER	Maximum number of logs processed

## 4.2.12.9.2.3.3 CL\_BALI\_LOG (Interface IF\_BALI\_LOG)

Class `CL_BALI_LOG` handles all read and change operations on a single application log. It contains methods to read and change the log header. In addition, it allows to read items from the log and to add items to the log. The public interface of the instance methods is `IF_BALI_LOG`.

### Public Methods

Create an instance of the log class:

CREATE (static)

Name	Description
<b>Returning parameter</b>	
LOG	Log object: A reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_INTERNAL_ERROR	Internal error during processing

Create an instance of the log class and set the header:

CREATE\_WITH\_HEADER (static)

Name	Description
<b>Importing parameter</b>	
HEADER	Header which is put into the log: Reference to interface IF_BALI_HEADER_SETTER
<b>Returning parameter</b>	
LOG	Log object: A reference to interface IF_BALI_LOG
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>OBJECT_NOT_ALLOWED: Access to the log object of the header is not allowed
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header don't exist
CX_BALI_INTERNAL_ERROR	Internal error during processing

Get the log handle which is the unique identifier of the log:

GET\_HANDLE

Name	Description
<b>Returning parameter</b>	
HANDLE	Log handle

Get the log header:

GET\_HEADER

Name	Description
<b>Returning parameter</b>	
HEADER	Log header: References to interface IF_BALI_HEADER_GETTER

Name	Description
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>LOG_WAS_INVALIDATED:  The memory of the log was released. The log can't be used
CX_BALI_INTERNAL_ERROR	Internal error during processing

Set the log header:

SET\_HEADER

Name	Description
<b>Importing parameter</b>	
HEADER	Header which is put into the log: References to interface IF_BALI_HEADER_SETTER

<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object of the header is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header don't exist
CX_BALI_INTERNAL_ERROR	Internal error during processing

Add an item (e.g. a message) to the log:

ADD\_ITEM

Name	Description
<b>Importing parameter</b>	
ITEM	Item which is added: Reference to interface IF_BALI_ITEM_SETTER
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	

Name	Description
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object of the header is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header don't exist
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

An exception may contain a message. This means that the ABAP exception class contains interface `IF_T100_MESSAGE`, or it contains at least the attributes `T100_MSGID` and `T100_MSGNO`. In this case, the exception is internally converted into a message before it is added to the log.

If the item is a message, it's checked whether the log already contains another message with identical message attributes. These are the attributes: severity, message ID, message number and message variable 1 - 4. If this message exist, the message counter of the message is increased by 1. Otherwise, a new message is added to the log. Also free texts and exceptions are always added to the log without cumulation.

CUMULATE\_ITEM

Name	Description
<b>Importing parameter</b>	
ITEM	Item which is cumulated or added: Reference to interface <code>IF_BALI_ITEM_SETTER</code>
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;OBJECT_NOT_ALLOWED: Access to the log object of the header is not allowed</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header don't exist
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

An exception may contain a message. This means that the ABAP exception class contains interface `IF_T100_MESSAGE`, or it contains at least the attributes `T100_MSGID` and `T100_MSGNO`. In this case,

the exception is internally converted to a message before it is added to the log (but this message is not cumulated to an already existing message).

Add all messages from an internal table of type `BAPIRETTAB` table to the log:

`ADD_MESSAGES_FROM_BAPIRETTAB`

Name	Description
<b>Importing parameter</b>	
<code>MESSAGE_TABLE</code>	An internal table with messages which use type <code>BAPIRETTAB</code>
<b>Exceptions (inherit from <code>CX_BALI_RUNTIME</code>)</b>	
<code>CX_BALI_NOT_POSSIBLE</code>	<ul style="list-style-type: none"> <li><b>ERROR_CODE: <code>CX_BALI_NOT_POSSIBLE=&gt;TOO_MANY_ITEMS</code>:</b> The maximum number 999999 of items was reached</li> <li><b>ERROR_CODE: <code>CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED</code>:</b> The memory of the log was released. The log can't be used</li> </ul>
<code>CX_BALI_INVALID_PARAMETER</code>	The message ID of one of the messages is initial
<code>CX_BALI_INTERNAL_ERROR</code>	Internal error during processing

### Note

If a message of the message table can't be added to the log, it's skipped and the processing continues until the end of the table is reached. Afterwards, an exception is raised to notify the caller that some of the messages couldn't be added to the log.

Add a message from the ABAP Restful Application Programming Model (interface `IF_ABAP_BEHV_MESSAGE`) to the log:

`ADD_ABAP_BEHAVIOR_MESSAGE`

Name	Description
<b>Importing parameter</b>	
<code>MESSAGE</code>	A reference to the interface <code>IF_ABAP_BEHV_MESSAGE</code>
<b>Exceptions (inherit from <code>CX_BALI_RUNTIME</code>)</b>	
<code>CX_BALI_NOT_POSSIBLE</code>	<ul style="list-style-type: none"> <li><b>ERROR_CODE: <code>CX_BALI_NOT_POSSIBLE=&gt;TOO_MANY_ITEMS</code>:</b> The maximum number 999999 of items was reached</li> <li><b>ERROR_CODE: <code>CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED</code>:</b> The memory of the log was released. The log can't be used</li> </ul>

Name	Description
CX_BALI_INVALID_PARAMETER	The message ID of the messages is initial
CX_BALI_INTERNAL_ERROR	Internal error during processing

Add all items from another log to this log:

ADD\_ALL\_ITEMS\_FROM\_OTHER\_LOG

Name	Description
<b>Importing parameter</b>	
SOURCE_LOG	Reference to the log whose items are to be copied
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	<ul style="list-style-type: none"> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;TOO_MANY_ITEMS: The maximum number of 999999 items was reached</li> <li>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</li> </ul>
CX_BALI_INVALID_PARAMETER	The source log is invalid. It contains a log handle which doesn't exist
CX_BALI_INTERNAL_ERROR	Internal error during processing

### Note

If the parameter SOURCE\_LOG is initial, the processing is skipped and no exception is raised.

Add an item filter to the log. The item filter is checked before an item is added to the log using the methods ADD\_ITEM, CUMULATE\_ITEM, ADD\_MESSAGES\_FROM\_BAPIRETTAB, or ADD\_ABAP\_BEHAVIOR\_MESSAGE. If an item doesn't pass the filter, it's ignored.

SET\_FILTER\_FOR\_ADD\_ITEM

Name	Description
<b>Importing parameter</b>	
FILTER	A reference to the item filter
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used

### Note

- If FILTER is initial, any item filter is removed from the log. The log then no longer uses an item filter.

- Since the method `ADD_ALL_ITEMS_FROM_OTHER_LOG` is intended for the mass-processing of items, it ignores the item filter because of performance reasons.
- The filter is only used by methods of the class `CL_BALI_LOG`. If an application uses the application log function modules to add an item to the log, the filter is ignored.

Get the item filter which was set using `SET_FILTER_FOR_ADD_ITEM`.

`GET_FILTER_FOR_ADD_ITEM`

Name	Description
<b>Returning parameter</b>	
<code>FILTER</code>	A reference to the item filter which is currently used by the log
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
<code>CX_BALI_NOT_POSSIBLE</code>	<code>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</code>

Get a single item from the log:

`GET_ITEM`

Name	Description
<b>Importing parameter</b>	
<code>LOG_ITEM_NUMBER</code>	Serial number of the item which shall be read (it is the position of the item in the log)
<b>Returning parameter</b>	
<code>ITEM</code>	Item which was read: Reference to interface <code>IF_BALI_ITEM_GETTER</code>
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
<code>CX_BALI_NOT_FOUND</code>	An item with the requested log item number does not exist
<code>CX_BALI_NOT_POSSIBLE</code>	<code>ERROR_CODE: CX_BALI_NOT_POSSIBLE=&gt;LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used</code>
<code>CX_BALI_INTERNAL_ERROR</code>	Internal error during processing

Get all items from the log:

`GET_ALL_ITEMS`

Name	Description
<b>Returning parameter</b>	

Name	Description
ITEM_TABLE	Table of all items which are stored in the log. The table has the following structure: <ul style="list-style-type: none"> <li>LOG_ITEM_NUMBER: The serial number of the item in the log</li> <li>ITEM: Item object: Reference to interface IF_BALI_ITEM_GETTER</li> </ul>
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_FOUND	No item was found in the log
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>LOG_WAS_INVALIDATED: The memory of the log was released. The log can't be used
CX_BALI_INTERNAL_ERROR	Internal error during processing

## RELEASE\_MEMORY

Remove the log from the memory. After this, the log is invalidated and can no longer be used.

Check whether the memory of the log was released in order to verify that the log is invalidated and can no longer be used.

IS\_INVALIDATED

Name	Description
<b>Returning parameter</b>	
IS_INVALIDATED	If set, the log is invalidated and can no longer be used

### 4.2.12.9.2.3.4 CL\_BALI\_HEADER\_SETTER (Interface IF\_BALI\_HEADER\_SETTER)

Class CL\_BALI\_HEADER\_SETTER is used to set the header attributes of an application log, such as the log object, subobject, and the external identifier. The public interface of the instance methods is IF\_BALI\_HEADER\_SETTER.

#### Public Methods

Create an instance of the header class with the settings of the descriptor (object, subobject and external identifier):

CREATE (static)

Name	Description
<b>Importing parameters</b>	
OBJECT	Object of the log
SUBOBJECT	Subobject of the log If no subobjects were defined for the log object, the parameter should be empty
EXTERNAL_ID	(Optional): External identifier of the log Default: ''

<b>Returning parameter</b>	
HEADER	Header object: A reference to interface IF_BALI_HEADER_SETTER

<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>OBJECT_NOT_ALLOWED: Access to the log object is not allowed
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header doesn't exist

Set object, subobject and external identifier of the log:

SET\_DESCRIPTOR

Name	Description
<b>Importing parameters</b>	
OBJECT	Object of the log
SUBOBJECT	Subobject of the log
EXTERNAL_ID	(Optional): External identifier of the log Default: ''
<b>Returning parameter</b>	
NEW_HEADER	Reference to current header object
<b>Exceptions (inherit from CX_BALI_RUNTIME)</b>	
CX_BALI_NOT_POSSIBLE	ERROR_CODE: CX_BALI_NOT_POSSIBLE=>OBJECT_NOT_ALLOWED: Access to the log object is not allowed
CX_BALI_INVALID_PARAMETER	The log object or subobject of the header doesn't exist

Set the expiry date and attributes:

SET\_EXPIRY

Name	Description
<b>Importing parameters</b>	
EXPIRY_DATE	Date when the log expires and can be deleted. If the parameter is initial, the expiry date remains unchanged; the default value of the expiry date is the creation date of the log + 7 days.
KEEP_UNTIL_EXPIRY	(Optional): If set: It is not allowed to delete the log before the expiry date Default: Not set
<b>Returning parameter</b>	
NEW_HEADER	Reference to current header object

Get all header values:

GET\_ALL\_VALUES

Name	Description
<b>Exporting parameters</b>	
OBJECT	Object of the log
SUBOBJECT	Subobject of the log
EXTERNAL_ID	External identifier of the log
EXPIRY_DATE	Date when the log expires and can be deleted
KEEP_UNTIL_EXPIRY	If set: It is not allowed to delete the log before the expiry date

### 4.2.12.9.2.3.5 CL\_BALI\_MESSAGE\_SETTER (Interface IF\_BALI\_MESSAGE\_SETTER)

To add a new message to an application log an object of class [CL\\_BALI\\_MESSAGE\\_SETTER](#) is used. The public interface of the instance methods is [IF\\_BALI\\_MESSAGE\\_SETTER](#). It contains the interface [IF\\_BALI\\_ITEM\\_SETTER](#).

#### Public Attributes

Name	Description
CATEGORY	Category of the item
(from IF_BALI_ITEM_SETTER)	Contains fixed value: IF_BALI_CONSTANTS=>C_CATEGORY_MESSAGE

### Public Methods

Create a message class instance and set the message attributes:

CREATE (static)

Name	Description
<b>Importing parameters</b>	
SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: IF_BALI_CONSTANTS=>C_SEVERITY_STATUS
ID	Message ID
NUMBER	Message number
VARIABLE_1	(Optional): Message variable 1
VARIABLE_2	(Optional): Message variable 2
VARIABLE_3	(Optional): Message variable 3
VARIABLE_4	(Optional): Message variable 4
<b>Returning parameter</b>	
MESSAGE	Message object: A reference to interface IF_BALI_MESSAGE_SETTER

Create a message class instance. The message attributes are read from the fields of structure SY (like SYMSGID):

CREATE\_FROM\_SY (static)

Name	Description
<b>Returning parameter</b>	
MESSAGE	Message object: A reference to interface IF_BALI_MESSAGE_SETTER

Create a message class instance. The message attributes are read from a structure of type BAPIRET2:

CREATE\_FROM\_BAPIRET2 (static)

Name	Description
<b>Importing parameter</b>	

Name	Description
MESSAGE_DATA	Message attributes (a structure of type BAPIRET2)

**Returning parameter**

MESSAGE	Message object: A reference to interface IF_BALI_MESSAGE_SETTER
---------	---

Set attributes of the message:

SET\_ATTRIBUTES

Name	Description
------	-------------

**Importing parameters**

SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: IF_BALI_CONSTANTS=>C_SEVERITY_STATUS
----------	--

ID	Message ID
----	------------

NUMBER	Message number
--------	----------------

VARIABLE_1	(Optional): Message variable 1
------------	--------------------------------

VARIABLE_2	(Optional): Message variable 2
------------	--------------------------------

VARIABLE_3	(Optional): Message variable 3
------------	--------------------------------

VARIABLE_4	(Optional): Message variable 4
------------	--------------------------------

**Returning parameter**

NEW_MESSAGE	Reference to current message object
-------------	-------------------------------------

Set message attributes from the fields of structure SY (like SY-MSGID):

SET\_FROM\_SY

Name	Description
------	-------------

**Returning parameter**

NEW_MESSAGE	Reference to current message object
-------------	-------------------------------------

Set message attributes from structure BAPIRET2:

SET\_FROM\_BAPIRET2

Name	Description
------	-------------

**Importing parameter**

MESSAGE_DATA	Message attributes (a structure of type BAPIRET2)
--------------	---

Name	Description
<b>Returning parameter</b>	
MESSAGE	Reference to current message object

Set the level of detail of the item:

SET\_DETAIL\_LEVEL

Name	Description
<b>Importing parameter</b>	
DETAIL_LEVEL	Detail level of the item Allowed values: Number between '1' and '9' or ''

<b>Returning parameter</b>	
MESSAGE	Reference to current message object

Get all message values:

GET\_ALL\_VALUES

Name	Description
<b>Exporting parameters</b>	
DETAIL_LEVEL	DETAIL_LEVEL Detail Level of the item (number between '1' and '9' or '')
SEVERITY	Severity of the message ('Error', 'Warning', etc)
ID	Message ID
NUMBER	Message number
VARIABLE_1	(Optional): Message variable 1
VARIABLE_2	(Optional): Message variable 2
VARIABLE_3	(Optional): Message variable 3
VARIABLE_4	(Optional): Message variable 4
<b>Returning parameter</b>	
NEW_MESSAGE	Reference to current message object

Check whether the message can pass an item filter:

CHECK\_PASSING\_ITEM\_FILTER (from IF\_BALI\_ITEM\_SETTER)

Name	Description
<b>Importing parameter</b>	

Name	Description
ITEM_FILTER	Reference to the item filter that is being checked
<b>Returning parameter</b>	
FILTER_PASSED	If set, the message can pass the item filter

### Note

If the severity of the message contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_SEVERITY_DEFAULT`. Allowed values of the severity can be found in interface `IF_BALI_CONSTANTS`.

If the detail level of the message contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_DETAIL_LEVEL_DEFAULT`. Allowed values of the detail level are a number between '1' and '9' and ' '.

If the message attributes are set from structure `BAPIRET2`, only the fields `TYPE`, `ID`, `NUMBER`, `MESSAGE_V1`, `MESSAGE_V2`, `MESSAGE_V3` and `MESSAGE_V4` of the structure are considered.

## 4.2.12.9.2.3.6 CL\_BALI\_FREE\_TEXT\_SETTER (Interface IF\_BALI\_FREE\_TEXT\_SETTER)

To add a new free text to an application log, an object of class `CL_BALI_FREE_TEXT_SETTER` is used. The public interface of the instance methods is `IF_BALI_FREE_TEXT_SETTER`. It contains the interface `IF_BALI_ITEM_SETTER`.

### Public Attributes

Name	Description
CATEGORY	Category of the item
(from <code>IF_BALI_ITEM_SETTER</code> )	Contains fixed value: <code>IF_BALI_CONSTANTS=&gt;C_CATEGORY_FREE_TEXT</code>

### Public Methods

Create an instance of the free text class and set the text and the severity:

CREATE (static)

Name	Description
<b>Importing parameters</b>	
SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: <code>IF_BALI_CONSTANTS=&gt;C_SEVERITY_STATUS</code>

Name	Description
TEXT	Free text
<b>Returning parameter</b>	
FREE_TEXT	Free text object: A reference to interface IF_BALI_FREE_TEXT_SETTER

Set the free text and severity:

SET\_TEXT

Name	Description
<b>Importing parameters</b>	
SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: IF_BALI_CONSTANTS=>C_SEVERITY_STATUS
TEXT	Free text
<b>Returning parameter</b>	
NEW_FREE_TEXT	Reference to current free text object

Set the level of detail of the free text:

SET\_DETAIL\_LEVEL

Name	Description
<b>Importing parameter</b>	
DETAIL_LEVEL	Detail level of the free text Allowed values: Number between '1' and '9' or ''
<b>Returning parameter</b>	
NEW_FREE_TEXT	Reference to current free text object

Get all free text values:

GET\_ALL\_VALUES

Name	Description
<b>Exporting parameters</b>	
DETAIL_LEVEL	Detail level of the free text Number between '1' and '9' or ''
SEVERITY	Severity of the free text ('Error', 'Warning', etc)

Name	Description
TEXT	Content of the free text

Check whether the free text can pass an item filter:

CHECK\_PASSING\_ITEM\_FILTER (from IF\_BALI\_ITEM\_SETTER)

Name	Description
<b>Importing parameter</b>	
ITEM_FILTER	Reference to the item filter that is being checked
<b>Returning parameter</b>	
FILTER_PASSED	If set, the free text can pass the item filter

#### ⓘ Note

If the severity of the free text contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_SEVERITY_DEFAULT`. Allowed values of the severity can be found in interface `IF_BALI_CONSTANTS`.

If the detail level of the free text contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_DETAIL_LEVEL_DEFAULT`. Allowed values of the detail level are a number between '1' and '9' and ''.

## 4.2.12.9.2.3.7 CL\_BALI\_EXCEPTION\_SETTER (Interface IF\_BALI\_EXCEPTION\_SETTER)

To add a new exception to an application log, an object of class `CL_BALI_EXCEPTION_SETTER` is used. The public interface of the instance methods is `IF_BALI_EXCEPTION_SETTER`. It contains the interface `IF_BALI_ITEM_SETTER`.

### Public Attributes

Name	Description
CATEGORY	Category of the item
(from IF_BALI_ITEM_SETTER)	Contains fixed value: <code>IF_BALI_CONSTANTS=&gt;C_CATEGORY_EXCEPTION</code>

### Public Methods

Create an instance of the exception class. Set the reference of the ABAP exception which is stored in the exception item and its severity:

CREATE (static)

Name	Description
<b>Importing parameters</b>	
SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: IF_BALI_CONSTANTS=>C_SEVERITY_STATUS
EXCEPTION	Reference to ABAP exception class instance
<b>Returning parameter</b>	
EXCEPTION_OBJ	Exception object: A reference to interface IF_BALI_EXCEPTION_SETTER

Set the ABAP exception class instance and severity:

SET\_EXCEPTION

Name	Description
<b>Importing parameters</b>	
SEVERITY	(Optional): Severity of the message ('Error', 'Warning', etc) Default: IF_BALI_CONSTANTS=>C_SEVERITY_STATUS
EXCEPTION	Reference to ABAP exception class instance
<b>Returning parameter</b>	
NEW_EXCEPTION_OBJ	Reference to current application log exception object

Set the level of detail of the exception:

SET\_DETAIL\_LEVEL

Name	Description
<b>Importing parameter</b>	
DETAIL_LEVEL	Detail level of the exception Allowed values: Number between '1' and '9' or ''
<b>Returning parameter</b>	
NEW_EXCEPTION_OBJ	Reference to current application log exception object

Get all exception values:

GET\_ALL\_VALUES

Name	Description
<b>Exporting parameters</b>	

Name	Description
DETAIL_LEVEL	Detail level of the exception (number between '1' and '9' or '')
SEVERITY	Severity of the exception ('Error', 'Warning', etc)
EXCEPTION	Reference to ABAP exception class instance

Check whether the exception can pass an item filter:

CHECK\_PASSING\_ITEM\_FILTER (from IF\_BALI\_ITEM\_SETTER)

Name	Description
<b>Importing parameter</b>	
ITEM_FILTER	Reference to the item filter that is being checked
<b>Returning parameter</b>	
FILTER_PASSED	If set, the exception can pass the item filter

#### Note

If the severity of the exception contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_SEVERITY_DEFAULT`. Allowed values of the severity can be found in interface `IF_BALI_CONSTANTS`.

If the detail level of the exception contains a value which is not allowed, it is changed to `IF_BALI_CONSTANTS=>C_DETAIL_LEVEL_DEFAULT`. Allowed values of the detail level are a number between '1' and '9' and ''.

## 4.2.12.9.2.3.8 IF\_BALI\_HEADER\_GETTER

If the header attributes of an application log are read, they are returned in an object which uses interface `IF_BALI_HEADER_GETTER`.

### Public Attributes

Name	Description
OBJECT	Object of the log
SUBOBJECT	Subobject of the log
EXTERNAL_ID	External identifier of the log
LOG_TIMESTAMP	UTC time stamp of the log (usually the creation time)

Name	Description
LOG_USER	Log user (usually the user who created the log)
EXPIRY_DATE	Date when the log expires and can be deleted
KEEP_UNTIL_EXPIRY	If set: It's not allowed to delete the log before the expiry date
NUMBER_ALL_ITEMS	Total number of items which are stored in the log
NUMBER_ABORT_ITEMS	Number of abort items which are stored in the log
NUMBER_ERROR_ITEMS	Number of error items which are stored in the log
NUMBER_WARNING_ITEMS	Number of warning items which are stored in the log
NUMBER_INFORMATION_ITEMS	Number of information items which are stored in the log
NUMBER_STATUS_ITEMS	Number of status items which are stored in the log

### Public Methods

Get description text of the log object in the logon language:

GET\_OBJECT\_DESCRIPTION

Name	Description
<b>Returning parameter</b>	
OBJECT_DESCRIPTION	Description of the object in the logon language

Get description text of log subobject in the logon language:

GET\_SUBOBJECT\_DESCRIPTION

Name	Description
<b>Returning parameter</b>	
SUBOBJECT_DESCRIPTION	Description of the subobject in the logon language

## 4.2.12.9.2.3.9 IF\_BALI\_EXCEPTION\_GETTER

If an exception is read from an application log, an object instance of interface `IF_BALI_EXCEPTION_GETTER` is returned. It contains the interface `IF_BALI_ITEM_GETTER`.

### Public Attributes

Name	Description
CATEGORY (from IF_BALI_ITEM_GETTER)	Category of the item Contains fixed value: IF_BALI_CONSTANTS=>C_CATEGORY_EXCEPTION
LOG_ITEM_NUMBER (from IF_BALI_ITEM_GETTER)	Serial number which is the position of the exception in the log
SEVERITY (from IF_BALI_ITEM_GETTER)	Severity of the exception ('Error', 'Warning', etc)
DETAIL_LEVEL (from IF_BALI_ITEM_GETTER)	Detail level of the exception (number between '1' and '9' or '')
TIMESTAMP (from IF_BALI_ITEM_GETTER)	UTC time stamp of the exception creation
EXCEPTION_CLASS	Name of the ABAP exception class
EXCEPTION_ID_NAME	Name of the Text ID of the ABAP exception

### Public Methods

Get the message short text of the exception (the output of method GET\_TEXT of the ABAP exception object):

GET\_MESSAGE\_TEXT (from interface IF\_BALI\_ITEM\_GETTER)

Name	Description
<b>Returning parameter</b>	
MESSAGE_TEXT	Message short text of the exception in the logon language

## 4.2.12.9.2.3.10 IF\_BALI\_FREE\_TEXT\_GETTER

If a free text is read from an application log, an object instance of interface IF\_BALI\_FREE\_TEXT\_GETTER is returned. It contains the interface IF\_BALI\_ITEM\_GETTER.

### Public Attributes

Name	Description
CATEGORY (from IF_BALI_ITEM_GETTER)	Category of the item Contains fixed value: IF_BALI_CONSTANTS=>C_CATEGORY_FREE_TEXT

Name	Description
LOG_ITEM_NUMBER (from IF_BALI_ITEM_GETTER)	Serial number which is the position of the free text in the log
SEVERITY (from IF_BALI_ITEM_GETTER)	Severity of the free text ('Error', 'Warning', etc)
DETAIL_LEVEL (from IF_BALI_ITEM_GETTER)	Detail level of the free text (number between '1' and '9' or '')
TIMESTAMP (from IF_BALI_ITEM_GETTER)	UTC time stamp of the free text creation

### Public Methods

Get the content of the free text:

GET\_MESSAGE\_TEXT (from interface IF\_BALI\_ITEM\_GETTER)

Name	Description
<b>Returning parameter</b>	
MESSAGE_TEXT	Content of the free text

## 4.2.12.9.2.3.11 IF\_BALI\_ITEM\_GETTER

If an item like a message or exception is read from an application log, its object instance contains the interface IF\_BALI\_ITEM\_GETTER. So, interface IF\_BALI\_ITEM\_GETTER contains all attributes and methods which are available for all items which are read from the log.

### Public Attributes

Name	Description
CATEGORY	Category of the item  Possible values: <ul style="list-style-type: none"> <li>IF_BALI_CONSTANTS=&gt;C_CATEGORY_MESSAGE: Item is a message</li> <li>IF_BALI_CONSTANTS=&gt;C_CATEGORY_FREE_TEXT: Item is a free text</li> <li>IF_BALI_CONSTANTS=&gt;C_CATEGORY_EXCEPTION: Item is an exception</li> </ul>

Name	Description
LOG_ITEM_NUMBER	Serial number which is the position of the item in the log
SEVERITY	Severity of the item ('Error', 'Warning', etc)
DETAIL_LEVEL	Detail level of the item (number between '1' and '9' or '')
TIMESTAMP	UTC time stamp of the item creation
(from IF_BALI_ITEM_GETTER)	

### Public Methods

Get the message text of the item. It is:

- The output of ABAP command **MESSAGE** for a message item
- The text of a free text item
- The output of method `GET_TEXT` of the ABAP exception object for an exception item

GET\_MESSAGE\_TEXT

Name	Description
<b>Returning parameter</b>	
MESSAGE_TEXT	ext of the item message in the logon language

## 4.2.12.9.2.3.12 IF\_BALI\_ITEM\_SETTER

### Context

If a new item, such as a message or an exception, is added to an application log, its object instance contains the interface `IF_BALI_ITEM_SETTER`.

## Public Attributes

Name	Description
CATEGORY	Category of the item  Possible values: <ul style="list-style-type: none"><li>• IF_BALI_CONSTANTS=&gt;C_CATEGORY_MESSAGE: Item is a message</li><li>• IF_BALI_CONSTANTS=&gt;C_CATEGORY_FREE_TEXT: Item is a free text</li><li>• IF_BALI_CONSTANTS=&gt;C_CATEGORY_EXCEPTION: Item is an exception</li></ul>

## Public Methods

Check whether the item can pass an item filter:

CHECK\_PASSING\_ITEM\_FILTER

Name	Description
<b>Importing parameter</b>	
ITEM_FILTER	Reference to the item filter that is being checked
<b>Returning parameter</b>	
FILTER_PASSED	If set, the item can pass the item filter

## 4.2.12.9.2.3.13 IF\_BALI\_MESSAGE\_GETTER

If a message is read from an application log, an object instance of interface IF\_BALI\_MESSAGE\_GETTER is returned. It contains the interface IF\_BALI\_ITEM\_GETTER.

### Public Attributes

Name	Description
CATEGORY	Category of the item
(from IF_BALI_ITEM_GETTER)	Contains fixed value: IF_BALI_CONSTANTS=>C_CATEGORY_MESSAGE

Name	Description
LOG_ITEM_NUMBER (from IF_BALI_ITEM_GETTER)	Serial number which is the position of the message in the log
SEVERITY (from IF_BALI_ITEM_GETTER)	Severity of the message ('Error', 'Warning', etc)
DETAIL_LEVEL (from IF_BALI_ITEM_GETTER)	Detail level of the message (number between '1' and '9' or '')
TIMESTAMP (from IF_BALI_ITEM_GETTER)	UTC time stamp of the message creation
ID	Message ID
NUMBER	Message number
VARIABLE_1	Message variable 1
VARIABLE_2	Message variable 2
VARIABLE_3	Message variable 3
VARIABLE_4	Message variable 4
COUNT	Count of cumulated messages

Get the message text of the message (the output of ABAP command **MESSAGE**):

GET\_MESSAGE\_TEXT (from interface IF\_BALI\_ITEM\_GETTER):

Name	Description
<b>Returning parameter</b>	
MESSAGE_TEXT	Text of the message in the logon language

### 4.2.12.9.3 How to Use the Fiori Reuse Library

You can use the *Reuse Library* to implement a reusable component that can display an application log.

#### ⚠ Restriction

Mind that you can only use the Fiori reuse library with the OData V2 protocol.

For more information on how to use the Fiori reuse library in a freestyle app, see [Freestyle App Integration \[page 1494\]](#).

For more information on how to use the Fiori reuse library in a Fiori elements app, see [Fiori Elements Integration \[page 1496\]](#).

## 4.2.12.9.3.1 Freestyle App Integration

You can implement the reusable component from the *Reuse Library* in a freestyle app in order to display an application log.

### Context

To be able to use the reusable components, you need to adapt the code that can be found in your view definition file and your controller file.

### Procedure

1. In the view definition file (`<MY_LOG_DISPLAY_VIEW.view.xml>`), the log display must be positioned on the page. Prepare a container control that will hold the log display component:

#### Sample Code

```
<!-- xmlns:core="sap.ui.core" -->
<core:ComponentContainer id="LogMessagesControlContainer" />
```

2. In the controller file (`<MY_LOG_DISPLAY_VIEW.controller.js>`), the relevant coding goes into the handler for the *onInit* event. Create the component and place it into the container control:

#### Note

Make sure to replace the string `<MY_LOG_DISPLAY_VIEW>` with your own view's name!

#### Sample Code

```
var that = this;

this.getOwnerComponent().createComponent({
  usage: "ApplicationLogs",
  id: "LogMessagesControlComponent",
  settings: {
    "persistencyKey": "MY_LOG_DISPLAY_VIEW",
    "showHeader": false,
    "showFilterBar": false,
    "showAsTree": false
  }
}).then(function (oComp) {
  that.byId("LogMessagesControlContainer").setComponent(oComp);
  oComp.setLogHandle("<LogHandle>");
  oComp.refresh();
});
```

## Note

The component you embed makes use of the [SmartFilter](#) and the [SmartTable](#) control. Both controls enable a user to configure the components interactively, and also to store a current set of configuration settings as a named variant. By providing a value for the `persistencyKey` parameter, you make sure that the variants that get created in your application become visible only to the users of your application, and not to all users of the component in all applications.

3. Adapt your `<manifest.json>` file and add the `sap.nw.core.applogs.lib.reuse.applogs` component:

## Sample Code

```
"sap.ui5": {
  "dependencies": {
    "libs": {
      "sap.nw.core.applogs.lib.reuse": {
        "lazy": true
      }
    },
    "components": {}
  },
  "componentUsages": {
    "ApplicationLogs": {
      "name": "sap.nw.core.applogs.lib.reuse.applogs",
      "lazy": true
    }
  }
}
```

After your app was deployed successfully to an SAP BTP, ABAP environment system, the *BSP application* and the *SAP Fiori launchpad* app descriptor item will appear under your created package in Eclipse.

4. Now, you need to create a new *IAM App*. Follow the instructions described here: [Defining an IAM App for the Business Service \[page 768\]](#).
5. Once created, you need to maintain the *Application Log* OData Service to call your application log data. To do this, go to the *Service* tab and add the *Application Log OData Service* by naming the service type `odata v2` and add the following service name: `APL_LOG_MANAGEMENT_SRV` `0001`. Mind that all 13 spaces between `SRV` and `0001` are required. Now, go to the *Authorization* tab and maintain your *log objects / sub objects* for the authorization object `S_APPL_LOG`.
6. Finally, you need to create a new *Business Catalog*. Please follow the procedure described here: [Creating a Business Catalog \[page 769\]](#)

Having created the business catalog, you have successfully implemented a reusable component to display your application logs.

## 4.2.12.9.3.2 Fiori Elements Integration

You can implement the reusable component from the *Reuse Library* in a Fiori Elements app in order to display an application log.

### Context

In order to implement the reusable component in a Fiori Elements app, you first have to add the application log reuse component to your manifest.

### Procedure

1. Open the `manifest.json` file of the application and locate the `sap.ui5` section.
2. Add the `sap.nw.core.applogs.lib.reuse.smarttemplate` component:

#### Sample Code

```
"sap.ui5": {
  "dependencies": {
    "libs": {
      "sap.nw.core.applogs.lib.reuse": {
        "lazy": true
      }
    },
    "components": {}
  },
  "componentUsages": {
    "ApplicationLogs": {
      "name": "sap.nw.core.applogs.lib.reuse.smarttemplate",
      "lazy": true
    }
  }
}
```

3. Next, you need to add the smarttemplate component of the application log reuse library to an `ObjectPage`. In the `manifest.json` file, you have to add the application log reuse component as an embedded component to your `ObjectPage`:

#### Sample Code

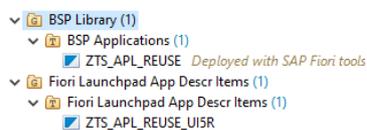

Snippet (embeddedComponents)

```
"embeddedComponents": {
  "appLog": {
    "id": "<enter an ID>",
    "componentUsage": "ApplicationLogs",
    "title": "<the name of the tab>",
    "settings": {
      "logHandle": "{LogHandle}",
      "persistencyKey": "<your content>"
    }
  }
}
```

```
}
```

- You can set the following parameters:
  - log handle:** The application log handle
  - Optional persistencyKey:** Set a personalization key which is then used to set app-specific variants for `SmartTable`. This parameter is optional. The default value is defined in the *Application Log* app. Make sure not to change the key value again, since users might lose their variants.
- Here are some examples for binding:
  - `logHandle: {myOdataServiceLogHandle}`
  - `logHandle: {path: 'myOdataServiceLogHandle' }`

After your app was deployed successfully to an SAP BTP, ABAP environment system, the *BSP application* and the *SAP Fiori Launchpad* app descriptor item will appear under your created package in Eclipse.

- Now, you need to create a new *IAM App*. Follow the instructions described here: [Defining an IAM App for the Business Service \[page 768\]](#).
- Once created, you need to maintain the *Application Log* OData Service to call your application log data. To do this, go to the *Service* tab and add the *Application Log OData Service* by naming the service type `OData v2` and add the following service name: `APL_LOG_MANAGEMENT_SRV 0001`. Please make sure to add all 13 spaces in between `SRV` and `0001`. Now, go to the *Authorization* tab and maintain your *log objects / sub objects* for the authorization object `S_APPL_LOG`.
- Finally, you need to create a new *Business Catalog*. Please follow the procedure described here: [Creating a Business Catalog \[page 769\]](#)

Having created the business catalog, you have successfully implemented a reusable component to display your application logs.

## 4.2.12.10 Data Archiving

Data archiving is used to extract data from the database, write it to archive files and delete the data from the database tables.

Data archiving is needed for data volume management. Usually, you want to remove data from the database which is not needed for your daily business anymore, but needs to be retained.

*Steps to implement a data archiving solution*

- [Create a storage manager implementation to store the archive data to an external storage system \[page 1498\]](#)
- [Select data and write it to archive files \[page 1499\]](#)
- [Delete data from the database \[page 1501\]](#)
- [Read archived data \[page 1504\]](#)
- [Reload archived data into the database \[page 1507\]](#)
- [Create a definition for archiving an object in ADT](#)

7. [Perform data archiving \[page 1509\]](#)

For data archiving in ABAP Cloud the *Archive Development Kit* ( ADK) provides released APIs or interfaces for all of these steps, which can be used in your implementation to archive content of your own tables.

## 4.2.12.10.1 Storage Manager Implementation

The storage manager integrates the data archiving runtime with the actual storage of the archiving files.

The storage manager will be processed in the different steps of the data archiving process. Within the storage manager implementation, you have the full flexibility to choose which storage will be integrated. Possible options to integrate external storages already exist in ABAP Cloud:

- [Via cloud connector for On-Premise integration](#)
- [Developing External Service Consumption \(Outbound Communication\) \[page 852\]](#)

As a precondition for data archiving, you need to create a class which implements the interface `IF_ARCH_STORAGE_MANAGER`. This interface provides the following methods:

- The method `IF_ARCH_STORAGE_MANAGER~STORE_FILE` stores the archived data to a physical storage location outside of the SAP system. It will be called by the ADK write API and has the following parameters:

Parameter	Description
Importing: <code>IV_ARCHIVE_KEY</code>	Key of the archive file to be stored
Importing: <code>IV_DATA</code>	Content of the archive file (binary data)
Importing: <code>IV_LENGTH</code>	Length of the binary content
Returning: <code>RV_DOCUMENT_ID</code>	Document identifier which can be used to access the archived data. The document ID needs to be returned by the storage manager and will be stored in a link table in the SAP system.

- The method `IF_ARCH_STORAGE_MANAGER~GET_BYTESTREAM` retrieves parts of the binary content of an archive file via range request. It will be called by an ADK API to read the archived data and has the following parameters:

Parameter	Description
Importing: <code>IV_DOCUMENT_ID</code>	Document identifier
Importing: <code>IV_FROM_OFFSET</code>	Data object address
Importing: <code>IV_LENGTH</code>	Length of the binary content
Exporting: <code>EV_DATA</code>	Content of the archive file (binary data)
Exporting: <code>EV_ACT_LENGTH</code>	Length of the byte stream which is returned

- The method `IF_ARCH_STORAGE~RETRIEVE_FILE` retrieves the entire binary content of an archive file.

Parameter	Description
Importing: <i>IV_DOCUMENT_ID</i>	Document identifier
Returning: <i>RV_DATA</i>	Content of the archive file (binary data) which will be returned by the storage manager

- The method *IF\_ARCH\_STORAGE\_MANAGER~DELETE FILE* deletes the archive file from the external storage system.

Parameter	Description
Importing: <i>IV_DOCUMENT_ID</i>	Document identifier

### Note

If any errors appear during any of the operations of the storage manager, please use the exception class *CX\_ARCH\_STORAGE\_MANAGER*.

## 4.2.12.10.2 Select Data and Write It to Archive Files

The runtime to write archived data to an external storage should be implemented in a central ABAP class. This ABAP class must register the interface *IF\_ARCH\_WRITE\_API* to be able to be selected in an archiving object definition in ADT. This ABAP class can be [performed within an application job \[page 1509\]](#).

The purpose of the ABAP class is the selection of application data which will be archived from the database. By using the ADK write API, this application data can be handed over to create a data object. A data object can contain entries of different tables that have been listed in the definition of the archiving object in ADT. Typically, these are all tables belonging to one business object instance, but there is no technical restriction. The application is free to group the tables according to their needs.

As soon as the data object is completed, the object will be transferred as an archiving file to the related storage manager implementation to store data in the related external storage.

The following table shows the write API to collect the data that will be archived:

<i>CL_ARCH_WRITE_API</i>		
Method	Parameter	Description
<i>GET_INSTANCE</i>	Importing: <i>IV_ARCHIVING_OBJECT</i>	Name of the archiving object which will be used
Static method which returns an instance of the write API via parameter <i>RO_WRITE_INSTANCE</i>	Importing: <i>IV_TESTMODE</i>	<i>True</i> : no storage takes place <i>False</i> : Archive content is written, and storage is requested
	Returning: <i>RO_WRITE_INSTANCE</i>	Instance of the write API for further processing

The following table shows the interface for writing archived data:

IF_ARCH_WRITE_API		
Method	Parameter	Description
<b>OPEN_DATA_OBJECT</b>		
Opens a new data object for the data of the business object instance		
<b>PUT_DATA_RECORDS</b>	Importing: <i>IV_TABLE_NAME</i>	Name of the table which will be archived
Writes the data for a specific table to the open data object	Importing: <i>IT_RECORDS</i>	Records of the table
<b>CLOSE_DATA_OBJECT</b>		
Closes the data object and writes it to the archive file	Exporting: <i>EV_OBJECT_OFFSET</i>	Offset at which the data of the data object starts (can be used to build application owned indices for the archived data)
	Exporting: <i>EV_ARCHIVE_KEY</i>	Archive key of the archive file to which the data was written (can be used to build application owned indices for the archived data)
	Exporting: <i>EV_ARCHIVING_SESSION</i>	Sessions of the archiving object to be used
<b>FINALIZE</b>		
Finalizes processing and closes the archiving session		

Typical flow of the archiving write process:

1. Create an instance of the write API and open the archiving write session by using method `CL_ARCH_WRITE_API=>GET_INSTANCE`.
2. Select the data from your application DB tables.
3. For each data object you want to archive, call method `OPEN_DATA_OBJECT`.
4. For each table you want to archive entries from, call method `PUT_DATA_RECORDS`.
5. As soon as all tables of your data object are passed to the API, call method `CLOSE_DATA_OBJECT`.
6. Either start with the next data object (step 3) or finish the archiving write session by calling method `FINALIZE`.

### Sample Code

```

CONSTANTS: lc_object TYPE sarch_object VALUE 'MY_OBJECT'.
" Replace with the name of your ADT archiving object
" select flight data (leading table) from the database (replace table names
with your names of your own tables)
      SELECT * FROM my_header_table
             WHERE carrid      IN @lt_range_carrid
                AND connid    IN @lt_range_connid
                AND fldate     IN @lt_range_fldate
      INTO TABLE @DATA(lt_flights).
" open a new archiving session to archive data
TRY.
      DATA(lo_write) =
cl_arch_write_api=>get_instance( iv_archiving_object =
lc_object                               iv_testmode = lv_test ).

```

```

        LOOP AT lt_flights ASSIGNING FIELD-SYMBOL(<ls_flight>).
        " select data of dependent tables (replace table names with your names of
        your own tables)
        INSERT <ls_flight> INTO lt_flights.
        SELECT * FROM my_item_table1
            WHERE carrid      = @<ls_flight>-carrid
            AND connid       = @<ls_flight>-connid
            AND fldate       = @<ls_flight>-fldate
        INTO TABLE @DATA(lt_bookings).
        SELECT * FROM my_item_table2
            WHERE carrid      = @<ls_flight>-carrid
            AND connid       = @<ls_flight>-connid
            AND fldate       = @<ls_flight>-fldate
        INTO TABLE @DATA(lt_tickets).
        SELECT * FROM my_item_table3
            WHERE carrid      = @<ls_flight>-carrid
            AND connid       = @<ls_flight>-connid
            AND fldate       = @<ls_flight>-fldate
        INTO TABLE @DATA(lt_invoices).
        " open new ADK data object
        lo_write->open_data_object( ).
        " write data of header table
        lo_write->put_data_records( iv_table_name = '<MY_HEADER_TALBE>'
it_records = lt_sflight_arch ).
        CLEAR lt_sflight_arch.
        " write data of depending tables
        lo_write->put_data_records( iv_table_name = '<MY_ITEM_TABLE1>'
it_records = lt_bookings ). " bookings
        CLEAR lt_sflight_arch.
        lo_write->put_data_records( iv_table_name = '<MY_ITEM_TABLE2>'
it_records = lt_tickets ). " tickets
        CLEAR lt_sflight_arch.
        lo_write->put_data_records( iv_table_name = '<MY_ITEM_TABLE3>'
it_records = lt_invoices ). " invoices
        CLEAR lt_sflight_arch.
        " write data object into the archive file
        lo_write->close_data_object( ).
        ENDLLOOP.
        " finalize and end writing
        lo_write->finalize( ).

```

### 4.2.12.10.3 Delete Data from the Database

The runtime to delete archived data from database should be implemented in a central ABAP class. This ABAP class must register interface `IF_ARCH_DELETE_API` to be able to be selected in an archiving object definition in ADT. This ABAP class can be [performed within an application job \[page 1509\]](#).

There are different ways to delete archived data from the database:

- Using a central delete API to delete all table entries of a data object
- Using a central delete API to delete specified tables of a data object
- Using a central delete API to get all table entries of a data object to perform an own deletion from the database

#### CL\_ARCH\_DELETE\_API (API for deleting archived data from the database)

Method	Parameter	Description
--------	-----------	-------------

**CL\_ARCH\_DELETE\_API (API for deleting archived data from the database)**

<p><i>GET_INSTANCE</i></p> <p>Returns an instance of the delete API. Reference to interface IF_ARCH_DELETE_API</p>	Importing: <i>IV_ARCHIVING_OBJECT</i>	Name of the archiving object which will be used
	Importing: <i>IV_ARCHIVE_KEY</i>	Archive key for which data should be deleted
	Importing: <i>IV_TESTMODE</i>	<p><i>True</i>: no storage takes place</p> <p><i>False</i>: Archive content is written, and storage is requested</p>
	Returning: <i>RO_DELETE_INSTANCE</i>	Instance of the delete API
<p><i>GET_FILES_TO_DELETE</i></p> <p>Returns a table with archive keys which have not yet been processed by deletion</p>	Importing: <i>IV_ARCHIVING_OBJECT</i>	Name of the archiving object which will be used
	Importing: <i>IT_DATE_SELECTION</i>	Range of dates on which archive files have been created
	ReturnsImporting: <i>IT_USER_SELECTION</i>	Range of users which have created archive files
	Returning: <i>RT_ARCHIVE_FILE_ATTRIBUTES</i>	Table of archive keys which fulfill the selection criteria for dates and users

**IF\_ARCH\_DELETE\_API (Interface for deleting archived data from the database)**

<i>Method</i>	<i>Parameter</i>	<i>Description</i>
<p><i>GET_NEXT_OBJECT</i></p> <p>Reads the next data object for the archived data</p>	Exporting: <i>EV_OBJECT_OFFSET</i>	Offset at which the data of the data object starts. This can be used to build application-owned indices for the archived data.
	Exporting: <i>EV_ARCHIVE_KEY</i>	Archive key of the archive file to which the data was written. This can be used to build application-owned indices for the archived data.
	Exporting: <i>EV_ARCHIVING_SESSION</i>	Sessions of the archiving object which will be used
	Exporting: <i>EV_END_OF_FILE</i>	<p><i>True</i>: All data contained in the files is processed, and the application should finalize the deletion</p> <p><i>False</i>: The application should continue processing the next data object</p>
<p><i>GET_DATA_RECORDS</i></p>	Importing: <i>IV_RECORD_STRUCTURE</i>	Name of the table for which archived data should be returned
	Exporting: <i>ET_DATA_RECORDS</i>	Records of the table
<p><i>DELETE_DATA_FOR_TABLE</i></p> <p>Deletes the data for a specific table from the database</p>	Importing: <i>IV_TABLE_NAME</i>	Name of the table for which archived data should be deleted
	Importing: <i>IT_RECORDS</i>	Records of the table to be deleted

## IF\_ARCH\_DELETE\_API (Interface for deleting archived data from the database)

### DELETE\_DATA\_FOR\_OBJECT

Deletes all table entries contained in the data object

### FINALIZE

Finalizes processing

Typical flow of the archiving delete process:

1. Determine files which are still available for deletion by using the method `CL_ARCH_DELETE_API=>GET_FILES_TO_DELETE`, with filter options on creating user and creation date of the archive file.
2. Create an instance of the delete API and open the archiving delete session for one of the selected archive files by using method `CL_ARCH_DELETE_API=>GET_INSTANCE`.
3. Open the next data object with the method `GET_NEXT_DATA_OBJECT`. If the method returns `EV_END_OF_FILE = TRUE ( 'X' )`, continue with step 6. Optional (can be used for reading archived data via index access): Update the index table with the data object archived.
4. Delete the data of the object from your database tables either by:
  - Use of the method `DELETE_DATA_FOR_OBJECT`
  - Use of the method `DELETE_DATA_FOR_TABLE`. Call this method once for each table.
  - Use of the method `GET_DATA_RECORDS`. Use the result to perform your own `DELETE` statements.
5. Continue with the next data object. See step 3.
6. Finish the archiving delete session by calling the method `FINALIZE`.

### Sample Code

```
CONSTANTS: lc_object TYPE if_arch_api_types=>ty_object_name VALUE 'MY_OBJECT'.
DATA: lv_test TYPE abap_bool VALUE abap_true,
lt_data TYPE STANDARD TABLE OF my_index_table,
lv_arkey TYPE sarch_archive_key.
DATA: ls_index TYPE my_index_table.

" get newest undeleted file
DATA(lt_files) =
cl_arch_delete_api=>get_files_to_delete( iv_archiving_object =
lc_object ).
SORT lt_files BY creation_date DESCENDING creation_time
DESCENDING.
READ TABLE lt_files ASSIGNING FIELD-SYMBOL(<ls_file>) INDEX
1.
DATA(lo_delete) = cl_arch_delete_api=>get_instance
( iv_archiving_object =
lc_object
iv_archive_key = lv_arkey
iv_testmode = lv_test ).
" read next data object from archive file into internal memory
DO.
lo_delete->get_next_data_object( IMPORTING ev_end_of_file =
DATA(lv_end_of_file)
ev_archive_key =
DATA(lv_archive_key)
ev_object_offset =
DATA(lv_offset) ).
IF lv_end_of_file = abap_true.
EXIT.
ENDIF.
```

```

" optional: Create customer owned index for single document
access during read
" read archived data for table MY_HEADER_TABLE
lo_delete->get_data_records( EXPORTING iv_record_structure =
'MY_HEADER_TABLE'
                                IMPORTING et_data_records =
lt_data ).
" map flight data to your index table MY_INDEX_TABLE
IF lv_test <> abap_true.
  LOOP AT lt_data ASSIGNING FIELD-SYMBOL(<ls_data>).
    MOVE-CORRESPONDING <ls_data> TO ls_index.
    Ls_index-archive_key = lv_archive_key.
    Ls_index-archive_offset = lv_offset.
    INSERT my_index_table FROM @ls_Index.
  ENDLOOP.
ENDIF.
" delete the data from the data base
lo_delete->delete_data_for_object( ).
ENDDO.
COMMIT WORK.
lo_delete->finalize( ).

```

Example of a customer-owned index table for archived flights:

#### Sample Code

```

@EndUserText.label : 'Archiving Index: Flights'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #A
@AbapCatalog.dataMaintenance : #ALLOWED
define table my_index_table {
@EndUserText.label : 'Client'
key mandt : abap.clnt not null;
@EndUserText.label : 'Airline Code'
key carrid : abap.char(3) not null;
@EndUserText.label : 'Flight Connection Number'
key connid : abap.numc(4) not null;
@EndUserText.label : 'Flight date'
key fldate : abap.dats not null;
archive_key : sarch_archive_key;
archive_offset : sarch_offset;

```

## 4.2.12.10.4 Read Archived Data

Applications can use the ADK read API to read the data which is contained in an archive file stored in an external storage system.

There are two possible ways to access the data:

- Read the data for entire archive files sequentially
- Read the data by index access

To optimize the reading access on archive files, an index solution can be established in the application. For an index-based read access, the archive key and the offset of a data object are needed. ADK API provides this information within methods `IF_ARCH_DELETE_API->GET_NEXT_DATA_OBJECT` and `IF_ARCH_READ_API->GET_NEXT_DATA_OBJECT`.

A typical index-based solution needs a transparent table containing columns for application attributes, a column for the archive key and a column for the offset. The archive key is the ID of the archive file, which contains the application attribute. The offset is the offset in the archive file at which the data for the application attribute starts. Usually, the initial construction of an archive index will be established by [deleting archived data from the database \[page 1501\]](#). In case the index should be constructed at a later point in time, the ADK read API can be used to determine archive key and offset (returned by method `IF_ARCH_READ_API->GET_NEXT_DATA_OBJECT`).

#### CL\_ARCH\_READ\_API (API to read archived data)

Method	Parameter	Description
<b>GET_FILES_TO_READ</b> Selection of archiving sessions and files	Importing: <i>IT_DATE_SELECTION</i>	Range on dates on which archive files have been created
	Importing: <i>IT_USER_SELECTION</i>	Range on users which have created archive files
	Importing: <i>IT_ARCHIVING_OBJECT</i>	Archiving object which will be used
	Returning: <i>RT_ARCHIVING_FILE_ATTRIBUTES</i>	Archiving sessions' attributes
<b>GET_INSTANCE</b> Returns an instance of the delete API. Reference to interface <code>IF_ARCH_READ_API</code>	Importing: <i>IV_ARCHIVING_OBJECT</i>	Name of the archiving object which will be used
	Importing: <i>IV_ARCHIVING_SESSION</i>	Sessions of the archiving object which will be used
	Importing: <i>IT_ARCHIVE_KEY</i>	Archive key for which data should be read
	Returning: <i>RO_READ_INSTANCE</i>	Instance of the read API for further processing

#### IF\_ARCH\_READ\_API (Interface to read archived data)

Method	Parameter	Description
<b>GET_DATA_RECORDS</b> Read records by structure from the current data object	Importing: <i>IV_RECORDS_STRUCTURE</i>	Name of the structure of all data records in the table
	Exporting: <i>EV_DATA_RECORDS</i>	Table containing the data records
<b>GET_NEXT_DATA_OBJECT</b> Read data object from the archive file	Exporting: <i>EV_ARCHIVE_KEY</i>	Archive key according to archive management
	Exporting: <i>EV_END_OF_FILE</i>	Boolean values: <i>TRUE</i> (= 'X') <i>FALSE</i> (= '')
	Exporting: <i>EV_ARCHIVING_SESSION</i>	Sessions of the archiving object which will be used
	Exporting: <i>EV_OBJECT_OFFSET</i>	Offset of data object in the archive
<b>CLOSE</b> Open archive files will be closed		

As mentioned before, there are two different ways to access the data. A typical procedure for the sequential read access would be as follows:

1. Determine files which are available for evaluation by using the method `CL_ARCH_READ_API=>GET_FILES_TO_READ`, with filter options on creating user and creation date of the archive file.
2. Create an instance of the read API and open the archiving read session for one of the selected archive files by using the method `CL_ARCH_READ_API=>GET_INSTANCE`.
3. Open the next data object with the method `GET_NEXT_DATA_OBJECT`. If the method returns `EV_END_OF_FILE = TRUE ( 'X' )`, continue with step 6.
4. Read the data with the method `GET_DATA_RECORDS`.
5. Continue with the next data object. See step 3.
6. Finish the read operation by calling method `CLOSE`.

A typical flow of the index-based read access would be as follows:

1. Determine the archive key and the offset of the data object by selecting the relevant entry from your index table.
2. Create an instance of the read API and open the archiving read session for the data object by using the method `CL_ARCH_READ_API=>GET_INSTANCE_BY_OFFSET`.
3. Read the data by using the method `GET_DATA_RECORDS`.
4. Finish the read operation by calling method `CLOSE`.

An example code for the index-based read operation:

#### Sample Code

```
CONSTANTS: lc_object TYPE if_arch_api_types=>ty_object_name VALUE 'MY_OBJECT'.
DATA: lt_data TYPE STANDARD TABLE OF my_item_table.
DATA: lt_index TYPE STANDARD TABLE OF my_index_table.
" let's assume, we want to read the archived bookings for flight AA/0040
on 20010110
TRY.
    " get archive key and offset for the given flight from the index table
    SELECT * FROM my_index_table WHERE carrid = 'AA' AND connid = '0040'
AND fldate = '20010110'
    INTO TABLE @lt_index.
    SORT lt_index BY archive_key DESCENDING.
    READ TABLE lt_index ASSIGNING FIELD-SYMBOL(<ls_index>) INDEX 1.
    IF NOT <ls_index> IS ASSIGNED.
        RETURN.
    ENDIF.
    " open a read instance for the archive key and offset found
    DATA(lo_read) = cl_arch_read_api=>get_instance_by_offset
( iv_archiving_object = lc_object
                                iv_archive_key =
<ls_index>-archive_key
                                iv_object_offset = <ls_index>-
archive_offset ).
    " get all archived booking entries for this flight
    lo_read->get_data_records( EXPORTING iv_record_structure =
'MY_ITEM_TABLE1'
                                IMPORTING et_data_records = lt_data ).
    " close the read instance
    lo_read->close( ).
```

## 4.2.12.10.5 Reload Archived Data into the Database

Reloading is optional and should only be used in exceptional cases. The application must decide if a reload is necessary or not.

In the standard process, a reloading of archived data is not required, as archived data and direct access to individual data objects can be performed by using the [Read API \[page 1504\]](#).

There are two cases which need to be distinguished:

1. Data must be reloaded shortly after deleting data from the database within the archiving process. An example for this case would be if selection criteria were set wrongly for the archiving process.
2. Reload of archived data after a long period of time. In this case it must be ensured that references to and within the reloaded data are still available in database. Furthermore, it needs to be guaranteed that no table key conflicts exist. Since this is not a real error, it's strongly recommended not to reload the data in this case.

The runtime to reload archived data from an external storage system back into the database should be implemented in a central ABAP class. This ABAP class has to register interface `IF_ARCH_RELOAD_API` to be able to be selected in an archiving object definition in ADT.

### CL\_ARCH\_RELOAD\_API (API to reload archived data)

Method	Parameter	Description
<i>GET_INSTANCE</i> Returns an instance of the delete API. Reference to interface <code>IF_ARCH_RELOAD_API</code>	Importing: <i>IV_ARCHIVING_OBJECT</i>	Name of the archiving object which will be used
	Importing: <i>IV_ARCHIVING_SESSION</i>	Sessions of the archiving object which will be used
	Importing: <i>IV_TESTMODE</i>	Reload program runs in test mode
	Returning: <i>RO_RELOAD_INSTANCE</i>	Instance of the reload API for further processing
<i>GET_SESSIONS_TO_RELOAD</i> Read a data object from an archive file	Importing: <i>IT_DATA_SELECTION</i>	Range on dates on which archive files have been created
	Importing: <i>IT_USER_SELECTION</i>	Range on users which have created archive files
	Importing: <i>IV_ARCHIVING_OBJECT</i>	Archiving object which will be used
	Returning: <i>RT_SESSION_ATTRIBUTES</i>	Archiving sessions' attributes

### IF\_ARCH\_RELOAD\_API (Interface to reload archived data)

Method	Parameter	Description
<i>GET_DATA_RECORDS</i> Read records by structure from the current data object	Importing: <i>IV_RECORDS_STRUCTURE</i>	Name of a structure of all data records in the table
	Exporting: <i>ET_DATA_RECORDS</i>	Table containing the data records
<i>GET_NEXT_DATA_OBJECT</i> Read data object from the archive file	Exporting: <i>EV_ARCHIVE_KEY</i>	Archive key according to archive management

## IF\_ARCH\_RELOAD\_API (Interface to reload archived data)

	Exporting: <i>EV_END_OF_FILE</i>	Boolean values: <i>TRUE</i> (= 'X') <i>FALSE</i> (= '')
	Exporting: <i>EV_ARCHIVING_SESSION</i>	Sessions of the archiving object which will be used
	Exporting: <i>EV_OBJECT_OFFSET</i>	Offset of data object in the archive
<i>RELOAD_DATA_FOR_OBJECT</i>		
<i>RELOAD_DATA_FOR_TABLE</i>	Importing: <i>IV_TABLE_NAME</i>	DDIC structure name of an internal table
Reloading the data of an internal table	Tables: <i>IT_TABLE_NAME</i>	
<i>FINALIZE</i>		
Open archive files will be closed		

A typical flow of the archiving reload process would be as follows:

1. Determine archiving sessions which are still available for reload by using the method `CL_ARCH_RELOAD_API=> GET_SESSIONS_TO_RELOAD`, with filter options on creating user and creation date of the archive file.
2. Create an instance of the reload API and open the archiving reload session for one of the selected archiving sessions by using the method `CL_ARCH_RELOAD_API=>GET_INSTANCE`.
3. Open the next data object via method `GET_NEXT_DATA_OBJECT`. If the method returns `EV_END_OF_FILE = TRUE ( 'X' )`, continue with step 6 to call the method `FINALIZE`.
4. Reload the data of the object from the external storage system back into your database tables, either by:
  - Use of the method `RELOAD_DATA_FOR_OBJECT`
  - Or use of the method `RELOAD_DATA_FOR_TABLE` . This method needs to be called once for each table.
  - Use of the method `GET_DATA_RECORDS`. With this method, the result needs to be used to perform your own `INSERT` statements.
5. Continue with the next data object. See step 3.
6. Finish the archiving reload session by calling the method `FINALIZE`.

An example coding snippet:

### Sample Code

```
CONSTANTS: lc_object TYPE if_arch_api_types=>ty_object_name VALUE 'MY_OBJECT'.
DATA:      lv_test TYPE abap_bool VALUE abap_true,
lt_data TYPE STANDARD TABLE OF my_header_table,
lv_session TYPE sarch_session_number.

      " get newest complete archiving session
      DATA(lt_sessions) =
cl_arch_reload_api=>get_sessions_to_reload(          iv_archiving_object =
lc_object ).
      SORT lt_sessions BY creation_date DESCENDING creation_time
DESCENDING.
      READ TABLE lt_sessions ASSIGNING FIELD-SYMBOL(<ls_session>)
INDEX 1.
```

```

        DATA(lo_reload) = cl_arch_reload_api=>get_instance
( iv_archiving_object = lc_object
                                iv_archiving_session =
lv_session
                                iv_testmode =
lv_test ).
    " read next data object from archive file into internal memory
    DO.
        lo_reload->get_next_data_object( IMPORTING ev_end_of_file =
DATA(lv_end_of_file)
                                ev_archive_key =
DATA(lv_archive_key)
                                ev_object_offset =
DATA(lv_offset) ).
        IF lv_end_of_file = abap_true.
            EXIT.
        ENDIF.
        " optional: remove
        " read archived data for table ZADK_SFLIGHT
        lo_reload->get_data_records( EXPORTING iv_record_structure =
'MY_HEADER_TABLE'
                                IMPORTING et_data_records =
lt_data ).
        " reload the data into the data base
        lo_reload->reload_data_for_object( ).
        " optional: delete data from customer owned index
        DELETE FROM <my_index_table>
            WHERE archive_key = @lv_archive_key.
    ENDDO.
    COMMIT WORK.
    lo_reload->finalize( ).

```

## 4.2.12.10.6 Archiving Classes

Archiving classes are used to archive object instances of reuse objects together with the business object instances in your application to which the reuse object instance belongs. If your application includes such reuse objects, and if SAP offers a released archiving class for the reuse object, you can easily integrate the archiving class into your archiving object:

- Enhance the archiving object by adding the archiving class to your archiving object in the ADT editor
- Enhance the write class by registering the object instance of the reuse object via a released method belonging to the archiving class
- Use the released read functionality belonging to the archiving class to read the data of the reuse object

## 4.2.12.10.7 Perform Data Archiving

Productive data archiving is a mass data processing and should therefore always be performed in the background, decoupled from the transactional business process. For background processing, regular performing and monitoring of data archiving runs, the *Application Job* framework is recommended to use. For that, an application job catalog entry with at least one application job template is required for each data archiving step:

- Write data to external storage
- Delete data from custom database tables

The application job catalog entry contains the implementation of the data archiving step: it uses the released corresponding ADK runtime API. For logging, the application log in the context of an application job can be used. Related monitoring is embedded in the application job apps.

All APIs for data archiving provide a test mode parameter. If this parameter is set, no changes are performed on the database and no data is stored via the storage manager. Applications themselves need to expose a test mode parameter to the user. They need to take care that no database changes are performed in their part of the write, delete, and reload ABAP classes in case the test mode option is chosen.

## 4.2.12.11 Output Management

[Printing \[page 1510\]](#)

Find out how to create a print queue item API.

[Print Forms \[page 1511\]](#)

ADS Rendering in ABAP environment

[Emailing \[page 1518\]](#)

### 4.2.12.11.1 Printing

Find out how to create a print queue item API.

You can use the method `CREATE_QUEUE_ITEM_BY_DATA` with the class `CL_PRINT_QUEUE_UTILS` to create a print queue item of a queue. One print queue item has one main document and can have either no or a variable amount of attachments. The method `CREATE_QUEUE_ITEM_BY_DATA` has the following importing parameters:

- `IV_QNAME`: Name of the print queue
- `IV_PRINT_DATA`: Print document contained in xstring format
- `IV_NAME_OF_MAIN_DOC`: Name of the main document
- `IV_NUMBER_OF_COPIES`: Number of copies
- `IV_PAGES`: Number of pages
- `IT_ATTACHMENT_DATA`: List of attachments within the structure. This includes the name and the attachment data in xstring

If a print queue item has been created successfully, it returns the ID of the item with the parameter `RV_ITEMID`. In case of any errors, you can find the error messages in the exporting parameter `EV_ERR_MSG`.

## ❁ Example

```
CLASS zcl_pq_test DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC .
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun .
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.
CLASS zcl_pq_test IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    DATA: l_print_data TYPE xstring.
    l_print_data = |...|.
    DATA(lv_qitem_id) = cl_print_queue_utils=>create_queue_item_by_data
      EXPORTING
        iv_qname          = '...'
        iv_print_data     = l_print_data
        iv_name_of_main_doc = '...'.
    out->write( lv_qitem_id ).
  ENDMETHOD.
ENDCLASS.
```

## 4.2.12.11.2 Print Forms

ADS Rendering in ABAP environment

The *Adobe Document Services* (ADS) can render Adobe XML Forms (XFA) to PDF documents and other print formats. The application sends the data and the form template using a secure connection and the service returns the rendered document. The rendered documents can be used by your applications for the screen output or for the output into the print queue. For more information, see [Maintain Print Queues \[page 2520\]](#).

For more information, see [Connecting the SAP Forms Service to ABAP](#).

### 4.2.12.11.2.1 Runtime API for ADS Rendering Calls

The `CL_FP_ADS_UTIL` class provides the ABAP Runtime API for *Adobe Document Services* (ADS) rendering calls. It contains the following *Public* methods to be used for the corresponding functions:

Public Methods

Method	Description
RENDER_PDF	Rendering PDF
RENDER_4_PQ	Rendering for Print Queue

The PDF rendering process on ADS creates the PDF file to be printed (or print output format) using the following both formats:

- XDP form template file
- Data for the form filling in XML format, for example, data from the [RAP Data Services for Print Forms \[page 1514\]](#).

The XDP form template file is a description of the form layout design in Adobe XFA format. The supported data binding type is an XML data schema.

The *Adobe LiveCycle Designer for SAP solutions* is the tool for visual design XDP form templates from Adobe Inc. It can be downloaded using the *Install Additional Software* app, which contains the download link to the SAP ONE Support Launchpad.

The data XML file contains the data that corresponds to the used data schema in the XDP form template.

## Rendering PDF

The `RENDER_PDF` method calls the ADS to render print PDF using the XDP form file and the XML data file. It has the following importing/exporting parameters:

Importing Parameters

Parameter	Description
IV_XML_DATA	XML data
IV_XDP_LAYOUT	Adobe XDP form template
IV_LOCALE	Locale for rendering the language: language_COUNTRY, for example en_US
IS_OPTIONS	PDF rendering parameters (optional)

Exporting Parameters

Parameter	Description
EV_PDF	PDF rendering result
EV_PAGES	Number of pages
EV_TRACE_STRING	Trace string

### Sample Code

```

TRY.
  *Render PDF
  cl_fp_ads_util=>render_pdf( EXPORTING iv_xml_data      = lv_xml_data
                              iv_xdp_layout          = lv_xdp
                              iv_locale              = 'de_DE'
                              is_options              = ls_options
                              IMPORTING ev_pdf         = ev_pdf
                              ev_pages               = ev_pages

```

```

                                ev_trace_string = ev_trace_string
                                ).
    CATCH cx_fp_ads_util INTO lx_fp_ads_util.

ENDTRY.

```

## Rendering for Print Queue

The `RENDER_4_PQ` method calls the ADS to render in the print output format required for the target print queue. The support of the *Print Definition Language* (PDL) print queue format will be taken from print queue properties.

Importing Parameters

Parameter	Description
IV_XML_DATA	XML data
IV_XDP_LAYOUT	Adobe XDP form template
IV_LOCALE	Locale for rendering the language: language_COUNTRY, for example en_US
IV_PQ_NAME	Print Queue name
IS_OPTIONS	PDL rendering parameters (optional)

Exporting Parameters

Parameter	Description
EV_PDL	PDF rendering result
EV_PAGES	Number of pages
EV_TRACE_STRING	Trace string

### Sample Code

```

TRY.
*Render in Print Queue Format
  cl_fp_ads_util=>render_4_pq( EXPORTING iv_xml_data      = lv_xml_data
                                iv_xdp_layout         = lv_xdp
                                iv_locale             = 'en_US'
                                iv_pq_name            = 'PQ1'
                                is_options             = ls_options
                                IMPORTING ev_pdf        = ev_pdf
                                ev_pages              = ev_pages
                                ev_trace_string       = ev_trace_string
                                ).
  CATCH cx_fp_ads_util INTO lx_fp_ads_util.
ENDTRY.

```

## 4.2.12.11.2.2 RAP Data Services for Print Forms

The XML data for print form rendering can be obtained from the RAP Business Services. The data model can be defined just as well as the *RAP Service Definition*. For more information, see [Service Definition](#).

The `CL_FP_FDP_SERVICES` class provides the ABAP API to receive the following:

- data in xml format for the use in print forms
- XML Schema Definition (XSD) used for the design of print forms in the *Adobe LiveCycle Designer*.

### Initiate Business Data Reader

To supply the rendering operation with business data, a reuse service can be applied. Beforehand, a service definition needs to be created.

#### Note

The service definition doesn't need a binding for RAP Data Services for print forms.

1. Initiate the reuse utility by specifying the service definition: `data(lo_fdp_api) = cl_fp_fdp_services=>get_instance( `FP_FDP_AUNIT_SO` ).`
2. Specify the key parameters. This is required to read the data for a specific item. The reuse utility offers the following functionality to retrieve all key fields for the service definition: `data(lt_keys) = lo_fdp_api->get_keys( ).`
3. Once you have retrieved the array with key values, assign the keys that fit to the document you want to output: `lt_keys[ name = 'UUID' ]-value = 'FA163EE47BDD1ED9A682A2E6F1ECF696'.`

#### Sample Code

```
DATA(lo_fdp_api) = cl_fp_fdp_services=>get_instance( `FP_FDP_SERVICE_EX1` ).  
DATA(lt_keys)    = lo_fdp_api->get_keys( ).  
    lt_keys[ name = 'UUID' ]-value = 'FA163EE47BDD1ED9A682A2E6F1ECF696'.
```

### Retrieve XML Data from Service Definition

The `READ_TO_XML` method retrieves the data structure of the service definition for a specific item. It has the following Importing parameters:

Importing Parameters

Parameter	Definition
IT_SELECT	Key parameters

Parameter	Definition
IV_LANGUAGE (Optional)	Overwrites the locale language (useful if you want to control how dynamic values (e.g. unites) are resolved

The READ\_TO\_XML method has the following returning parameters:

Returning Paramaters

Parameter	Definition
RV_XML	Resulting XML as XSTRING

### Sample Code

```

TRY.
  DATA(lt_keys) = lo_fdp_api->get_keys( ).
  lt_keys[ name = 'UUID' ]-VALUE = 'FA163EE47BDD1ED9A682A2E6F1ECF696'.
  DATA(lv_data) = lo_fdp_api->read_to_xml( lt_keys ).
  CATCH cx_fp_fdp_error INTO DATA(lo_exception).
ENDTRY.

```

## Retrieve XML Schema Definition from Service Definition

The GET\_XSD method retrieves the XML Schema Definition (XSD) for the service definition. It has the following returning parameters:

Returning Paramaters

Parameter	Definition
RV_XML	Resulting XSD as XSTRING

### Sample Code

```

TRY.
  DATA(lv_xml) = lo_fdp_api->get_xsd( ).
  CATCH cx_fp_fdp_error INTO DATA(lo_exception).
ENDTRY.

```

## 4.2.12.11.2.3 PDF Merger API

You can use a class-based API to merge the content of different PDF files into a single PDF file. The result file contains all pages of the source files in the sequence of the original files.

If you want to merge PDF files, you require an instance of class `CL_RSPO_PDF_MERGER`. To create this instance, class `CL_RSPO_PDF_MERGER` provides the method `CREATE_INSTANCE`. After using this method, the following two steps are necessary:

- With method `ADD_DOCUMENT` you can add the data of a PDF document to the list of files you want to merge. You should call this method for each source file.
- With method `MERGE_DOCUMENTS` you can start the merge process. The method returns the data of the merged document.

### Sample Code

```
...
" Create an instance of the PDF merger class
DATA(l_merger) = cl_rspo_pdf_merger=>create_instance( ).
"Add the data of the first PDF document to the list of files which shall
be merged
l_merger->add_document( l_data_of_first_pdf ).
" Add the data of the second PDF document
l_merger->add_document( l_data_of_second_pdf ).
TRY.
    " Merge both documents and receive the result
    DATA(l_merged_PDF) = l_merger->merge_documents( ).
    CATCH cx_rspo_pdf_merger INTO DATA(l_exception).
    " Add a useful error handling here
ENDTRY.
...
```

If you try to merge damaged documents, or documents that don't fulfill the requirements of the PDF merger, an exception of type `CX_RSPO_PDF_MERGER` is raised. The exception object contains the following attributes that contain more information regarding the problem:

- `DOCUMENT_INDEX`: The index of the PDF document that was responsible for the exception
- `ERROR_CODE`: The internal error code of the exception
- `ERROR_TEXT`: The description text of the error code

The PDF merger has the following restrictions:

- It can only handle PDF files.
- It can't handle encrypted PDF files. Usually, you can check whether a PDF file is encrypted by checking the [Security](#) section of the file properties. Another possibility is that you open the file with a text editor and search for the key word **Encrypt**, which marks an encrypted file.
- It can't handle damaged PDF files. For example, if parts of the file are missing, or if some bytes were changed, the file can't be processed. PDF files are usually binary data, so any conversion like a code page conversion damages the file.
- Further restrictions can be found in SAP note [2264208](#).

## Related Information

[Class and Interface of the PDF Merger API \[page 1517\]](#)

### 4.2.12.11.2.3.1 Class and Interface of the PDF Merger API

Class `CL_RSPO_PDF_MERGER` uses interface `IF_RSPO_PDF_MERGER`. Find out which public methods it contains.

## Context

The following public methods exist in interface `IF_RSPO_PDF_MERGER` :

### CREATE\_INSTANCE (static)

Create an instance of the PDF merger class.

Name	Description
<b>Returning parameter</b>	
MERGER_INSTANCE	PDF merger instance: A reference to interface <code>IF_RSPO_PDF_MERGER</code>

### ADD\_DOCUMENT

Add a PDF document to the list of files that you want to merge.

Name	Description
<b>Importing parameter</b>	
DOCUMENT	Data of the PDF document that you want to merge (type <code>XSTRING</code> )

### MERGE\_DOCUMENTS

Merge all PDF documents into a single PDF file.

Name	Description
<b>Returning parameter</b>	
MERGED_DOCUMENT	Data of the merged document (type <code>XSTRING</code> )
<b>Exceptions</b>	
CX_RSPO_PDF_MERGER	Exceptions of the PDF merger

## Related Information

[PDF Merger API \[page 1516\]](#)

### 4.2.12.11.3 Emailing

#### 4.2.12.11.3.1 Sending Mails Using SMTP

Send mails using the Simple Message Transfer Protocol (SMTP).

You can send mails with the Simple Message Transfer Protocol (SMTP) using a mail server connected via the *SAP Business Technology Platform (SAP BTP), Cloud Connector* or use a publicly available SMTP server.

For more information, see [Configure Access Control \(TCP\)](#)

#### Prerequisites

You must define the following configurations in a communication system. See [How to Create Communication Systems](#) for more information.

- Host
- Port
- Enable *Cloud Connector* to access your customer owned SMTP server
- Disable *Cloud Connector* when the communication is done directly to a publicly available SMTP server
- *SCC Location ID* of the *SAP BTP Cloud Connector* (only needed when the Cloud connector is enabled)

##### Note

This parameter is only required if several SAP BTP, Cloud connectors are used in one subaccount (to define the target SAP BTP, Cloud Connector with the same *SCC Location ID*).

- A referenced outbound communication user with authentication method *User and Password*

##### Note

- Instead of maintaining the information directly in the communication system, it's also possible to enter a referenced destination of type *MAIL* in the destination service. For more information, see [Create Mail Destinations](#).

Afterwards, create a communication arrangement for the *SAP\_COM\_0548* communication scenario using this communication system.

## Application Programming Interface (API)

Use the `CL_BCS_MAIL_MESSAGE` class to create and send mails. You can specify sender and recipient. Furthermore, you can add textual body parts using class `CL_BCS_MAIL_TEXTPART` or binary attachments (e.g. PDF documents) represented by class `CL_BCS_MAIL_BINARYPART`, respectively.

With the send method of the API, the mail is sent via the mail server configured in the destination using the cloud connector. Sending is performed synchronously.

### Sample Code

```
try.  
  data(lo_mail) = cl_bcs_mail_message=>create_instance( ).  
  lo_mail->set_sender( 'noreply@yourcompany.com' ).  
  lo_mail->add_recipient( 'recipient1@yourcompany.com' ).  
  lo_mail->add_recipient( iv_address = 'recipient2@yourcompany.com' iv_copy  
= cl_bcs_mail_message=>cc ).  
  lo_mail->set_subject( 'Test Mail' ).  
  lo_mail->set_main( cl_bcs_mail_textpart=>create_instance(  
  iv_content      = '<h1>Hello</h1><p>This is a test mail.</p>'  
  iv_content_type = 'text/html'  
  ) ).  
  lo_mail->add_attachment( cl_bcs_mail_textpart=>create_instance(  
  iv_content      = 'This is a text attachment'  
  iv_content_type = 'text/plain'  
  iv_filename     = 'Text_Attachment.txt'  
  ) ).  
  lo_mail->send( importing et_status = data(lt_status) ).  
catch cx_bcs_mail into data(lx_mail).  
  "handle exceptions here  
endtry.
```

## Bodyparts in a Message

Each mail message consists of one or more body parts (MIME parts). A body part consists of the text or binary content, the type and additional attributes like the filename for an attachment. A main body part (`SET_MAIN`) must be set and additional body parts can be set as attachments (`ADD_ATTACHMENT`) or alternatives (`ADD_MAIN_ALTERNATIVE`). Attachments are usually files that are attached to the mail. Alternative body parts are different representations of the main part of the email. For example, a mail can have an HTML representation and clients that can only display text or plain text will see this alternative body part.

The factory methods `CREATE_TEXT_PLAIN`, `CREATE_TEXT_HTML` of class `CL_BCS_MAIL_TEXTPART` can be used for the most common body parts. If a body part is to be sent with a different content-type, the `CREATE_INSTANCE` method can be used and a content-type can be passed.

For more information, see

- [Create Mail Destinations](#)
- [Communication Systems \[page 2397\]](#)
- [How to Create a Communication Arrangement \[page 2395\]](#)
- [Integrating On-Premise Systems \[page 1070\]](#)
- [Configure Access Control \(TCP\)](#)

## 4.2.12.11.3.2 Configuration of the System Email Outbound

Configure the email system using class `CL_BCS_MAIL_SYSTEM_CONFIG`. This configuration provides additional functionality to an SMTP email configuration.

### Configuring the Email Outbound Check

You can restrict the email outbound by checking the sender and recipient addresses. The check is executed when the email is sent. If the address doesn't match with the sender or recipient domains or addresses on the allowlist, the email will not be sent and is not displayed in the app.

In addition, you can set a default sender address.

#### Activating the Email Outbound Check

Use class `CL_BCS_MAIL_SYSTEM_CONFIG` and method `SET_ADDRESS_CHECK_ACTIVE()` to activate the email outbound check. The importing parameter `ABAP_TRUE` activates the check, `ABAP_FALSE` deactivates it. The functionality is inactive per default.

#### Configuring the Email Outbound Allow Tables

To restrict the email outbound, two tables can be filled with allowed domains or email addresses. The first table contains allowed recipients (filled with method `ADD_ALLOWED_RECIPIENT_DOMAINS()`). The second table contains allowed senders (filled with method `ADD_ALLOWED_SENDER_DOMAINS()`). The check can be used for both the sender address and recipient address(es). If either all sender or recipient addresses should be allowed, add a `*.*` to the corresponding allow domain table.

The configuration must be done as system customizing. It's not allowed to set the configuration in a session together with any email outbound.

#### Configuring the Default Sender

In addition to the allowed domains, you can define a default sender. This default sender will be used as sender at anytime when no sender has been defined for an outgoing email. Please keep in mind that the default sender must be a valid email address. If no default sender is maintained and no sender is set in the outgoing email, the sender will be set to `do.not.reply@(system-default-domain)`.

#### Note

You can define only one default sender per system.

#### Application Programming Interface (API)

To maintain the allowed domains and the default sender, further methods are provided to read or delete the current table data:

#### Sample Code

```
DATA(config_instance) = cl_bcs_mail_system_config=>create_instance( ).
DATA recipient_domains TYPE cl_bcs_mail_system_config=>tyt_recipient_domains.
DATA sender_domains TYPE cl_bcs_mail_system_config=>tyt_sender_domains.
recipient_domains = VALUE #( ( 'recipient1domain.com' )
( 'recipient2domain.com' ) ).
sender_domains = VALUE #( ( 'sender1domain.com' ) ( 'sender2domain.com' ) ).
```

```

"Add allowed domains
TRY.
    config_instance->set_address_check_active( abap_true ).
    config_instance->add_allowed_recipient_domains( recipient_domains ).
    config_instance->add_allowed_sender_domains( sender_domains ).
    config_instance->modify_default_sender_address( iv_default_address =
'DefaultSender@yourcompany.com'
                                                    iv_default_name = 'Default
Sender' ).
    CATCH cx_bcs_mail_config INTO DATA(write_error).
        "handle exception
ENDTRY.
"Read allowed domains
DATA(allowed_recipient_domains) = config_instance-
>read_allowed_recipient_domains( ).
DATA(allowed_sender_domains) = config_instance-
>read_allowed_sender_domains( ).
config_instance->read_default_sender_address(
    IMPORTING
        ev_default_sender_address = DATA(default_sender_address)
        ev_default_sender_name = DATA(default_sender_name) ).
"Delete allowed domains
TRY.
    config_instance->delete_allowed_rec_domains( allowed_recipient_domains ).
    config_instance->delete_allowed_sender_domains( allowed_sender_domains ).
    config_instance-
>delete_default_sender_addr( 'DefaultSender@yourcompany.com' ).
    CATCH cx_bcs_mail_config INTO DATA(deletion_error).
        "handle exception
ENDTRY.

```

## Configuring the Email Expiry Date

The expiry date of email send attempts can be defined using method `SET_DAYS_UNTIL_MAIL_EXPIRES()`. The default value for mail expiry is 30 days. After this time, sent and failed emails attempts will be deleted and no longer visible within the [Monitor Email Transmission](#) app.

If the `DELETE_DAYS_UNTIL_MAIL_EXPIRES()` method is used, the expiry date is set back to 30 days.

### 4.2.12.11.3.3 Email Address Check

The class `CL_MAIL_ADDRESS` implements the interface `IF_MAIL_ADDRESS` and allows the user to check if it contains a syntactic valid email address in the input string according to the standard RFC 5322.

## Create an Email Address instance

Method	Description
Create_instance	Provides an email address instance.

Method	Description
validate	Validates whether a string is a syntactic valid mail address (according to RFC 5322 Standard).

## Methods

### Sample Code

```

Try.
    Data(lo_mail_address) =
    cl_mail_address=>create_instance( iv_address_string = 'testmail@ok.com' ).
    Catch cx_bcs_mail into data(lx_err).
        "exception handling
    endtry.

Data(lv_address_valid) = lo_mail_address->validate( ).

```

## 4.2.12.12 Units of Measurement

Many business applications use units of measurement in their business processes. To standardize these processes, you need a central maintenance of units and related dimensions. Beside that, there's a business need for conversion between different units.

We provide a subset of common standardized units, dimensions, and ISO codes for use as predelivered content. In addition, you need to define customer-owned units and dimensions in customer applications.

### How are Units and Dimensions Linked?

Units are related to a dimension. In each dimension, a unit is defined as an SI unit (International System of Units). This is the basis for the conversion from one unit to another.

### Related Information

[Maintaining Dimensions \[page 1523\]](#)

[Maintaining Units of Measurement \[page 1529\]](#)

[Conversion Functions for Units of Measurement \[page 1537\]](#)

## 4.2.12.12.1 Maintaining Dimensions

Class `CL_UOM_DIM_MAINTENANCE` provides methods for maintaining a dimension.

For more information, see the following:

- [Creating a Dimension \[page 1523\]](#)
- [Changing a Dimension \[page 1525\]](#)
- [Deleting a Dimension \[page 1527\]](#)
- [Reading a Dimension \[page 1528\]](#)

### 4.2.12.12.1.1 Creating a Dimension

Use method `CREATE` to create a new dimension. For customer dimensions, the name of the dimension ID must start with a 'Z'.

## Import Parameters

Parameter Name	Field Name	Value Help
DIM_CRE_TS		Structure for creating a dimension
	DIMID	Dimension key
	TXDIM	Description of the dimension key
	LENGTH	Length exponent of the dimension
	MASS	Mass exponent of the dimension
	TIME	Time exponent of the dimension
	CURRENT	Electric current exponent of the dimension
	TEMPERATURE	Temperature exponent of the dimension
	MOLE_QTY	Mole quantity exponent of the dimension
	LUMINOSITY	Light exponent of the dimension

## Export Parameters

Parameter Name	Value Help
ERROR	<b>Space</b> : No error <b>'X'</b> : Save error

### Note

Class exception CX\_UOM\_ERROR is raised to check the integrity of the data import parameters.

### Sample Code

```
CLASS zcl_uom_dimension_create_test DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC.

  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.

CLASS zcl_uom_dimension_create_test IMPLEMENTATION.

  METHOD if_oo_adt_classrun~main.

    DATA(lo_dim) = cl_uom_dim_maintenance=>get_instance( ).
    DATA(ls_dim) = VALUE cl_uom_dim_maintenance=>ty_dim_cre_ts( dimid =
'ZNEWDI'
                                                                txdim = 'New
Dimension'
                                                                mass = 89 ).

    TRY.
      lo_dim->create( EXPORTING dim_cre_ts = ls_dim
                    IMPORTING error      = DATA(lv_error) ).

      CATCH cx_uom_error INTO DATA(lo_error).
        out->write( |Exception raised| ).
        out->write( lo_error->get_text( ) ).
    ENDTRY.
    IF lv_error = abap_true.
      out->write( |Error occurred while saving the data in the database| ).
    ENDIF.
  ENDMETHOD.
ENDCLASS.
```

## 4.2.12.12.1.2 Changing a Dimension

Use method `UPDATE` to change an existing dimension. For customer dimensions, the name of the dimension ID must start with a 'Z' for any changes.

### Import Parameters

Parameter Name	Field Name	Value Help
DIMID		Dimension key
DIM_UPD_TS		Structure for updating a dimension
		<b>⚠ Caution</b> Be aware that all the fields belonging to the structure will be updated.
	TXDIM	Description of the dimension key
	SI_UNIT	Base unit of a dimension
	LENGTH	Length exponent of the dimension
	MASS	Mass exponent of the dimension
	TIME	Time exponent of the dimension
	CURRENT	Electric current exponent of the dimension
	TEMPERATURE	Temperature exponent of the dimension
	MOLE_QTY	Mole quantity exponent of the dimension
	LUMINOSITY	Light exponent of the dimension

## Export Parameters

ENDCLASS.
```

## 4.2.12.12.2 Maintaining Units of Measurement

Class `CL_UOM_MAINTENANCE` provides methods for maintaining units of measurement.

For more information, see the following:

- [Creating a Unit of Measurement \[page 1530\]](#)
- [Changing a Unit of Measurement \[page 1532\]](#)
- [Deleting a Unit of Measurement \[page 1534\]](#)
- [Reading a Unit of Measurement \[page 1535\]](#)

## 4.2.12.12.2.1 Creating a Unit of Measurement

Use method `CREATE` to create a unit of measurement. For customer units, the name of the internal unit must start with a 'Z'.

### Import Parameters

Parameter Name	Field Name	Value Help
UNIT_DIMID		Dimension key
UNIT_INT		Internal unit of measurement
UNIT_CRE_TS		Structure for creating a unit of measurement
	COMMERCIAL	Commercial/external measurement unit format
	TECHNICAL	Technical measurement unit format
	DEC_ROUND	Number of decimal places to which this measurement unit should be rounded for conversion
	NUMERATOR	Numerator for conversion to SI unit
	DENOMINATOR	Denominator for conversion into SI unit
	EXPONENT	Base ten exponent for conversion to SI unit
	CONSTANT	Additive constant for conversion to SI unit
	DEC_DISP	Number of decimal places with which this measurement unit is displayed
	ISOCODE	ISO code for measurement units. An ISO code can be assigned to several internal measurement units of a dimension.
	PRIMARY	Unit of measure flagged as a primary unit for an ISO code  <b>Space:</b> Not primary <b>'X':</b> Set as primary

Parameter Name	Field Name	Value Help
	TEXT	Description of a unit of measurement
	LONG_TEXT	Long description of a unit of measurement

## Export Parameters

Parameter Name	Value Help

```

### 4.2.12.12.3 Conversion Functions for Units of Measurement

Class `CL_UOM_CONVERSION` provides methods for simple conversion functions for units of measurement.

For more information, see the following:

- [Simple Conversion Between Two Units \[page 1537\]](#)
- [Determining the SI Unit \[page 1540\]](#)
- [Determining the Conversion Factors \[page 1541\]](#)
- [Converting Fraction to Fraction with a 5-Digit Numerator/Denominator \[page 1542\]](#)

#### 4.2.12.12.3.1 Simple Conversion Between Two Units

Use method `UNIT_CONVERSION_SIMPLE` to convert values from one measurement unit to another and round the result to the number of decimal places maintained in the measurement unit table `T006`, if necessary. Depending on the parameter `ROUND_SIGN`, the rounding is up ('+'), down ('-'), commercial ('X'), or no rounding (SPACE).

##### 📌 Note

Make sure that both units are maintained in the measurement unit table and are not dimensionless, but have both the **same** dimension.

## Import Parameters

Parameter Name	Value Help
INPUT	Input value
NO_TYPE_CHECK	Conversion factor type check <b>'X'</b> : No check <b>Space</b> : Type check
ROUND_SIGN	Rounding flag <b>'+'</b> : Up <b>'-'</b> : Down <b>'X'</b> : Commercial
UNIT_IN	Unit of input value

## Export Parameters

Parameter Name	Value Help
ADD_CONST	Additive constant for conversion
DECIMALS	Number of decimal places for rounding
DENOMINATOR	Denominator for conversion
NUMERATOR	Numerator for conversion
OUTPUT	Output value

## Exceptions

Exception Name	Value Help
CONVERSION_NOT_FOUND	Conversion factor could not be determined
DIVISION_BY_ZERO	Division by zero caught
INPUT_INVALID	Input value is not a number
OUTPUT_INVALID	Output parameter is not a number

Exception Name	Value Help
OVERFLOW	Field overflow
TYPE_INVALID	Output parameter is not a number
UNITS_MISSING	No units specified
UNIT_IN_NOT_FOUND	UNIT_IN is not maintained
UNIT_OUT_NOT_FOUND	UNIT_OUT is not maintained

### Sample Code

```

CLASS zcl_uom_conversion DEFINITION

## 4.2.12.12.3.2 Determining the SI Unit

Use method `SI_UNIT_GET` to determine the SI unit.

### Import Parameters

Parameter Name	Value Help
DIMENSION	Dimension key
UNIT	Unit of measurement

### Export Parameters

Parameter Name	Value Help
SI_UNIT	Base unit/SI unit of a dimension

### Exceptions

Exception Name	Value Help
DIMENSION_NOT_FOUND	Dimension is not defined
UNIT_NOT_FOUND	Unit of measurement is not maintained
SI_UNIT_NOT_FOUND	SI unit is not defined

#### Sample Code

```
CLASS zcl_uom_conversion DEFINITION
  PUBLIC
  FINAL
  CREATE PUBLIC.
  PUBLIC SECTION.
    INTERFACES if_oo_adt_classrun.
  PROTECTED SECTION.
  PRIVATE SECTION.
ENDCLASS.

CLASS zcl_uom_conversion IMPLEMENTATION.
  METHOD if_oo_adt_classrun~main.
    DATA(lo_unit) = cl_uom_conversion=>create( ).
    lo_unit->si_unit_get(
      EXPORTING
        dimension          = 'MASS'
```

```

        unit                = 'G'
IMPORTING
    si_unit                = DATA(lv_si_unit)
EXCEPTIONS
    dimension_not_found = 1
    unit_not_found     = 2
    si_unit_not_found  = 3
    OTHERS              = 4 ).

IF sy-subrc = 0.
    out->write( lv_si_unit ).
ENDIF.
ENDMETHOD.
ENDCLASS.

```

### 4.2.12.12.3.3 Determining the Conversion Factors

Use method `UNIT_PARAMETERS_GET` to determine the data conversion factors of a unit.

#### Import Parameters

Parameter Name	Value Help
UNIT	Unit of measurement

#### Export Parameters

Parameter Name	Value Help
DECIMALS	Number of decimal places for rounding
DIMENSION	Dimension key
NUMERATOR	Numerator for conversion to SI unit
DENOMINATOR	Denominator for conversion to SI unit
EXPONENT	Base ten exponent for conversion to SI unit
ADD_CONST	Additive constant for conversion to SI unit
DECAN	Number of decimal places for number display
FAMUNIT	Unit of measurement family

## Exceptions

Exception Name	Value Help
UNIT_NOT_FOUND	Unit of measurement is not maintained

### Sample Code

```
CLASS zcl_uom_conversion DEFINITION
PUBLIC
FINAL
CREATE PUBLIC.

PUBLIC SECTION.
INTERFACES if_oo_adt_classrun.
PROTECTED SECTION.
PRIVATE SECTION.
ENDCLASS.

CLASS zcl_uom_conversion IMPLEMENTATION.
METHOD if_oo_adt_classrun~main.

IF sy-subrc = 0.
out->write( lv_dimension ).
out->write( lv_decimal ).
out->write( lv_numerator ).
out->write( lv_denominator ).
ENDIF.
ENDMETHOD.
ENDCLASS.
```

### 4.2.12.12.3.4 Converting Fraction to Fraction with a 5-Digit Numerator/Denominator

Use method `CONVERT_TO_FRACT5` to convert a fraction to a fraction with a maximum of 5-digit numerators/denominators.

If the numerator or denominator contain more than 5 digits, the result will be an approximation as close as possible.

## Import Parameters

Parameter Name	Value Help
NOMIN	Nominator input
DENOMIN	Denominator input

## Export Parameters

Parameter Name	Value Help
NOMOUT	Nominator output (5-digit max.)
DENOMOUT	Denominator output (5-digit max.)

## Exceptions

Exception Name	Value Help
CONVERSION_OVERFLOW	Unit of measurement is not maintained.

### Sample Code

```
CLASS zcl_uom_convert_to_fract5 DEFINITION

## 4.2.12.13 Identity and Access Management

Get an overview of the ABAP classes and methods you can use to access business roles and business users.

The following classes and methods allow you to read, create and modify business roles and business users.

These classes and methods can only be used if the authorizations are defined via standard IAM catalogs.

Business Roles

Class/Method	Description
CL_IAM_BUSINESS_ROLE_FACTORY	Factory class for IF_IAM_BUSINESS_ROLE_FACTORY
IF_IAM_BUSINESS_ROLE_FACTORY	Allows you to query and retrieve business role instances
IF_IAM_BUSINESS_ROLE	Allows you to read and modify attributes of business roles

## Query for Business Roles

### Sample Code

```

* Get instance
  data(lo_br_factory) = cl_iam_business_role_factory=>create_instance( ).
* Query for Business Roles
  lo_br_factory->query_business_roles(
    exporting
      ir_brole_id = value #( ( sign = 'I'
option = 'CP'
low = 'SAP_BR_QUALITY_ENGINEER_DWH' ) )
    importing
      et_result = data(lt_result) ).
* get details of the Business Roles
  loop at lt_result assigning field-symbol(<fs_result>).
* Get Business Role instance
  lo_br_factory->get_business_role(
    exporting
      iv_uuid = <fs_result>-uuid
    importing
      eo_business_role = data(lo_brole)
      et_return = data(lt_return) ).
* Business Role ID
  data(lv_id) = lo_brole->get_id( ).
* Business Role description
  data(lv_description) = lo_brole->get_description( ).
  out->write( |{ lv_id } : { lv_description }| ).
* Get Business Role Access restrictions
  lo_brole->get_access_restriction(
    importing

```

```

        ev_write = data(lv_w)
        ev_read  = data(lv_r)
        ev_f4    = data(lv_f4) ).
    out->write( |Access-Restrictions: Write: { lv_w },
              Read: { lv_r }, F4: { lv_f4 }| ).
* Get assigned Business Catalogs
  data(lt_bc) = lo_brole->get_business_catalogs( ).
* Get assigned Business Users
  data(lo_user_factory) =
cl_iam_business_user_factory=>create_instance( ).
  data(lt_users) = lo_brole->get_users( ).
  loop at lt_users assigning field-symbol(<fs_user>).
    out->write( <fs_user> ).
    lo_user_factory->get_business_user(
      exporting
        iv_user_id      = <fs_user>

```

## Create Business Role from Business Role Template

### Sample Code

```

  data: lv_id type if_iam_business_role=>ty_id.
  data(lo_br_factory) = cl_iam_business_role_factory=>create_instance( ).
* Create Business From Business Role Template
  lv_id = 'ZZ_MY_BR_ADMINISTRATOR'.
  lo_br_factory->create_brole_from_template(
    exporting
      iv_id      = lv_id
      iv_template_id = 'SAP_BR_ADMINISTRATOR'
    importing
      eo_business_role = data(lo_brole)
      et_return        = data(lt_return) ).
* Set Business Role: Read = unrestricted, Write = Unrestricted, F4 =
unrestricted
  lo_brole->set_access_restriction(
    exporting
      iv_write = if_iam_business_role=>co_access_restriction_code-
unrestricted
      iv_read  = if_iam_business_role=>co_access_restriction_code-
unrestricted
      iv_f4    = if_iam_business_role=>co_access_restriction_code-
unrestricted
    importing
      et_return = lt_return ).
* Assign Business User to Business Role
  lo_brole->add_user(
    exporting
      iv_user_id = 'CB0000000051'
    importing
      et_return = lt_return ).
  lo_brole->save(
    importing
      et_return = lt_return ).

```

## Create Restricted Business Role

### Sample Code

```
data: ls_restriction type if_iam_business_role=>ty_restriction,
      lv_id          type if_iam_business_role=>ty_id.
data(lo_br_factory) = cl_iam_business_role_factory=>create_instance( ).
* Create Business from Business Role Template
lv_id = 'ZZ_MY_BUSINESS_ROLE'.
lo_br_factory->create_business_role(
  exporting
    iv_id = lv_id
  importing
    eo_business_role = data(lo_brole)
    et_return        = data(lt_return) ).
lo_brole->set_description( 'My Business Role' ).
lo_brole->set_long_text( 'This Business Role grant access to ....' ).
* Add Business Catalog
lo_brole->add_business_catalog(
  exporting
    iv_bu_catalog_id = 'ZZ_MY_BUSINESS_CATALOG'
  importing
    et_return        = lt_return ).
* Set Business Role: Read = Unrestricted, Write = Restricted, F4 =
Unrestricted
lo_brole->set_access_restriction(
  exporting
    iv_write = if_iam_business_role=>co_access_restriction_code-
restricted
    iv_read  = if_iam_business_role=>co_access_restriction_code-
unrestricted
    iv_f4    = if_iam_business_role=>co_access_restriction_code-
unrestricted
  importing
    et_return = lt_return ).
* Define restriction values for Write access
ls_restriction-access_category_code =
if_iam_business_role=>co_access_category_code-write.
ls_restriction-restriction_type = 'ZZ_SALES_AREA'.
ls_restriction-restriction_field_value = value #(
  ( field_name = 'ZSALES_ORG'
    values = value #( ( low_value = 'A' )
                     ( low_value = 'B' ) ) )
  ( field_name = 'ZDIST_CHANNEL'
    values = value #( ( low_value = 'A*' high_value = 'F*' ) ) )
  ( field_name = 'ZDIVISION'
    values = value #( ( low_value = '*' ) ) ) ).
lo_brole->create_restriction(
  exporting
    is_restriction = ls_restriction
  importing
    es_restriction = data(ls_restriction_set)
    et_return      = lt_return ).
* Assign Business User to Business Role
lo_brole->add_user(
  exporting
    iv_user_id = 'CB0000000051'
  importing
    et_return  = lt_return ).
lo_brole->save(
  importing
    et_return = lt_return ).
```

## Business Users

Class/Method	Description
CL_IAM_BUSINESS_USER_FACTORY	Factory class for IF_IAM_BUSINESS_USER_FACTORY
IF_IAM_BUSINESS_USER_FACTORY	Allows you to query and retrieve business user instances
IF_IAM_BUSINESS_USER	Allows you to read and modify attributes of business users

## Query for Business Users and Their Assigned Business Roles

### Sample Code

```
* Get Business user by UserID
data(lo_bu_factory) = cl_iam_business_user_factory=>create_instance( ).
lo_bu_factory->get_business_user(
  exporting
    iv_user_id      = 'CB0000000051'
  importing
    eo_business_user = data(lo_buser)
    et_return        = data(lt_return) ).
* Get User properties
data(lv_user) = lo_buser->get_user_name( ).
* get assigned Business Roles
data(lo_br_factory) = cl_iam_business_role_factory=>create_instance( ).
data(lt_brole_id) = lo_buser->get_business_roles( ).
loop at lt_brole_id assigning field-symbol(<fs_brole_id>).
  lo_br_factory->get_business_role_by_id(
    exporting
      iv_id          = <fs_brole_id>
    importing
      eo_business_role = data(lo_brole)
      et_return        = lt_return ).
  out->write( |ID: { lo_brole->get_id( ) }| ).
endloop.
```

## Create Business User and Add Business Role

### Sample Code

```
data(lo_bu_factory) = cl_iam_business_user_factory=>create_instance( ).
* Create Business user for Employee ID
lo_bu_factory->create_business_user(
  exporting
    iv_bupa_id      = '0000000023'
    iv_user_name    = 'ZMY_BUSINESS_USER'
  importing
    eo_business_user = data(lo_buser)
    et_return        = data(lt_return) ).
* Set Date Format to MM-DD-YYYY (Gregorian Date)
lo_buser->set_date_format( '3' ).
* Set logon language to English
lo_buser->set_logon_language( 'E' ).
* Assign Business Role to the User
lo_buser->add_business_roles(
```

```

        exporting
            it_business_role_id = value #( ( 'ZZ_MY_BUSINESS_ROLE' ) )
        importing
            et_return           = lt_return ).
* Save Business user
lo_buser->save(
    importing
        et_return = lt_return ).

```

## Lock Business User

### Sample Code

```

* get business user user name
data(lo_bu_factory) = cl_iam_business_user_factory=>create_instance( ).
lo_bu_factory->get_business_user(
    exporting
        iv_user_name      = 'ZMY_BUSINESS_USER'
    importing
        eo_business_user = data(lo_buser)
        et_return         = data(lt_return) ).
* Get lock status
lo_buser->get_lock_status(
    importing
        ev_locked = data(lv_locked) ).
* Lock user
if lv_locked = abap_false.
    lo_buser->lock(
        importing
            et_return = lt_return ).
endif.

```

## 4.2.12.14 Communication Management

Get an overview of the ABAP classes and methods you can use to access communication scenarios, communication systems, communication arrangements and communication users.

The following classes and methods allow you to read communication scenarios, communication systems, communication arrangements and communication users.

These classes and methods can only be used if the authorizations are defined via standard COM catalogs.

Communication Scenarios

Class/Method	Description
CL_COM_SCENARIO_FACTORY	Factory class for IF_COM_SCENARIO_FACTORY
IF_COM_SCENARIO_FACTORY	Allows you to query and retrieve communication scenarios
IF_COM_SCENARIO	Allows you to read attributes of communication scenarios

#### Communication Users

Class/Method	Description
CL_COM_USER_FACTORY	Factory class for IF_COM_USER_FACTORY
IF_COM_USER_FACTORY	Allows you to query and retrieve communication users
IF_COM_USER	Allows you to read attributes of communication users

#### Communication Systems

Class/Method	Description
CL_COM_SYSTEM_FACTORY	Factory class for IF_COM_SYSTEM_FACTORY
IF_COM_SYSTEM_FACTORY	Allows you to query and retrieve communication systems
IF_COM_SYSTEM	Allows you to read attributes of communication systems

#### Communication Arrangements

Class/Method	Description
CL_COM_ARRANGEMENT_FACTORY	Factory class for IF_COM_ARRANGEMENT_FACTORY
IF_COM_ARRANGEMENT_FACTORY	Allows you to query and retrieve communication arrangements
IF_COM_ARRANGEMENT	Allows you to read attributes of communication arrangements

## 4.2.12.15 Proxy API for the Workflow Capability

With the proxy API, you can start workflows of the workflow capability within SAP Workflow Management out of your ABAP Environment.

The overall starting point is the class CL\_SWF\_CPWF\_API\_FACTORY\_A4C. Once you have the API object of interface IF\_SWF\_CPWF\_API, see the ABAP documentation on supported actions.

### Prerequisites

You've executed the integration steps in your ABAP environment. See [Integrating Workflow \[page 2674\]](#).

#### Sample Code

This coding sample shows how to start a workflow of the workflow capability.

```
TYPES: BEGIN OF ty_context,  
        some_property TYPE string,  
        END OF ty_context.  
DATA(lo_cpwf_api) = cl_swf_cpwf_api_factory_a4c=>get_api_instance( ).  
DATA(ls_context) = VALUE ty_context(  
    some_property = 'someValue'  
).  
DATA(lv_context_json) = lo_cpwf_api->get_start_context_from_data(  
    iv_data = ls_context  
).
```

```

DATA(lv_cpwf_handle) = lo_cpwf_api->start_workflow(
  iv_cp_workflow_def_id = 'SAP Workflow Management Workflow Definition ID'
  iv_context            = lv_context_json
  iv_retention_time    = 30
  iv_callback_class    = 'ZCL_SWF_CPWF_CALLBACK'
).

```

## ↔ Sample Code

This coding sample shows a completion callback that includes reading the context.

```

METHOD if_swf_cpwf_callback~workflow_instance_completed.
  TYPES: BEGIN OF ty_context,
         some_result TYPE string,
        END OF ty_context.
  TRY.
    data(lo_cpwf_api) = cl_swf_cpwf_api_factory_a4c=>get_api_instance( ).
    data(lv_context_json) = lo_cpwf_api-
>get_workflow_context( iv_cpwf_handle = iv_cpwf_handle ).
    DATA ls_context TYPE ty_context.
    lo_cpwf_api->get_context_data_from_json(
      EXPORTING
        iv_context = lv_context_json
      IMPORTING
        ev_data = ls_context
    ).
    CATCH cx_swf_cpwf_api INTO DATA(lx_exc).
    RAISE EXCEPTION TYPE zcx_swf_cpwf_callback
      EXPORTING
        previous = lx_exc.
  ENDTRY.
  " your business coding
ENDMETHOD.

```

## ↔ Sample Code

This coding sample shows the raising of an event towards SAP Business Technology Platform.

```

TYPES: BEGIN OF ty_example_context,
       value TYPE int4,
       END OF ty_example_context.
CONSTANTS: lc_cp_workflow_def_id TYPE
if_swf_cpwf_api=>cpwf_def_id      VALUE '<SAP Workflow Management Workflow
Definition ID>',
          lc_event_def_id        TYPE
if_swf_cpwf_api=>cpwf_evt_def_id  VALUE '<SAP Workflow Management Event
Definition ID>'.
  TRY.
    " Get a Instance for the CPWF Integration API
    DATA(lo_cpwf_api) = cl_swf_cpwf_api_factory_a4c=>get_api_instance( ).
    " There should be a started workflow in order to raise an event
    DATA(lv_cpwf_handle) = lo_cpwf_api->start_workflow(
      EXPORTING
        iv_cp_workflow_def_id = lc_cp_workflow_def_id
        iv_retention_time    = 30
    ).
    COMMIT WORK.
    " provide relevant event context data => in this case a meaningful
integer
    DATA(lv_event_context_data) = VALUE ty_example_context( value =
4711 ).
    DATA(lv_event_context) = lo_cpwf_api->get_context_from_data( iv_data
= lv_event_context_data ).

```

```

" actually raise the event
  lo_cpwf_api->raise_event(
    EXPORTING
      iv_cpwf_handle = lv_cpwf_handle
      iv_event_def_id = lc_event_def_id
      iv_event_context = lv_event_context
  ).
  COMMIT WORK.
  CATCH cx_swf_cpwf_api INTO DATA(lx_api).
    WRITE: 'Exception occurred: ' && lx_api->get_longtext( ).
  ENDTRY.

```

## ABAP RESTful Application Programming Model (RAP)

### Early Numbering

In the RAP version of the Workflow Service API, workflows can be registered using the following command:

#### Sample Code

Example: EML Create

```

MODIFY ENTITIES OF i_cpwf_inst
  ENTITY CPWFInstance
  EXECUTE registerWorkflow
    FROM VALUE #( ( %key = '<a UUID which is mandatory for mass enabled
callers>'
                  %param-RetentionTime = '<retention time in days>'
                  %param-CpWfDefId = '<SAP Workflow Service Definition
ID>'
                  %param-CallbackClass = '<Callback class for final state
handling>'
                  %param-Consumer = '<SAP Workflow Scenario ID>' ) ).

```

#### Note

It's not allowed to call the `registerWorkflow` method multiple times with an identical set of parameters. This also applies to cases where the otherwise optional `%key` parameter stays empty. Therefore, if you want to use the `registerWorkflow` method in a mass-enabled context you must provide the unique `%key` parameter.

The parameters `RetentionTime`, `CpWfDefId`, and `Consumer` must be provided.

The workflow context can be provided using the following EML statement:

#### Sample Code

Example: EML Create

```

MODIFY ENTITIES OF i_cpwf_inst
  ENTITY CPWFInstance
  EXECUTE setPayload
    FROM VALUE #( ( %key-CpWfHandle = '<required key (UUID) of the CPWF
instance>'
                  %param-context = '<workflow context in JSON
format>' ) ).

```

Both commands should be part of a determination on save. During the save sequence, the workflow is started with the provided data.

### Late Numbering

As for early numbering, the `registerWorkflow` method can be called in a determination on save for late numbering, too.

The workflow context can be set even later in the `adjust_numbers` method of your business object using the `setPayload` method.

#### Sample Code

Example: EML Create

```
MODIFY ENTITIES OF i_cpwf_inst
  ENTITY CPWFInstance
  EXECUTE setPayload
  FROM VALUE #( ( %key-CpWfHandle = <required key (UUID) of the CPWF
instance>
                %param-context = <workflow context in JSON format> ) ).
```

During the save sequence, the workflow is started with the provided data. The instance is removed from the draft table and is entered into the active table.

Note, that in the `adjust_numbers` method you must fill the key of each line of the mapped table to make sure the save sequence is executed successfully.

Note also that if you have multiple workflows per instance of your business object you might need to store the assignments yourself in an internal table to be able to call the `set_payload` method during `adjust_numbers` method with the correct data.

#### Sample Code

This coding sample shows reading the workflow instance context.

```
TYPES: BEGIN OF ty_context,
  attr1 TYPE string,
  attr2 TYPE int4,
  attr3 TYPE string,
END OF ty_context.

DATA(lo_cpwf_api) = cl_swf_cpwf_api_factory=>get_api_instance( 'DEFAULT' ).
DATA(lo_cp_json_with_empty) = lo_cpwf_api->get_json_converter( ).
DATA(lo_wf_inst_ctxt) = lo_cpwf_api-
>if_swf_cpwf_capi~workflow_instance_context( ).

DATA ls_context TYPE ty_context.
lo_wf_inst_ctxt->get_instance_context( EXPORTING iv_cpwf_handle =
<cpwf_handle> io_cp_json = lo_cp_json IMPORTING data = ls_context ).
```

### Cancel Workflow Capability Instances

To register a running workflow capability instance for cancelation, use the `registerWorkflowCancel` action using the command:

### Sample Code

Example: EML Cancel

```
MODIFY ENTITIES OF i_cpwf_inst
  ENTITY CPWFInstance
  EXECUTE registerWorkflowCancel
  FROM VALUE #( ( %key = '<a UUID which is mandatory for mass enabled
callers>' ) ).
```

Note, that this action should be part of the interaction phase.

During the save sequence, the workflow instance is canceled in a background unit..

## 4.2.12.16 XCO Library

The XCO (“Extension Components”) library is a general-purpose development library for ABAP aimed at providing a highly efficient ABAP development experience. The Cloud Platform (CP) edition of the XCO library is specifically designed to support ABAP development scenarios in the new SAP BTP, ABAP environment.

### 4.2.12.16.1 Core Principles

The design of the XCO library is based on the following core principles:

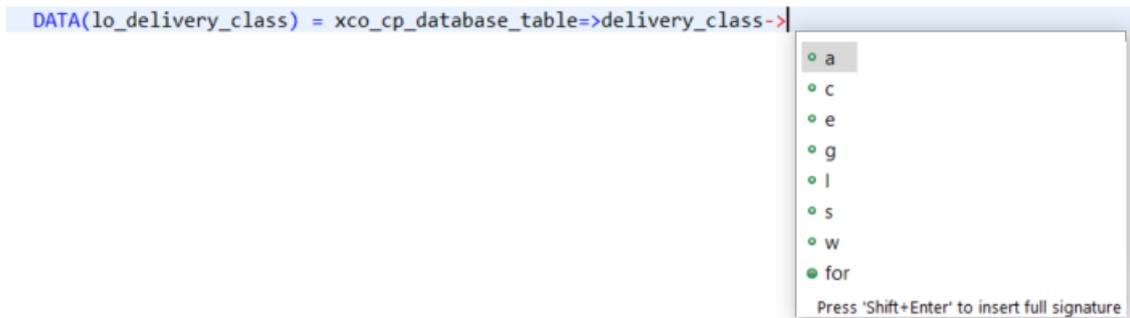

- **Modules**

The XCO library is organized as a collection of (largely) independent modules (corresponding to ABAP packages). The public API of each module is exposed via a special class, called the API “class” of the module. It is distinguished from all other XCO classes and interfaces in that it starts with “XCO\_CP\_”. The API class acts as the single point of entry for the functionality offered by a given module. Starting with the API class, code completion can be used to easily discover the scope of a given module.

- **Enumerated Values**

In the XCO library enumerated values are represented by pre-created objects which can be accessed via the API class of the module they belong to. Besides offering a strongly typed way to work with fixed values they also provide additional properties specific to the enumeration as well as access to the underlying primitive value.

- **Exception Handling**

All XCO modules follow a uniform error propagation strategy. Unless the caller of an API can be expected to recover from an error situation (e.g. when attempting to acquire an exclusive lock), all error situations are handled through `no_check` exceptions.

Any runtime exception that is raised explicitly by the XCO library is a subclass of

`CX_XCO_RUNTIME_EXCEPTION` (cf. section Exception philosophy in [Standard Library \[page 1678\]](#)).

## 4.2.12.16.2 Overview of XCO Modules

The Cloud Platform (CP) edition of the XCO library is comprised of the following modules:

- **ABAP (XCO\_CP\_ABAP)**  
Provides access to conceptual abstractions for classes and interfaces as well as to representations of ABAP built-in and generic types.
- **Application log object (XCO\_CP\_APPLICATION\_LOG\_OBJECT)**  
Provides access to text attributes specific to application log objects.
- **ABAP Dictionary (XCO\_CP\_ABAP\_DICTIONARY)**  
Provides access to conceptual abstractions for ABAP Dictionary elements (Database tables, data elements, structures, table types and domains) as well as to representations of ABAP Dictionary built-in types and their corresponding reference types.
- **ABAP Objects (XCO\_CP\_ABAP\_OBJECTS)**  
Provides access to enumerations specific to ABAP Objects, e.g. the visibility of class or interface components, as well as to supported origins for the XCO Read APIs for classes and interfaces.
- **ABAP Repository (XCO\_CP\_ABAP\_REPOSITORY)**  
Provides APIs and abstractions for retrieving and filtering development objects of the ABAP Repository in a strongly typed manner.
- **ABAP SQL (XCO\_CP\_ABAP\_SQL)**  
Provides ways to build ABAP SQL constraints to be used in conjunction with the filtering offerings of the XCO ABAP Repository module.
- **ABAP Unit (XCO\_CP\_ABAP\_UNIT)**  
Provides access to enumerations in the context of ABAP Unit.
- **AMDP (XCO\_CP\_AMDP)**  
Provides access to enumerations in the context of ABAP-managed database procedures.
- **ARS (XCO\_CP\_ARS)**

Provides standard abstractions in the context of the API Release (ARS) framework (e.g. for compatibility contracts) to be used when programmatically setting or getting API states via the XCO ABAP Repository APIs.

- Business Application Log (XCO\_CP\_BAL)  
Provides APIs for creating, deleting and searching logs as well as standard abstractions for integrating logging functionality into custom application logic.
- Behavior definition (XCO\_CP\_BEHAVIOR\_DEFINITION)  
Provides access to enumerations specific to behavior definitions.
- Behavior implementation (XCO\_CP\_BEHAVIOR\_IMPLEMENTATION)  
Provides access to enumerations specific to behavior implementations.
- Binary (XCO\_CP\_BINARY)  
Provides access to binary text encodings, e.g. Base64.
- Business configuration object (XCO\_CP\_BUSINESS\_CNFGRTN\_OBJECT)  
Provides access to text attributes specific to business configuration objects.
- Call stack (XCO\_CP\_CALL\_STACK)  
Provides access to abstractions for programmatically working with all stacks (e.g. supported formats)
- Core Data Services (XCO\_CP\_CDS)  
Provides access to enumerations specific to the field of Core Data Services (CDS) as well as conceptual abstractions for behavior definitions, data definitions, metadata extensions and CDS entities.
- CDS Annotation (XCO\_CP\_CDS\_ANNOTATION)  
Provides ways to build CDS annotation values to be used when generating DDLS, DDLX or SRVD objects via the XCO Generation APIs.
- CDS Type Definition (XCO\_CP\_CDS\_TYPE\_DEFINITION)  
Provides access to enumerations specific to CDS type definitions as well as to supported versions and origins as they can be used in the context of the XCO Read APIs for CDS type definitions.
- Character (XCO\_CP\_CHARACTER)  
Provides access to abstractions useful when working with character-like data, e.g. code pages which can be used to translate between STRINGS and XSTRINGS
- Correction and Transport System (XCO\_CP\_CTS)  
Provides abstractions for working with the Correction and Transport System (CTS), e.g. for creating and releasing Workbench transport requests.
- Database table (XCO\_CP\_DATABASE\_TABLE)  
Provides access to database table specific enumerations, e.g. the size category of a database table, as well as to supported origins for the XCO Read APIs for database tables.
- Data definition (XCO\_CP\_DATA\_DEFINITION)  
Provides access to enumerations and text attributes specific to CDS data definitions.
- Data element (XCO\_CP\_DATA\_ELEMENT)  
Provides access to text attributes specific to data elements as well as to supported origins for the XCO Read APIs for data elements.
- Data control language (XCO\_CP\_DCL)  
Provides ways to build DCL (Data control language) expressions to be used when generating DCLS objects via the XCO Generation APIs
- Data definition language (XCO\_CP\_DDL)  
Provides ways to build DDL (Data definition language) expressions to be used when generating DDLS objects via the XCO Generation APIs.
- Domain (XCO\_CP\_DOMAIN)

Provides access to text attributes specific to domains as well as to supported origins for the XCO Read APIs for domains.

- Event binding (XCO\_CP\_EVENT\_BINDING)  
Provides access to supported origins and versions for the XCO Read APIs for event bindings.
- Function group (XCO\_CP\_FUNCTION\_GROUP)  
Provides access to supported origins for the XCO Read APIs for function groups.
- Function module (XCO\_CP\_FUNCTION\_MODULE)  
Provides access to function module-specific enumerations as well as to supported origins for the XCO Read APIs for function modules.
- Generation (XCO\_CP\_GENERATION)  
Provides access to the XCO Generation APIs, i.e. allows to obtain a generation environment which can be used to create POST, PUT, PATCH and DELETE operations (as supported by the respective object type).
- Hash (XCO\_CP\_HASH)  
Provides access to supported hash algorithms which can be used to calculate the hash value of strings with the XCO Standard Library.
- Internationalization (XCO\_CP\_I18N)  
Provides access to the XCO I18N APIs, i.e. allows to obtain domain, data element, data definition and message class targets which can be used to programmatically maintain language-dependent texts.
- Identify and Access Management (XCO\_CP\_IAM)  
Provides access to standard abstractions (e.g. for IAM business catalogs) within the area of Identify and Access Management.
- IAM Business Catalog  
Provides access to text attributes specific to IAM business catalogs.
- JSON (XCO\_CP\_JSON)  
Provides access to facilities used when working with JSON data in the context of the XCO standard library, such as the JSON builder or standard JSON transformations.
- Language (XCO\_CP\_LANGUAGE)  
Provides access to abstractions when working with languages, e.g. different formats.
- Message (XCO\_CP\_MESSAGE)  
Provides access to enumerations specific to messages, such as the message type.
- Message class (XCO\_CP\_MESSAGE\_CLASS)  
Provides access to text attributes specific to message classes.
- Metadata extension (XCO\_CP\_METADATA\_EXTENSION)  
Provides access to enumerations specific to metadata extensions.
- Name (XCO\_CP\_NAME)  
Provides access to IF\_XCO\_NAME\_CHOICES to be used in conjunction with POST operations in the context of the XCO Generation APIs.
- Package (XCO\_CP\_PACKAGE)  
Provides access to enumerations specific to packages.
- RESTful Application Programming (XCO\_CP\_RAP)  
Provides access to abstractions to integrate RAP specific types (e.g. RAP behavior messages) with standard abstractions (e.g. for business application logs) of the XCO Library.
- Regular expression (XCO\_CP\_REGULAR\_EXPRESSION)  
Provides access to abstractions used when working with regular expressions in the context of the XCO standard library, such as different regular expression engines.
- SAP object node type (XCO\_CP\_SAP\_OBJECT\_NODE\_TYPE)

Provides access to enumerations specific to SAP object node types as well as to supported versions and origins as they can be used in the context of the XCO Read APIs for SAP object node types.

- SAP object type (XCO\_CP\_SAP\_OBJECT\_TYPE)  
Provides access to enumerations specific to SAP object types as well as to supported versions and origins as they can be used in the context of the XCO Read APIs for SAP object types.
- Service binding (XCO\_CP\_SERVICE\_BINDING)  
Provides access to enumerations specific to service bindings as well as to supported versions and origins that can be used in the context of XCO Read APIs for service bindings.
- Service consumption model (XCO\_CP\_SERVICE\_CONS\_MODEL)  
Provides access to supported versions and origins that can be used in the context of XCO Read APIs for service consumption models.
- Service definition (XCO\_CP\_SERVICE\_DEFINITION)  
Provides access to supported versions and origins as they can be used in the context of the XCO Read APIs for service definitions.
- Software component (XCO\_CP\_SOFTWARE\_COMPONENT)  
Provides access to enumerations specific to software components.
- String (XCO\_CP\_STRING)  
Provides access to abstractions used when working with strings in the context of the XCO standard library, such as the string builder or standard string compositions and decompositions.
- System (XCO\_CP\_SYSTEM)  
Provides access to abstractions for system-wide entities such as software components or application components..
- Table (XCO\_CP\_TABLE)  
Provides access to enumerations specific to tables (i.e. structures and database tables).
- Table type (XCO\_CP\_TABLE\_TYPE)  
Provides access to enumerations specific to table types.
- Tenant (XCO\_CP\_TENANT)  
Provides access to enumerations specific to tenants.
- Time (XCO\_CP\_TIME)  
Provides access to the XCO time library.
- Transport (XCO\_CP\_TRANSPORT)  
Provides access to enumerations and abstractions specific to transports.
- UUID (XCO\_CP\_UUID)  
Provides access to abstractions used when working with UUIDs in the context of the XCO standard library, such as different UUID formats.
- XSLX (XCO\_CP\_XSLX, XCO\_CP\_XLSX\_SELECTION, XCO\_CP\_XLSX\_READ\_ACCESS, XCO\_CP\_XLSX\_WRITE\_ACCESS)  
)  
The XCO XLSX module supports the programmatic processing of XLSX documents. The various external APIs provide access to central abstractions required when reading data from XLSX documents.

## 4.2.12.16.3 ABAP Repository

### 4.2.12.16.3.1 Query APIs

The XCO ABAP Repository module provides Query APIs that allow to easily navigate through the ABAP Repository.

#### Context

To this extent, an object selection functionality is provided that is based on the following two central abstractions:

- Object source: An entity that can naturally act as a source of ABAP repository objects, e.g. a package or a transport or even the complete ABAP repository
- Object filter: An encapsulation for any kind of filter that can be applied to a selection of ABAP Repository objects. Examples are software or application components or type specific properties like foreign key attributes of database table fields

The entry point for retrieving a collection of objects from the ABAP Repository is `XCO_CP_ABAP_REPOSITORY=>OBJECTS`. Note that independently of any filters, the visible ABAP Repository objects are those which either have been explicitly released by SAP or which belong to customer software components. The overall usage is illustrated by two examples below.

In the first example, all repository objects of the whole ABAP Repository whose software component is ZLOCAL and whose name contains the fragment CAL are retrieved. As no explicit object type is specified the retrieved objects have the type `IF_XCO_AR_OBJECT`:

#### Sample Code

```
DATA(lo_software_component_filter) = xco_cp_system=>software_component->get_filter( xco_cp_abap_sql=>constraint->equal( 'ZLOCAL' ) ).
DATA(lo_name_filter) = xco_cp_abap_repository=>object_name->get_filter( xco_cp_abap_sql=>constraint->contains_pattern( '%CAL%' ) ).
DATA(lt_objects) = xco_cp_abap_repository=>objects->where( VALUE #(
    ( lo_software_component_filter )
    ( lo_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).
LOOP AT lt_objects INTO DATA(lo_object).
    DATA(lv_object_type) = lo_object->type->value.
    DATA(lv_object_name) = lo_object->name->value.
    " ...
ENDLOOP.
```

In the second example all database tables of the package Z\_MY\_OBJECTS that have at least one field which has a foreign key whose check table is ZHOLIDAY are retrieved. As in this case the object type (database table) is explicitly specified the retrieved objects are of type `IF_XCO_DATABASE_TABLE`:

#### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( 'Z_MY_OBJECTS' ).
DATA(lo_filter) = xco_cp_table=>field_property->foreign_key_check_table->get_filter(
```

```

xco_cp_abap_sql=>constraint->equal( 'ZHOLIDAY' )
).

DATA(lt_database_tables) = xco_cp_abap_repository=>objects->tabl-
>database_tables->where( VALUE #(
  ( lo_filter )
) )->in( lo_package )->get( ).

LOOP AT lt_database_tables INTO DATA(lo_database_table).
  DATA(lv_name) = lo_database_table->name.

  " ...
ENDLOOP.

```

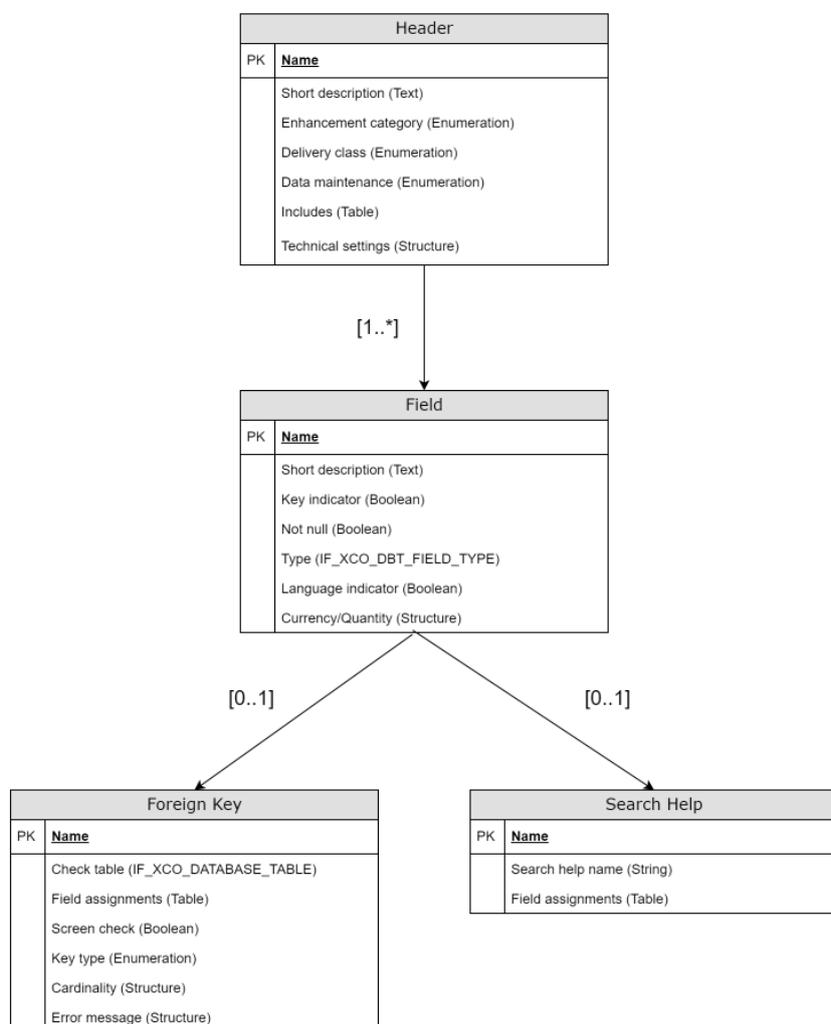

## 4.2.12.16.3.2 Read APIs

The XCO Read APIs provide homogenous, yet strongly-typed, APIs that allow to access the content of ABAP Repository objects in a structured way.

### Hierarchical Object Model

The overall design of the XCO Read APIs (regardless of the concrete object type) is based on a natural hierarchical model for each respective object type. The hierarchical model used by the XCO Read APIs regards an object as a rooted tree, with the root node given by the header of the object and all other nodes

corresponding to parts of the object. To illustrate, the diagram below contains the hierarchical object model for a database table of the ABAP Dictionary as used by the XCO Read APIs:

For each node in the hierarchical object model for an object type, two abstractions are provided:

- Object/part handle
- Content handle

## Object/Part Handles

The object/part handle provides an abstraction which encapsulates all key values (object name and keys of the parts if applicable) of an object/part. For the database table example above we have:

- IF\_XCO\_DATABASE\_TABLE: The object handle for the database table (encapsulating the name of the database table)
- IF\_XCO\_DBT\_FIELD: The handle for the field of a database table (encapsulating the name of the database table and the name of the field)
- IF\_XCO\_DBT\_FOREIGN\_KEY: The handle for the foreign key of a field of a database table (encapsulating the name of the database table and the name of the field for which to consider the foreign key)

- IF\_XCO\_DBT\_SEARCH\_HELP: The handle for the search help of a field of a database table (encapsulating the name of the database table and the name of the field for which to consider the search help)

The following code sample illustrates how these four handles can be obtained:

#### Sample Code

```
" Handle for database table ZMY_DBT (IF_XCO_DATABASE_TABLE).
DATA(lo_database_table) = xco_cp_abap_dictionary=>database_table( 'ZMY_DBT' ).

" Handle for the field KEY_FIELD of database table ZMY_DBT (IF_XCO_DBT_FIELD).
DATA(lo_field) = lo_database_table->field( 'KEY_FIELD' ).

" Handle for the foreign key of field KEY_FIELD of database table ZMY_DBT
(IF_XCO_DBT_FOREIGN_KEY).
DATA(lo_foreign_key) = lo_field->foreign_key.

" Handle for the search help of field KEY_FIELD of database table ZMY_DBT
(IF_XCO_DBT_SEARCH_HELP).
DATA(lo_search_help) = lo_field->search_help.
```

A given object/part handle allows to check the existence via the EXISTS method and provides access to the content handle of the respective object/part via the CONTENT method.

## Content Handles

Content handles exist in a natural 1:1 relationship with object/part handles and can be obtained via the CONTENT method of the object/part handle. In case the object type supports different versions (e.g. active and inactive) a choice for the version needs to be made before obtaining a content handle. More generally, a content handle fixes all degrees of freedom except for the origin (see below) such that the attributes exposed by the content handle can be read out.

A given content handle provides a dedicated GET\_\* method for each exposed attribute as well as a method GET which will return all exposed attributes in a single structure. Note that for language-dependent attributes, e.g. short descriptions, the value will always be retrieved in the original language of the underlying ABAP Repository object.

For the database table example we have:

- IF\_XCO\_DBT\_CONTENT: The content handle for the header of the database table
- IF\_XCO\_DBT\_FIELD\_CONTENT: The content handle for a field of a database table
- IF\_XCO\_DBT\_FOREIGN\_KEY\_CONTENT: The content handle for the foreign key of a field of a database table
- IF\_XCO\_DBT\_SEARCH\_HELP\_CONTENT: The content handle for the search help of a field of a database table

The code sample below illustrates how the content handle for a database table field is obtained and used to read out the attributes of the field:

#### Sample Code

```
" Content handle for the field KEY_FIELD of database table ZMY_DBT.
DATA(lo_field_content) = xco_cp_abap_dictionary=>database_table( 'ZMY_DBT'
)->field( 'KEY_FIELD'
```

```

)->content( ).

" Get the complete content (i.e. all the available attributes of the field)
" as a structure of all attributes.
DATA(ls_field_content) = lo_field_content->get( ).

" Get each attribute individually.
DATA(lv_short_description) = lo_field_content->get_short_description( ).
DATA(lv_key_indicator) = lo_field_content->get_key_indicator( ).
DATA(lv_not_null) = lo_field_content->get_not_null( ).
DATA(lo_type) = lo_field_content->get_type( ).
DATA(lv_language_indicator) = lo_field_content->get_language_indicator( ).
DATA(ls_currency_quantity) = lo_field_content->get_currency_quantity( ).

```

## Origins

An origin is an abstraction that encapsulates where the content (and existence status) of an object or part thereof are read from. As explained above, object/part as well as content handles are only backed by the semantic identifiers (e.g. the name of the database table) but do not make any choices if the content is read from the local system or from elsewhere. To this extent, each GET\* method on a content handle asks for an (optional) origin from which the attribute will henceforth be read. In short:

- Content handle: Encapsulates **what** shall be read
- Origin: Encapsulates **where** content shall be read from

As of now, the XCO Read APIs define the following three kinds of origins (availability depending on the implementation status of each object type):

- Default: The default origin will be used when no explicit origin is supplied. With the default origin, an object will be read exactly once per ABAP session from the local system. Once read from the local database, the content will be cached for the duration of the ABAP Session and used for any subsequent reads
- Local: The local origin reads from the local database. The caching behavior for individual or groups of objects can be configured freely
- Remote: Based on an RFC destination (given as IF\_RFC\_DEST) objects are read from remote systems. The caching behavior for individual or groups of objects can be configured freely

Note that not all object types support the origin concept yet (see table below). In case an object type does not yet support the origin concept the content will always be read from the local database.

## Object Type Feature Matrix

Object Type		Supports Origins?	Origin Factory	Supports Local Origin	Supports Remote Origin
APLO	Application Log Object	No	-	-	-
CLAS	Class	Yes	XCO_CP_ABAP_OBJECTS=>ORIGIN	Yes	Yes

Object Type		Supports Origins?	Origin Factory	Supports Local Origin	Supports Remote Origin
DDLS	Data Definition	No	-	-	-
DOMA	Domain	Yes	XCO_CP_DO- MAIN=>ORIGIN	Yes	No
DRTY	CDS Type Definition	Yes	XCO_CP_CDS_TY PE_DEFINITION	Yes	No
DTEL	Data Element	Yes	XCO_CP_DATA_EL EMENT=>ORIGIN	Yes	No
EVTB	Event Binding	Yes	XCO_CP_EVENT_ BINDING=>ORI- GIN	Yes	No
FUGR	Function Group	Yes	XCO_CP_FUNC- TION_GROUP=>O RIGIN	Yes	No
	Function Module	Yes	XCO_CP_FUNC- TION_MOD- ULE=>ORIGIN	Yes	No
INTF	Interface	Yes	XCO_CP_ABAP_O BJECTS=>ORIGIN	Yes	Yes
MSAG	Message Class	No	-	-	-
NONT	SAP Object Node Type	Yes	XCO_CP_SAP_OB- JECT_NODE_TYPE =>ORIGIN	Yes	No
RONT	SAP Object Type	Yes	XCO_CP_SAP_OB- JECT_TYPE=>ORI- GIN	Yes	No
SRVB	Service Binding	Yes	XCO_CP_SERV- ICE_BIND- ING=>ORIGIN	Yes	No
SRVC	Service Consumption Model	Yes	XCO_CP_SERV- ICE_CONS_MODE L=>ORIGIN	Yes	No
SRVD	Service Definition	Yes	XCO_CP_SERV- ICE_DEFINI- TION=>ORIGIN	Yes	No
TABL	Structure	No	-	-	-
	Database Table	Yes	XCO_CP_DA- TABASE_TA- BLE=>ORIGIN	Yes	No
	Global Temporary Table	No	-	-	-
TTYP	Table Type	No	-	-	-
XSLT	Transformation	No	-	-	-

## 4.2.12.16.3.2.1 Reading a Class

Given the following class

```
CLASS zcl_xco_doc_cp_cs_class DEFINITION PUBLIC FINAL CREATE PUBLIC.
  PUBLIC SECTION.
  CLASS-METHODS:
    "! <p class="shorttext synchronized" lang="en">
    "! Calculate the factorial for the given natural number
    "! </p>
    "!
    "! @parameter iv_n |
    "! <p class="shorttext synchronized" lang="en">
    "! The natural number for which to calculate the factorial
    "! </p>
    "! @parameter rv_factorial_n |
    "! <p class="shorttext synchronized" lang="en">
    "! The factorial for the given natural number
    "! </p>
    "! @raising cx_abap_invalid_value |
    "! <p class="shorttext synchronized" lang="en">
    "! If IV_N is less than 0
    "! </p>
    factorial
    IMPORTING
      iv_n TYPE i
    RETURNING
      VALUE(rv_factorial_n) TYPE i
    RAISING
      cx_abap_invalid_value.
ENDCLASS.
CLASS zcl_xco_doc_cp_cs_class IMPLEMENTATION.
  METHOD factorial.
    IF iv_n LT 0.
      RAISE EXCEPTION TYPE cx_abap_invalid_value.
    ELSEIF iv_n EQ 0.
      rv_factorial_n = 1.
    ELSE.
      rv_factorial_n = iv_n * factorial( iv_n - 1 ).
    ENDIF.
  ENDMETHOD.
ENDCLASS.
```

its contents can be read and written to the console as follows

### Sample Code

```
CLASS zcl_xco_doc_cp_cs_read_clas DEFINITION PUBLIC FINAL

source code of the
        " transformation.
        DATA(ls_transformation) = lo_transformation->content( )->get( ).
        out->write( ls_transformation ).

        " The source code of the transformation is represented as an object of
type IF_XCO_TF_SOURCE_CODE.
        " Via the IF_XCO_TEXT~GET_LINES method the source code can also be easily
obtained as a string_table.
        DATA(lt_source_code) = ls_transformation->source_code-
>if_xco_text~get_lines( )->value.
        out->write( lt_source_code ).
    ENDMETHOD.
ENDCLASS.

```

## 4.2.12.16.3.2.5 Reading Classes and Interfaces from a Remote Destination

Besides the default and local origin, the Read APIs for both classes and interfaces offer the option to read the content of classes and interfaces from remote systems. Remote systems are identified via an IF\_RFC\_DEST for which objects can be obtained via CL\_RFC\_DESTINATION\_PROVIDER. Origins for classes and interfaces are obtained via XCO\_CP\_ABAP\_OBJECTS=>ORIGIN which provides a common basis for both classes and interfaces. To obtain a remote origin, the following code can be used:

### Sample Code

```
TRY.  
    DATA(lo_rfc_destination) =  
    cl_rfc_destination_provider=>create_by_comm_arrangement( 'MY_COMM_ARRANGEMENT'  
    ).  
    CATCH cx_rfc_dest_provider_error INTO DATA(lx_rfc_dest_provider_error).  
        " Handle exception.  
ENDTRY.  
  
DATA(lo_remote_origin) = xco_cp_abap_objects=>origin-  
>remote( lo_rfc_destination ).
```

### Note

#### Authorization requirements for remote reading

Note that the user used for the system identified by the RFC destination needs to have the following authorizations in order to support the remote reading of classes and interfaces:

- S\_RFC with RFC\_TYPE = Function module, RFC\_NAME = SEO\_CLASS\_TYPEINFO\_GET\_RFC, SEO\_INTERFACE\_TYPEINFO\_GET\_RFC and ACTVT = Execute

or alternatively for the complete function group, meaning

- S\_RFC with RFC\_TYPE = Function group, RFC\_NAME = SEO\_REMOTE and ACTVT = Execute

Once the origin has been obtained, it can be used for any of the exposed GET\_\* methods as part of the Read APIs for classes and interfaces. The code sample below illustrates how the public methods of the active version of a class can be read out for a remote destination:

### Sample Code

```
DATA(lt_public_methods) = xco_cp_abap=>class( 'MY_REMOTE_CLASS' )->definition-  
>section-public->components->method->all->get(  
    io_version = xco_cp_abap_objects=>version->active  
    io_origin  = lo_remote_origin  
).  
  
LOOP AT lt_public_methods INTO DATA(lo_public_method).  
    " The name of the public method.  
    DATA(lv_public_method_name) = lo_public_method->name.  
  
    " The short description of the method.  
    DATA(lv_short_description) = ls_public_method->short_description.  
  
    " The indicator whether the method is ABSTRACT.  
    DATA(lv_abstract_indicator) = ls_public_method->abstract_indicator.
```

```

" The indicator whether the method is FINAL.
DATA(lv_final_indicator) = ls_public_method-final_indicator.

" The indicator whether the method is a REDEFINITION.
DATA(lv_redefinition_indicator) = ls_public_method-redefinition_indicator.

" A structure containing the AMDP attributes of the method (definition).
DATA(ls_amdp) = ls_public_method-amdp.
ENDLOOP.

```

Similarly, using the same LO\_REMOTE\_ORIGIN as in the example above, we can read the constants of the inactive version of a remote interface:

#### Sample Code

```

DATA(lt_constants) = xco_cp_abap=>interface( 'MY_REMOTE_INTERFACE' )-
>components->constant->all->get(
  io_version = xco_cp_abap_objects=>version->inactive
  io_origin  = lo_remote_origin
).

LOOP AT lt_constants INTO DATA(lo_constant).
  " The name of the constant.
  DATA(lv_constant_name) = lo_constant->name.

  DATA(ls_constant) = lo_constant->content( xco_cp_abap_objects=>version-
>inactive )->get( lo_remote_origin ).

  " The typing method of the constant.
  DATA(lo_typing_method) = ls_constant-typing_method.

  " The typing definition of the constant.
  DATA(lo_typing_definition) = ls_constant-typing_definition.

  " The value of the constant
  DATA(lv_value) = ls_constant-value.
ENDLOOP.

```

## 4.2.12.16.3.3 Generation APIs

The XCO Generation APIs are the part of the XCO library that allows the programmatic creation, update and deletion of ABAP repository objects. It consists of high-level and strongly typed APIs for the following objects types:

- BDEF (Behavior Definitions)
- CLAS (Classes)
- DCLS (Access Controls)
- DDLS (Data Definitions)
- DDLX (Metadata Extensions)
- DEVC (Packages)
- DOMA (Domains)
- DRTY (CDS Type Definitions)

- DTEL (Data Elements)
- EVTB (Event Bindings)
- FUGR (Function Groups)
- INTF (Interfaces)
- MSAG (Message Classes)
- NONT (SAP Object Node Types)
- RONT (SAP Object Types)
- SRVB (Service Bindings)
- SRVD (Service Definitions)
- TABL (Structures, Database Tables and Global Temporary Tables)
- TTYP (Table Types)
- XSLT (Transformations)

The following kinds of operations are supported:

- POST Create the object according to a provided specification
- PUT Create or update the object according to a provided specification
- PATCH Update the object according to a provided specification
- DELETE Delete the object

The matrix below shows which kinds of operations are supported for which object types:

	PUT	POST	PATCH	DELETE
BDEF	X			X
CLAS	X		X	X
DCLS	X			X
DDLS	X			X
DDLX	X			X
DEVC	X			X
DOMA	X		X	X
DRTY	X			X
DTEL	X		X	X
EVTB	X		X	X
FUGR		X	X	X
INTF	X		X	X
MSAG	X		X	X
NONT	X		X	X
RONT	X		X	X
SRVB	X			X
SRVD	X			X
TABL	X			X

	PUT	POST	PATCH	DELETE
TTYP	X			X
XSLT	X			X

### 4.2.12.16.3.3.1 Design of the XCO Generation APIs

As with the whole XCO library, the design of the XCO Generation APIs is governed by core principles:

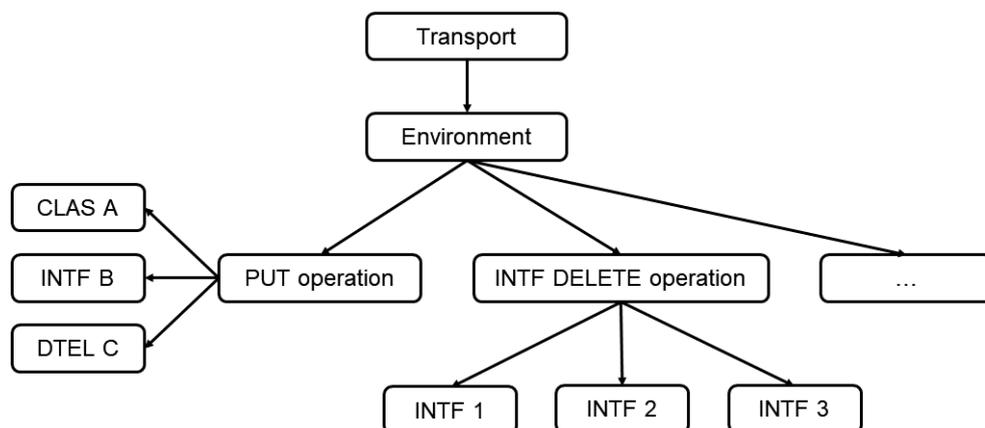

- **Environment**

The prerequisite for building and executing operations is a generation environment. A generation environment is backed by a transport which must be in status 'Modifiable' and is obtained via the XCO\_CP\_GENERATION API.

#### Sample Code

```
" In this example, X08K123456 would need to be a modifiable Workbench
" transport.
DATA(lo_environment) = xco_cp_generation=>environment-
>dev_system( 'X08K123456' ).
DATA(lo_put_operation) = lo_environment->create_put_operation( ).
lo_put_operation->for-dtel->add_object( '...' ).
" ...
```

The environment acts as the entry point to the type-specific Generation APIs which allow to build and successively execute PUT and DELETE operations. All system changes caused by an operation created for an environment will be written to the environment's transport.

- **Operations**

Operations consist of a set of objects (identified by their type and name) and allow to perform an action for these objects (determined by the kind of operation).

#### *PUT operations*

Upon execution, a PUT operation either creates or updates its objects according to provided specifications (depending on whether the object already exists in the system). Each object type defines a form-based

specification tailored to the specific attributes of the object type which is used to describe the content of each object of the PUT operation. As a PUT operation potentially creates new objects a valid package must be provided for all objects without a package. This package is used when the object is newly created but is ignored when the object already exists and is only updated.

### Sample Code

```
DATA(lo_put_operation) = lo_environment->create_put_operation( ).
DATA(lo_specification) = lo_put_operation->for-dtel-
>add_object( 'ZDATA_ELEMENT'
  )->set_package( 'ZPACKAGE'
  )->create_form_specification( ).
lo_specification->set_short_description( 'My generated data element' ).
lo_specification->set_data_type( xco_cp_abap_dictionary=>built_in_type-
>char( 10 ) ).
lo_specification->field_label-short->set_text( 'ID' ).
lo_specification->field_label-medium->set_text( 'Identifier' ).
lo_specification->field_label-long->set_text( 'User identifier' ).
lo_specification->field_label-heading->set_text( 'User identifier' ).
lo_put_operation->execute( ).
```

Object types that support inactive versions can be combined into a single PUT operation. Once the objects have either been created or updated (in inactive version) all the objects of the PUT operation will be activated together in a single mass activation. This provides support for interdependencies (even circular ones) between the objects of a PUT operation.

It is furthermore possible to influence the execution of a PUT operation with so-called options. Currently the following options are offered:

- Skip activation: Create or update the objects of the PUT operation but do not perform a mass activation afterwards

Using an option is as simple as supplying it to the EXECUTE method invocation of the corresponding PUT operation:

### Sample Code

```
lo_put_operation->execute( VALUE
#( ( xco_cp_generation=>put_operation_option->skip_activation ) ) ).
```

### POST operations

The objects on a POST operation consist of a name choice (IF\_XCO\_NAME\_CHOICE) and a specification. In contrast to PUT operations, objects are not explicitly identified by their name, but instead a name choice is provided which will be evaluated upon execution of the POST operation.

By providing a name choice instead of a fixed name it is possible to potentially pick a fallback name in case the preferred name is already taken. However, this is not mandatory and it is also possible to provide a fixed name, e.g. for the creation of function group:

```
DATA(lo_post_operation) = lo_environment->for-fugr->create_post_operation( ).
DATA(lo_fixed_name_choice) = xco_cp_name=>choice->fixed( 'ZMY_FNCTN_GRP' ).
lo_post_operation->add_object( lo_fixed_name_choice
  )->set_package( 'ZLOCAL'
  )->create_form_specification( ).
" ...
lo_post_operation->execute( ).
```

In any case, upon execution the name choices for all the objects on the POST operation are resolved. The operation will only proceed if all name choices can be resolved, i.e. a name can be determined for which no

object already exists in the ABAP repository. If all name choices were resolved successfully the semantics of a POST operation are those of a PUT operation where the objects do not exist prior to the execution.

#### *PATCH operations*

Upon execution, a PATCH operation will update its objects according to the changes provided in the specifications. The available changes depend on the object type.

For message classes (MSAG) it is e.g. possible to insert, update, modify or delete messages of the message class. The semantics are as follows:

- **INSERT** Add a new part to the object if it does not exist yet. If it already exists, no action will be performed.
- **UPDATE** Update an existing part of the object. If the part does not exist, no action will be performed.
- **MODIFY** Modify the specified part of the object. If the part does not exist, it will be created according to the specification, otherwise it will be updated.
- **DELETE** Delete the specified part of the object. If the specified part does not exist no action will be performed

#### *DELETE operations*

Upon execution, a DELETE operation will delete all its objects (in case they exist in the system). DELETE operations are always built and executed for a given type and it is the responsibility of the caller to ensure that objects of different types are deleted in the correct order (e.g. a domain still in use by a data element cannot be deleted; the data element must be deleted first).

#### *COMMIT behavior of operations*

The execution of an operation will always execute a COMMIT WORK.

#### *Errors during operation execution*

If the execution of an operation fails, the following exceptions are used to communicate the failure:

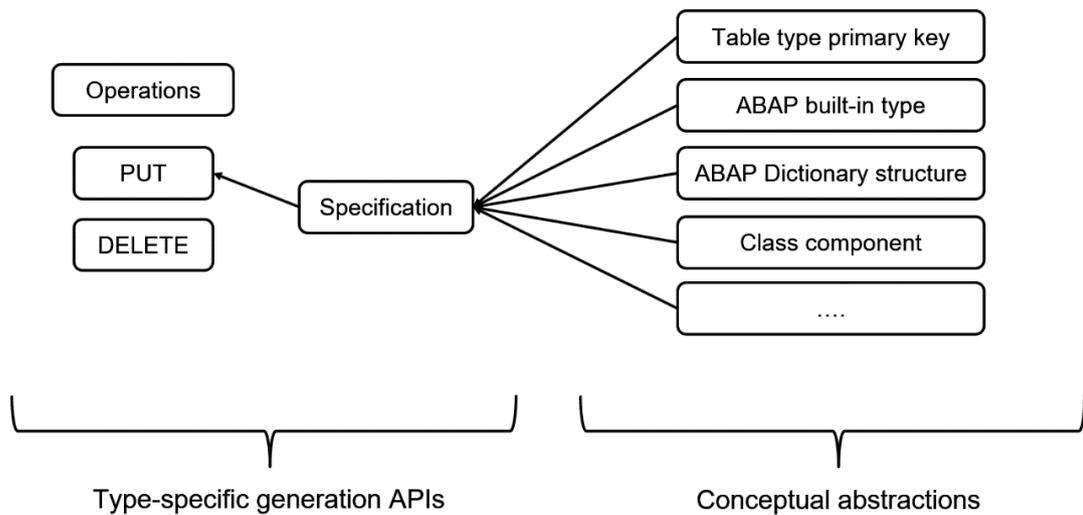

- **CX\_XCO\_GEN\_PUT\_EXCEPTION** for a failed PUT operation
- **CX\_XCO\_GEN\_DELETE\_EXCEPTION** for a failed DELETE operation
- **CX\_XCO\_GEN\_PATCH\_EXCEPTION** for a failed PATCH operation

Each exception provides access to the findings, i.e. all the messages and which object they belong to, that were encountered when attempting to execute the operation.

In case the mass activation of a PUT operation fails, the already existing inactive versions will not be deleted.

- **Conceptual Abstractions**

The overall design and architecture of the XCO Generation functionality is based on the differentiation between conceptual abstractions and type-specific generation APIs.

Conceptual abstractions represent entities in the ABAP system which can be used in conjunction with different object types. For example, a built-in type of the ABAP Dictionary may be used as the format for a domain (DOMA), the data type of a data element (DTEL) or the row type of a table type (TTYP). Conceptual abstractions create a common language which can be used across different object types in the context of generation.

#### Sample Code

```
DATA(lo_char_10) = xco_cp_abap_dictionary=>built_in_type->char( 10 ).
lo_doma_specification->set_format( lo_char_10 ).
lo_dtel_specification->set_data_type( lo_char_10 ).
lo_tttyp_specification->set_row_type( lo_char_10 ).
```

#### 4. Templates

Instead of manually filling a form specification, templates can be used to prefill an empty form specification from an existing ABAP Repository object. Currently the following object types support templates:

- DOMA (Domain)
- DTEL (Data element)
- TABL (Database tables and structures)
- TTYP (Table types)
- DDLS (Data Definitions)

Using templates, it is e.g. possible to easily copy an existing object. The following code sample uses the active version of domain ZSOURCE\_DOMAIN as a template and will create (resp. update) domain ZCOPIED\_DOMAIN to reflect the content of ZSOURCE\_DOMAIN:

#### Sample Code

```
DATA(lo_template) = xco_cp_generation_doma=>template->for_domain(
  iv_name      = 'ZSOURCE_DOMAIN'
  io_read_state = xco_cp_abap_dictionary=>object_read_state->active_version
).
DATA(lo_put_operation) = lo_environment->create_put_operation( ).
lo_put_operation->for_doma->add_object( 'ZCOPIED_DOMAIN'
  )->set_package( 'ZPACKAGE'
```

```

)->set_template( lo_template ).
lo_put_operation->execute( ).

```

## 4.2.12.16.3.3.2 RAP BO Generation

The following code sample illustrates how a complete RAP business object, starting from domains for fixed values all the way up to a service binding, can be generated with the XCO Generation APIs:

### Sample Code

```

"! Code sample for executing PUT operations to generate a full RAP business
object.

## 4.2.12.16.3.3.3 Generation Error Handling

Each type of operation within the XCO Generation APIs defines its own exception class that can be used to deal with errors that were encountered during the execution of the operation:

- CX\_XCO\_GEN\_POST\_EXCEPTION for POST operations
- CX\_XCO\_GEN\_PUT\_EXCEPTION for PUT operations
- CX\_XCO\_GEN\_PATCH\_EXCEPTION for PATCH operations
- CX\_XCO\_GEN\_DELETE\_EXCEPTION for DELETE operations

The following code sample shows how the findings of a failed PUT operation can be extracted:

### Sample Code

```

"! Code sample for handling errors of a PUT operation.
"!
"! IMPORTANT: The values of the constants CO_PACKAGE and CO_TRANSPORT must be
replaced
"! with an existing package and a modifiable Workbench transport matching the
transport
"! target of the package.

{ co_interface_name }~GET_FAVORITE_PRODUCTS|
    )->set_source( VALUE #(
    ( |" Source code goes here...| )
    ) ).
ENDMETHOD.
ENDCLASS.

```

Note that the XCO Generation APIs for classes also allow the specification of local types and local test classes:

- Method `ADD_LOCAL_CLASS` on `IF_XCO_CP_GEN_CLAS_S_FORM` can be used to add a local type to the generated class. The content of the local class can be fully specified via the returned local class specification `IF_XCO_GEN_CLAS_S_FO_LCL_CLASS`
- Method `ADD_TEST_CLASS` on `IF_XCO_CP_GEN_CLAS_S_FORM` can be used to add a local test class to the generated class. The content of the local test class can be fully specified via the returned test class specification `IF_XCO_GEN_CLAS_S_FO_TST_CLASS`. Note that the API `XCO_CP_ABAP_UNIT` offers XCO enumeration constants for ABAP Unit durations and risk levels

## 4.2.12.16.3.3.7 Patching a Message Class

```

## 4.2.12.16.3.3.8 Patching Methods of Interfaces and Classes

The XCO Generation APIs allow to incrementally modify existing interfaces and classes through PATCH operations.

The following two code samples illustrate how methods of interfaces and classes can be patched. In each code sample, the MAIN method will execute one of four phases depending on the current state of the interface or class. To see each phase in action simply execute each class several times in a row.

Here is how it looks for interfaces:

### Sample Code

```

"! Code sample for patching methods of an interface.

## 4.2.12.16.3.3.9 Patching Attributes of Interfaces and Classes

The code samples illustrate how the interface and class Read APIs can be combined with `PATCH` operations to conditionally change attributes of interfaces and classes.

In the first example an attribute is inserted into an interface if it's not yet part of it and deleted if it's already a part of the interface. By running the class several times in a row the attribute will be continuously inserted and deleted.

### Sample Code

```
"! Code sample for using the interface Read APIs together with the INTF PATCH
operation
"! functionality to "toggle" a DATA attribute on an interface.
"!
"! IMPORTANT: The interface referred to by the constant CO_INTERFACE_NAME
needs to
"! exist prior to executing this code sample.
CLASS zcl_xco_doc_cp_cs_chg_intf DEFINITION PUBLIC FINAL
  INHERITING FROM cl_xco_cp_adt_simple_classrun CREATE PUBLIC.
  PUBLIC SECTION.
    METHODS:
      constructor.

  PROTECTED SECTION.
    METHODS:
      main REDEFINITION.

  PRIVATE SECTION.
    CONSTANTS:
      co_interface_name TYPE sxco_ao_object_name VALUE 'ZIF_INTERFACE',
      co_numeric_id     TYPE sxco_ao_component_name VALUE 'NUMERIC_ID'.

    METHODS:
      get_transport_request
        IMPORTING
          io_interface          TYPE REF TO if_xco_ao_interface
          out                   TYPE REF TO if_xco_adt_classrun_out
        RETURNING
          VALUE(ro_transport_request) TYPE REF TO if_xco_cp_tr_request.
ENDCLASS.

CLASS zcl_xco_doc_cp_cs_chg_intf IMPLEMENTATION.
  METHOD constructor.
    super->constructor( ).
  ENDMETHOD.

  METHOD main.
    DATA(lo_interface) = xco_cp_abap=>interface( co_interface_name ).

    DATA(lo_transport_request) = get_transport_request(
      io_interface = lo_interface
      out          = out
    ).

    DATA(lo_environment) = xco_cp_generation=>environment-
    >dev_system( lo_transport_request->value ).
```

```

        DATA(lo_patch_operation) = lo_environment->for-intf-
>create_patch_operation( ).
        DATA(lo_object) = lo_patch_operation->add_object( co_interface_name ).

        IF lo_interface->component->data( co_numeric_id )->exists( ) EQ
abap_false.
            lo_object->for-insert->add_data( co_numeric_id
                )->set_type( xco_cp_abap=>type-built_in->int8
                )->set_read_only( ).

            out->write( |Inserting DATA { co_numeric_id }| ).
        ELSE.
            lo_object->for-delete->add_data( co_numeric_id ).

            out->write( |Deleting DATA { co_numeric_id }| ).
        ENDIF.

        lo_patch_operation->execute( ).
    ENDMETHOD.

METHOD get_transport_request.
    DATA(lo_lock) = io_interface->if_xco_cts_changeable~get_object(
        )->get_lock( ).

    IF lo_lock->exists( ) EQ abap_true.
        DATA(lv_transport) = lo_lock->get_transport( ).

        ro_transport_request = xco_cp_cts=>transport->for( lv_transport
            )->get_request( ).

        out->write( |Using transport request { ro_transport_request->value }
(Interface is already locked).| ).
    ELSE.
        DATA(lo_transport_target) = io_interface->if_xco_ar_object~get_package(
            )->read(
                )->property-transport_layer->get_transport_target( ).

        ro_transport_request = xco_cp_cts=>transports-
>workbench( lo_transport_target->value
            )->create_request( 'Generated transport request' ).

        out->write( |Using newly generated transport request
{ ro_transport_request->value }.| ).
    ENDIF.
ENDMETHOD.
ENDCLASS.

```

The second example "moves" an attribute through all three sections of a class. By running the below class several times in a row the attribute will first move from the public section to the protected section, then to the private section and then back to the public section to repeat the cycle:

### Sample Code

```

"! Code sample for using the class Read APIs together with the CLAS PATCH
operation
"! functionality to "move" a DATA attribute across the sections of the class.
"!
"! IMPORTANT: The class referred to by the constant CO_CLASS_NAME needs to
"! exist prior to executing this code sample.

ENDCLASS.

```

## 4.2.12.16.3.3.13 Generating Transformations

The XCO Generation APIs offer support for PUT and DELETE operations for transformations (XSLT objects).

The first code sample below illustrates how a transformation can be generated via a PUT operation and directly invoked dynamically to extract data from a provided XML string as well as present data as XML (making use of XCO Standard Library functionality to conveniently translate between strings and xstrings based on UTF-8).

### Sample Code

```

DATA(lv_transport_request) = CONV sxco_transport( '...' ).
DATA(lv_transformation_name) = CONV
sxco_tf_object_name( 'ZMY_TRANSFORMATION' ).

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( lv_transport_request
->create_put_operation( ).

DATA(lo_specification) = lo_put_operation->for-xslt-
>add_object( lv_transformation_name
->set_package( 'Z_MY_PACKAGE'
->create_form_specification( ).
lo_specification->set_short_description( 'Generated transformation'
->set_source( VALUE #(
( |<tt:transform xmlns:tt="http://www.sap.com/transformation-
templates">| )
( | <tt:root name="ROOT"/>| )
( | <tt:template>| )
( | <record>| )
( | <tt:attribute name="text" value-ref="root.text"/>| )
( | </record>| )
( | </tt:template>| )
( | </tt:transform>| )
) ).

lo_put_operation->execute( ).

" At this point a transformation with the name ZMY_TRANSFORMATION exists in
the system in active
" state.

```

```

TYPES:
  BEGIN OF ts_record,
    text TYPE string,
  END OF ts_record.
DATA ls_record TYPE ts_record.

" Using the generated transformation, it is now possible to dynamically apply
it to provided XML
" data.
DATA(lv_xml_string) = |<?xml version="1.0" encoding="UTF-8"?><record
text="Hello World"/>|.

" Converts 'string' to 'xstring' using 'UTF-8' code page.
DATA(lv_xml_xstring) = xco_cp=>string( lv_xml_string
  )->as_xstring( xco_cp_character=>code_page->utf_8
  )->value.

CALL TRANSFORMATION (lv_transformation_name)
  SOURCE XML lv_xml_xstring
  RESULT root = ls_record.

" At this point the TEXT component of the structure LS_RECORD will have the
value Hello World
" In the same manner, an XML string can be also be obtained from the ABAP
data object.
ls_record-text = 'Hello XCO'.

CALL TRANSFORMATION (lv_transformation_name)
  SOURCE root = ls_record
  RESULT XML lv_xml_xstring.

" Converts 'xstring' to 'string' using 'UTF-8' code page.
lv_xml_string = xco_cp=>xstring( lv_xml_xstring
  )->as_string( xco_cp_character=>code_page->utf_8
  )->value.

" Now the variable LV_XML_STRING will have the value <?xml version="1.0"
encoding="UTF-8"?><record text="Hello XCO"/>.

```

Just as with other object types, transformations can also be deleted:

### Sample Code

```

DATA(lv_transport_request) = CONV sxco_transport( '...' ).
DATA(lv_transformation_name) = CONV
sxco_tf_object_name( 'ZMY_TRANSFORMATION' ).

DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( lv_transport_request
  )->for-xslt->create_delete_operation( ).
lo_delete_operation->add_object( lv_transformation_name ).
lo_delete_operation->execute( ).

```

## 4.2.12.16.3.3.14 Changing the Content of Existing Domains

Using `PATCH` operations, it's possible to change the content of an existing domain. The following changes can be specified:

- Changes to header-level properties, such as the format of a domain or its output length
- Insertions, updates, or deletions of fixed values

The code sample below illustrates how the following changes can be performed with a single `PATCH` operation:

- Update the short description, case-sensitive indicator, and output style
- Update an existing fixed value
- Delete an existing fixed value
- Insert a new fixed value

### Sample Code

```
DATA(lv_transport) = CONV sxco_transport( '...' ).
DATA(lv_domain_name) = CONV sxco_ad_object_name( 'MY_DOMAIN' ).

DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( lv_transport
) ->for-domain->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation->add_object( lv_domain_name
) ->create_change_specification( ).

" Change header-level properties.
lo_change_specification->for-update->set_short_description( 'My new short
description'
) ->set_case_sensitive( abap_true
) ->set_output_style( xco_cp_domain=>output_style->normal ).

" Update the description of fixed value "A".
lo_change_specification->for-update->add_fixed_value( 'A'
) ->set_description( 'Fixed Value A' ).

" Delete fixed value "B".
lo_change_specification->for-delete->add_fixed_value( 'B' ).

" Insert fixed value "C".
lo_change_specification->for-insert->add_fixed_value( 'C'
) ->set_description( 'Fixed Value C' ).

lo_patch_operation->execute( ).
```

## 4.2.12.16.3.3.15 Changing the Content of Existing Data Elements

Using `PATCH` operations, it's possible to change the content of an existing data element. The following changes can be specified:

- Changes to header-level properties, such as the data type or the field labels

The code sample below illustrates how the following changes can be performed with a single PATCH operation:

- Update the short description
- Update the data type
- Update the short field label

#### Sample Code

```
DATA(lv_transport) = CONV sxco_transport( '...' ).
DATA(lv_data_element_name) = CONV sxco_ad_object_name( 'MY_DATA_ELEMENT' ).

DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( lv_transport
  )->for-dtel->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation-
>add_object( lv_data_element_name
  )->create_change_specification( ).

" Change header-level properties.
lo_change_specification->for-update->set_short_description( 'My new short
description'
  )->set_data_type( xco_cp_abap_dictionary=>built_in_type->int4
  )->field_label-short->set_text( 'Sh. FL' )->set_length( 10 ).

lo_patch_operation->execute( ).
```

## 4.2.12.16.3.3.16 Generating CDS Type Definitions

The following code sample illustrates how you can generate a CDS simple type with the XCO library by means of running a PUT operation:

#### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-drt-
>add_object( 'ZMY_CDS_TYPE_DEFINITION'
  )->set_package( 'ZMY_PACKAGE'
  )->create_form_specification( ).
lo_form_specification->set_short_description( 'Generated CDS Type Definition' ).

DATA(lo_simple_type_definition) = lo_form_specification-
>add_simple_type_definition( ).
lo_simple_type_definition->add_annotation( 'EndUserText.label' )->value-
>build(
  )->add_string( 'My CDS type definition' ).

lo_simple_type_definition->set_type( xco_cp_abap_dictionary=>built_in_type-
>char( 10 ) ).

lo_put_operation->execute( ).
```

Running this PUT operation will produce the CDS type definition ZMY\_CDS\_TYPE\_DEFINITION with the following source:

### Sample Code

```
@EndUserText.label: 'My CDS type definition'  
define type ZMY_CDS_TYPE_DEFINITION : abap.char( 10 )
```

In general, the following objects are eligible to be used as the type for a simple type definition:

- ABAP dictionary built-in type (objects of type CL\_XCO\_AD\_BUILT\_IN\_TYPE)
- Data elements (objects of type IF\_XCO\_AD\_DATA\_ELEMENT)
- CDS type definitions (objects of type IF\_XCO\_CDS\_TYPE\_DEFINITION)

CDS type definitions can also be deleted again, as is illustrated by the following code sample:

### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-  
>dev_system( '$TRANSPORT_REQUEST$'  
)->for-drty->create_delete_operation( ).  
lo_delete_operation->add_object( 'ZMY_CDS_TYPE_DEFINITION' ).  
lo_delete_operation->execute( ).
```

## 4.2.12.16.3.3.17 Patching Structures and Database Tables

Using PATCH operations, it's possible to change the content of an existing structure or database table. The following changes can be specified:

- Choose to update the type and/or the currency and/or the quantity information of an existing database table field or structure component
- Update of the structure of an existing include of a database table or a structure

The following code sample illustrates how the changes described above can be applied to an existing database table:

### Sample Code

```
DATA(lv_transport) = CONV sxco_transport( '...' ).  
DATA(lv_database_table_name) = CONV sxco_dbt_object_name( 'ZMY_DBT' ).  
  
DATA(lo_patch_operation) = xco_cp_generation=>environment-  
>dev_system( lv_transport  
)->create_patch_operation( ).  
  
DATA(lo_change_specification) = lo_patch_operation->for-tabl-for-  
database_table->add_object( lv_database_table_name  
)->create_change_specification( ).  
  
" Update the type of field DATA_FIELD to abap.char( 10 )  
lo_change_specification->for-update->add_field( 'DATA_FIELD'  
)->set_type( xco_cp_abap_dictionary=>built_in_type->char( 10 ) ).  
  
" Update the currency/quantity reference information for field CURR_QUAN  
lo_change_specification->for-update->add_field( 'CURR_QUAN'  
)->currency_quantity->set_reference_table( 'ZMY_REF_TABLE'  
)->set_reference_field( 'ZMY_REF_FIELD' ).
```

```

" Update the structure that is used for the first include of the
" database table.
lo_change_specification->for-update->add_include( 1
    )->set_structure( 'ZMY_INCL_STR' ).

lo_patch_operation->execute( ).

```

The same changes could also be applied to an existing structure by adding a structure to the `PATCH` operation created above:

### Sample Code

```

lo_patch_operation->for-table-for-structure->add_object( 'ZMY_STRUCTURE' ).

```

Note that the `PATCH` operation obtained via `XCO_CP_GENERATION=>ENVIRONMENT->DEV_SYSTEM( LV_TRANSPORT )->CREATE_PATCH_OPERATION( )` is a mass-enabled operation which can contain several objects at once. Upon execution, first, the specified changes will be applied to all objects that have been added to the `PATCH` operation, and afterwards, all objects will be activated together in a single mass activation. Currently, the following object types are enabled for mass `PATCH` operations:

- DOMA (Domains)
- DTEL (Data Elements)
- TABL (Database Tables and Structures)

## 4.2.12.16.3.4 I18N APIs

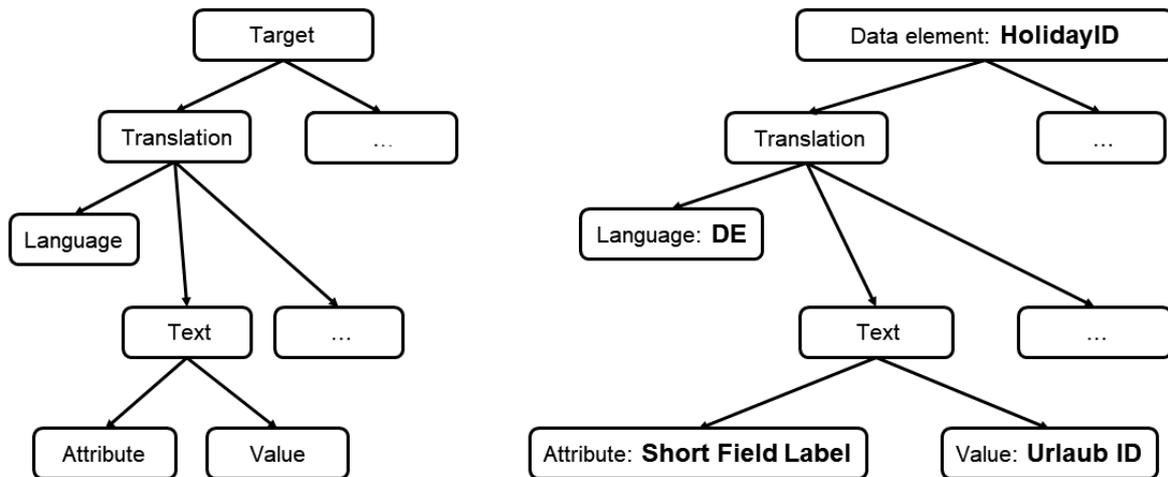

The XCO I18N APIs allow the programmatic maintenance of translations for language-dependent texts. The I18N module consists of high-level and strongly typed APIs and provides support for the following targets:

- Domains
- Data elements
- Data definitions
- Metadata extensions
- Message classes
- Application log objects
- Business configuration objects
- IAM business catalogs
- Text pools
- Text tables

### Design of the XCO I18N APIs

The goal of the XCO I18N architecture is to provide a homogenous way to programmatically maintain and access translations for different kinds of language-dependent texts with a public API that is independent of the

underlying concrete object type. The overall structure is illustrated in the following diagram:

The left side of the diagram shows the general abstractions while the right side shows what the general abstractions would correspond to in the case of the short field label of a given data element. The following terminology is used:

- Target: A collection of translations
- Translation: A tuple consisting of a language and a collection of texts
- Language: A language that is installed in the system and is identified by an SPRAS value
- Text: A tuple consisting of an attribute and a value

The following sections will describe and illustrate the available targets and text attributes in more detail:

## Domains

For a given domain a single fixed value (identified by its lower limit) defines a target. The only available text attribute is the description of a fixed value. Here's how the translation for language German could be maintained for the fixed value DE of domain ZCOUNTRY:

### Sample Code

```

DATA(lo_text_attribute) = xco_cp_domain=>text_attribute-
>fixed_value_description.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Deutschland' ) ).
DATA(lo_target) = xco_cp_i18n=>target->domain->fixed_value(
  iv_domain_name = 'ZCOUNTRY'
  iv_lower_limit = 'DE'
).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  
```

```

    io_language          = lo_language
    it_text_attributes = VALUE #( ( lo_text_attribute ) )
  ).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Deutschland`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## Data elements

Unlike domains, once a data element is fixed there are no more degrees of freedom for language-dependent texts as all the different field labels are directly defined on the level of the data element itself. The following example illustrates how the short field label of data element ZFIRST\_NAME can be translated to German (first name = Vorname) and how the translated value can be read back again:

### Sample Code

```

DATA(lo_text_attribute) = xco_cp_data_element=>text_attribute-
>short_field_label.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute->create_text( xco_cp=>string( 'Vorname' ) ).
DATA(lo_target) = xco_cp_il8n=>target->data_element->object( 'ZFIRST_NAME' ).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Vorname`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## Data definitions

For data definitions all language-dependent texts are supplied via annotations provided directly in the source of the data definition. A data definition defines the following targets:

- Entity
- A parameter identified by its name
- A field identified by its name

Depending on the annotation it may be necessary to specify an array index (e.g. UI.lineltem.label) to fully specify a text attribute. The APIs in XCO\_CP\_DATA\_DEFINITION=>TEXT\_ATTRIBUTE provide an easy overview of maintainable text attributes for the three different kinds of data definition targets.

The code sample below illustrates how the `EndUserText.label` annotation value can be translated to German for the field `startDate` of the CDS view entity `ZVACATION_REQUEST` (start date = `Startdatum`):

### Sample Code

```
DATA(lo_text_attribute) = xco_cp_data_definition=>text_attribute->field-
>endusertext_label.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Startdatum' ) ).
DATA(lo_target) = xco_cp_il8n=>target->data_definition->field(
  iv_entity_name = 'ZVACATION_REQUEST'
  iv_field_name  = 'startDate'
).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Startdatum`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.
```

## Metadata extensions

Metadata extensions are structurally equivalent to data definitions in that all language-dependent texts are supplied via annotations provided directly in the source of the metadata extension and the available targets are

- Entity
- A parameter identified by its name
- A field identified by its name

The maintainable text attributes are available via the `XCO_CP_METADATA_EXTENSION=>TEXT_ATTRIBUTE` API.

The code sample below illustrates how the `UI.LineItem.label` annotation value can be translated to German for the field `endDate` of the metadata extension `ZVACATION_REQUEST_EXT` (end date = `Enddatum`):

### Sample Code

```
DATA(lo_text_attribute) = xco_cp_metadata_extension=>text_attribute->field-
>ui_lineitem_label( 1 ).
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Enddatum' ) ).
DATA(lo_target) = xco_cp_il8n=>target->metadata_extension->field(
  iv_metadata_extension_name = 'ZVACATION_REQUEST_EXT'
  iv_field_name              = 'endDate'
).
" Set the translation.
```

```

lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Enddatum`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## Message class

Messages classes follow a structure similar to that of domains: A single message of a message class (identified by its number) defines a target and the only available text attribute is the short text of a message.

In the code sample below message 005 of message class ZMESSAGES ("Record created." = "Eintrag angelegt.") is translated to German:

### Sample Code

```

DATA(lo_text_attribute) = xco_cp_message_class=>text_attribute-
>message_short_text.
  DATA(lo_language) = xco_cp=>language( 'D' ).
  DATA(lo_text) = lo_text_attribute->create_text( xco_cp=>string( 'Eintrag
angelegt.' ) ).
  DATA(lo_target) = xco_cp_il8n=>target->message_class->message(
    iv_message_class_name = 'ZMESSAGES'
    iv_message_number     = '005'
  ).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Eintrag angelegt.`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## Application log objects

For a given application log object both the object itself as well as each of its subobjects act as targets. The only available text attribute is the short description. The following code sample illustrates how the German

translation for the short description of the application log object Z\_PROGRESS\_RECORDING can be set and read:

### Sample Code

```
DATA(lo_text_attribute) = xco_cp_application_log_object=>text_attribute-
>object->short_description.

DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Fortschrittsaufzeichnung' ) ).

DATA(lo_target) = xco_cp_il8n=>target->application_log_object-
>object( 'Z_PROGRESS_RECORDING' ).

" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).

" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).

LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Fortschrittsaufzeichnung`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.
```

Setting and getting translations for subobjects works in completely analogous fashion by first obtaining the subobject target and then using text attribute XCO\_CP\_APPLICATION\_LOG\_OBJECT=>TEXT\_ATTRIBUTE->SUBOBJECT->SHORT\_DESCRIPTION.

## Business configuration objects

Translations can also be maintained for business configuration objects which are available for maintenance via the "Maintain Business Configurations" Fiori app. Each business configuration object has a name and description which is visible in the Maintain Business Configurations app. The code sample below illustrates how the description of a business configuration object can be translated (and read out).

### Sample Code

```
DATA(lo_text_attribute) = xco_cp_business_cnfgtrn_object=>text_attribute-
>description.

DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Urlaubskalender' ) ).

DATA(lo_target) = xco_cp_il8n=>target->business_configuration_object-
>object( 'Z_HOLIDAY_CALENDAR' ).

" Set the translation.
```

```

lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).

" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).

LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Urlaubskalender`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## IAM business catalogs

Translations can also be maintained for IAM business catalogs. The only text attribute of an IAM business catalog is its description. The code sample below illustrates how the description of an IAM business catalog can be translated (and read out).

### Sample Code

```

DATA(lo_text_attribute) = xco_cp_iam_business_catalog=>text_attribute-
>description.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute-
>create_text( xco_cp=>string( 'Buchhaltung' ) ).
DATA(lo_target) = xco_cp_iam=>business_catalog->for( 'Z_ACCOUNTING' )-
>il8n_target->object( ).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Buchhaltung`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.

```

## Text pools

Both classes and function groups allow the definition of text symbols which are stored in the text pool associated with the respective class or function group. Maintaining the translations for such text symbols can be accomplished like:

## Sample Code

```
DATA(lo_text_attribute) = xco_cp_text_pool=>text_attribute->text_element_text.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute->create_text( xco_cp=>string( 'Auftrag
abgeschickt.' ) ).
DATA(lo_target) = xco_cp_il8n=>target->text_pool->class_text_symbol(
  iv_class_name      = 'ZCL_MY_CLASS'
  iv_text_symbol_id = '001'
).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Auftrag abgeschickt.`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.
```

In the above example the German translation is maintained for the text of text symbol 001 (the original text is "Request sent.") of class ZCL\_MY\_CLASS. If the text symbol belonged to a function group instead of a class the code would look like:

## Sample Code

```
DATA(lo_text_attribute) = xco_cp_text_pool=>text_attribute->text_element_text.
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = lo_text_attribute->create_text( xco_cp=>string( 'Auftrag
abgeschickt.' ) ).
DATA(lo_target) = xco_cp_il8n=>target->text_pool->function_group_text_symbol(
  iv_function_group_name = 'ZMY_FNCTN_GRP'
  iv_text_symbol_id      = '001'
).
" Set the translation.
lo_target->set_translation(
  it_texts          = VALUE #( ( lo_text ) )
  io_language       = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language       = lo_language
  it_text_attributes = VALUE #( ( lo_text_attribute ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Auftrag abgeschickt.`.
  DATA(lv_value) = lo_text_attribute-
>if_xco_il8n_text_attribute~get_string_for_text( lo_german_text->value ).
ENDLOOP.
```

## Text tables

Any database table with delivery class C or S which has exactly one key field with the underlying ABAP Dictionary built-in type LANG is considered a text table and can act as a source of targets. Each key field of a text table is uniquely associated with one of the following three groups:

- Client key field
- Master key fields
- Language key field

The semantics are such that a full specification of all master key fields of a text table defines a target and that each non-key field which is character-like and has at least length 2 is considered a text attribute of that target.

As an example, consider the database table ZXCO\_CAL\_HOLITXT which contains the language-dependent texts for public holidays maintained in database table ZXCO\_CAL\_HLDY:

```
{ZXCO_CAL_HLDY}
```

```
{ZXCO_CAL_HOLITXT}
```

Here CLIENT is the client key field of the text table ZXCO\_CAL\_HOLITXT, HOLIDAY\_ID is the master key field and LANGUAGE is the language key field. Fixing a value for the HOLIDAY\_ID key field (e.g. "CHRISTMAS") determines a target for which the text attribute DESCRIPTION can then be read and written, as is illustrated by the code sample below:

### Sample Code

```
DATA(lo_language) = xco_cp=>language( 'D' ).
DATA(lo_text) = xco_cp=>string( 'Weihnachten' ).
DATA(lo_target) = xco_cp_il18n=>target->text_table->record(
  iv_database_table_name      = 'ZCAL_XCO_HOLITXT'
  it_master_key_fields       = VALUE #( ( name = 'HOLIDAY_ID' value =
xco_cp=>data_object->for( 'CHRISTMAS' ) ) )
  iv_language_key_field_name = 'LANGUAGE'
).
" Set the translation.
lo_target->set_translation(
  it_texts      = VALUE #( ( attribute = 'DESCRIPTION' value =
lo_text ) )
  io_language   = lo_language
  io_change_scenario = lo_transport_request
).
" Read the translation.
DATA(lo_translation) = lo_target->get_translation(
  io_language   = lo_language
  it_text_attributes = VALUE #( ( 'DESCRIPTION' ) )
).
LOOP AT lo_translation->texts INTO DATA(lo_german_text).
  " LV_VALUE is of type STRING and contains `Weihnachten`.
  DATA(lv_value) = lo_german_text->get_string_value( ).
ENDLOOP.
```

## 4.2.12.16.3.5 API Release Framework

Find out how to set the API state.

Setting and getting API states programmatically is supported for the following objects:

- Classes (IF\_XCO\_AO\_CLASS)
- Entities of data definitions (IF\_XCO\_CDS\_ENTITY)
- Domains (IF\_XCO\_DOMAIN)
- Data elements (IF\_XCO\_AD\_DATA\_ELEMENT)
- Function modules of function groups (IF\_XCO\_FUNCTION\_MODULE)
- Interfaces (IF\_XCO\_AO\_INTERFACE)
- Structures (IF\_XCO\_AD\_STRUCTURE)
- Database tables (IF\_XCO\_DATABASE\_TABLE)
- Table types (IF\_XCO\_AD\_TABLE\_TYPE)
- Transformations (IF\_XCO\_TRANSFORMATION)

Each of the above interfaces defines the two methods SET\_API\_STATE and GET\_API\_STATE to programmatically set or get the API state of the represented object. For data elements, for example, this looks like:

### Sample Code

```
DATA(lo_transport) = xco_cp_cts=>transport->for( '...' ).
DATA(lo_api_state) = xco_cp_ars=>api_state->released( VALUE
#( ( xco_cp_ars=>visibility->sap_cloud_platform ) ) ).

DATA(lo_data_element) = xco_cp_abap_repository=>object->dtel-
>for( 'ZMY_DATA_ELEMENT' ).
lo_data_element->set_api_state(
    io_change_scenario = lo_transport
    io_api_state       = lo_api_state
).
```

## 4.2.12.16.3.6 Core Data Services

The XCO library provides several abstractions and APIs to simplify working with objects in the area of Core Data Services. The functionality ranges from reading the content of CDS entities to querying annotations.

## Read APIs

With the CDS Read APIs it is possible to access the content of a given CDS entity in a strongly typed manner, as is illustrated by the following example:

### Sample Code

```
DATA(lo_view_entity) = xco_cp_cds=>view_entity( 'MY_VIEW_ENTITY' ).
DATA(lo_view_entity_content) = lo_view_entity->content( ).
DATA(ls_view_entity_content) = lo_view_entity_content->get( ).
DATA(lv_short_description) = ls_view_entity_content-short_description.
DATA(ls_data_source) = ls_view_entity_content-data_source.
DATA(lv_root_indicator) = ls_view_entity_content-root_indicator.
DATA(lt_name_list) = ls_view_entity_content-name_list.
DATA(lo_where) = ls_view_entity_content-where.
DATA(lt_group_by) = ls_view_entity_content-group_by.
" Attributes can be accessed directly via corresponding get methods, such as:
lt_name_list = lo_view_entity_content->get_name_list( ).
LOOP AT lo_view_entity->parameters->all->get( ) INTO DATA(lo_parameter).
  DATA(ls_parameter) = lo_parameter->content( )->get( ).
ENDLOOP.
LOOP AT lo_view_entity->associations->all->get( ) INTO DATA(lo_association).
  DATA(ls_association) = lo_association->content( )->get( ).
ENDLOOP.
LOOP AT lo_view_entity->compositions->all->get( ) INTO DATA(lo_composition).
  DATA(ls_composition) = lo_composition->content( )->get( ).
ENDLOOP.
LOOP AT lo_view_entity->fields->all->get( ) INTO DATA(lo_field).
  DATA(ls_field) = lo_field->content( )->get( ).
ENDLOOP.
" Fields/parameters/associations/compositions can be addressed directly, such
as:
lo_field = lo_view_entity->field( 'FIELD_1' ).
DATA(lv_does_field_exist) = lo_field->exists( ).
IF lv_does_field_exist EQ abap_true.
  ls_field = lo_field->content( )->get( ).
ENDIF.
```

## Data Definition Language

Using the Data Definition Language (DDL) module of the XCO Library, different kinds of DDL expressions can be built and successively used in conjunction with the XCO Generation APIs when providing specifications for DDLS objects. Complex expressions like case, cast, or conditional expressions as well as literals, field, and data source expressions can be easily specified using the XCO\_CP\_DDL API:

### Sample Code

```
" Case expression
DATA(lo_case_expression_builder) = xco_cp_ddl=>expression->case->builder( ).
lo_case_expression_builder->set_operand( xco_cp_ddl=>field( 'NAME' )
)->add_when(
  io_operand = xco_cp_ddl=>expression->for( 'JOHN' )
  io_result = xco_cp_ddl=>literal->numeric( 1 )
)->add_when(
  io_operand = xco_cp_ddl=>expression->for( 'MARK' )
  io_result = xco_cp_ddl=>literal->numeric( 2 )
)->add_when(
```

```

        io_operand = xco_cp_ddl=>expression->for( 'JULIA' )
        io_result  = xco_cp_ddl=>literal->numeric( 3 )
    )->set_else( xco_cp_ddl=>literal->numeric( 4 ) ).
" Conditional expression
DATA(lo_condition_expression) = xco_cp_ddl=>expression->for( 'CITY'
)->ne( xco_cp_ddl=>literal->character( 'BERLIN' )
)->or( xco_cp_ddl=>expression->for( 'CITY'
)->is_not_initial( ) ).
" Data source expression
DATA(lo_data_source_expression) = xco_cp_ddl=>data_source-
>entity( 'XCO_TEST_ENTITY'
)->inner_join(
    io_data_source = xco_cp_ddl=>data_source-
>database_table( 'XCO_TEST_TABLE' )
    io_condition   = xco_cp_ddl=>field( 'FIELD' )->of_projection(
        )->eq( xco_cp_ddl=>field( 'FIELD' )->of( 'XCO_TEST_TABLE' )
    )
).

```

## Annotations Query APIs

The XCO CDS module may be used to conveniently retrieve the value of annotations that have been provided for CDS entities as well as their fields or parameters. As with the XCO JSON module it is possible to write the annotation value to an explicitly defined ABAP structure to enable further processing of the value:

### ↔ Sample Code

```

TYPES:
    BEGIN OF ts_title,
        type TYPE string,
        label TYPE string,
        value TYPE string,
    END OF ts_title,
    BEGIN OF ts_header_info,
        typename TYPE string,
        typenameplural TYPE string,
        title TYPE ts_title,
    END OF ts_header_info,
    BEGIN OF ts_ui,
        headerinfo TYPE ts_header_info,
    END OF ts_ui.
DATA ls_ui TYPE ts_ui.
" Direct annotations.
DATA(lo_view_entity) = xco_cp_cds=>view_entity( 'MY_VIEW_ENTITY' ).
xco_cp_cds=>annotations->direct->of( lo_view_entity
)->pick( 'UI'
)->get_value(
)->write_to( REF #( ls_ui ) ).

```

In the example above, the value of the "UI" annotation defined directly on the provided CDS view entity is read and written to the specifically defined ABAP structure. Parts of the annotation value not specified in the ABAP structure will be ignored.

Annotations for CDS entities are aggregated at runtime from different sources. With the XCO annotation Query APIs it is easy to specify which source should be considered when annotations are retrieved, e.g. it is possible to consider only annotations defined in metadata extensions:

#### Sample Code

```
DATA(lo_view_entity_field) = xco_cp_cds=>view_entity( 'MY_VIEW_ENTITY'
  )->field( 'MY_FIELD' ).
DATA(lv_ui_annotation_contained) = xco_cp_cds=>annotations-
>metadata_extension->of( lo_view_entity_field
  )->contain( 'UI' ).
```

The following annotation sources are available via XCO\_CP\_CDS=>ANNOTATIONS:

- Aggregated: The aggregation of all the different sources according to the preference rules reflecting the value that will be present at runtime
- Derived: Annotations that are derived from data elements
- Direct: Annotations that are defined directly in the source for the given CDS entity
- Inherited: Annotations that are inherited from a CDS entity that the given CDS entity is based on
- Metadata extension: Annotations that are defined in a metadata extension that extends the given CDS entity

## 4.2.12.16.3.7 Correction and Transport System

The XCO CTS module provides APIs which support the creation and release of Workbench and Customizing transports and integrates seamlessly into the XCO ABAP Repository module to support locating objects contained on transports.

Creation and releasing transport requests programmatically is especially useful in combination with the XCO Generation APIs to build completely self-contained generation programs.

### Creating and releasing Workbench transport requests

A prerequisite for creating a new Workbench transport is a valid transport target which is usually derived from the structural package for which objects are supposed to be created, changed or deleted in a corresponding development subpackage.

Using the XCO ABAP Repository APIs the transport layer and transport target associated with a given structure package can be determined easily:

#### Sample Code

```
DATA(ls_package) = xco_cp_abap_repository=>package-
>for( 'ZMY_STRUCTURE_PACKAGE'
  )->read( ).
DATA(lv_transport_layer) = ls_package-property-transport_layer->value.
DATA(lv_transport_target) = ls_package-property-transport_layer-
>get_transport_target( )->value.
```

Once the correct transport target has been determined a new transport request can be created like this:

#### Sample Code

```
DATA(lo_transport_request) = xco_cp_cts=>transports-  
>workbench( lv_transport_target  
  )->create_request( 'My generated Workbench transport request' ).
```

This statement will create a new workbench transport request with one unclassified task in the name of the active user. Once all required changes have been recorded on the tasks of the transport request releasing the transport request along with all open tasks is performed as follows:

#### Sample Code

```
DATA(lt_transport_tasks) = lo_transport_request->get_tasks( ).  
LOOP AT lt_transport_tasks INTO DATA(lo_transport_task).  
  CHECK lo_transport_task->get_status( ) EQ xco_cp_transport=>status-  
>modifiable.  
  lo_transport_task->release( ).  
ENDLOOP.  
lo_transport_request->release( ).
```

When releasing a transport, it's also possible to specify dedicated release options that should be considered when the transport is released. Transport release options are accessible via `XCO_CP_TRANSPORT=>RELEASE_OPTION` and as of now, the following transport release options are offered:

- `IGNORE_OBJECTS_CHECK`: If non-critical issues are detected with objects contained on the transport (such as issues due to ATC violations), this option allows you to ignore these issues and release the transport anyways. Setting this option has an effect equivalent to explicitly confirming the release of the transport when an interactive tool, such as the ADT Transport Organizer, is used to release the transport.

Releasing a transport request with the ignore objects check option can be done like this:

#### Sample Code

```
DATA(lo_ignore_objects_check_option) = xco_cp_transport=>release_option-  
>ignore_objects_check( ).  
lo_transport_request->release( VALUE  
  #( ( lo_ignore_objects_check_option ) ) ).
```

Besides being able to easily release transport tasks and requests, it is also possible to protect and unprotect transport requests:

#### Sample Code

```
" Protect a transport request.  
lo_transport_request->protect( ).  
" Unprotect a transport request.  
lo_transport_request->unprotect( ).
```

## Creating Customizing transport requests

A Customizing transport request for a given transport target can be created as follows:

### Sample Code

```
DATA(lo_transport_request) = xco_cp_cts=>transports-  
>customizing( '$TRANSPORT_TARGET$'  
  )->create_request( 'My generated Customizing transport request' ).
```

Once created, a Customizing transport request can be further used in the context of Business Configuration, e.g. the *Export Customizing Transports* Fiori app.

## Querying and reading transports

Within the XCO Library, a transport (IF\_XCO\_CP\_TRANSPORT) represents either a transport request or a task of a transport request. One of the characteristic properties of a transport is that it always has an associated request which is either the transport itself in case it already represents a transport request or otherwise the transport request of the task represented by the transport.

In a style similar to the ABAP Repository Query APIs it is possible to efficiently obtain a list of transports matching user-defined filters. Filters are obtained via the XCO\_CP\_TRANSPORT=>FILTER API and currently cover the following aspects of transports:

- Kind (Request or Task)
- Owner
- Request
- Target of the request
- Type of the request
- Status
- Type
- Attributes

Specific to the CTS transport Query APIs is the concept of a resolution that is applied to a transport query. A resolution defines a mapping of the matched transports to the final list of transports. Currently, the following resolutions are offered:

- Request: Map each matched transport to its associated request
- Identity: Map each matched transport to itself

As a first example, obtaining a list of transport requests for a given target on which the current user has at least one modifiable task can be accomplished like:

### Sample Code

```
DATA(lo_current_user) = xco_cp=>sy->user( ).  
DATA(lo_kind_filter) = xco_cp_transport=>filter->kind( xco_cp_transport=>kind-  
>task ).  
DATA(lo_owner_filter) = xco_cp_transport=>filter-  
>owner( xco_cp_abap_sql=>constraint->equal( lo_current_user->name ) ).
```

```

DATA(lo_request_target_filter) = xco_cp_transport=>filter-
>request_target( xco_cp_abap_sql=>constraint->equal( 'ZX11' ) ).
DATA(lo_status_filter) = xco_cp_transport=>filter-
>status( xco_cp_transport=>status->modifiable ).
DATA(lt_transports) = xco_cp_cts=>transports->where( VALUE #(
  ( lo_kind_filter )
  ( lo_owner_filter )
  ( lo_request_target_filter )
  ( lo_status_filter )
) )->resolve( xco_cp_transport=>resolution->request ).
LOOP AT lt_transports INTO DATA(lo_transport).
  DATA(lo_transport_request) = lo_transport->get_request( ).
  " LO_TRANSPORT is of type IF_XCO_CP_TRANSPORT. Based on the applied
  resolution
  " it is guaranteed that every LO_TRANSPORT object already represents a
  request.
ENDLOOP.

```

As a second example, obtaining a list of all transport requests which are both released and have the attribute SAP\_CUS\_TRANSPORT\_CATEGORY with the value DEFAULT\_CUS can be accomplished like:

#### Sample Code

```

DATA(lo_attribute_filter) = xco_cp_transport=>filter->attribute(
  io_name_constraint = xco_cp_abap_sql=>constraint-
>equal( 'SAP_CUS_TRANSPORT_CATEGORY' )
  io_value_constraint = xco_cp_abap_sql=>constraint->equal( 'DEFAULT_CUS' )
).
DATA(lo_status_filter) = xco_cp_transport=>filter-
>status( xco_cp_transport=>status->released ).
DATA(lt_transport_requests) = xco_cp_cts=>transports->where( VALUE #(
  ( lo_attribute_filter )
  ( lo_status_filter )
) )->resolve( xco_cp_transport=>resolution->identity ).
LOOP AT lt_transport_requests INTO DATA(lo_transport_request).
  " LV_TRANSPORT_REQUEST will be a transport request which is both in status
  "Released"
  " and has attribute SAP_CUS_TRANSPORT_CATEGORY set to value DEFAULT_CUS.
  DATA(lv_transport_request) = lo_transport_request->value.
ENDLOOP.

```

## Integration with the ABAP Repository APIs

The XCO CTS module integrates directly into the XCO ABAP Repository module which allows to take advantage of the powerful filtering mechanisms provided by the XCO ABAP Repository module. To this extent, the type IF\_XCO\_CP\_TRANSPORT implements the IF\_XCO\_AR\_OBJECT\_SOURCE interface.

With this integration, locating all domains on a given transport is as easy as

#### Sample Code

```

DATA(lo_transport) = xco_cp_cts=>transport->for( '...' ).
DATA(lt_domains) = xco_cp_abap_repository=>objects->doma-
>all-
>in( lo_transport )->get( ).

```

All filters that can be applied when objects are being queried in a package or the whole ABAP Repository can also be applied when a transport is used as the object source.

Conversely, it is also possible to check if a given ABAP Repository object is currently locked on a transport request:

#### Sample Code

```
DATA(lo_domain) = xco_cp_abap_repository=>object->doma->for( 'ZMY_DOMAIN' ).
IF lo_domain->if_xco_cts_changeable~get_object( )->is_locked( ) EQ abap_true.
  DATA(lv_transport) = lo_domain->if_xco_cts_changeable~get_object(
    )->get_lock(
    )->get_transport( ).
  " LO_TRANSPORT_REQUEST will be the transport request that ZMY_DOMAIN is
  " currently locked on (if it is locked at all).
  DATA(lo_transport_request) = xco_cp_cts=>transport->for( lv_transport
    )->get_request( ).
ENDIF.
```

## 4.2.12.16.3.7.1 Transport Read APIs

### Reading properties of a transport

Given a transport request (represented as an object of type `IF_XCO_CP_TR_REQUEST`), its properties can be read out as follows:

#### Sample Code

```
DATA(ls_properties) = lo_transport_request->properties( )->get( ).

" LS_PROPERTIES is a structure providing the short description, owner, target,
" status and last changed moment of the transport request.
```

The properties of a transport task (represented as an object of type `IF_XCO_CP_TR_TASK`) can similarly be read out like this:

#### Sample Code

```
DATA(ls_properties) = lo_transport_task->properties( )->get( ).

" LS_PROPERTIES is a structure providing the short description, owner,
" status and last changed moment of the transport task.
```

Properties of both transport requests and transport tasks can also be retrieved individually by using one of the specialized `GET_` methods, e.g. `GET_SHORT_DESCRIPTION`, instead of the general `GET` method which retrieves all available properties.

## Reading attributes of a transport request

Given a transport request (represented as an object of the type `IF_XCO_CP_TR_REQUEST`), its attributes can be read out as follows:

### Sample Code

```
DATA(lt_attributes) = lo_transport_request->attributes->all->get( ).
LOOP AT lt_attributes INTO DATA(lo_attribute).
  " The name of the attribute (as a CHAR of length 30).
  DATA(lv_name) = lo_attribute->get_attribute( )->name.
  " The value of the attribute (as a CHAR of length 32).
  DATA(lv_value) = lo_attribute->get_value( ).
ENDLOOP.
```

## Reading entries of a transport

A transport can contain two kinds of entries:

- Object entries: An object entry of a transport is identified by its values for Program ID (R3TR, LIMU or LANG), its object type and object name
- Key entries: A key entry of a transport identifies one or several rows in a database table that are to be transported once the transport is released. A key entry always has a corresponding object entry on the same transport

Both object and key entries of a transport can easily be retrieved via the XCO transport module. The starting point for retrieving entries of a transport is `XCO_CP_TRANSPORT->ENTRIES`.

### Reading object entries

The following code sample shows how to read all object entries contained on a given transport:

### Sample Code

```
" Get all object entries on a transport (given as an object LO_TRANSPORT of
type IF_XCO_CP_TRANSPORT).
DATA(lt_object_entries) = xco_cp_transport=>entries->object->all-
>on( lo_transport )->get( ).

LOOP AT lt_object_entries INTO DATA(lo_object_entry).
  " The Program ID of the object entry represented as an XCO enumeration
  constant
  " of type CL_XCO_CTS_PROGRAM_ID. The primitive value for the program ID can
  be
  " obtained via LO_PROGRAM_ID->VALUE.
  DATA(lo_program_id) = lo_object_entry->object->program_id.

  " The object type of the object entry (e.g. DOMA for a domain of the ABAP
  Dictionary).
  DATA(lv_object_type) = lo_object_entry->object->type.

  " The object name of the object entry (e.g. the name of the domain if the
  object entry
  " refers to a domain of the ABAP Dictionary).
  DATA(lv_object_name) = lo_object_entry->object->name.
```

```
ENDLOOP.
```

In addition to retrieving all objects it is furthermore possible to provide one or more entry filters to restrict the object entries to those matching the provided entry filters:

### Sample Code

```
" The program ID filter will only match object entries where the program ID
is LIMU.
DATA(lo_program_id_filter) = xco_cp_transport=>entry_filter->object-
>program_id(
  xco_cp_cts=>program_id->limu
).

" The object type filter will only match object entries where the object type
is FUNC.
DATA(lo_object_type_filter) = xco_cp_transport=>entry_filter->object-
>object_type(
  xco_cp_abap_sql=>constraint->equal( 'FUNC' )
).

" The object name filter will only match object entries where the object name
starts with Z.
DATA(lo_object_name_filter) = xco_cp_transport=>entry_filter->object-
>object_name(
  xco_cp_abap_sql=>constraint->contains_pattern( 'Z%' )
).

" LT_OBJECT_ENTRIES will contain all LIMU FUNC object entries on LO_TRANSPORT
where the object name starts with Z
" (where LO_TRANSPORT is an object of type IF_XCO_CP_TRANSPORT).
DATA(lt_object_entries) = xco_cp_transport=>entries->object->where( VALUE #(
  ( lo_program_id_filter )
  ( lo_object_type_filter )
  ( lo_object_name_filter )
) )->on( lo_transport )->get( ).
```

### Reading key entries

Reading key entries on a transport works in a similar manner as when object entries are being read. Obtaining all key entries on a given transport can be accomplished like this:

### Sample Code

```
" Get all key entries on a transport (given as an object LO_TRANSPORT of type
IF_XCO_CP_TRANSPORT).
DATA(lt_key_entries) = xco_cp_transport=>entries->key->all-
>on( lo_transport )->get( ).

LOOP AT lt_key_entries INTO DATA(lo_key_entry).
  " Get the object entry to which this key entry belongs.
  DATA(lo_object_entry) = lo_key_entry->get_object_entry( ).

  " Get the table key for the entry which can be used to subsequently retrieve
  " the column values used to select the database table entries that shall be
  " transported.
  DATA(lo_table_key) = lo_key_entry->get_table_key( ).

  DATA(lt_table_key_components) = lo_table_key->get_components( ).

  LOOP AT lt_table_key_components INTO DATA(lo_table_key_component).
    " The name of the field in the underlying database table.
    DATA(lv_field_name) = lo_table_key_component->field_name.
```

```

" The value which is used for this field. The WRITE_TO method of
" LO_VALUE can be used to write the value for the field to an actual
" data object.
DATA(lo_value) = lo_table_key_component->get_value( ).

" The type of the value depends on the type of the field in the database
table.
" In the case where it is of type C of length 10, the actual value can be
" obtained like this:
DATA lv_value TYPE c LENGTH 10.

lo_value->write_to( REF #( lv_value ) ).
ENDLOOP.
ENDLOOP.

```

An R3TR TABU object entry always has exactly one corresponding key entry. Thanks to a direct integration of R3TR TABUs with the entry query APIs, all key entries coming from R3TR TABU object entries can be conveniently retrieved as follows:

#### Sample Code

```

" Get all R3TR TABU entries on a transport (given as an object LO_TRANSPORT
of type IF_XCO_CP_TRANSPORT).
DATA(lt_r3tr_tabu_entries) = xco_cp_transport=>entries->object->r3tr->tabu-
>all->on( lo_transport )->get( ).

LOOP AT lt_r3tr_tabu_entries INTO DATA(lo_r3tr_tabu_entry).
" The key entry corresponding to this R3TR TABU object entry.
DATA(lo_key_entry) = lo_r3tr_tabu_entry->get_key_entry( ).
ENDLOOP.

```

## 4.2.12.16.3.8 Object Type References

### 4.2.12.16.3.8.1 CDS Type Definitions

Find out how to create CDS type definitions.

CDS type definitions, meaning objects of type DRTY, are supported by the following API families within the XCO library:

- Query APIs
- Read APIs
- Generation APIs

## Query APIs

Obtaining an object handle for a CDS type definition with a given name can be accomplished via

### Sample Code

```
DATA(lo_cds_type_definition) = xco_cp_abap_repository=>object->drty->for( '$CDS_TYPE_DEFINITION_NAME$' ).
```

The obtained object handle can then be used to, for example, check the existence of the CDS type definition in the ABAP repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible CDS type definitions in the ABAP repository can be done via

### Sample Code

```
DATA(lt_cds_type_definitions) = xco_cp_abap_repository=>objects->drty->all->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_cds_type_definitions ASSIGNING FIELD-
SYMBOL(<fs_cds_type_definition>).
  " Process the found CDS type definition.
ENDLOOP.
```

Instead of searching for CDS type definitions in the entire ABAP repository, it's also possible to only search for CDS type definitions in a dedicated subset of the ABAP repository, such as in a single package:

### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_cds_type_definitions) = xco_cp_abap_repository=>objects->drty->all->in( lo_package )->get( ).

LOOP AT lt_cds_type_definitions ASSIGNING FIELD-
SYMBOL(<fs_cds_type_definition>).
  " Process the found CDS type definition.
ENDLOOP.
```

Furthermore, you can refine a search for CDS type definitions by using filters to specify exactly which CDS type definitions should be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_CDS_TYPE_DEFINITIONS will be a list of all visible CDS type definitions
" in the ABAP Repository whose name starts with /ABC/.
DATA(lt_cds_type_definitions) = xco_cp_abap_repository=>objects->drty->where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_cds_type_definitions ASSIGNING FIELD-
SYMBOL(<fs_cds_type_definition>).
  " Process the found CDS type definition.
```

```
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of a CDS type definition is possible via its object handle `IF_XCO_CDS_TYPE_DEFINITION`. The Read APIs for CDS type definitions are based on the origin infrastructure with the following origins being offered currently for CDS type definitions:

- **DEFAULT:** Can be obtained via `XCO_CP_CDS_TYPE_DEFINITION=>ORIGIN->DEFAULT` and will read a given CDS type definition exactly once per ABAP session from the local system, with all subsequent reads of the CDS type definition being fulfilled from a dedicated buffer. This origin is used by default, meaning if no origin is explicitly specified when reading the content or checking the existence of a CDS type definition.
- **LOCAL:** Can be obtained via `XCO_CP_CDS_TYPE_DEFINITION=>ORIGIN->LOCAL` and will read a given CDS type definition from the local system. By default, every read of the content as well as existence checks of a CDS type definition will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_DRTY_CACHEABLE_ORIGIN`.

Next, when reading a CDS type definition or checking its existence, it can explicitly be specified which version of the CDS type definition should be considered. The following versions are supported:

- **ACTIVE:** Can be obtained via `XCO_CP_CDS_TYPE_DEFINITION=>VERSION->ACTIVE`. The active version is used by default, meaning if no version is explicitly specified when reading the content of a CDS type definition or checking its existence.
- **INACTIVE:** Can be obtained via `XCO_CP_CDS_TYPE_DEFINITION=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of a CDS type definition can be read out separately:

### Header

Reading out the header of a CDS type definition can be done like this:

#### Sample Code

```
DATA(lo_cds_type_definition) = xco_cp_abap_repository=>object->drty-
>for( '$CDS_TYPE_DEFINITION_NAME$' ).

" Read out the complete header of the active version of the CDS type
" definition using the default origin:
DATA(ls_header) = lo_cds_type_definition->content( )->get( ).

" Read out only the short description of the inactive version of the CDS
" type definition using an explicitly obtained local origin (without
" caching).
DATA(lo_local_origin) = xco_cp_cds_type_definition=>origin->local( ).

DATA(lv_short_description) = lo_cds_type_definition-
>content( xco_cp_cds_type_definition=>version->inactive
)->get_short_description( lo_local_origin ).
```

## Generation APIs

CDS type definitions are integrated with the XCO Generation APIs with the following operations being offered currently for CDS type definitions:

- **PUT:** Create or update a CDS type definition based on an entire content specification so that after running the operation successfully, the CDS type definition exists and its content is exactly as specified
- **DELETE:** Delete a CDS type definition (if it exists)

### PUT Operations

A form specification is used to specify the entire content of a CDS type definition, which is the basis for running a PUT operation. Upon running the PUT operation, depending on whether the CDS type definition already exists or not, it will either be newly created, or updated. This is so that after the successful completion of the PUT operation, the CDS type definition exists with the content resembling exactly what was specified in the provided form specification. Consider the following code sample which illustrates how to run a PUT operation for a CDS type definition:

#### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-drty-
>add_object( '$CDS_TYPE_DEFINITION_NAME$'
  )->set_package( '$PACKAGE_NAME$'
  )->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description' ).

DATA(lo_simple_type_definition) = lo_form_specification-
>add_simple_type_definition( ).
lo_simple_type_definition->add_annotation( 'EndUserText.label'
  )->value->build(
  )->add_string( 'My simple type definition' ).
lo_simple_type_definition->set_type( xco_cp_abap_dictionary=>built_in_type-
>char( 30 ) ).

lo_put_operation->execute( ).
```

### DELETE Operations

CDS type definitions can be deleted via DELETE operations. As per the standard semantics of DELETE operations, if the CDS type definition for which a DELETE operation is being run doesn't exist, no action will be performed (and no error will be raised). If the CDS type definition does exist, it will be deleted. The code sample below illustrates how to run a DELETE operation for a CDS type definition:

#### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->for-drty->create_delete_operation( ).

lo_delete_operation->add_object( '$CDS_TYPE_DEFINITION_NAME$' ).

lo_delete_operation->execute( ).
```

## 4.2.12.16.3.8.2 Data Definitions

Find out how to create data definitions.

Data definitions, also called objects of type DDLs, are supported by the following API families within the *XCO Library*:

- Query APIs
- Read APIs
- Generation APIs

In addition to the standard API families listed above, dedicated APIs are offered for the following aspects:

- Setting and getting the API state of a CDS entity

### Query APIs

Obtaining an object handle for a data definition with a given name can be accomplished via

#### Sample Code

```
DATA(lo_data_definition) = xco_cp_abap_repository=>object->ddls->for( '$DATA_DEFINITION_NAME$' ).
```

The obtained object handle can then be used to check the existence of the data definition in the ABAP Repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible data definitions in the ABAP Repository can simply be accomplished via

#### Sample Code

```
DATA(lt_data_definitions) = xco_cp_abap_repository=>objects->ddls->all->in( xco_cp_abap=>repository )->get( ).  
  
LOOP AT lt_data_definitions ASSIGNING FIELD-SYMBOL(<fs_data_definition>).  
  " Process the found data definition.  
ENDLOOP.
```

Instead of searching for data definitions in the entire ABAP Repository, it's also possible to only search for data definitions in a dedicated subset of the ABAP Repository, such as a single package:

#### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).  
  
DATA(lt_data_definitions) = xco_cp_abap_repository=>objects->ddls->all->in( lo_package )->get( ).  
  
LOOP AT lt_data_definitions ASSIGNING FIELD-SYMBOL(<fs_data_definition>).  
  " Process the found data definition.  
ENDLOOP.
```

Another way to refine a search for data definitions is to use filters to specify exactly which data definitions shall be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_DATA_DEFINITIONS will be a list of all visible data definitions in the
ABAP
" Repository whose name starts with /ABC/.
DATA(lt_data_definitions) = xco_cp_abap_repository=>objects->ddls-
>where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_data_definitions ASSIGNING FIELD-SYMBOL(<fs_data_definition>).
  " Process the found data definition.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of a data definition is possible via its object handle `IF_XCO_DATA_DEFINITION`, respectively the corresponding interfaces for each supported data definition type:

- View entity: `IF_XCO_CDS_VIEW_ENTITY`
- Project view: `IF_XCO_CDS_PROJECTION_VIEW`
- Abstract entity: `IF_XCO_CDS_ABSTRACT_ENTITY`
- Custom entity: `IF_XCO_CDS_CUSTOM_ENTITY`
- Table function: `IF_XCO_CDS_TABLE_FUNCTION`

When reading the content of a CDS entity, the read state for which the content shall be read can explicitly be specified. The following read states are supported:

- **ACTIVE**: Can be obtained via `XCO_CP_DATA_DEFINITION=>OBJECT_READ_STATE->ACTIVE`. The active read state is used by default, so if no read state is explicitly specified when reading the content of a data definition or checking its existence
- **LATEST**: Can be obtained via `XCO_CP_DATA_DEFINITION=>OBJECT_READ_STATE->LATEST`

Following the general style of the XCO Read APIs, each part of a CDS entity can be read out separately:

### View Entities

The following code sample illustrates how the (structured) content of a view entity can be read out:

### Sample Code

```
DATA(lo_view_entity) = xco_cp_cds=>view_entity( '$VIEW_ENTITY_NAME$' ).

" The (structured) header content.
DATA(ls_header) = lo_view_entity->content( )->get( ).

" Read out the parameters of the view entity.
```

```

DATA(lt_parameters) = lo_view_entity->parameters->all->get( ).

LOOP AT lt_parameters ASSIGNING FIELD-SYMBOL(<fs_parameter>).
  " The (structured) content of the parameter.
  DATA(ls_parameter) = <fs_parameter>->content( )->get( ).
ENDLOOP.

" Read out the associations of the view entity.
DATA(lt_associations) = lo_view_entity->associations->all->get( ).

LOOP AT lt_associations ASSIGNING FIELD-SYMBOL(<fs_association>).
  " The (structured) content of the association.
  DATA(ls_association) = <fs_association>->content( )->get( ).
ENDLOOP.

" Read out the compositions of the view entity.
DATA(lt_compositions) = lo_view_entity->compositions->all->get( ).

LOOP AT lt_compositions ASSIGNING FIELD-SYMBOL(<fs_composition>).
  " The (structured) content of the composition.
  DATA(ls_composition) = <fs_composition>->content( )->get( ).
ENDLOOP.

" Read out the fields of the view entity.
DATA(lt_fields) = lo_view_entity->fields->all->get( ).

LOOP AT lt_fields ASSIGNING FIELD-SYMBOL(<fs_field>).
  " The (structured) content of the field.
  DATA(ls_field) = <fs_field>->content( )->get( ).
ENDLOOP.

```

## Projection Views

The following code sample illustrates how the (structured) content of a projection view can be read out:

### ↔ Sample Code

```

DATA(lo_projection_view) =
xco_cp_cds=>projection_view( '$PROJECTION_VIEW_NAME$' ).

" The (structured) header content.
DATA(ls_header) = lo_projection_view->content( )->get( ).

" Read out the fields of the projection view.
DATA(lt_fields) = lo_projection_view->fields->all->get( ).

LOOP AT lt_fields ASSIGNING FIELD-SYMBOL(<fs_field>).
  " The (structured) content of the field.
  DATA(ls_field) = <fs_field>->content( )->get( ).
ENDLOOP.

```

## Abstract Entities

The following code sample illustrates how the (structured) content of an abstract entity can be read out:

### ↔ Sample Code

```

DATA(lo_abstract_entity) =
xco_cp_cds=>abstract_entity( '$ABSTRACT_ENTITY_NAME$' ).

" The (structured) header content.
DATA(ls_header) = lo_abstract_entity->content( )->get( ).

```

```

" Read out the parameters of the abstract entity.
DATA(lt_parameters) = lo_abstract_entity->parameters->all->get( ).

LOOP AT lt_parameters ASSIGNING FIELD-SYMBOL(<fs_parameter>).
  " The (structured) content of the parameter.
  DATA(ls_parameter) = <fs_parameter>->content( )->get( ).
ENDLOOP.

" Read out the fields of the abstract entity.
DATA(lt_fields) = lo_abstract_entity->fields->all->get( ).

LOOP AT lt_fields ASSIGNING FIELD-SYMBOL(<fs_field>).
  " The (structured) content of the field.
  DATA(ls_field) = <fs_field>->content( )->get( ).
ENDLOOP.

```

## Custom Entities

The following code sample illustrates how the (structured) content of a custom entity can be read out:

### Sample Code

```

DATA(lo_custom_entity) = xco_cp_cds=>custom_entity( '$CUSTOM_ENTITY_NAME$' ).

" The (structured) header content.
DATA(ls_header) = lo_custom_entity->content( )->get( ).

" Read out the parameters of the custom entity.
DATA(lt_parameters) = lo_custom_entity->parameters->all->get( ).

LOOP AT lt_parameters ASSIGNING FIELD-SYMBOL(<fs_parameter>).
  " The (structured) content of the parameter.
  DATA(ls_parameter) = <fs_parameter>->content( )->get( ).
ENDLOOP.

" Read out the fields of the custom entity.
DATA(lt_fields) = lo_custom_entity->fields->all->get( ).

LOOP AT lt_fields ASSIGNING FIELD-SYMBOL(<fs_field>).
  " The (structured) content of the field.
  DATA(ls_field) = <fs_field>->content( )->get( ).
ENDLOOP.

```

## Table Functions

The following code sample illustrates how the (structured) content of a table function can be read out:

### Sample Code

```

DATA(lo_table_function) =
xco_cp_cds=>table_function( '$TABLE_FUNCTION_NAME$' ).

" The (structured) header content.
DATA(ls_header) = lo_table_function->content( )->get( ).

" Read out the parameters of the table_function.
DATA(lt_parameters) = lo_table_function->parameters->all->get( ).

LOOP AT lt_parameters ASSIGNING FIELD-SYMBOL(<fs_parameter>).
  " The (structured) content of the parameter.
  DATA(ls_parameter) = <fs_parameter>->content( )->get( ).
ENDLOOP.

```

```

" Read out the fields of the table function.
DATA(lt_fields) = lo_table_function->fields->all->get( ).

LOOP AT lt_fields ASSIGNING FIELD-SYMBOL(<fs_field>).
  " The (structured) content of the field.
  DATA(ls_field) = <fs_field>->content( )->get( ).
ENDLOOP.

```

## Generation APIs

Data definitions are integrated with XCO Generation APIs. The following operations are currently offered:

- **PUT**: Create or update a data definition based on a complete specification of its content, so that after the successful execution of the operation, the data definition exists and its content is exactly as specified. Both form specifications as well as source templates can be used to provide a complete content specification
- **DELETE**: Delete a data definition (if it exists)

### PUT Operations

Upon running the `PUT` operation, depending on whether the data definition already exists or not, it will either be newly created or updated. This is done so that after the successful completion of the `PUT` operation, the data definition exists with the content resembling exactly what was specified in the provided content specification. In addition to the traditional form specification, data definitions also support the usage of source templates to specify the source for the data definition directly.

#### Note

Note that the data definition examples given below are intended exclusively to illustrate how the respective facilities of the XCO Generation APIs can be used to programmatically create (or update) data definitions. The examples are chosen in a way that syntactically error-free data definitions are generated and are not meant to be real-world modelling examples. In particular, note that certain examples, such as those for projection views, might not correlate with general best modelling practices.

### View Entity Form Specification

The content of a view entity can be specified via a form specification. The following code sample illustrates how a simple view entity (based on `I_Language` for the purposes of this example) can be generated:

#### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment->
dev_system( '$TRANSPORT_REQUEST$' )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ddls->
add_object( '$VIEW_ENTITY_NAME$' )->set_package( '$PACKAGE_NAME$' )->
create_form_specification( ).
lo_form_specification->set_short_description( 'Generated view entity' ).

DATA(lo_view_entity) = lo_form_specification->add_view_entity( ).
lo_view_entity->add_annotation( 'EndUserText.label' )->value->build( )->
add_string( |My view entity| ).
lo_view_entity->set_root( ).
lo_view_entity->data_source->set_view_entity( 'I_Language' ).

```

```

DATA(lo_parameter) = lo_view_entity->add_parameter( 'myParameter' ).
lo_parameter->set_data_type( xco_cp_abap_dictionary=>built_in_type->
char( 10 ) ).
lo_parameter->add_annotation( 'EndUserText.label' )->value->build( )->
add_string( |My parameter| ).

DATA(lo_field) = lo_view_entity->add_field( xco_cp_ddl=>field( 'Language' )
)->set_key(
)->set_alias( 'myKeyField' ).
lo_field->add_annotation( 'EndUserText.label' )->value->build( )->
add_string( |My key field| ).

lo_put_operation->execute( ).

```

After successfully running the above PUT operation, a view entity with the name `VIEW_ENTITY_NAME` will exist in an active version with the following (source) content:

### Sample Code

```

@EndUserText.label: 'My view entity'
define root view entity VIEW_ENTITY_NAME
  with parameters
    @EndUserText.label: 'My parameter'
    myParameter : abap.char( 10 )
  as select from I_Language
  {
    @EndUserText.label: 'My key field'
    key Language as myKeyField
  }
}

```

### Projection View Form Specification

The content of a projection view can be specified via a form specification. The following code sample illustrates how a simple projection view (based on `I_Language` and modelled as an analytical query for the purposes of this example) can be generated:

### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment->
dev_system( '$TRANSPORT_REQUEST' )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ddls->
add_object( '$PROJECTION_VIEW_NAME' )->set_package( '$PACKAGE_NAME' )->
create_form_specification( ).
lo_form_specification->set_short_description( 'Generated projection view' ).

DATA(lo_projection_view) = lo_form_specification->add_projection_view( ).
lo_projection_view->add_annotation( 'EndUserText.label' )->value->build( )->
add_string( |My projection view| ).
lo_projection_view->add_annotation( 'AccessControl.authorizationCheck' )->
value->build( )->add_enum( 'NOT_ALLOWED' ).
lo_projection_view->set_transient( ).
lo_projection_view->set_provider_contract( xco_cp_cds=>provider_contract->
analytical_query ).
lo_projection_view->data_source->set_view_entity( 'I_Language' ).

DATA(lo_field) = lo_projection_view->
add_field( xco_cp_ddl=>field( 'Language' ) )->set_alias( 'myField' ).

```

```

lo_field->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My field| ).

lo_put_operation->execute( ).

```

After the successful execution of the above PUT operation, a projection view with the name \$PROJECTION\_VIEW\_NAME\$ will exist in active version with the following (source) content:

### Sample Code

```

@EndUserText.label: 'My projection view'
@AccessControl.authorizationCheck: #NOT_ALLOWED
define transient view entity $PROJECTION_VIEW_NAME$
  provider contract analytical_query
  as projection on I_Language
  {
    @EndUserText.label: 'My field'
    Language as myField
  }

```

### Abstract Entity Form Specification

The content of an abstract entity can be specified via a form specification. The following code sample illustrates how a simple abstract entity can be generated:

### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
)->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ddls-
>add_object( '$ABSTRACT_ENTITY_NAME$'
)->set_package( '$PACKAGE_NAME$'
)->create_form_specification( ).
lo_form_specification->set_short_description( 'Generated abstract entity' ).

DATA(lo_abstract_entity) = lo_form_specification->add_abstract_entity( ).
lo_abstract_entity->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My abstract entity| ).

DATA(lo_parameter) = lo_abstract_entity->add_parameter( 'MY_PARAMETER' ).
lo_parameter->set_data_type( xco_cp_abap_dictionary=>built_in_type-
>char( 10 ) ).
lo_parameter->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My parameter| ).

DATA(lo_field) = lo_abstract_entity-
>add_field( xco_cp_ddl=>field( 'MY_FIELD' ) ).
lo_field->set_type( xco_cp_abap_dictionary=>data_element( 'SPRAS' ) ).
lo_field->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My field| ).

lo_put_operation->execute( ).

```

After successfully running the above PUT operation, an abstract entity with the name \$ABSTRACT\_ENTITY\_NAME\$ will exist in an active version with the following (source) content:

## Sample Code

```
@EndUserText.label: 'My abstract entity'
define abstract entity $ABSTRACT_ENTITY_NAME$
  with parameters
    @EndUserText.label: 'My parameter'
    MY_PARAMETER : abap.char( 10 )
  {
    @EndUserText.label: 'My field'
    MY_FIELD : SPRAS;
  }
}
```

## Custom Entity Form Specification

The content of a custom entity can be specified via a form specification. The following code sample illustrates how a simple custom entity can be generated:

## Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ddls-
>add_object( '$CUSTOM_ENTITY_NAME$'
  )->set_package( '$PACKAGE_NAME$'
  )->create_form_specification( ).
lo_form_specification->set_short_description( 'Generated custom entity' ).

DATA(lo_custom_entity) = lo_form_specification->add_custom_entity( ).
lo_custom_entity->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My custom entity| ).

DATA(lo_parameter) = lo_custom_entity->add_parameter( 'myParameter' ).
lo_parameter->set_data_type( xco_cp_abap_dictionary=>built_in_type-
>char( 10 ) ).
lo_parameter->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My parameter| ).

DATA(lo_key_field) = lo_custom_entity-
>add_field( xco_cp_ddl=>field( 'myKeyField' ) ).
lo_key_field->set_key( ).
lo_key_field->set_type( xco_cp_abap_dictionary=>built_in_type->char( 10 ) ).
lo_key_field->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My key field| ).

DATA(lo_data_field) = lo_custom_entity-
>add_field( xco_cp_ddl=>field( 'myDataField' ) ).
lo_data_field->set_type( xco_cp_abap_dictionary=>data_element( 'MSEHI' ) ).
lo_data_field->add_annotation( 'EndUserText.label' )->value->build( )-
>add_string( |My data field| ).

lo_put_operation->execute( ).
```

After successful execution, a custom entity with the name \$CUSTOM\_ENTITY\_NAME\$ will exist in an active version with the following (source) content:

## Sample Code

```
@EndUserText.label: 'My abstract entity'
define custom entity $CUSTOM_ENTITY_NAME$
```

```

with parameters
  @EndUserText.label: 'My parameter'
  myParameter : abap.char( 10 )
{
  @EndUserText.label: 'My key field'
  key myKeyField : abap.char( 10 );
  @EndUserText.label: 'My data field'
  myDataField : MSEHI;
}

```

## Table Function Form Specification

The content of a table function can be specified via a form specification. The following code sample illustrates how a simple table function can be generated:

### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ddls-
>add_object( '$TABLE_FUNCTION_NAME$'
  )->set_package( '$PACKAGE_NAME$'
  )->create_form_specification( ).
lo_form_specification->set_short_description( 'Generated table function' ).

DATA(lo_table_function) = lo_form_specification->add_table_function( ).
lo_table_function->add_annotation( 'AccessControl.authorizationCheck'
  )->value->build(
  )->add_enum( 'NOT_REQUIRED' ).
lo_table_function->add_annotation( 'ClientHandling.type'
  )->value->set( xco_cp_cds_annotation=>value->enum( 'CLIENT_INDEPENDENT' ) ).

DATA(lo_parameter) = lo_table_function->add_parameter( 'p_identifier'
  )->set_data_type( xco_cp_abap_dictionary=>data_element( 'syuname' ) ).

DATA(lo_field) = lo_table_function-
>add_field( xco_cp_ddl=>field( 'val_identifier' ) ).
lo_field->set_type( xco_cp_abap_dictionary=>built_in_type->char( 30 ) ).

lo_field->add_annotation( 'EndUserText.label'
  )->value->set( xco_cp_cds_annotation=>value->string( 'Identifier field' ) )
##NO_TEXT.

lo_table_function->set_amdp_class( '$AMDP_CLASS_NAME$'
  )->set_amdp_method( '$AMDP_CLASS_METHOD$' ).

lo_put_operation->execute( ).

```

After successful execution, a table function with the name `$TABLE_FUNCTION_NAME$` will exist in an active version with the following (source) content:

### Sample Code

```

@AccessControl.authorizationCheck: #NOT_REQUIRED
@ClientHandling.type: #CLIENT_INDEPENDENT
define table function $TABLE_FUNCTION_NAME$
  with parameters
    p_identifier : syuname
  returns
  {

```

```

@EndUserText.label: 'Identifier field'
val_identifier : abap.char( 30 );
}
implemented by method
$AMDP_CLASS_NAME$=>$AMDP_METHOD_NAME$

```

## Source Templates

As an alternative to providing the content of a data definition via a form specification, it's possible to use a source template where the source of the data definition can be passed as a plain string. The following example illustrates how this can be used to generate a simple abstract entity by supplying its complete source directly:

### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
)->create_put_operation( ).

DATA(lo_source_template) = xco_cp_generation_ddls=>template->source( ).

DATA(lv_source) = xco_cp=>strings( VALUE #(
( `define abstract entity $ABSTRACT_ENTITY_NAME$` )
( `{` )
( ` // My field` )
( ` MY_FIELD : spras;` )
( `}` )
) )->join( |{ cl_abap_char_utilities=>cr_lf }| )->value.

lo_source_template->set_short_description( 'Generated abstract entity'
)->set_source( lv_source ).

lo_put_operation->for-ddls->add_object( '$ABSTRACT_ENTITY_NAME$'
)->set_package( '$PACKAGE_NAME$'
)->set_template( lo_source_template ).

lo_put_operation->execute( ).

```

Once the PUT operation has run successfully, an abstract entity with the name `$ABSTRACT_ENTITY_NAME$` will exist in an active version with the following (source) content:

### Sample Code

```

define abstract entity $ABSTRACT_ENTITY_NAME$
{
// My field
MY_FIELD : spras;
}

```

## DELETE Operations

Data definitions (regardless of the type of entity they define) can be deleted via `DDL$ DELETE` operations. As per the standard semantics of `DELETE` operations, if the data definition for which a `DELETE` operation is run doesn't exist, no action will be performed (and no error will be raised). If the data definition does exist, it will be deleted. The code sample below illustrates how to execute a `DELETE` operation for a data definition:

### Sample Code

```

DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'

```

```

)->for-ddls->create_delete_operation( ).
lo_delete_operation->add_object( '$DATA_DEFINITION_NAME$' ).
lo_delete_operation->execute( ).

```

## Setting and Getting the API State of a CDS Entity

A CDS entity defined by a data definition can be released via the API state mechanisms of the [API Release Framework](#) (ARS). The *XCO Library* allows to programmatically set and get the API state of a CDS entity (represented as `IF_XCO_CDS_ENTITY`). The following code sample illustrates how the API state of a given CDS entity can be read:

### Sample Code

```

DATA(lo_cds_entity) = xco_cp_cds=>entity( '$CDS_ENTITY_NAME$' ).

" Get the (current) API state of the CDS entity for the C1 release contract.
DATA(lo_api_state) = lo_cds_entity->
>get_api_state( xco_cp_ars=>release_contract->c1 ).

" The returned LO_API_STATE object allows to inspect the individual attributes
" of the API state.
DATA(lo_release_state) = lo_api_state->get_release_state( ).

" Release states supported by the XCO Library can be obtained via
XCO_CP_ARS=>RELEASE_STATE.
" Checking whether the API state of the CDS entity has the release state
"RELEASED"
" would look like this:
IF lo_release_state EQ xco_cp_ars=>release_state->released.
" ...
ENDIF.

DATA(lt_visibilities) = lo_api_state->get_visibilities( ).

" Visibilities supported by the XCO Library can be obtained via
XCO_CP_ARS=>VISIBILITY.
" Note that due to compatibility and historical reasons, the visibility
" CLOUD_DEVELOPMENT is called SAP_CLOUD_PLATFORM within the XCO Library.
Checking
" whether the visibilities of the API state include CLOUD_DEVELOPMENT would
" then look like this:
IF line_exists( lt_visibilities[ table_line = xco_cp_ars=>visibility->
>sap_cloud_platform ] ).
" ...
ENDIF.

```

Setting the API state for a CDS entity can be done like this:

### Sample Code

```

" The API state which shall be set for the CDS entity is built via
XCO_CP_ARS=>API_STATE:
DATA(lo_api_state) = xco_cp_ars=>api_state->released( VALUE
#( ( xco_cp_ars=>visibility->sap_cloud_platform ) ) ).

" Setting the API state for a CDS entity implies a change which must be
recorded

```

```

" on an appropriate transport.
DATA(lo_transport) = xco_cp_cts=>transport->for( '$TRANSPORT$' ).

" The API state is set via the handle for the CDS entity.
DATA(lo_cds_entity) = xco_cp_cds=>entity( '$CDS_ENTITY_NAME$' ).

" We set the previously built API State (Released for Cloud Development) using
" the C1-release contract for the CDS entity (recording the changes on the
" provided transport).
lo_cds_entity->set_api_state(
  io_release_contract = xco_cp_ars=>release_contract->c1
  io_change_scenario  = lo_transport
  io_api_state        = lo_api_state
).

```

## 4.2.12.16.3.8.3 Domains

Find out how to create domains.

Domains, meaning objects of type `DOMA`, are supported by the following API families within the XCO library:

- Query APIs
- Read APIs
- Generation APIs

In addition to the standard API families listed above, dedicated APIs are offered for the following aspects:

- Setting and getting the API state of a domain

## Query APIs

Obtaining an object handle for a domain with a given name can be accomplished via

### 🔗 Sample Code

```

DATA(lo_domain) = xco_cp_abap_repository=>object->doma-
>for( '$DOMAIN_NAME$' ).

```

The obtained object handle can then be used to, for example, check the existence of the domain in the ABAP repository (via method `IF_XCO_AR_OBJECT~EXISTS` or read out its content via the Read APIs (see below). Obtaining a list of all visible domains in the ABAP repository can be done via

### 🔗 Sample Code

```

DATA(lt_domains) = xco_cp_abap_repository=>objects->doma->all-
>in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_domains ASSIGNING FIELD-SYMBOL(<fs_domain>).
  " Process the found domain.
ENDLOOP.

```

Instead of searching for domains in the entire ABAP repository, it's also possible to only search for domains in a dedicated subset of the ABAP repository, such as in a single package:

### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_domains) = xco_cp_abap_repository=>objects->doma->all->in( lo_package )->get( ).

LOOP AT lt_domains ASSIGNING FIELD-SYMBOL(<fs_domain>).
  " Process the found domain.
ENDLOOP.
```

Furthermore, you can refine a search for domains by using filters to specify exactly which domains should be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_DOMAINS will be a list of all visible domains in the ABAP Repository
" whose name starts with /ABC/.
DATA(lt_domains) = xco_cp_abap_repository=>objects->doma->where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_domains ASSIGNING FIELD-SYMBOL(<fs_domain>).
  " Process the found domain.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of a domain is possible via its object handle `IF_XCO_DOMAIN`. The Read APIs for domains are based on the origin infrastructure with the following origins being offered currently for domains:

- **DEFAULT:** Can be obtained via `XCO_CP_DOMAIN=>ORIGIN->DEFAULT` and will read a given domain exactly once per ABAP session from the local system, with all subsequent reads of the domain being fulfilled from a dedicated buffer. This origin is used by default, meaning if no origin is explicitly specified when reading the content or checking the existence of a domain.
- **LOCAL:** Can be obtained via `XCO_CP_DOMAIN=>ORIGIN->LOCAL` and will read a given domain from the local system. By default, every read of the content as well as existence checks of a domain will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_DOMAIN_CACHEABLE_ORIGIN`.

Next, when reading a domain or checking its existence, it can explicitly be specified which read state of the domain should be considered. The following read states are supported:

- **ACTIVE VERSION:** Can be obtained via `XCO_CP_ABAP_TYPE_DICTIONARY=>OBJECT_READ_STATE->ACTIVE_VERSION`. The active version is

used by default, meaning if no read state is explicitly specified when reading the content of a domain or checking its existence.

- **NEWEST VERSION:** Can be obtained via  
XCO\_CP\_ABAP\_DICTIONARY=>OBJECT\_READ\_STATE->NEWEST\_VERSION.

Following the general style of the XCO Read APIs, each part of a domain can be read out separately:

## Header

Reading out the header of a domain can be done like this:

### Sample Code

```
DATA(lo_domain) = xco_cp_abap_repository=>object->doma-
>for( '$DOMAIN_NAME$' ).

" Read out the complete header of the active version of the domain using the
" default origin:
DATA(ls_header) = lo_domain->content( )->get( ).

" Read out only the short description of the newest version of the domain
" using an explicitly obtained local origin (without caching).
DATA(lo_local_origin) = xco_cp_domain=>origin->local( ).

DATA(lv_short_description) = lo_domain-
>content( xco_cp_abap_dictionary=>object_read_state->newest_version
)->get_short_description( lo_local_origin ).
```

## Fixed Values

Obtaining a list of the fixed values of a domain and reading out an individual fixed value can be done like this:

### Sample Code

```
DATA(lo_domain) = xco_cp_abap_repository=>object->doma-
>for( '$DOMAIN_NAME$' ).

" Get a list of all the fixed values of the active version of the domain
" using the default origin:
DATA(lt_fixed_values) = lo_domain->fixed_values->all->get( ).

LOOP AT lt_fixed_values ASSIGNING FIELD-SYMBOL(<fs_fixed_value>).
  " Process the fixed value.
ENDLOOP.

" Obtain the handle for an individual fixed value.
DATA(lo_fixed_value) = lo_domain->fixed_value( 'A' ).

" Read out the complete content of the active version of the fixed value
" using the default origin.
DATA(ls_fixed_value) = lo_fixed_value->content( )->get( ).

" Read out only the description of the newest version of the fixed value
" using an explicitly obtained local origin with caching enabled.
DATA(lo_local_origin) = xco_cp_domain=>origin->local( ).
lo_local_origin->if_xco_domain_cacheable_origin~enable_caching( ).

DATA(lv_description) = lo_fixed_value-
>content( xco_cp_abap_dictionary=>object_read_state->newest_version
)->get_description( lo_local_origin ).
```

## Generation APIs

Domains are integrated with the XCO Generation APIs with the following operations being offered:

- **PUT:** Create or update a domain based on an entire content specification so that after running the operation successfully, the domain exists and its content is exactly as specified
- **PATCH:** Change an existing domain by applying the changes which have been provided in a change specification
- **DELETE:** Delete a domain (if it exists)

### PUT Operations

Upon running a PUT operation, depending on whether the domain already exists or not, it will either be newly created or updated. This is so that after the successful completion of the PUT operation, the domain exists with the content resembling exactly what was specified in the provided content specification. In addition to the traditional form specification, domains also support the use of object templates to use the content of an existing domain as the content for the domain of the PUT operation.

#### Form specification

Consider the following code sample which illustrates how to run a PUT operation for a domain using a form specification:

#### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
) ->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-doma-
>add_object( '$DOMAIN_NAME$'
) ->set_package( '$PACKAGE_NAME$'
) ->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description'
) ->set_format( xco_cp_abap_dictionary=>built_in_type->numc( 2 ) ).

DATA(lo_fixed_value_01) = lo_form_specification->fixed_values-
>add_fixed_value( '01' ).
lo_fixed_value_01->set_description( 'January' ).

lo_put_operation->execute( ).
```

#### Object template

An object template can be used to effectively copy an already existing domain to a new domain. The following code sample illustrates the use:

#### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
) ->create_put_operation( ).

DATA(lo_object_template) = xco_cp_generation_doma=>template->for_domain(
  iv_name          = '$SOURCE_DOMAIN_NAME$'
  io_read_state    = xco_cp_abap_dictionary=>object_read_state->active_version
).
```

```

lo_put_operation->for-domain->add_object( '$DOMAIN_NAME$'
    )->set_package( '$PACKAGE_NAME$'
    )->set_template( lo_object_template ).

lo_put_operation->execute( ).

```

## PATCH Operations

A change specification is used to specify the changes that should be applied to an existing domain, and is the basis for running a PATCH operation for a domain. Upon running a PATCH operation, the changes will be applied to the domain. The following kinds of changes can be specified:

- **DELETE:** If the specified part exists in the domain, it'll be deleted. If it doesn't exist, no action will be performed.
- **INSERT:** If the specified part doesn't exist in the domain, it'll be inserted according to the provided specification. If it exists, no action will be performed.
- **UPDATE:** If the specified part exists in the domain, it'll be updated according to the provided specification.

Note that the different kinds of changes are always evaluated in the order Delete, Insert, Update with the changes that are applied for one kind being directly visible to the changes that are applied for a subsequent kind. This orchestration can be exploited to, for example, implement a MODIFY by specifying both a DELETE and an INSERT for a given object part. The following code example illustrates selected changes and how they can be applied via a (single) PATCH operation:

### Sample Code

```

DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
    )->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation->for-domain-
>add_object( '$DOMAIN_NAME$'
    )->create_change_specification( ).

" Update the short description.
lo_change_specification->for-update->set_short_description( 'New short
description' ).

" Modify fixed version 02 by specifying both a deletion and an insertion for
" it.
lo_change_specification->for-delete->add_fixed_value( '02' ).

DATA(lo_fixed_value_02) = lo_change_specification->for-insert-
>add_fixed_value( '02' ).
lo_fixed_value_02->set_description( 'February' ).

" Update the description of fixed value 01 (if it exists in the domain).
lo_change_specification->for-update->add_fixed_value( '01'
    )->set_description( 'January' ).

" Delete fixed value 03 (if it exists in the domain).
lo_change_specification->for-delete->add_fixed_value( '03' ).

lo_patch_operation->execute( ).

```

## DELETE Operations

Domains can be deleted via DELETE operations. As per the standard semantics of DELETE operations, if the domain for which a DELETE operation is run doesn't exist, no action will be performed (and no error will

be raised). If the domain exists, it will be deleted. The code sample below illustrates how to run a DELETE operation for a domain:

#### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->for-doma->create_delete_operation( ).

lo_delete_operation->add_object( '$DOMAIN_NAME$' ).

lo_delete_operation->execute( ).
```

## Setting and Getting the API State of a Domain

A domain can be released via the API state mechanisms of the API Release Framework (ARS). The XCO library allows you to programmatically set and get the API state of a domain (represented as `IF_XCO_DOMAIN`). The following code sample illustrates how the API state of a given domain can be read:

#### Sample Code

```
DATA(lo_domain) = xco_cp_abap_dictionary=>domain( '$DOMAIN_NAME$' ).

" Get the (current) API state of the domain for the C1 release contract.
DATA(lo_api_state) = lo_domain->get_api_state( ).

" The returned LO_API_STATE object allows to inspect the individual
" attributes of the API state.
DATA(lo_release_state) = lo_api_state->get_release_state( ).

" Release states supported by the XCO Library can be obtained via
XCO_CP_ARS=>RELEASE_STATE.
" Checking whether the API state of the domain has the release state
" "RELEASED" would look like this:
IF lo_release_state EQ xco_cp_ars=>release_state->released.
  " ...
ENDIF.

DATA(lt_visibilities) = lo_api_state->get_visibilities( ).

" Visibilities supported by the XCO Library can be obtained via
XCO_CP_ARS=>VISIBILITY.
" Note that due to compatibility and historical reasons, the visibility
" CLOUD_DEVELOPMENT is called SAP_CLOUD_PLATFORM within the XCO Library.
Checking
" whether the visibilities of the API state include CLOUD_DEVELOPMENT would
" then look like this:
IF line_exists( lt_visibilities[ table_line = xco_cp_ars=>visibility-
>sap_cloud_platform ] ).
  " ...
ENDIF.
```

Setting the API state for a domain can be done like this:

#### Sample Code

```
" The API state which should be set for the domain is built via
XCO_CP_ARS=>API_STATE:
```

```

DATA(lo_api_state) = xco_cp_ars=>api_state->released( VALUE
#( ( xco_cp_ars=>visibility->sap_cloud_platform ) ) ).

" Setting the API state for a domain implies a change which must be recorded
" on an appropriate transport.
DATA(lo_transport) = xco_cp_ars=>transport->for( '$TRANSPORT$' ).

" The API state is set via the handle for the domain.
DATA(lo_domain) = xco_cp_abap_dictionary=>domain( '$DOMAIN_NAME$' ).

" We set the previously built API State (Released for Cloud Development)
" using the CI-release contract for the domain (recording the changes on the
" provided transport).
lo_domain->set_api_state(
  io_change_scenario = lo_transport
  io_api_state       = lo_api_state
).

```

## 4.2.12.16.3.8.4 Event Bindings

Find out how to create event bindings.

Event bindings, also called objects of type `EVTB`, are supported by the following API families within the *XCO Library*:

- Query APIs
- Read APIs
- Generation APIs

### Query APIs

Obtaining an object handle for an event binding with a given name can be accomplished via

#### Sample Code

```

DATA(lo_event_binding) = xco_cp_abap_repository=>object->evtb-
>for( '$EVENT_BINDING_NAME$' ).

```

The obtained object handle can then be used to check the existence of the event binding in the ABAP Repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible event bindings in the ABAP Repository can simply be accomplished via

#### Sample Code

```

DATA(lt_event_bindings) = xco_cp_abap_repository=>objects->evtb->all-
>in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_event_bindings ASSIGNING FIELD-SYMBOL(<fs_event_binding>).
  " Process the found event binding.
ENDLOOP.

```

Instead of searching the entire ABAP Repository for service bindings, it's also possible to only search for data definitions in a dedicated subset of the ABAP Repository, such as a single package:

### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_event_bindings) = xco_cp_abap_repository=>objects->evtb->all->in( lo_package )->get( ).

LOOP AT lt_event_bindings ASSIGNING FIELD-SYMBOL(<fs_event_binding>).
  " Process the found event binding.
ENDLOOP.
```

Another way to refine a search for event bindings is to use filters to specify exactly which event bindings shall be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_EVENT_BINDINGS will be a list of all visible event bindings in the ABAP
" Repository whose name starts with /ABC/.
DATA(lt_event_bindings) = xco_cp_abap_repository=>objects->evtb->where( VALUE
#(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_event_bindings ASSIGNING FIELD-SYMBOL(<fs_event_binding>).
  " Process the found event binding.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of an event binding is possible via its object handle `IF_XCO_EVENT_BINDING`. The read APIs for event bindings are based on the origin infrastructure with the following origins being currently offered for event bindings:

- **DEFAULT**: Can be obtained via `XCO_CP_EVENT_BINDING=>ORIGIN->DEFAULT` and will read a given event binding exactly once per ABAP session from the local system with all subsequent reads of the event binding being fulfilled from a dedicated buffer. This origin is used by default if no origin is explicitly specified when reading the content or checking the existence of an event binding.
- **LOCAL**: Can be obtained via `XCO_CP_EVENT_BINDING=>ORIGIN->LOCAL` and will read a given event binding from the local system. By default, every read of the content as well as existence check of an event binding will read directly from the database but the caching behavior can be configured via the methods of `IF_XCO_EB_CACHEABLE_ORIGIN`.

Furthermore, when reading an event binding or checking its existence, it can explicitly be specified which version of the event binding shall be considered. The following versions are supported:

- **ACTIVE**: Can be obtained via `XCO_CP_EVENT_BINDING=>VERSION->ACTIVE`. The active version is used by default, if no version is explicitly specified when reading the content of an event binding or checking its existence.
- **INACTIVE**: Can be obtained via `XCO_CP_EVENT_BINDING=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of an event binding can be read out separately:

## Header

The following code sample illustrates how the header of an event binding can be read out:

### Sample Code

```
DATA(lo_event_binding) = xco_cp_abap_repository=>object->evtb-
>for( '$EVENT_BINDING_NAME$' ).

" Read out the complete header of the active version of the event binding
" using the default origin:
DATA(ls_header) = lo_event_binding->content( )->get( ).

" Read out only the short description of the inactive version of the event
" binding using an explicitly obtained local origin (without caching).
DATA(lo_local_origin) = xco_cp_event_binding=>origin->local( ).

DATA(lv_short_description) = lo_event_binding-
>content( xco_cp_event_binding=>version->inactive
)->get_short_description( lo_local_origin ).
```

## Event Versions

Obtaining a list of the event versions of an event binding and reading out an individual event version can be done like this:

```
DATA(lo_event_binding) = xco_cp_abap_repository=>object->evtb-
>for( '$EVENT_BINDING_NAME$' ).

" Get a list of all the event versions of the active version of the event
" binding using the default origin:
DATA(lt_event_versions) = lo_event_binding->event_versions->all->get( ).

LOOP AT lt_event_versions ASSIGNING FIELD-SYMBOL(<fs_event_version>).
  " Process the event version.
ENDLOOP.

" Obtain the handle for an individual event version.
DATA(lo_event_version) = lo_event_binding->event_version( 0001 ).

" Read out the complete content of the active version of the event version
" using the default origin.
DATA(ls_event_version) = lo_event_version->content( )->get( ).

" Read out only the minor version of the inactive version of the event
" version using an explicitly obtained local origin with caching enabled.
DATA(lo_local_origin) = xco_cp_event_binding=>origin->local( ).
lo_local_origin->if_xco_eb_cacheable_origin~enable_caching( ).

DATA(lv_minor_version) = lo_event_version-
>content( xco_cp_event_binding=>version->inactive
)->get_minor_version( lo_local_origin ).
```

## Generation APIs

Event bindings are integrated with XCO Generation APIs. The following operations are currently offered:

- **PUT**: Create or update an event binding based on a complete specification of its content, so that after the successful execution of the operation, the event binding exists and its content is exactly as specified
- **PATCH**: Change an existing event binding by applying the changes which have been provided in a change specification
- **DELETE**: Delete an event binding (if it exists)

### PUT operations

A form specification is used to specify the complete content of an event binding which is the basis for executing a PUT operation. Upon execution of the PUT operation, depending on whether the event binding already exists or not, it will either be newly created or updated. After the successful completion of the PUT operation the event binding exists with the content resembling exactly what was specified in the provided form specification. Consider the following code sample which illustrates how to execute a PUT operation for an event binding:

#### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-evtb-
>add_object( '$EVENT_BINDING_NAME$'
  )->set_package( '$PACKAGE_NAME$'
  )->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description'
  )->set_type_namespace( '$TYPE_NS$'
  )->set_sap_object_type( '$SAP_OBJECT_TYPE$'
  )->set_operation( '$OPERATION' ).

DATA(lo_event_version_0001) = lo_form_specification-
>add_event_version( 0001 ).
lo_event_version_0001->set_entity_name( '$ENTITY_NAME$'
  )->set_entity_event_name( '$ENTITY_EVENT_NAME$' ).

lo_put_operation->execute( ).
```

### PATCH operations

A change specification is used to specify the changes that shall be applied to an existing event binding and is the basis for executing a PATCH operation for an event binding. Upon execution of a PATCH operation, the changes will be applied to the event binding. The following kinds of changes can be specified:

- **DELETE**: If the specified part exists in the event binding it will be deleted. If it doesn't exist no action will be performed.
- **INSERT**: If the specified part doesn't exist in the event binding it will be inserted according to the provided specification. If it exists no action will be performed.
- **UPDATE**: If the specified part exists in the event binding it will be updated according to the provided specification.

#### Note

Note that the different kinds of changes are always evaluated in the order delete, insert, update with the changes that are applied for one kind being directly visible to the changes that are applied for a subsequent

kind. This orchestration can be exploited to, for example, implement a *MODIFY* by specifying both a *DELETE* and an *INSERT* for a given object part. The following code example illustrates selected changes and how they can be applied via a (single) *PATCH* operation

```
DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation->for-evtb-
>add_object( '$EVENT_BINDING_NAME$'
  )->create_change_specification( ).

" Update the short description.
lo_change_specification->for-update->set_short_description( 'New short
description' ).

" Modify event version 0001 by specifying both a deletion and an insertion
" for it.
lo_change_specification->for-delete->add_event_version( 0001 ).

DATA(lo_event_version_0001) = lo_change_specification->for-insert-
>add_event_version( 0001 ).
lo_event_version_0001->set_minor_version( 0000 ).
lo_event_version_0001->set_patch_version( 0000 ).
lo_event_version_0001->set_entity_name( '$ENTITY_NAME' ).
lo_event_version_0001->set_entity_event_name( '$ENTITY_EVENT_NAME$' ).

" Update the Entity Event Name of event version 0002 (if it exists in the
" event binding).
lo_change_specification->for-update->add_event_version( 0002
  )->set_entity_event_name( 'CREATED2' ).

" Delete event version 0003 (if it exists in the event binding).
lo_change_specification->for-delete->add_event_version( 0003 ).

lo_patch_operation->execute( ).
```

## DELETE operations

Event bindings can be deleted via *DELETE* operations. As per the standard semantics of *DELETE* operations, if the data definition for which a *DELETE* operation is run doesn't exist, no action will be performed (and no error will be raised). If the data definition does exist, it will be deleted. The code sample below illustrates how to execute a *DELETE* operation for a data definition:

### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->for-evtb->create_delete_operation( ).

lo_delete_operation->add_object( '$EVENT_BINDING_NAME$' ).

lo_delete_operation->execute( ).
```

## 4.2.12.16.3.8.5 SAP Object Node Types

Find out how to create SAP object node types.

SAP object node types, meaning objects of type `NONT`, are supported by the following API families within the XCO library:

- Query APIs
- Read APIs
- Generation APIs

### Query APIs

Obtaining an object handle for an SAP object node type with a given name can be accomplished via

#### Sample Code

```
DATA(lo_sap_object_node_type) = xco_cp_abap_repository=>object->nont->for( '$SAP_OBJECT_NODE_TYPE_NAME$' ).
```

The obtained object handle can then be used to, for example, check the existence of the SAP object node type in the ABAP repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible SAP object node types in the ABAP repository can be done via

#### Sample Code

```
DATA(lt_sap_object_node_types) = xco_cp_abap_repository=>objects->nont->all->in( xco_cp_abap=>repository )->get( ).  
  
LOOP AT lt_sap_object_node_types ASSIGNING FIELD-  
SYMBOL(<fs_sap_object_node_type>).  
    " Process the found SAP object node type.  
ENDLOOP.
```

Instead of searching for SAP object node types in the entire ABAP repository, it's also possible to only search for SAP object node types in a dedicated subset of the ABAP repository, such as in a single package:

#### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).  
  
DATA(lt_sap_object_node_types) = xco_cp_abap_repository=>objects->nont->all->in( lo_package )->get( ).  
  
LOOP AT lt_sap_object_node_types ASSIGNING FIELD-  
SYMBOL(<fs_sap_object_node_type>).  
    " Process the found SAP object node type.  
ENDLOOP.
```

Furthermore, you can refine a search for SAO object node types by using filters to specify exactly which SAP object node types should be matched, for example:

## Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_SAP_OBJECT_NODE_TYPES will be a list of all visible SAP object node
" types in the ABAP Repository whose name starts with /ABC/.
DATA(lt_sap_object_node_types) = xco_cp_abap_repository=>objects->nont-
>where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_sap_object_node_types ASSIGNING FIELD-
SYMBOL(<fs_sap_object_node_type>).
  " Process the found SAP object node type.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of an SAP object node type is possible via its object handle `IF_XCO_SAP_OBJECT_NODE_TYPE`. The Read APIs for SAP object node types are based on the origin infrastructure with the following origins being offered currently for SAP object node types:

- **DEFAULT:** Can be obtained via `XCO_CP_SAP_OBJECT_NODE_TYPE=>ORIGIN->DEFAULT` and will read a given SAP object node type exactly once per ABAP session from the local system, with all subsequent reads of the SAP object node type being fulfilled from a dedicated buffer. This origin is used by default, meaning if no origin is explicitly specified when reading the content or checking the existence of an SAP object node type.
- **LOCAL:** Can be obtained via `XCO_CP_SAP_OBJECT_NODE_TYPE=>ORIGIN->LOCAL` and will read a given SAP object node type from the local system. By default, every read of the content as well as existence checks of an SAP object node type will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_NONT_CACHEABLE_ORIGIN`.

Next, when reading an SAP object node type or checking its existence, it can explicitly be specified which version of the SAP object node type should be considered. The following versions are supported:

- **ACTIVE:** Can be obtained via `XCO_CP_SAP_OBJECT_NODE_TYPE=>VERSION->ACTIVE`. The active version is used by default, meaning if no version is explicitly specified when reading the content of an SAP object node type or checking its existence.
- **INACTIVE:** Can be obtained via `XCO_CP_SAP_OBJECT_NODE_TYPE=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of an SAP object node type can be read out separately:

### Header

Reading out the header of an SAP object node type can be done like this:

## Sample Code

```
DATA(lo_sap_object_node_type) = xco_cp_abap_repository=>object->nont-
>for( '$SAP_OBJECT_NODE_TYPE_NAME$' ).
```

```

" Read out the complete header of the active version of the SAP object node
" type using the default origin:
DATA(ls_header) = lo_sap_object_node_type->content( )->get( ).

" Read out only the short description of the inactive version of the SAP
" object node type using an explicitly obtained local origin (without
" caching).
DATA(lo_local_origin) = xco_cp_sap_object_node_type=>origin->local( ).

DATA(lv_short_description) = lo_sap_object_node_type-
>content( xco_cp_sap_object_node_type=>version->inactive
)->get_short_description( lo_local_origin ).

```

## Generation APIs

SAP object node types are integrated with the XCO Generation APIs with the following operations being offered currently for SAP object node types:

- **PUT:** Create or update an SAP object node type based on an entire content specification so that after running the operation successfully, the SAP object node type exists and its content is exactly as specified
- **PATCH:** Change an existing SAP object node type by applying the changes which have been provided in a change specification
- **DELETE:** Delete an SAP object node type (if it exists)

### PUT Operations

A form specification is used to specify the entire content of an SAP object node type, which is the basis for running a PUT operation. Upon running the PUT operation, depending on whether the SAP object node type already exists or not, it will either be newly created or updated. This is so that after the successful completion of the PUT operation, the SAP object node type exists with the content resembling exactly what was specified in the provided form specification. Consider the following code sample which illustrates how to run a PUT operation for an SAP object node type:

#### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
)->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-nont-
>add_object( '$SAP_OBJECT_NODE_TYPE_NAME$'
)->set_package( '$PACKAGE_NAME$'
)->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description'
)->set_name( '$sapObjectTypeName$'
)->set_sap_object_type( '$SAP_OBJECT_TYPE_NAME$'
)->set_root_node( abap_true ).

lo_put_operation->execute( ).

```

### PATCH Operations

A change specification is used to specify the changes that should be applied to an existing SAP object node type, and is the basis for running a PATCH operation for an SAP object node type. Upon running a PATCH

operation, the changes will be applied to the SAP object node type. The following code example illustrates selected changes and how they can be applied via a PATCH operation:

#### Sample Code

```
DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation->for-nont-
>add_object( '$SAP_OBJECT_NODE_TYPE_NAME$'
  )->create_change_specification( ).

" Update the short description.
lo_change_specification->for-update->set_short_description( 'New short
description' ).

lo_patch_operation->execute( ).
```

### DELETE Operations

SAP object node types can be deleted via DELETE operations. As per the standard semantics of DELETE operations, if the SAP object node type for which a DELETE operation is being run doesn't exist, no action will be performed (and no error will be raised). If the SAP object node type exists, it will be deleted. The code sample below illustrates how to run a DELETE operation for an SAP object node type:

#### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->for-nont->create_delete_operation( ).

lo_delete_operation->add_object( '$SAP_OBJECT_NODE_TYPE_NAME$' ).

lo_delete_operation->execute( ).
```

## 4.2.12.16.3.8.6 SAP Object Types

Find out how to create SAP object types.

SAP object types, meaning objects of type RONT, are supported by the following API families within the XCO library:

- Query APIs
- Read APIs
- Generation APIs

### Query APIs

Obtaining an object handle for an SAP object type with a given name can be accomplished via

### Sample Code

```
DATA(lo_sap_object_type) = xco_cp_abap_repository=>object->ront->for( '$SAP_OBJECT_TYPE_NAME$' ).
```

The obtained object handle can then be used to, for example, check the existence of the SAP object type in the ABAP repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible SAP object types in the ABAP repository can be done via

### Sample Code

```
DATA(lt_sap_object_types) = xco_cp_abap_repository=>objects->ront->all->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_sap_object_types ASSIGNING FIELD-SYMBOL(<fs_sap_object_type>).
  " Process the found SAP object type.
ENDLOOP.
```

Instead of searching for SAP object types in the entire ABAP repository, it's also possible to only search for SAP object types in a dedicated subset of the ABAP repository, such as in a single package:

### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_sap_object_types) = xco_cp_abap_repository=>objects->ront->all->in( lo_package )->get( ).

LOOP AT lt_sap_object_types ASSIGNING FIELD-SYMBOL(<fs_sap_object_type>).
  " Process the found SAP object type.
ENDLOOP.
```

Furthermore, you can refine a search for SAP object types by using filters to specify exactly which SAP object types should be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_SAP_OBJECT_TYPES will be a list of all visible SAP object types in the
" ABAP Repository whose name starts with /ABC/.
DATA(lt_sap_object_types) = xco_cp_abap_repository=>objects->ront->where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_sap_object_types ASSIGNING FIELD-SYMBOL(<fs_sap_object_type>).
  " Process the found SAP object type.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of an SAP object type is possible via its object handle `IF_XCO_SAP_OBJECT_TYPE`. The Read APIs for SAP object types are based on the origin infrastructure with the following origins being offered currently for SAP object types:

- **DEFAULT:** Can be obtained via `XCO_CP_SAP_OBJECT_TYPE=>ORIGIN->DEFAULT` and will read a given SAP object type exactly once per ABAP session from the local system, with all subsequent reads of the SAP object type being fulfilled from a dedicated buffer. This origin is used by default, meaning if no origin is explicitly specified when reading the content or checking the existence of an SAP object type.
- **LOCAL:** Can be obtained via `XCO_CP_SAP_OBJECT_TYPE=>ORIGIN->LOCAL` and will read a given SAP object type from the local system. By default, every read of the content as well as existence checks of an SAP object type will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_NON_CACHEABLE_ORIGIN`.

Next, when reading an SAP object type or checking its existence, it can explicitly be specified which version of the SAP object type should be considered. The following versions are supported:

- **ACTIVE:** Can be obtained via `XCO_CP_SAP_OBJECT_TYPE=>VERSION->ACTIVE`. The active version is used by default, meaning if no version is explicitly specified when reading the content of an SAP object type or checking its existence.
- **INACTIVE:** Can be obtained via `XCO_CP_SAP_OBJECT_TYPE=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of an SAP object type can be read out separately:

### Header

Reading out the header of an SAP object type can be done like this:

#### Sample Code

```
DATA(lo_sap_object_type) = xco_cp_abap_repository=>object->ron-
>for( '$SAP_OBJECT_TYPE_NAME$' ).

" Read out the complete header of the active version of the SAP object type
" using the default origin:
DATA(ls_header) = lo_sap_object_type->content( )->get( ).

" Read out only the short description of the inactive version of the SAP
" object type using an explicitly obtained local origin (without caching).
DATA(lo_local_origin) = xco_cp_sap_object_type=>origin->local( ).

DATA(lv_short_description) = lo_sap_object_type-
>content( xco_cp_sap_object_type=>version->inactive
)->get_short_description( lo_local_origin ).
```

## Generation APIs

SAP object types are integrated with the XCO Generation APIs with the following operations being offered currently for SAP object types:

- **PUT:** Create or update an SAP object type based on an entire content specification so that after running the operation successfully, the SAP object type exists and its content is exactly as specified

- **PATCH:** Change an existing SAP object type by applying the changes which have been provided in a change specification
- **DELETE:** Delete an SAP object type (if it exists)

## PUT Operations

A form specification is used to specify the entire content of an SAP object type which is the basis for running a PUT operation. Upon running the PUT operation, depending on whether the SAP object type already exists or not, it will either be newly created or updated. This is so that after the successful completion of the PUT operation, the SAP object type exists with the content resembling exactly what was specified in the provided form specification. Consider the following code sample which illustrates how to run a PUT operation for an SAP object type:

### Sample Code

```
DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-ron-
>add_object( '$SAP_OBJECT_TYPE_NAME$'
  )->set_package( '$PACKAGE_NAME$'
  )->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description'
  )->set_type_category( xco_cp_sap_object_type=>type_category->business_object
  )->set_name( '$sapObjectTypeName$'
  )->set_object_type_code( '00000' ).

lo_put_operation->execute( ).
```

## PATCH Operations

A change specification is used to specify the changes that should be applied to an existing SAP object type and is the basis for running a PATCH operation for an SAP object type. Upon running a PATCH operation, the changes will be applied to the SAP object type. The following code example illustrates selected changes and how they can be applied via a PATCH operation:

### Sample Code

```
DATA(lo_patch_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_patch_operation( ).

DATA(lo_change_specification) = lo_patch_operation->for-ron-
>add_object( '$SAP_OBJECT_TYPE_NAME$'
  )->create_change_specification( ).

" Update the short description.
lo_change_specification->for-update->set_short_description( 'New short
description' ).

lo_patch_operation->execute( ).
```

## DELETE Operations

SAP object types can be deleted via DELETE operations. As per the standard semantics of DELETE operations, if the SAP object type for which a DELETE operation is being run doesn't exist, no action will be performed (and

no error will be raised). If the SAP object type exists, it will be deleted. The code sample below illustrates how to run a DELETE operation for an SAP object type:

#### Sample Code

```
DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->for-ron->create_delete_operation( ).

lo_delete_operation->add_object( '$SAP_OBJECT_TYPE_NAME$' ).

lo_delete_operation->execute( ).
```

## 4.2.12.16.3.8.7 Service Bindings

Find out how to create service bindings.

Service bindings, also called objects of type SRVB, are supported by the following API families within the [XCO Library](#):

- Query APIs
- Read APIs
- Generation APIs

In addition to the standard API families listed above, dedicated APIs are offered for the following aspects:

- Publishing and unpublishing local service endpoints

### Query APIs

Obtaining an object handle for a service binding with a given name can be accomplished via

#### Sample Code

```
DATA(lo_service_binding) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$' ).
```

The obtained object handle can then be used to, for example, check the existence of the service binding in the ABAP Repository (via method `IF_XCO_AR_OBJECT-EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible service bindings in the ABAP Repository can be accomplished via

#### Sample Code

```
DATA(lt_service_bindings) = xco_cp_abap_repository=>objects->srvb->all-
>in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_service_bindings ASSIGNING FIELD-SYMBOL(<fs_service_binding>).
  " Process the found service binding.
ENDLOOP.
```

Instead of searching the entire ABAP Repository for service bindings, it's also possible to only search for service bindings in a dedicated subset of the ABAP Repository, such as in a single package:

#### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_service_bindings) = xco_cp_abap_repository=>objects->srvb->all->in( lo_package )->get( ).

LOOP AT lt_service_bindings ASSIGNING FIELD-SYMBOL(<fs_service_binding>).
  " Process the found service binding.
ENDLOOP.
```

Another way to refine a search for service bindings is to use filters to specify exactly which service bindings shall be matched, for example:

#### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
  xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_SERVICE_BINDINGS will be a list of all visible service bindings in the
ABAP
" Repository whose name starts with /ABC/.
DATA(lt_service_bindings) = xco_cp_abap_repository=>objects->srvb->where( VALUE #(
  ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_service_bindings ASSIGNING FIELD-SYMBOL(<fs_service_binding>).
  " Process the found service binding.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of a service binding is possible via its object handle `IF_XCO_SERVICE_BINDING`. The Read APIs for service bindings are based on the origin infrastructure with the following origins being currently offered for service bindings:

- **DEFAULT**: Can be obtained via `XCO_CP_SERVICE_BINDING=>ORIGIN->DEFAULT` and will read a given service binding exactly once per ABAP session from the local system with all subsequent reads of the service binding being done from a dedicated buffer. As the name suggests, this origin is used by default, so if no origin is explicitly specified when reading the content or checking the existence of a service binding.
- **LOCAL**: Can be obtained via `XCO_CP_SERVICE_BINDING=>ORIGIN->LOCAL` and will read a given service binding from the local system. By default, every read of the content and check of the existence of a service binding will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_SRVB_CACHEABLE_ORIGIN`.

Furthermore, when reading a service binding or checking its existence, it can explicitly be specified which version of the service binding to consider. The following versions are supported:

- **ACTIVE**: Can be obtained via `XCO_CP_SERVICE_BINDING=>VERSION->ACTIVE`. The active version is used by default, so if no version is explicitly specified when reading the content or checking the existence of a service binding.
- **INACTIVE**: Can be obtained via `XCO_CP_SERVICE_BINDING=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of a service binding can be read out separately:

## Header

Reading out the header of a service binding can be done like this:

### Sample Code

```
DATA(lo_service_binding) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$' ).

" Read out the complete header of the active version of the service binding
" using the default origin:
DATA(ls_header) = lo_service_binding->content( )->get( ).

" Read out only the short description of the inactive version of the service
" binding using an explicitly obtained local origin (without caching).
DATA(lo_local_origin) = xco_cp_service_binding=>origin->local( ).

DATA(lv_short_description) = lo_service_binding-
>content( xco_cp_service_binding=>version->inactive
) ->get_short_description( lo_local_origin ).
```

## Services

Obtaining a list of the services of a service binding can be done like this:

### Sample Code

```
DATA(lo_service_binding) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$' ).

" Get a list of all the services of the active version of the service binding
" using
" the default origin:
DATA(lt_services) = lo_service_binding->services->all->get( ).

LOOP AT lt_services ASSIGNING FIELD-SYMBOL(<fs_service>).
" Process the service.
ENDLOOP.
```

## Service Versions

Obtaining a list of the service versions of a service and reading out an individual service version can be done like this:

### Sample Code

```
" Note that in this example we would be reading the content of a service
" with a binding type for which services can be added freely (e.g. an OData v4
" service binding).
```

```

DATA(lo_service) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$'
  )->service( '$SERVICE_NAME$' ).

" Get a list of all the service versions of the service for the active version
" of the service binding using the default origin.
DATA(lt_service_versions) = lo_service->versions->all->get( ).

LOOP AT lt_service_versions ASSIGNING FIELD-SYMBOL(<fs_service_version>).
  " Process the service version.
ENDLOOP.

" Obtain the handle for an individual service version.
DATA(lo_service_version) = lo_service->version( 0001 ).

" Read out the complete content of the service version for the active version
of the
" service binding using the default origin.
DATA(ls_service_version) = lo_service_version->content( )->get( ).

" Read out only the service definition of the service version for the
inactive version
" of the service binding using an explicitly obtained local origin (with
caching enabled).
DATA(lo_local_origin) = xco_cp_service_binding=>origin->local( ).
lo_local_origin->if_xco_srvb_cacheable_origin~enable_caching( ).

DATA(lo_service_definition) = lo_service_version-
>content( xco_cp_service_binding=>version->inactive
  )->get_service_definition( lo_local_origin ).

```

## Generation APIs

Service bindings are integrated with the XCO Generation APIs with the following operations being currently offered for service bindings:

- **PUT**: Create or update a service binding based on a complete specification of its content, so that after successfully running the operation, the service binding exists and its content is exactly as specified.
- **DELETE**: Delete a service binding (if it exists).

### PUT Operations

A form specification is used to specify the entire content of a service binding, which is the foundation for running a **PUT** operation. Upon execution of the **PUT** operation, depending on whether the service binding already exists or not, it will either be newly created or updated. This is so that after the successful completion of the **PUT** operation, the service binding exists with the content resembling exactly what was specified in the provided form specification. Consider the following code sample which illustrates how to run a **PUT** operation for a service binding:

#### Sample Code

```

DATA(lo_put_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST$'
  )->create_put_operation( ).

DATA(lo_form_specification) = lo_put_operation->for-srvb-
>add_object( '$SERVICE_BINDING_NAME$'
  )->set_package( '$PACKAGE_NAME$' ).

```

```

    )->create_form_specification( ).

lo_form_specification->set_short_description( 'My short description'
    )->set_binding_type( xco_cp_service_binding=>binding_type->odata_v4_ui ).

DATA(lo_service) = lo_form_specification->add_service( '$SERVICE_NAME$' ).

DATA(lo_service_version_0001) = lo_service->add_version( 0001 ).
lo_service_version_0001-
>set_service_definition( '$SERVICE_DEFINITION_NAME$' ).

lo_put_operation->execute( ).

```

## DELETE Operations

Service bindings can be deleted via `DELETE` operations. As per the standard semantics of `DELETE` operations, if the service binding for which a `DELETE` operation is run doesn't exist, no action will be performed (and no error will be raised). If the service binding does exist, it will be deleted. The code sample below illustrates how to run a `DELETE` operation for a service binding:

### Sample Code

```

DATA(lo_delete_operation) = xco_cp_generation=>environment-
>dev_system( '$TRANSPORT_REQUEST'
    )->for-srvb->create_delete_operation( ).

lo_delete_operation->add_object( '$SERVICE_BINDING_NAME$' ).

lo_delete_operation->execute( ).

```

## Publishing and Unpublishing Local Service Endpoints

For service bindings with binding types `OData V2 - UI/Web API` or `OData V4 - UI/Web API`, it's possible to publish (or unpublish) a local service endpoint for the service binding. The exact granularity of a local service endpoint depends on whether the binding type belongs to the `OData V2` or `V4` binding type family:

### Local Service Endpoints and OData V2 Service Bindings

For service bindings with binding type `OData V2 - UI` or `OData V2 - Web API`, a local service endpoint can be published (or unpublished) for each (service) version defined in the service binding. To programmatically trigger the publish (or unpublish) of a local service endpoint, the *XCO Library* provides designated operations which are available via `XCO_CP_SERVICE_BINDING=>LOCAL_SERVICE_ENDPOINT->ODATA_V2->OPERATION`, namely:

- **PUBLISH**: Triggers a publish of the local service endpoint of the provided service version
- **UNPUBLISH**: Triggers an unpublish of the local service endpoint of the provided service version

Moreover, it's possible to check whether the local service endpoint of a given service version is currently published via `XCO_CP_SERVICE_BINDING=>LOCAL_SERVICE_ENDPOINT->ODATA_V2->IS_PUBLISHED`. The following code illustrates the use of the operations as well as of the `IS_PUBLISHED` method:

## Sample Code

```
DATA(lo_service_version) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$'
) ->service(
) ->version( 0001 ).

" First we check whether the local service endpoint for LO_SERVICE_VERSION is
" currently published.
DATA(lv_is_published) = xco_cp_service_binding=>local_service_endpoint-
>odata_v2->is_published( lo_service_version ).

" Depending on whether the local service endpoint is currently published we
" either
" trigger an unpublish or a publish of the local service endpoint.
DATA lo_operation TYPE REF TO if_xco_srvb_operation.

IF lv_is_published EQ abap_true.
    lo_operation = xco_cp_service_binding=>local_service_endpoint->odata_v2-
>operation->unpublish( lo_service_version ).
ELSE.
    lo_operation = xco_cp_service_binding=>local_service_endpoint->odata_v2-
>operation->publish( lo_service_version ).
ENDIF.

" Note that both a publish as well as an unpublish operation are concrete
" realizations of an IF_XCO_SRVB_OPERATION and can thus be treated uniformly.
" Regardless of the concrete realization of the operation, its execution can
" always be triggered via the method EXECUTE.
lo_operation->execute( ).
```

## Local Service Endpoints for OData V4 Service Bindings

For service bindings with binding type OData V4 - UI or OData V4 - Web API, a local service endpoint can only be published (or unpublished) for the entire service binding. To programmatically trigger the publish (or unpublish) of a local service endpoint, the *XCO Library* provides designated operations which are available via `XCO_CP_SERVICE_BINDING=>LOCAL_SERVICE_ENDPOINT->ODATA_V4->OPERATION`, namely:

- **PUBLISH**: Triggers a publish of the local service endpoint of the provided service binding
- **UNPUBLISH**: Triggers an unpublish of the local service endpoint of the provided service binding

Moreover, it's possible to check whether the local service endpoint of a given service binding is currently published via `XCO_CP_SERVICE_BINDING=>LOCAL_SERVICE_ENDPOINT->ODATA_V4->IS_PUBLISHED`. The following code illustrates the use of the operations as well as of the `IS_PUBLISHED` method:

## Sample Code

```
DATA(lo_service_binding) = xco_cp_abap_repository=>object->srvb-
>for( '$SERVICE_BINDING_NAME$' ).

" First we check whether the local service endpoint for LO_SERVICE_BINDING is
" currently published.
DATA(lv_is_published) = xco_cp_service_binding=>local_service_endpoint-
>odata_v4->is_published( lo_service_binding ).

" Depending on whether the local service endpoint is currently published we
" either
" trigger an unpublish or a publish of the local service endpoint.
DATA lo_operation TYPE REF TO if_xco_srvb_operation.

IF lv_is_published EQ abap_true.
    lo_operation = xco_cp_service_binding=>local_service_endpoint->odata_v4-
>operation->unpublish( lo_service_binding ).
```

```

ELSE.
  lo_operation = xco_cp_service_binding=>local_service_endpoint->odata_v4-
>operation->publish( lo_service_binding ).
ENDIF.

" Note that both a publish as well as an unpublish operation are concrete
" realizations of an IF_XCO_SRV_B_OPERATION and can thus be treated uniformly.
" Regardless of the concrete realization of the operation, its execution can
" always be triggered via the method EXECUTE.
lo_operation->execute( ).

```

## 4.2.12.16.3.8.8 Service Consumption Models

Find out how to create service consumption models.

Service consumption models, also called objects of type `SRVC`, are supported by the following API families within the *XCO Library*:

- Query APIs
- Read APIs

### Query APIs

Obtaining an object handle for a service consumption model with a given name can be accomplished via

#### Sample Code

```

DATA(lo_service_consumption_model) = xco_cp_abap_repository=>object->srvc-
>for( '$SRVC_NAME$' ).

```

The obtained object handle can then be used to, for example, check the existence of the service consumption model in the ABAP Repository (via method `IF_XCO_AR_OBJECT~EXISTS`) or read out its content via the Read APIs (see below). Obtaining a list of all visible service consumption models in the ABAP Repository can be accomplished via

#### Sample Code

```

DATA(lt_service_consumption_models) = xco_cp_abap_repository=>objects->srvc-
>all->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_service_consumption_models ASSIGNING FIELD-
SYMBOL(<fs_service_consumption_model>).
  " Process the found service consumption model.
ENDLOOP.

```

Instead of searching the entire ABAP Repository for service consumption models, it's also possible to only search for service consumption models in a dedicated subset of the ABAP Repository, such as in a single package:

### Sample Code

```
DATA(lo_package) = xco_cp_abap_repository=>package->for( '$PACKAGE_NAME$' ).

DATA(lt_service_consumption_models) = xco_cp_abap_repository=>objects->srvc->all->in( lo_package )->get( ).

LOOP AT lt_service_consumption_models ASSIGNING FIELD-
SYMBOL(<fs_service_consumption_model>).
    " Process the found service consumption model.
ENDLOOP.
```

Another way to refine a search for service consumption models is to use filters to specify exactly which service consumption models shall be matched, for example:

### Sample Code

```
DATA(lo_object_name_filter) = xco_cp_abap_repository=>object_name->get_filter(
    xco_cp_abap_sql=>constraint->contains_pattern( '/ABC/%' )
).

" LT_SERVICE_CONSUMPTION_MODELS will be a list of all visible service
consumption
" models in the ABAP Repository whose name starts with /ABC/.
DATA(lt_service_consumption_models) = xco_cp_abap_repository=>objects->srvc->where( VALUE #(
    ( lo_object_name_filter )
) )->in( xco_cp_abap=>repository )->get( ).

LOOP AT lt_service_consumption_models ASSIGNING FIELD-
SYMBOL(<fs_service_consumption_model>).
    " Process the found service consumption model.
ENDLOOP.
```

## Read APIs

Reading out the content and checking the existence of a service consumption model is possible via its object handle `IF_XCO_SERVICE_CONSUMPTION_MDL`. The Read APIs for service consumption models are based on the origin infrastructure with the following origins being currently offered for service consumption models:

- **DEFAULT**: Can be obtained via `XCO_CP_SERVICE_CONS_MODEL=>ORIGIN->DEFAULT` and will read a given service consumption model exactly once per ABAP session from the local system, with all subsequent reads of the service consumption model being done from a dedicated buffer. As the name suggests, this origin is used by default, so if no origin is explicitly specified when reading the content or checking the existence of a service consumption model.
- **LOCAL**: Can be obtained via `XCO_CP_SERVICE_CONS_MODEL=>ORIGIN->LOCAL` and will read a given service consumption model from the local system. By default, every read of a service consumption model will read directly from the database, but the caching behavior can be configured via the methods of `IF_XCO_SRVC_CACHEABLE_ORIGIN`.

Furthermore, when reading a service consumption model or checking its existence, it can explicitly be specified which version of the service consumption model shall be considered. The following versions are supported:

- **ACTIVE**: Can be obtained via `XCO_CP_SERVICE_CONS_MODEL=>VERSION->ACTIVE`. The active version is used by default, so if no version is explicitly specified when reading the content of a service consumption model or checking its existence.
- **INACTIVE**: Can be obtained via `XCO_CP_SERVICE_CONS_MODEL=>VERSION->INACTIVE`.

Following the general style of the XCO Read APIs, each part of a service consumption model can be read out separately:

## Header

Reading out the header of a service consumption model can be done like this:

### Sample Code

```
DATA(lo_service_consumption_model) = xco_cp_abap_repository=>object->srvc-
>for( '$SRVC_NAME$' ).

" Read out the complete header of the active version of the service
consumption model
" using the default origin:
DATA(ls_header) = lo_service_consumption_model->content( )->get( ).

" Read out only the short description of the inactive version of the service
" consumption model using an explicitly obtained local origin (without
caching).
DATA(lo_local_origin) = xco_cp_service_cons_model=>origin->local( ).

DATA(lv_short_description) = lo_service_consumption_model-
>content( xco_cp_service_cons_model=>version->inactive
)->get_short_description( lo_local_origin ).
```

## Service Entity Sets

For service consumption models with consumption type ODATA (the corresponding XCO enumeration constant is obtainable via `XCO_CP_SERVICE_CONS_MODEL=>CONSUMPTION_TYPE->ODATA`), it's possible to read the list of service entity sets of the service consumption model as well as the details of a given service entity set:

### Sample Code

```
DATA(lo_service_consumption_model) = xco_cp_abap_repository=>object->srvc-
>for( '$SRVC_NAME$' ).

" Get a list of all the service entity sets of the active version of the
service
" consumption model using the default origin:
DATA(lt_service_entity_sets) = lo_service_consumption_model-
>service_entity_sets->all->get( ).

LOOP AT lt_service_entity_sets ASSIGNING FIELD-
SYMBOL(<fs_service_entity_set>).
" Process the service entity sets.
ENDLOOP.

" Obtain the handle for an individual service entity set.
DATA(lo_service_entity_set) = lo_service_consumption_model-
>service_entity_set( '$SERVICE_ENTITY_SET$' ).

" Read out the complete content of the service entity set for the active
version of the service
```

```

" consumption model using the default origin.
DATA(ls_service_entity_set) = lo_service_entity_set->content( )->get( ).

" Read out only the data definition of the service entity set for the
inactive version of the service
" consumption model using an explicitly obtained local origin (with caching
enabled).
DATA(lo_local_origin) = xco_cp_service_cons_model=>origin->local( ).
lo_local_origin->if_xco_srvc_cacheable_origin~enable_caching( ).

DATA(lo_data_definition) = lo_service_entity_set-
>content( xco_cp_service_cons_model=>version->inactive
)->get_data_definition( lo_local_origin ).

```

## Service Operations

For service consumption models with consumption type `WEB_SERVICE` (the corresponding XCO enumeration constant is obtainable via `XCO_CP_SERVICE_CONS_MODEL=>CONSUMPTION_TYPE->WEB_SERVICE`), it's possible to read the list of service operations of the service consumption model:

### Sample Code

```

DATA(lo_service_consumption_model) = xco_cp_abap_repository=>object->srvc-
>for( '$SRVC_NAME$' ).

" Get a list of all the service operations of the active version of the
service
" consumption model using the default origin:
DATA(lt_service_operations) = lo_service_consumption_model-
>service_operations->all->get( ).

LOOP AT lt_service_operations ASSIGNING FIELD-SYMBOL(<fs_service_operation>).
" Process the service operations.
ENDLOOP.

```

## Remote Functions

For service consumption models with consumption type `RFC` (the corresponding XCO enumeration constant is obtainable via `XCO_CP_SERVICE_CONS_MODEL=>CONSUMPTION_TYPE->RFC`), it's possible to read the list of remote functions of the service consumption model:

### Sample Code

```

DATA(lo_service_consumption_model) = xco_cp_abap_repository=>object->srvc-
>for( '$SRVC_NAME$' ).

" Get a list of all the remote functions of the active version of the service
" consumption model using the default origin:
DATA(lt_remote_functions) = lo_service_consumption_model->remote_functions-
>all->get( ).

LOOP AT lt_remote_functions ASSIGNING FIELD-SYMBOL(<fs_remote_function>).
" Process the remote functions.
ENDLOOP.

```

## 4.2.12.16.3.9 Miscellaneous Code Samples

### 4.2.12.16.3.9.1 Getting the Text Table of a Database Table

The XCO standard abstraction for database tables (`IF_XCO_DATABASE_TABLE`) provides a convenient way to determine the text table of a given database table (if it has one):

#### Sample Code

```
DATA(lo_database_table) = xco_cp_abap_dictionary=>database_table( 'ZMY_DBT' ).

" From a database table handle (in this case LO_DATABASE_TABLE) we can obtain
" the handle for its text table.
DATA(lo_text_table) = lo_database_table->text_table( ).

" Using this text table handle, we can first check if a text table exists at
all
" (for the previously fixed database table) and if so, obtain information
about
" it.
DATA(lv_text_table_exists) = lo_text_table->exists( ).

IF lv_text_table_exists EQ abap_true.
    " The name of the text table that belongs to database table ZMY_DBT.
    DATA(lv_text_table_name) = lo_text_table->get( )->name.

    " We can also use the text table handle to get the name of the check field
of the
    " database table/text table relationship.
    DATA(lv_check_field_name) = lo_text_table->get_check_field( )->name.
ENDIF.
```

### 4.2.12.16.3.9.2 Retrieving a List of All Classes Implementing an Interface

The standard abstraction provided by the XCO library for ABAP interfaces (`IF_XCO_AO_INTERFACE`) can be used to retrieve a list of all implementations of a given interface:

#### Sample Code

```
DATA(lo_interface) = xco_cp_abap=>interface( 'ZMY_INTERFACE' ).

" From an interface handle (in this case LO_INTERFACE) we can easily obtain
" access to its implementations via the IMPLEMENTATIONS data member. Obtaining
" a list of all implementations for an interface can be accomplished like
this:
DATA(lt_implementations) = lo_interface->implementations->all->get( ).

" Once the previous statement has been executed, LT_IMPLEMENTATIONS will be a
" table of IF_XCO_AO_CLASS objects which can then subsequently be used to e.g.
" read the content of each class. Note that only those implementations will be
" considered which are either C1-released or part of a customer software
component.
" Additionally, if only the names of the classes implementing the interface
```

```
" shall be obtained the following statement can be used:
DATA(lt_implementation_names) = lo_interface->implementations->all-
>get_names( ).
```

### 4.2.12.16.3.9.3 Retrieving a List of all Subclasses of a Given Class

Find out how to retrieve a list of all subclasses of a given class.

The standard abstraction provided by the XCO library for ABAP classes (IF\_XCO\_AO\_CLASS) can be used to retrieve a list of all subclasses (including both direct and indirect subclasses) of a given class:

#### Sample Code

```
DATA(lo_class) = xco_cp_abap=>class( 'ZMY_CLASS' ).

" From a class handle (in this case LO_CLASS) we can easily obtain access to
" its subclasses via the SUBCLASSES data member. Accessing all subclasses
" via SUBCLASSES->ALL will resolve the subclasses of the class recursively
" along the inheritance tree, i.e. all subclasses including subclasses of
" subclasses and so forth will be included.
DATA(lt_subclasses) = lo_class->subclasses->all->get( ).

" Once the previous statement has been executed, LT_SUBCLASSES will be a
" table of IF_XCO_AO_CLASS objects which can then subsequently be used to
" e.g. read the content of each class. Furthermore, note that only those
" subclasses will be considered which are either C1-released or part of a
" customer software component. If only the names of the subclasses shall be
" obtained, the following variation can be used:
DATA(lt_subclass_names) = lo_class->subclasses->all->get_names( ).
```

## 4.2.12.16.4 Standard Library

The XCO standard library provides lightweight abstractions to simplify everyday programming tasks and defines central abstractions, most notably IF\_XCO\_NEWS and IF\_XCO\_TEXT, that provide a common language to foster synergies between different XCO modules.

### Building blocks

There are several basic building blocks defined within the XCO standard library that are used throughout the modules of the whole XCO library and may even be integrated into custom coding.

### Exception philosophy

Unless a caller can be reasonably expected to recover from an error situation is always handled through NO\_CHECK exceptions that are derived from CX\_XCO\_RUNTIME\_EXCEPTION.

The class `CX_XCO_RUNTIME_EXCEPTION` is an abstract class that defines aspects that are common to all kinds of unexpected error situations. Most importantly, it provides access to the messages of the exceptional situation via `IF_XCO_NEWS`.

On top of that, every time a `CX_XCO_RUNTIME_EXCEPTION` is raised the active call stack is captured when the exception object is constructed. By having exception classes inherit from `CX_XCO_RUNTIME_EXCEPTION` stack traces can also be easily enabled for self-defined exceptions.

When such an exception is logged via the XCO BAL module the stack trace will be included along with the message of the exception (assuming the `XCO_CP_BAL=>EXCEPTION_ADDITION->STACK_TRACE` exception addition has been enabled).

## News

The interface `IF_XCO_NEWS` provides a central abstraction that is applicable to any object that can naturally act as a source of messages. A message is defined as an object of type `IF_XCO_MESSAGE` which in turn is characterized by a SYMSG value.

As the interface `IF_XCO_NEWS` can be flexibly mixed in with existing class hierarchies it provides a common denominator that enables communication between independent modules both within the XCO library as well as between the XCO library and custom coding.

A good example for the synergies created by the `IF_XCO_NEWS` abstraction is the interplay of the XCO BAL module with the XCO ADT standard library functionality which is described below. Even though the XCO ADT functionality has no knowledge and is completely independent of the XCO BAL module writing all the messages contained in a log to the console is as simple as

### Sample Code

```
out->write( lo_log->messages->all )
```

Notable implementations of `IF_XCO_NEWS` are:

- `IF_XCO_RAP_BEHAVIOR_MESSAGE`. Obtainable via `XCO_CP_RAP=>BEHAVIOR_MESSAGE( ... )`, an `IF_XCO_RAP_BEHAVIOR_MESSAGE` encapsulates an `IF_ABAP_BEHV_MESSAGE` and allows it to be used anywhere where an `IF_XCO_NEWS` object can be used.

## Text

Closely related to the `IF_XCO_NEWS` abstraction is the `IF_XCO_TEXT` interface. The main difference is that it represents an object that can naturally act as a source of strings (as compared to an object that can naturally act as a source of messages as is the case with `IF_XCO_NEWS`).

Like `IF_XCO_NEWS` it provides a common ground for many different XCO modules. It is furthermore the basis of the `IF_XCO_PRINTABLE` interface which allows to define a print version for any object that is used when the object is written to the console via the XCO ADT functionality (see [ADT \[page 1680\]](#)).

## Related Information

[ADT \[page 1680\]](#)

[JSON \[page 1688\]](#)

[Regular Expression \[page 1690\]](#)

[String \[page 1691\]](#)

[UUID \[page 1697\]](#)

## 4.2.12.16.4.1 ADT

By having a class implement the interface `IF_OO_ADT_CLASSRUN` it is possible to easily write programs that can be run directly within ADT using the console as output.

The XCO library provides an abstract implementation of this interface via `CL_XCO_CP_ADT_SIMPLE_CLASSRUN` that exposes all the original functionality of `IF_OO_ADT_CLASSRUN` but adds several additional functionalities that enable a natural integration of XCO library abstractions with ADT classruns.

The following sample class illustrates how the `OUT` object provided by `CL_XCO_CP_ADT_SIMPLE_CLASSRUN` can be used to flexibly write complex data structures or even object references to the console. Using the interface `IF_XCO_PRINTABLE` any object can define a text that is used when the object is written to the console.

### Sample Code

```
CLASS zcl_xco_doc_cp_std_adt DEFINITION PUBLIC FINAL
  INHERITING FROM cl_xco_cp_adt_simple_classrun CREATE PUBLIC.
  PROTECTED SECTION.
  METHODS:
    main REDEFINITION.
ENDCLASS.
CLASS zcl_xco_doc_cp_std_adt IMPLEMENTATION.
  METHOD main.
    TYPES:
      BEGIN OF ts_address,
        street      TYPE string,
        house_number TYPE n LENGTH 2,
        postal_code  TYPE n LENGTH 5,
        city         TYPE string,
      END OF ts_address,
      BEGIN OF ts_member,
        first_name TYPE string,
        last_name  TYPE string,
        address    TYPE ts_address,
      END OF ts_member,
      tt_member TYPE STANDARD TABLE OF ts_member WITH EMPTY KEY.
    " Print a JSON-style serialization (works for arbitrarily deep data
    structures)
    DATA(lt_members) = VALUE tt_member(
      ( first_name = 'John' last_name = 'Doe' address = VALUE #( street =
      'Main street' house_number = 12 postal_code = 12345 city = 'City' ) )
    ).
    " Will print: [{FIRST_NAME: John, LAST_NAME: Doe, ADDRESS: {STREET: Main
    street, HOUSE_NUMBER: 12, POSTAL_CODE: 12345, CITY: City}}]
    out->write( lt_members ).
    " IF_XCO_PRINTABLE example: Will print "WARNING"
    out->write( xco_cp_message=>type->warning ).
    " IF_XCO_PRINTABLE example: Will print "Field MY_FIELD of View entity
    MY_VIEW_ENTITY"
    DATA(lo_field) = xco_cp_cds=>view_entity( 'MY_VIEW_ENTITY' )-
    >field( 'MY_FIELD' ).
    out->write( lo_field ).
  ENDMETHOD.
```

```
ENDCLASS.
```

On top of the rich console writing functionalities, any `NO_CHECK` exception that is not caught by the `MAIN` method of a class implementing `CL_XCO_CP_ADT_SIMPLE_CLASSRUN` will be caught and written to the console with maximum information. This includes the raise position, messages and even the stack trace if the exception is carrying one (cf. explanation of `CX_XCO_RUNTIME_EXCEPTION` above).

## 4.2.12.16.4.2 Business Application Log

The XCO BAL module provides APIs and abstractions that allow a smooth integration of logging into application logic based on the standard Business Application Log (BAL) and provide maximum synergy with the facilities offered by the XCO library in general.

### Terminology

Within the BAL module of the XCO Library, the following terminology is used:

- **Log object:** The design time ABAP Repository object (type `APLO`) defining an application log object together with its subobjects.
- **Log:** A single log instance for a given log object and subobject with an optional external ID into which messages can be written and read from. Represented by an object of type `IF_XCO_CP_BAL_LOG` and uniquely identified by a log handle.
- **Log handle:** A unique identifier for a log (UUID in `CHAR22` format) associated with a log (available through attribute `LOG_HANDLE` of interface `IF_XCO_CP_BAL_LOG`).

### Persistence

The first and one of the central abstractions within the XCO BAL module is that of the persistence given by the interface `IF_XCO_CP_BAL_PERSISTENCE`. A persistence decides where logs are created (resp. loaded from) and where the messages and exceptions are written to (resp. read from).

The following two flavors are offered:

- **Memory:** Logs are created only in memory and messages as well as exceptions are not written to the database
- **Database:** Logs are created and loaded from the database and messages and exceptions are always saved to the database. Whenever a message or exception is added to the log a `COMMIT WORK` is performed on a secondary database connection

## Searching logs

In a style like that of the XCO ABAP Repository Query APIs it is possible to easily locate existing logs based on filters for standard log attributes, like the object, subobject or external ID of a log:

### Sample Code

```
DATA(lo_external_id_filter) = xco_cp_bal=>log_filter->external_id(  
  xco_cp_abap_sql=>constraint->equal( '%INVOICE%' )  
  ).  
DATA(lt_logs) = xco_cp_bal=>for->database( )->logs->where( VALUE #(  
  ( lo_external_id_filter )  
  )->get( ).
```

In this example, all logs in the database whose external ID contains the fragment INVOICE will be located.

## Creating and loading logs

Once the desired persistence has been selected via XCO\_CP\_BAL=>FOR a log can be created like

### Sample Code

```
DATA(lo_log) = xco_cp_bal=>for->database( )->log->create(  
  iv_object      = 'MY_LOG_OBJECT'  
  iv_subobject   = 'MY_LOG_SUBOBJECT'  
  iv_external_id = 'MY_EXTERNAL_ID'  
  ).
```

If a log shall not be created newly but already exists in the database it can be loaded like

### Sample Code

```
DATA(lo_log) = xco_cp_bal=>for->database( )->log->load( 'MY_LOG_HANDLE' ).
```

for a given log handle.

## Profiles

Associated with each IF\_XCO\_CP\_BAL\_LOG object is a profile (IF\_XCO\_CP\_BAL\_PROFILE) that influences how messages and exceptions are added to the log. For messages, a profile provides a default value for the level of detail that is used when messages are added to the log and no explicit level of detail is supplied.

For exceptions, the XCO BAL module offers a rich set of extra information that can be added along with the exception message to achieve maximum information that can be used for detailed error analysis.

The standard profile (XCO\_CP\_BAL=>PROFILE->STANDARD) defines a default level of detail of 4 and includes all possible exception additions as well as an automatic recursive descent for exceptions, i.e. all the previous exceptions of an exception are added to the log as well.

## Adding and reading messages and exceptions

Messages can be added to a log in number of ways. They can be added directly via an explicit SYMSG value like

### Sample Code

```
" Logging a plain SYMSG using the level of detail given by the underlying
" profile.
DATA(ls_symsg) = VALUE symsg(
  msgty = 'W'
  msgid = 'MSG_CLASS'
  msgno = '001'
  msgv1 = 'Item 1'
).
lo_log->add_message( ls_symsg ).
" Logging the same message but this time with an explicitly specified
" level of detail.
lo_log->add_message(
  is_symsg      = ls_symsg
  io_level_of_detail = xco_cp_bal=>level_of_detail->nine
).
```

or by resorting to the standard abstractions IF\_XCO\_NEWS and IF\_XCO\_TEXT from the XCO standard library:

### Sample Code

```
" Support for IF_XCO_NEWS and IF_XCO_TEXT provides a high degree of
" integration with other
" parts of the XCO library.
MESSAGE w001(msg_class) WITH |Item 1| INTO DATA(lv_message).
lo_log->add_news( xco_cp=>sy ).
DATA(lv_string) = |MyStringValue|.
lo_log->add_text( xco_cp=>string( lv_string ) ).
```

Following the pattern which is also used when reading the content of an object of the ABAP Repository, it is easy to access all the messages contained in a log:

### Sample Code

```
DATA(lt_messages) = lo_log->messages->all->get( ).
```

### Note

Note that in order to be able to read from a log, an authorization is required for authorization object S\_APPL\_LOG for the following authorization field values:

- ALG\_OBJECT The object of the application log that is being read
- ALG\_SUBOBJ The subobject of the application log that is being read
- ACTVT: 03

Adding and getting exceptions is identical to how messages are added to and read from the log: Exceptions are added via the ADD\_EXCEPTION method and read via the EXCEPTIONS attribute of an IF\_XCO\_CP\_BAL\_LOG object.

Note that when an exception is added to a log it will automatically be transformed into a message by the underlying Business Application Log if it provides a T100 message. Only when an exception does not provide a T100 message will it be available via the EXCEPTIONS read attribute of IF\_XCO\_CP\_BAL\_LOG.

## 4.2.12.16.4.3 Call Stack

The XCO call stack module allows to programmatically capture and process ABAP call stacks during execution.

The following example call stack, captured by running a locally created ADT classrun (ZCL\_XCO\_CALL\_STACK) will be used to illustrate the different functionalities.

Line	Positive position	Negative position
ZCL_XCO_CALL_STACK main [method]	1	-17
CL_XCO_ADT_CR_SIMPLE_ACTION execute [method]	2	-16
CL_XCO_DP_ACTION_ABSTRACT if_xco_dp_action~execute [method]	3	-15
CL_XCO_ADT_CALL_CLASSRUN if_xco_rt_adt_call_classrun~dispatch [method]	4	-14
CL_XCO_RT_ADT_CLASSRUN_ABSTR if_oo_adt_classrun~main [method]	5	-13
CL_OO_ADT_RES_CLASSRUN execute_clas [method]	6	-12
CL_OO_ADT_RES_CLASSRUN post [method]	7	-11
CL_ADT_REST_RESOURCE if_rest_handler~handle [method]	8	-10
CL_REST_ROUTER if_rest_handler~handle [method]	9	-9
CL_REST_ROUTER if_rest_handler~handle [method]	10	-8
CL_REST_HTTP_HANDLER if_http_extension~handle_request [method]	11	-7
CL_ADT_WB_RES_APP lif_request_handler~handle_request [method]	12	-6
CL_ADT_WB_RES_APP handle_request [method]	13	-5
CL_ADT_WB_RES_APP if_http_extension~handle_request	14	-4
CL_HTTP_SERVER [system] execute_request [method]	15	-3

Line	Positive position	Negative position
SAPLHTTP_RUNTIME [system] http_dispatch_request [function]	16	-2
SAPMHTTP [system] %_http_start [module (pbo)]	17	-1

In a manner analogous to how characters of a string are indexed when substrings are extracted via `IF_XCO_STRING`, the XCO call stack module associates both a positive and a negative index/position with each call stack entry as illustrated above.

## Capturing the current call stack

The current call stack can be captured by using the API `XCO_CP=>CURRENT->CALL_STACK`. The following two methods are available:

- `FULL`: Captures the full current call stack, i.e. all available entries up the lowest entry point will be included
- `UP_TO`: Captures the current call stack up to the given depth, i.e. only the topmost `IV_DEPTH` call stack entries will be captured

Once captured, a call stack is represented as an immutable object of type `IF_XCO_CP_CALL_STACK`.

## Extracting parts of a call stack

Given a call stack (represented as an object of type `IF_XCO_CP_CALL_STACK`) various ways are provided to extract specific parts of the call stack. As the result of any extraction is again an object of type `IF_XCO_CP_CALL_STACK` it's easy to cascade multiple extractions to form complex and highly customized extractions.

The following kinds of extractions are provided:

- `POSITION`: Uses a position (either positive or negative) to fix a reference call stack entry
- `FIRST_OCCURRENCE_OF`: Uses the first occurrence of a given call stack line pattern to fix a reference call stack entry
- `LAST_OCCURRENCE_OF`: Uses the last occurrence of a given call stack line pattern to fix a reference call stack entry

Each extraction is applied in either a `TO` or `FROM` manner:

- `TO`: Extracts that part of the call stack that starts from the top of the call stack to the determined reference call stack entry
- `FROM`: Extracts that part of the call stack that starts from the determined reference call stack entry to the bottom of the call stack

To illustrate these concepts, consider the following extractions where `LO_CALL_STACK` represents the call stack from the above table:

## Sample Code

```
DATA(lo_line_pattern) = xco_cp_call_stack=>line_pattern->method(
  )->where_class_name_starts_with( 'CL_XCO_' ).

DATA(lo_extracted_call_stack) = lo_call_stack->from->position( 2
  )->to->last_occurrence_of( lo_line_pattern
  )->to->position( -2 ).
```

In total three extractions are applied. The first extraction, `->FROM->POSITION( 2 )`, will produce the following call stack:

Line	Positive position	Negative position
CL_XCO_ADT_CR_SIMPLE_ACTION execute [method]	1	-16
CL_XCO_DP_ACTION_ABSTRACT if_xco_dp_action~execute [method]	2	-15
CL_XCO_ADT_CALL_CLASSRUN if_xco_rt_adt_call_classrun~dispatch [method]	3	-14
CL_XCO_RT_ADT_CLASSRUN_ABSTR if_oo_adt_classrun~main [method]	4	-13
CL_OO_ADT_RES_CLASSRUN exe- cute_clas [method]	5	-12
CL_OO_ADT_RES_CLASSRUN post [method]	6	-11
CL_ADT_REST_RESOURCE if_rest_han- dler~handle [method]	7	-10
CL_REST_ROUTER if_rest_handler~han- dle [method]	8	-9
CL_REST_ROUTER if_rest_handler~han- dle [method]	9	-8
CL_REST_HTTP_HANDLER if_http_ex- tension~handle_request [method]	10	-7
CL_ADT_WB_RES_APP lif_request_han- dler~handle_request [method]	11	-6
CL_ADT_WB_RES_APP handle_request [method]	12	-5
CL_ADT_WB_RES_APP if_http_exten- sion~handle_request	13	-4
CL_HTTP_SERVER [system] exe- cute_request [method]	14	-3
SAPLHTTP_RUNTIME [system] http_dispatch_request [function]	15	-2
SAPMHTTP [system] %_http_start [module (pbo)]	16	-1

The second extraction, `->to->last_occurrence_of( lo_line_pattern )`, applied to the result of the first extraction, will then produce the following call:

Line	Positive position	Negative position
CL_XCO_ADT_CR_SIMPLE_ACTION execute [method]	1	-4
CL_XCO_DP_ACTION_ABSTRACT if_xco_dp_action~execute [method]	2	-3
CL_XCO_ADT_CALL_CLASSRUN if_xco_rt_adt_call_classrun~dispatch [method]	3	-2
CL_XCO_RT_ADT_CLASSRUN_ABSTR if_oo_adt_classrun~main [method]	4	-1

Finally, the application of the third extraction, `->to->position( -2 )`, to the result of the second extraction yields the following call stack:

Line	Positive position	Negative position
CL_XCO_ADT_CR_SIMPLE_ACTION execute [method]	1	-3
CL_XCO_DP_ACTION_ABSTRACT if_xco_dp_action~execute [method]	2	-2
CL_XCO_ADT_CALL_CLASSRUN if_xco_rt_adt_call_classrun~dispatch [method]	3	-1

Note that the reference call stack entries are always treated inclusively, i.e. they will be included in the extracted call stack.

## Formatting a call stack

To be written to the console or into an application log (using `IF_XCO_CP_BAL_LOG`), a given call stack can be formatted which will produce an `IF_XCO_TEXT` for the call stack. As of now, the following formats are supported:

- ADT: The ADT format will render a call stack in the same style as the ADT Debugger. Optionally, the captured line numbers (if present) can be added to each resulting call stack entry line whereby source or include based line number flavors are available for selection

Using the call stack from the beginning, formatting it with source-based line numbers and writing the resulting `IF_XCO_TEXT` to the console of an ADT classrun (obtained by inheriting from `CL_XCO_CP_ADT_SIMPLE_CLASSRUN`) can be accomplished as follows:

### Sample Code

```
DATA(lo_format) = xco_cp_call_stack=>format->adt(
    )->with_line_number_flavor( xco_cp_call_stack=>line_number_flavor->source ).
```

```
DATA(lo_call_stack_text) = lo_call_stack->as_text( lo_format ).
out->write( lo_call_stack_text ).
```

This will produce the following output on the console (line numbers may vary on local execution):

```
ZCL_XCO_CALL_STACK main [method] Source line: 10
CL_XCO_ADT_CR_SIMPLE_ACTION execute [method] Source line: 39
CL_XCO_DP_ACTION_ABSTRACT if_xco_dp_action~execute [method] Source line: 59
CL_XCO_ADT_CALL_CLASSRUN if_xco_rt_adt_call_classrun~dispatch [method] Source line:
30
CL_XCO_RT_ADT_CLASSRUN_ABSTR if_oo_adt_classrun-main [method] Source line: 36
CL_OO_ADT_RES_CLASSRUN execute_clas [method] Source line: 206
CL_OO_ADT_RES_CLASSRUN post [method] Source line: 395
CL_ADT_REST_RESOURCE if_rest_handler~handle [method] Source line: 150
CL_REST_ROUTER if_rest_handler~handle [method] Source line: 325
CL_REST_HTTP_HANDLER if_http_extension~handle_request [method] Source line: 190
CL_ADT_WB_RES_APP lif_request_handler~handle_request [method] Source line: 19
CL_ADT_WB_RES_APP handle_request [method] Source line: 317
CL_ADT_WB_RES_APP if_http_extension~handle_request [method] Source line: 435
CL_HTTP_SERVER [system] execute_request [method] Source line: 2840
SAPLHTTP_RUNTIME [system] http_dispatch_request [function] Source line: 1626
SAPMHTTP [system] %_http_start [module (pbo)] Source line: 12
```

## 4.2.12.16.4.4 JSON

The goal of the XCO JSON module is to make working with JSON data as simple as possible. This includes the creation of JSON strings (both from ABAP data structures and from scratch) as well as the translation of JSON strings to ABAP.

### Reading JSON strings

The following code shows an example of how a JSON string (e.g. the response of an outbound service call) can be translated into a corresponding ABAP structure:

#### Sample Code

```
DATA(lv_json_string) = '{
  && |"SessionId": "7cd44fff-036a-4155-b0d2-f5a4dfbcee92", |
  && |"UserName": "John Doe", |
  && |"IsPremiumUser": true |
  && |}' .
TYPES:
  BEGIN OF ts_input,
```

```

    session_id      TYPE sysuuid_c36,
    user_name       TYPE string,
    is_premium_user TYPE abap_bool,
  END OF ts_input.
DATA ls_input TYPE ts_input.
" After execution, the structure components will have the following values
" session_id = 7cd44fff-036a-4155-b0d2-f5a4dfbcee92
" user_name = John Doe
" is_premium_user = X
xco_cp_json=>data->from_string( lv_json_string )->apply( VALUE #(
  ( xco_cp_json=>transformation->pascal_case_to_underscore )
  ( xco_cp_json=>transformation->boolean_to_abap_bool )
) )->write_to( REF #( ls_input ) ).

```

To make it easy to adjust JSON data to ABAP requirements (e.g. to switch between camel case and underscore notation) the XCO library provides built-in transformations which are accessible via the XCO\_CP\_JSON API. The current version of the XCO library comes with the following three built-in transformations:

- Camel case/Pascal case to underscore: Transforms the name of each object member in the JSON data from Camel case/Pascal case to underscore notation
- Underscore to Camel case/Pascal case: Transforms the name of each object member in the JSON data from underscore to Camel case/Pascal case notation
- Boolean to abap\_bool: Transforms each JSON boolean value to its abap\_bool equivalent, i.e. true becomes 'X' and false becomes ''

Note that the XCO library uses the following terminology:

- Camel case: The first character of each word is capitalized except for the first word.
- Pascal case: The first character of each word is capitalized including the first word.

## Creating JSON strings

JSON strings can be created in two ways, either from scratch or from a corresponding ABAP data structure. Using the XCO JSON data builder, JSON data can be built like:

### Sample Code

```

DATA(lo_json_builder) = xco_cp_json=>data->builder( ).
lo_json_builder->begin_object(
  )->add_member( 'SessionId' )->add_string( '7cd44fff-036a-4155-b0d2-
f5a4dfbcee92'
  )->add_member( 'UserName' )->add_string( 'John Doe'
  )->add_member( 'IsPremiumUser' )->add_boolean( abap_true
  )->end_object( ).
" After execution LV_JSON_STRING will have the value
" {"SessionId":"7cd44fff-036a-4155-b0d2-f5a4dfbcee92","UserName":"John
Doe","IsPremiumUser":true}
DATA(lv_json_string) = lo_json_builder->get_data( )->to_string( ).

```

In the same way that a JSON string can be translated to an appropriate ABAP data structure an ABAP data structure can be translated to a JSON string. It is again possible to apply transformations to e.g. transform underscore to camel case notation.

### Sample Code

```

TYPES:
  BEGIN OF ts_output,
    session_id      TYPE sysuuid_c36,

```

```

        user_name          TYPE string,
        is_premium_user TYPE xsdboolean,
    END OF ts_output.
DATA(ls_output) = VALUE ts_output(
    session_id      = '7cd44fff-036a-4155-b0d2-f5a4dfbcee92'
    user_name       = |John Doe|
    is_premium_user = abap_true
).
" After execution LV_JSON_STRING will have the value
" {"SessionId":"7cd44fff-036a-4155-b0d2-f5a4dfbcee92","UserName":"John
Doe","IsPremiumUser":true}
DATA(lv_json_string) = xco_cp_json=>data->from_abap( ls_output )-
>apply( VALUE #(
    ( xco_cp_json=>transformation->underscore_to_pascal_case )
) )->to_string( ).

```

## 4.2.12.16.4.5 Regular Expression

Regular expressions can be used to match strings against patterns or extract substrings that match certain criteria.

The regular expression engines offered by XCO are based on the standards offered by CL\_ABAP\_REGEX:

- POSIX
- PCRE
- XPATH2
- XSD

In XCO, these regular expression standards are encapsulated in the IF\_XCO\_REGEX\_ENGINE abstraction which is accessible via the XCO\_CP\_REGULAR\_EXPRESSION API:

### Sample Code

```

" Example for a POSIX regular expression engine (More configuration options
are available
" as optional parameters of the method POSIX).
DATA(lo_posix_engine) = xco_cp_regular_expression=>engine->posix(
    iv_ignore_case = abap_true
).
" Example for a PCRE regular expression engine (More configuration options
are available
" as optional parameters of the method PCRE).
DATA(lo_pcre_engine) = xco_cp_regular_expression=>engine->pcre(
    iv_ignore_case      = abap_false
    iv_enable_multiline = abap_false
).
" Example for an XPATH 2.0 regular expression engine (More configuration
options are available
" as optional parameters of the method XPATH2).
DATA(lo_xpath2_engine) = xco_cp_regular_expression=>engine->xpath2(
    iv_ignore_case      = abap_true
    iv_enable_multiline = abap_false
).
" Example for an XSD regular expression engine (More configuration options
are available
" as optional parameters of the method XSD).
DATA(lo_xsd_engine) = xco_cp_regular_expression=>engine->xsd(
    iv_ignore_case      = abap_true
    iv_enable_multiline = abap_false

```

```
).
```

The parameters of the regular expression engine factory methods can be used to configure the behavior of the engine when it is used against a string. The default engine (which is used when no explicit engine is supplied) is POSIX in the default configuration as provided by CL\_ABAP\_REGEX.

A regular expression can be used to easily check if a given string matches a pattern

#### ↔ Sample Code

```
" LV_CASE_INSENSITIVE_MATCHES will have the value abap_true as
" LO_POSIX_ENGINE is case insensitive (see above).
DATA(lv_case_insensitive_matches) = xco_cp=>string( |abc| )->matches(
  iv_regular_expression = '^a.*C$'
  io_engine              = lo_posix_engine
).
" LV_CASE_SENSITIVE_MATCHES will have the value abap_false as the
" default POSIX engine is case sensitive.
DATA(lv_case_sensitive_matches) = xco_cp=>string( |abc| )->
>matches( '^a.*C$' ).
```

or to retrieve certain parts from it

#### ↔ Sample Code

```
DATA(lo_name_parts) = xco_cp=>string( |John Doe| )->grep( '^(\S+)\s+(\S+)$' ).
" LV_FIRST_NAME = John
DATA(lv_first_name) = lo_name_parts->value[ 1 ].
" LV_LAST_NAME = Doe
DATA(lv_last_name) = lo_name_parts->value[ 2 ].
```

## 4.2.12.16.4.6 String

Besides providing a straightforward integration with regular expressions (see [Regular Expression \[page 1690\]](#)), the XCO string abstraction offers further simplifications when working with strings.

### The methods TO and FROM

The methods TO and FROM provide flexible ways to extract a substring from a string. Their functionality is based on the following character indexing scheme (The table is based on the example string ABCDEF):

A	B	C	D	E	F
1	2	3	4	5	6
-6	-5	-4	-3	-2	-1

Both TO and FROM have an inclusive behavior, i.e. the provided index is always included in the retrieved substring. Furthermore, if the provided index is out of bounds the behavior is as if the index had pointed to the first (resp. last) character of the string.

The following sample illustrates several usages:

### Sample Code

```
DATA(lo_string) = xco_cp=>string( |ABCDEF| ).
" LV_SUBSTRING_1 = DEF
DATA(lv_substring_1) = lo_string->from( 4 )->value.
" LV_SUBSTRING_2 = DEF
DATA(lv_substring_2) = lo_string->from( -3 )->value.
" LV_SUBSTRING_3 = ABC
DATA(lv_substring_3) = lo_string->to( 3 )->value.
" LV_SUBSTRING_4 = ABC
DATA(lv_substring_4) = lo_string->to( -4 )->value.
" LV_SUBSTRING_5 = CD
DATA(lv_substring_5) = lo_string->from( 3 )->to( 2 )->value.
" LV_SUBSTRING_6 = BC
DATA(lv_substring_6) = lo_string->to( -4 )->from( 2 )->value.
```

## Splitting and joining

The XCO string library also provides a way to split strings and join a list of strings:

### Sample Code

```
DATA(lo_name_parts) = xco_cp=>string( |John Doe| )->split( | | ).
" LV_REVERSED_NAME = Doe, John
DATA(lv_reversed_name) = lo_name_parts->reverse( )->join( |, | )->value.
```

## Composing and decomposing

A generalization of split and join operations on strings are string compositions and decompositions.

String compositions and decompositions encapsulate algorithms which can transform a string to a list of strings (decomposition) and vice versa (composition) according to a certain formula. Currently, both Camel Case and Pascal Case are supported in both directions.

The following example illustrates how the camel case composition and decomposition can be used to easily translate between underscore and camel case notation.

### Sample Code

```
DATA(lv_string_with_underscores) = |FIRST_NAME|.
" LV_STRING_IN_CAMEL_CASE = firstName
DATA(lv_string_in_camel_case) = xco_cp=>string( lv_string_with_underscores
)->split( |_|
)->compose( xco_cp_string=>composition->camel_case
)->value.
" LV_RESTORED_STRING = FIRST_NAME
DATA(lv_restored_string) = xco_cp=>string( lv_string_in_camel_case
)->decompose( xco_cp_string=>decomposition->camel_case
)->join( |_|
)->to_upper_case(
)->value.
```

## Converting strings to xstrings

Converting a given string to its xstring representation for a given code page can be easily accomplished by making use of `IF_XCO_CHAR_CODE_PAGES` which are available via `XCO_CP_CHARACTER`:

### Sample Code

```
DATA(lv_string) = |ABC|.
" The representation of LV_STRING as an XSTRING where the given character
" code page is used for the conversion.
DATA(lv_xstring) = xco_cp=>string( lv_string
    )->as_xstring( xco_cp_character=>code_page->utf_8 ).
```

## Calculating Hash Codes

Calculating the hash value of a given string for a given hash algorithm can be accomplished as follows:

### Sample Code

```
" Upon execution, LV_HASH_VALUE will have the value
C79C561BB2CC3D0430A54B3D014C89C3089FE089.
DATA(lv_hash_value) = xco_cp=>string( 'MY_STRING'
    )->as_xstring( xco_cp_hash=>algorithm->sha_1
    )->value.
```

Note the following details:

- Supported hash algorithms (represented as objects of type IF\_XCO\_HASH\_ALGORITHM) can be obtained via XCO\_CP\_HASH=>ALGORITHM. The SHA-1 hash algorithm is statically available via the SHA\_1 property while the FOR method can be used to obtain hash algorithms based on their string identifiers, e.g. XCO\_CP\_HASH=>ALGORITHM->FOR( 'MD5' ) for the MD5 hash algorithm
- When calculating the hash value of a string, an IF\_XCO\_HASH\_ALGORITHM object acts as an IF\_XCO\_STRING\_XSTRING\_CNVRSN, where the XSTRING that is derived from the string corresponds to the hash value

## 4.2.12.16.4.7 System

With the XCO system module, you can easily request information about the current system.

## Namespaces

You can get a handle for a given namespace via the API XCO\_CP\_SYSTEM=>NAMESPACE. Once obtained, you can use a namespace handle to find out whether the given namespace exists in the system and, if so, whether it's changeable:

### Sample Code

```
" LO_NAMESPACE is a handle that can be used to request information
" about namespace /ABC/.
DATA(lo_namespace) = xco_cp_system=>namespace->for( '/ABC/' ).
```

```

" LV_NAMESPACE is an ABAP_BOOL value indicating whether the namespace
" represented by LO_NAMESPACE exists or not.
DATA(lv_namespace_exists) = lo_namespace->exists( ).

" LV_NAMESPACE_IS_CHANGEABLE is an ABAP_BOOL value indicating whether the
" namespace represented by LO_NAMESPACE is changeable or not. Note that,
" before invoking this method, it should be ensured that the namespace exists
" as otherwise a runtime exception will be raised.
DATA(lv_namespace_is_changeable) = lo_namespace->is_changeable( ).

```

## 4.2.12.16.4.8 Tenant

The XCO tenant module provides standard abstractions for querying information about tenants, in particular the tenant associated with the current ABAP session.

The central abstraction `IF_XCO_CP_TENANT` represents a tenant and is used to retrieve its public information. As of now, the following information can be retrieved:

- ID: The ID for the tenant
- GUID: The GUID for the tenant (represented as an `IF_XCO_UUID`)
- URL: The URL of the tenant for the given URL type (URL types are available via `XCO_CP_TENANT=>URL_TYPE`)
- Global Account ID: The ID of the global account associated with the tenant
- Subaccount ID: The ID of the subaccount associated with the tenant

The currently active tenant can be obtained via:

```
DATA(lo_current_tenant) = xco_cp=>current->tenant( ).
```

Note that depending on the overall system infrastructure and setup a current tenant doesn't necessarily exist, which would be indicated by an initial reference returned by the statement above. Once the current tenant has been obtained by the URL (in the example below for the type UI) along with its different components, the currently active tenant can be obtained as follows:

### Sample Code

```

" UI URL of the current tenant.
DATA(lo_ui_url) = lo_current_tenant->get_url( xco_cp_tenant=>url_type->ui ).

" The protocol of the UI URL (Type string).
DATA(lv_ui_url_protocol) = lo_ui_url->get_protocol( ).

" The host (including the domain) of the UI URL (Type string).
DATA(lv_ui_url_host) = lo_ui_url->get_host( ).

" The port of the UI URL (Type i).
DATA(lv_ui_url_port) = lo_ui_url->get_port( ).

```

In a similar way it's also possible to access the information about the associated global account and subaccount:

### Sample Code

```
" The string value of the global account ID of the current tenant.
DATA(lv_global_account_id) = lo_current_tenant->get_global_account_id(
  )->as_string( ).
" The string value of the subaccount ID of the current tenant.
DATA(lv_subaccount_id) = lo_current_tenant->get_subaccount_id(
  )->as_string( ).
```

## 4.2.12.16.4.9 Time Library

The XCO time library provides standard abstractions for working with temporal values.

- A date (IF\_XCO\_CP\_TM\_DATE) consists of values for year, month and day
- A time (IF\_XCO\_CP\_TM\_TIME) consists of values for hour, minute and second
- A moment (IF\_XCO\_CP\_TM\_MOMENT) consists of a fully specified date and time
- A UNIX timestamp (IF\_XCO\_CP\_TM\_UNIX\_TIMESTAMP) consists of an INT8 value specifying the number of seconds that have elapsed since 00:00:00 UTC on Jan 1st, 1970.

### Dates, times and moments

The abstractions date, time and moment correspond to the ABAP temporal types DATS, TIMS and TZNTSTMPs. Given a date, time or moment object, a new object can be derived from each of them by adding or subtracting values from their components or directly overriding specific values. Note that date, time and moment objects are always immutable, i.e. once constructed their values will never change.

Time zone information is explicitly not part of the state of a date, time or moment object.

### Time formats

A time format is a unique representation of a date, time or moment. Currently, the following time formats are supported:

- ABAP: Will provide the DATS, TIMS and TZNTSTMPs value, respectively
- ISO 8601 Basic
- ISO 8601 Extended

Time formats are accessible via XCO\_CP\_TIME=>FORMAT and can be used either directly or passed to the AS method of a date, time or moment object to obtain the string representation of the object according to the provided time format.

The following code sample illustrates the usage of the various time formats for a moment object:

### Sample Code

```
DATA(lo_moment) = xco_cp_time=>moment(
  iv_year   = '2020'
  iv_month  = '09'
  iv_day    = '16'
  iv_hour   = '22'
  iv_minute = '33'
  iv_second = '49'
).
" LV_ABAP_FORMAT will be of type STRING and have the value 20200916223349.
```

```

DATA(lv_abap_format) = lo_moment->as( xco_cp_time=>format->abap )->value.
" LV_ISO_8601_BASIC will be of type STRING and have the value 20200916T223349.
DATA(lv_iso_6801_basic) = lo_moment->as( xco_cp_time=>format->iso_8601_basic )->value.
" LV_ISO_8601_EXTENDED will be of type STRING and have the value
2020-09-16T22:33:49.
DATA(lv_iso_6801_extended) = lo_moment->as( xco_cp_time=>format->iso_8601_extended )->value.
" Restore the moment from LV_ISO_8601_EXTENDED. LO_RESTORED_MOMENT will be an
object of type
" IF_XCO_CP_TM_MOMENT with values equal to LO_MOMENT.
DATA(lo_restored_moment) = xco_cp_time=>format->iso_8601_extended->to_moment( lv_iso_6801_extended ).

```

## Integration with XCO\_CP=>SY

The XCO time library is tightly integrated with the XCO abstraction for the ABAP SY structure to provide an easy way to access the current time, either as a date, time or moment object or as a UNIX timestamp.

When a date, time or moment object is obtained, the time zone according to which the values should be calculated can be specified in addition. Note that a UNIX timestamp will always be in UTC.

### Sample Code

```

" The current moment in the time zone of the active user.
DATA(lo_moment_user) = xco_cp=>sy->moment( xco_cp_time=>time_zone->user ).
" The current moment in UTC.
DATA(lo_moment_utc) = xco_cp=>sy->moment( xco_cp_time=>time_zone->utc ).
" The current UNIX timestamp.
DATA(lo_unix_timestamp) = xco_cp=>sy->unix_timestamp( ).

```

Note that if a time zone is not explicitly specified when a date, time or moment object is retrieved from XCO\_CP=>SY, the time zone of the active user will be taken.

## UNIX timestamps

UNIX timestamps are a common way for describing a given point in time by denoting the number of elapsed seconds since 00:00:00 UTC on Jan 1st, 1970. The XCO time library makes it easy to convert from a given UNIX timestamp to a moment and vice versa:

### Sample Code

```

" The current UNIX timestamp.
DATA(lo_unix_timestamp) = xco_cp=>sy->unix_timestamp( ).
" Get the moment for the UNIX timestamp (in the time zone of the active
" user).
DATA(lo_moment) = lo_unix_timestamp->get_moment( xco_cp_time=>time_zone->user ).
" Restore the original UNIX timestamp. The value of
LO_RESTORED_UNIX_TIMESTAMP is
" equal to that of LO_UNIX_TIMESTAMP.
DATA(lo_restored_unix_timestamp) = lo_moment->get_unix_timestamp( xco_cp_time=>time_zone->user ).

```

## 4.2.12.16.4.10 UUID

To effectively work with UUIDs the XCO standard library provides a simple way to translate between different UUID formats:

### Sample Code

```
DATA(lo_uuid) = xco_cp_uuid=>format->c36->to_uuid( '7cd44fff-036a-4155-b0d2-
f5a4dfbcee92' ).
" LV_UUID_C32 will hold the value 7CD44FFF036A4155B0D2F5A4DFBCEE92
DATA(lv_uuid_c32) = CONV sysuuid_c32( xco_cp_uuid=>format->c32-
>from_uuid( lo_uuid ) ).
```

## 4.2.12.16.4.11 XLSX

The XCO XLSX module offers a set of standard abstractions and APIs to programmatically work with XLSX workbooks and their worksheets (e.g. coming from an uploaded Microsoft Excel .XLSX file).

The XCO XLSX module exposes three external APIs:

- XCO\_CP\_XLSX: Access to general abstractions used throughout the XCO XLSX module
- XCO\_CP\_XLSX\_SELECTION: Access to selection pattern builders used to build selection patterns
- XCO\_CP\_XLSX\_READ\_ACCESS: Access to abstractions used when reading the content of an XLSX worksheet

## Document handles

The starting point for any programmatic interaction with an XLSX workbook and its worksheets is obtaining a handle for the containing document via XCO\_CP\_XLSX=>DOCUMENT. As of now, document handles can be obtained for the complete file content of an .XLSX file, which must be provided as an XSTRING:

### Sample Code

```
DATA lv_file_content TYPE xstring.

" LV_FILE_CONTENT must be populated with the complete file content of
the .XLSX file
" whose content shall be processed programmatically.

DATA(lo_document) = xco_cp_xlsx=>document-
>for_file_content( lv_file_content ).
```

The obtained document handle then allows to obtain a read access, which is the starting point for accessing the cell contents of the worksheets contained in the document [XLSX Read Access \[page 1700\]](#).

## Coordinates

Within the XCO XLSX module, a worksheet is regarded as a space with two dimensions, with the first dimension being the column and the second dimension being the row. Consequently, a cell in a worksheet is uniquely determined by providing values for its column and row. A coordinate (an object of type `CL_XCO_XLSX_COORDINATE`) uniquely fixes a value for a given dimension, for example, for a value for a column or row. In office suites, e.g. Microsoft Excel, alphabetic values are used to identify columns and numeric values are used to identify rows. The XCO XLSX module provides support for both variants so that alphabetic as well as numeric values can be used freely when values are provided for columns and rows.

- Alphabetic coordinates: A, B, C, ... Z, AA, AB, ...ZZ, AAA, AAB, ...
- Numeric coordinates: 1, 2, 3, ...

Coordinates can be obtained via `XCO_CP_XLSX=>COORDINATE` for both alphabetic and numeric values and once obtained, both the alphabetic as well as the numeric value can be retrieved for a coordinate. This also provides an easy way to translate between alphabetic and numeric coordinate values, for example:

### Sample Code

```
DATA(lo_coordinate_1) = xco_cp_xlsx=>coordinate->for_alphabetic_value( 'AA' ).  
  
" LV_COORD_1_NUMERIC_VALUE will be an integer with value 27.  
DATA(lv_coord_1_numeric_value) = lo_coordinate_1->get_numeric_value( ).  
  
" LV_COORD_1_ALPHABETIC_VALUE will be a string with value AA.  
DATA(lv_coord_1_alphabetic_value) = lo_coordinate_1->get_alphabetic_value( ).  
  
DATA(lo_coordinate_2) = xco_cp_xlsx=>coordinate->for_numeric_value( 27 ).  
  
" LV_COORD_2_NUMERIC_VALUE will be an integer with value 27.  
DATA(lv_coord_2_numeric_value) = lo_coordinate_2->get_numeric_value( ).  
  
" LV_COORD_2_ALPHABETIC_VALUE will be a string with value AA.  
DATA(lv_coord_2_alphabetic_value) = lo_coordinate_2->get_alphabetic_value( ).
```

It's possible to derive new coordinates from existing coordinates such as objects of type `CL_XCO_XLSX_COORDINATE`, by using the `SHIFT` method to either increment or decrement the value of the coordinate (depending on the sign of the provided offset).

## Selection patterns

Selections are a central concept within the XCO XLSX module. A selection is based on a selection pattern which encapsulates a prescription according to which individual cells are identified in a given worksheet which then form the selection. To illustrate the concepts and offered selection patterns consider the following exemplary portion of an XLSX worksheet:

	A	B	C	D	E	F	...
1							
2		1	2	3	4		

	A	B	C	D	E	F	...
3		5	6	7	8		
4		9	10	11	12		
5		13	14	15	16		
6							
...							

For the purposes of the following code samples, it's assumed that except for the cell values shown above, all other cells of the worksheet are initial. Supported selection patterns can be built via selection pattern builders which are obtainable via `XCO_CP_XLSX_SELECTION=>PATTERN_BUILDER`.

## Simple from-to selection patterns

A simple from-to selection pattern allows to define static boundary values for columns and rows. It's not required to specify a boundary value for each dimension, hence both bounded and unbounded selections are possible. Consider the following characteristic examples:

### Sample Code

```
" The selection pattern LO_PATTERN_1 will be a bounded rectangle, matching
values
" 6, 7, 10 and 11 of the above worksheet.
DATA(lo_pattern_1) = xco_cp_xlsx_selection=>pattern_builder->simple_from_to(
  )->from_column( xco_cp_xlsx=>coordinate->for_alphabetic_value( 'C' )
  )->to_column( xco_cp_xlsx=>coordinate->for_alphabetic_value( 'D' )
  )->from_row( xco_cp_xlsx=>coordinate->for_numeric_value( 3 )
  )->to_row( xco_cp_xlsx=>coordinate->for_numeric_value( 4 )
  )->get_pattern( ).

" The selection pattern LO_PATTERN_2 will be unbounded at the bottom, matching
" values 6, 7, 10, 11, 14 and 15 of the above worksheet.
DATA(lo_pattern_2) = xco_cp_xlsx_selection=>pattern_builder->simple_from_to(
  )->from_column( xco_cp_xlsx=>coordinate->for_alphabetic_value( 'C' )
  )->to_column( xco_cp_xlsx=>coordinate->for_alphabetic_value( 'D' )
  )->from_row( xco_cp_xlsx=>coordinate->for_numeric_value( 3 )
  )->get_pattern( ).

" The selection pattern LO_PATTERN_3 will be unbounded at the bottom and at
the
" right, matching values 6, 7, 8, 10, 11, 12, 14, 15 and 16 of the above
worksheet.
DATA(lo_pattern_3) = xco_cp_xlsx_selection=>pattern_builder->simple_from_to(
  )->from_column( xco_cp_xlsx=>coordinate->for_alphabetic_value( 'C' )
  )->from_row( xco_cp_xlsx=>coordinate->for_numeric_value( 3 )
  )->get_pattern( ).

" The selection pattern LO_PATTERN_4 is completely unbounded, matching all
cells of the
" worksheet, hence also all values of the above worksheet.
DATA(lo_pattern_4) = xco_cp_xlsx_selection=>pattern_builder->simple_from_to(
  )->get_pattern( ).
```

## 4.2.12.16.4.11.1 XLSX Read Access

The starting point for programmatically reading the content of an XLSX document is to obtain a read access for the document. This document shows how this is done.

### ⚠ Caution

Note that when data is read from a given XLSX document via the XCO XLSX module, the data is provided in exactly the way it's stored within the XLSX document. This implies that no security or any other kind of additional validations are performed against the data contained in the worksheets of the XLSX workbook when it's accessed by the means described below. Please ensure that when the read data is further processed by application logic (for example, stored in a database table or shown in a Fiori app), dedicated checks are in place to guard your application against potentially malicious content (such as string values in an XLSX worksheet containing JavaScript code).

Consider the following:

### 🔗 Sample Code

```
DATA lv_file_content TYPE xstring.  
  
" LV_FILE_CONTENT must be populated with the complete file content of  
the .XLSX file  
" whose content shall be processed programmatically.  
  
DATA(lo_read_access) = xco_cp_xlsx=>document-  
>for_file_content( lv_file_content  
)->read_access( ).
```

Once obtained, the next step is to obtain the read access for the worksheet which contains the data that shall be read. It's possible to identify a worksheet based on its name or position:

### 🔗 Sample Code

```
" Read access for the worksheet at position 1, i.e. the first worksheet in  
the workbook.  
DATA(lo_first_worksheet) = lo_read_access->get_workbook(  
)->worksheet->at_position( 1 ).  
  
" Read access for the worksheet with name INVOICES.  
DATA(lo_invoices_worksheet) = lo_read_access->get_workbook(  
)->worksheet->for_name( 'INVOICES' ).
```

## Accessing data via a stream

The first way to gain access to the data stored in a worksheet is by selecting a collection of cells based on a selection pattern (see [XLSX \[page 1697\]](#)=> *Selection patterns*). This is done via method SELECT on IF\_XCO\_XLSX\_RA\_WORKSHEET. Accessing the cells contained in the selection is done following a stream-based approach, meaning a dedicated stream is obtained for the selection which will provide sequential access to the individual blocks of the selection. Two kinds of streams are offered:

- Cell stream: A cell stream provides access to the selection one cell at a time, traversing the selection from left to right and top to bottom
- Row stream: A row stream provides access to the selection one row at a time, traversing the selection from top to bottom

## Cell streams

Cell streams are intended for dynamic reading scenarios where it's required to process each cell individually. As such, the following operations are offered for cell streams:

- Visit: The visit operation takes a visitor implementation as the input (an object of type `IF_XCO_XLSX_RA_CS_VISITOR`) which defines the logic that shall be performed for each cell. This construction follows the `visitor` design pattern.

Consider the following example of how a visit operation can be obtained and executed:

### Sample Code

```
" A selection pattern that was obtained via
XCO_CP_XLSX_SELECTION=>PATTERN_BUILDER.
DATA lo_selection_pattern TYPE REF TO if_xco_xlsx_slc_pattern.

" The read access to the worksheet.
DATA lo_worksheet TYPE REF TO if_xco_xlsx_ra_worksheet.

" The implementation of the visitor, e.g. a dedicated local class containing
the
" logic that shall be performed for each visited cell.
DATA lo_visitor TYPE REF TO if_xco_xlsx_ra_cs_visitor.

lo_worksheet->select( lo_selection_pattern
) -> cell_stream(
) -> operation->visit( lo_visitor
) -> if_xco_xlsx_ra_operation~execute( ).
```

## Row streams

Row streams are best used when the structure of the data that shall be read is statically known. The primary use case is to read a portion of a worksheet (as identified by a selection) into an internal table. As such, the following operations are offered for row streams:

- Write To: The write to operation takes a reference to an internal table as the input to which the selected data shall be written (upon execution of the operation)

Consider the following example of how a write to operation can be obtained and executed:

### Sample Code

```
" A selection pattern that was obtained via
XCO_CP_XLSX_SELECTION=>PATTERN_BUILDER.
DATA lo_selection_pattern TYPE REF TO if_xco_xlsx_slc_pattern.

" The read access to the worksheet.
DATA lo_worksheet TYPE REF TO if_xco_xlsx_ra_worksheet.

" The type definition resembling the structure of the rows in the worksheet
selection.
TYPES:
  BEGIN OF ts_row,
    first_name TYPE string,
    last_name  TYPE string,
```

```

    day_of_birth TYPE d,
  END OF ts_row,

  tt_row TYPE STANDARD TABLE OF ts_row WITH DEFAULT KEY.

DATA lt_rows TYPE tt_row.

lo_worksheet->select( lo_selection_pattern
  )->row_stream(
  )->operation->write_to( REF #( lt_rows )
  )->if_xco_xlsx_ra_operation~execute( ).

" At this point, the internal table LT_ROWS will contain the rows from the
worksheet
" selection.

```

## Accessing data via a cursor

An alternative to accessing the data in a worksheet via selections and streams is to obtain a cursor for a worksheet read access via method `CURSOR` on `IF_XCO_XLSX_RA_WORKSHEET`. Just as with desktop office suites, a cursor can first be positioned on any given cell (identified by coordinate values for both the column and row of the cell). Afterwards, it can be moved around the worksheet freely via the methods on `IF_XCO_XLSX_RA_CURSOR`:

- Methods `MOVE_UP`, `MOVE_RIGHT`, `MOVE_DOWN` and `MOVE_LEFT` can be used to move the cursor relative to its current position by the given number of steps
- Methods `SET_COLUMN` and `SET_ROW` can be used to set the new column or row for the cursor
- Method `HAS_CELL` can be used to determine if the underlying worksheet contains a cell for the current position of the cursor. If so, it can be accessed via method `GET_CELL`

The following example illustrates how the string values of the cells in column A starting at row 5 can be read out until the first row is encountered for which the worksheet has no cell or the cell has no value:

### Sample Code

```

" The read access to the worksheet.
DATA lo_worksheet TYPE REF TO if_xco_xlsx_ra_worksheet.

DATA(lo_cursor) = lo_worksheet->cursor(
  io_column = xco_cp_xlsx=>coordinate->for_alphabetic_value( 'A' )
  io_row     = xco_cp_xlsx=>coordinate->for_numeric_value( 5 )
  ).

WHILE lo_cursor->has_cell( ) EQ abap_true
  AND lo_cursor->get_cell( )->has_value( ) EQ abap_true.
  DATA(lo_cell) = lo_cursor->get_cell( ).

  DATA(lv_string_value) = ``.
  lo_cell->get_value(
    )->set_transformation( xco_cp_xlsx_read_access=>value_transformation-
>string_value
    )->write_to( REF #( lv_string_value ) ).

" At this point LV_STRING_VALUE contains the string value of the cell
" at the current position of the cursor.

" Move the cursor down one row.
lo_cursor->move_down( ).

```

## Reading out hyperlinks

When data is accessed via a cursor, it's also possible to read out the hyperlink associated with a given cell. To this extent, once a handle for a cell has been obtained in the form of an object of type `IF_XCO_XLSX_RA_CELL`, it's possible to

- Check if a hyperlink is associated to the given cell via method `HAS_HYPERLINK` on `IF_XCO_XLSX_RA_CELL`
- Obtain the handle for the hyperlink of the given cell via method `GET_HYPERLINK` on `IF_XCO_XLSX_RA_CELL`

The handle for a hyperlink, `IF_XCO_XLSX_RA_HYPERLINK`, can then be used to obtain both the target and the location of the hyperlink via methods `GET_TARGET` and `GET_LOCATION`. Both target and location are returned exactly as they are stored within the XLSX document.

## Value transformations

When accessing the value of an individual cell (via `IF_XCO_XLSX_RA_CELL_VALUE`) or of a complete row (as part of a row stream operation), it's possible to apply transformations to the value, which will affect how the cell value is written to an ABAP data field. Technically, a value transformation (obtainable via `XCO_CP_XLSX_READ_ACCESS=>VALUE_TRANSFORMATION`) encapsulates a transformation routine that can be applied to

- Values of individual cells (in case the value transformation implements the interface `IF_XCO_XLSX_RA_VT_CELL_VALUE`)
- Values of rows (in case the value transformation implements the interface `IF_XCO_XLSX_RA_VT_ROW_VALUE`)

The following value transformations are currently offered:

- Identity
- String value
- Best effort

The default value transformation is the best effort value transformation. It can be overwritten using

- Method `SET_VALUE_TRANSFORMATION` of `IF_XCO_XLSX_RA_CELL_VALUE` when the value of an individual cell is read
- Method `SET_VALUE_TRANSFORMATION` of `IF_XCO_XLSX_RA_RS_OP_WRITE_TO` when row values are read and written to an internal table as part of the write to row stream operation

### 'Identity' value transformation

The 'identity' value transformation doesn't apply any modification to the XLSX type or value of a cell. As such, the ABAP field that the cell value shall be written to must be fully compliant with the type and value of the cell as it's stored in the XLSX file. Technically, the value as it's stored in the XLSX file is first written to a string

data object, which is then written to the provided ABAP field without changes and as such, if this write can't be performed successfully, a runtime error is to be expected.

### 'String value' value transformation

The 'string value' value transformation gets the stringified value of any cell such that it can always be safely written to an ABAP field of type STRING.

### 'Best effort' value transformation

The 'best effort' value transformation is based on an inspection (based on ABAP runtime type services) of the ABAP field that a given cell value shall be written to. Based on the type determined for the target ABAP field a transformation is applied to the cell value. The 'best effort' value transformation behaves just as the 'identity' value transformation except for the following types of ABAP fields:

- D: When a cell value is written to an ABAP date field the value of the cell is interpreted as a date and it is converted to the ABAP date format
- T: When a cell value is written to an ABAP time field the value of the cell is interpreted as a time and it is converted to the ABAP time format
- Data element MSEHI: When a cell value is written to an ABAP field typed against data element MSEHI the cell value is interpreted as the external value for a unit of measurement which is converted to the internal ABAP format using conversion routine CUNIT
- Data element SPRAS: When a cell value is written to an ABAP field typed against data element SPRAS the cell value is interpreted as the external value for a language which is converted to the internal ABAP format using conversion routine ISOLA

## 4.2.12.16.4.11.2 XLSX Write Access

The starting point for programmatically writing the content of an XLSX document is to obtain a write access for the document. This document shows how this is done.

### Context

Creating a new, empty XLSX document and obtaining write access for it can be accomplished like this:

#### Sample Code

```
DATA(lo_write_access) = xco_cp_xlsx=>document->empty( )->write_access( ).
```

An empty XLSX document consists of one worksheet named `sheet1` which is accessible via

#### Sample Code

```
DATA(lo_worksheet) = lo_write_access->get_workbook(
  )->worksheet->at_position( 1 ).
```

It can be populated with data using the means described below. Once the worksheet has been filled as desired, the corresponding file content of the document can be obtained as an XSTRING via

### Sample Code

```
DATA(lv_file_content) = lo_write_access->get_file_content( ).
```

Adding a new worksheet works like this:

### Sample Code

```
DATA(lo_worksheet) = lo_write_access->get_workbook(
  )->add_new_sheet( ).
```

You can provide a name for the sheet by filling the optional parameter `iv_name`.

## Writing Data via a Stream

The first way how you can write data into a worksheet is by selecting a collection of cells based on a selection pattern (see also the section [Selection patterns](#) here: [XLSX \[page 1697\]](#)) via the method `SELECT` on `IF_XCO_XLSX_WA_WORKSHEET`. Accessing the cells contained in the selection is done following a stream-based approach, which means that a dedicated stream is obtained for the selection that will provide sequential access to the individual blocks of the selection. One kind of stream is currently offered:

- Row stream: A row stream provides access to the selection one row at a time, traversing the selection from top to bottom

### Row streams

Row streams are best used when the structure of the data that should be written is statically known. The primary use case is to write the rows of an internal table into a corresponding portion of the worksheet (as identified by a selection). As such, the following operations are offered for row streams:

- Write From: The write from operation takes a reference to an internal table as the input whose rows shall be written to the selected rows in the worksheet (upon execution of the operation)

Consider the following example of how a write from operation can be obtained and executed:

### Sample Code

```
" A selection pattern that was obtained via
XCO_CP_XLSX_SELECTION=>PATTERN_BUILDER.
DATA lo_selection_pattern TYPE REF TO if_xco_xlsx_slc_pattern.

" The write access to the worksheet.
DATA lo_worksheet TYPE REF TO if_xco_xlsx_wa_worksheet.

" The type definition for the internal table.
TYPES:
  BEGIN OF ts_row,
    first_name  TYPE string,
    last_name   TYPE string,
    day_of_birth TYPE d,
  END OF ts_row,
```

```

tt_row TYPE STANDARD TABLE OF ts_row WITH DEFAULT KEY.

DATA lt_rows TYPE tt_row.

lo_worksheet->select( lo_selection_pattern
  )->row_stream(
  )->operation->write_from( REF #( lt_rows )
  )->execute( ).

" At this point, the rows of internal table LT_ROWS will have been written
into the
" worksheet selection.

```

## Writing Data via a Cursor

An alternative to writing data into a worksheet via selections and streams is to obtain a cursor for a worksheet write access via method `CURSOR` on `IF_XCO_XLSX_WA_WORKSHEET`. Just as with desktop office suites, a cursor can first be positioned on any given cell (identified by coordinate values for both the column and row of the cell). Afterwards, it can be moved around the worksheet freely via the methods on `IF_XCO_XLSX_WA_CURSOR`:

- Methods `MOVE_UP`, `MOVE_RIGHT`, `MOVE_DOWN` and `MOVE_LEFT` can be used to move the cursor relative to its current position by the given number of steps
- Methods `SET_COLUMN` and `SET_ROW` can be used to set the new column or row for the cursor
- Method `GET_CELL` provides access to the cell at the current position of the cursor

The following example illustrates how the current date and time (stored in ABAP variables `LV_DATE` and `LV_TIME`) can be written into a worksheet:

### Sample Code

```

" The write access to the worksheet.
DATA lo_worksheet TYPE REF TO if_xco_xlsx_wa_worksheet.

DATA(lo_cursor) = lo_worksheet->cursor(
  io_column = xco_cp_xlsx=>coordinate->for_alphabetic_value( 'B' )
  io_row     = xco_cp_xlsx=>coordinate->for_numeric_value( 2 )
).

" Write the current date.
lo_cursor->get_cell( )->value->write_from( 'Date:' ).

DATA(lv_date) = CONV d( xco_cp=>sy->date( )->as( xco_cp_time=>format->abap )-
>value ).
lo_cursor->move_right( )->get_cell( )->value->write_from( lv_date ).

" Write the current time.
lo_cursor->move_down( )->move_left( )->get_cell( )->value-
>write_from( 'Time:' ).

DATA(lv_time) = CONV t( xco_cp=>sy->time( )->as( xco_cp_time=>format->abap )-
>value ).
lo_cursor->move_right( )->get_cell( )->value->write_from( lv_time ).

```

For an otherwise empty worksheet, this will produce the following content:

	A	B	C
1			
2		Date:	\$LV_DATE\$
3		Time:	\$LV_TIME\$

where \$LV\_DATE\$ is the current date and \$LV\_TIME\$ is the current time.

## Value Transformations

When writing the value of an individual cell (via `IF_XCO_XLSX_WA_CELL_VALUE`) or of a complete row (as part of a row stream operation) it's possible to apply transformations to the value, which will affect what XLSX value is written to the cell in the worksheet. Technically, a value transformation (obtainable via `XCO_CP_XLSX_WRITE_ACCESS=>VALUE_TRANSFORMATION`) contains a transformation routine that can be applied to

- Values of individual cells (in case the value transformation implements the interface `IF_XCO_XLSX_WA_VT_CELL_VALUE`)
- Values of rows (in case the value transformation implements the interface `IF_XCO_XLSX_WA_VT_ROW_VALUE`)

The following value transformations are currently offered:

- Best effort

The default value transformation is the best effort value transformation. Value transformations can be set explicitly via the following methods:

- Method `SET_VALUE_TRANSFORMATION` of `IF_XCO_XLSX_WA_CELL_VALUE` when the value of an individual cell is written
- Method `SET_VALUE_TRANSFORMATION` of `IF_XCO_XLSX_WA_RS_OP_WRITE_FRM` when row values are written as part of the write from row stream operation

### "Best effort" value transformation

The **best effort** value transformation is based on an inspection (based on ABAP runtime type services) of the ABAP field that should be written to a given cell. Based on the type determined for the ABAP field, a transformation is applied to the value before it's written to the cell of the worksheet. The **best effort** value transformation provides support for the following types of ABAP fields:

- Type `ABAP_BOOL`: When an ABAP field of type `ABAP_BOOL` is written to a cell, a boolean value will be written to the worksheet
- D: When an ABAP field of type D is written to a cell, a date value will be written to the worksheet
- T: When an ABAP field of type T is written to a cell, a time value will be written to the worksheet
- Data element `MSEHI`: When an ABAP field typed against data element `MSEHI` is written to a cell, the external value of the corresponding unit of measurement as determined by conversion routine `CUNIT` will be written to the worksheet
- Data element `SPRAS`: When an ABAP field typed against data element `SPRAS` is written to a cell, the external value of the corresponding language as determined by conversion routine `ISOLA` will be written to the worksheet

- C, N and `STRING`: When an ABAP field of type C, N or `STRING` is written to a cell, a string value will be written to the worksheet
- I, INT8 and P: When an ABAP field of type I, INT8 or P is written to a cell, a numeric value will be written to the worksheet

If an attempt is made to write an ABAP field of any other type to a cell of a worksheet using the best effort value transformation, a runtime error is to be expected.

## 4.2.12.16.4.12 XString

To offer a convenient way to incorporate standard operations on binary data into application logic, the XCO Library provides a standard abstraction for xstrings, `IF_XCO_XSTRING`, that is tightly integrated with the XCO string abstraction `IF_XCO_STRING`.

### Using the Base64 binary-to-text encoding

Built-in conversions are provided to support working with the Base64 binary-to-text encoding. Encoding raw binary data to its Base64 representation and decoding a given Base64 representation to its underlying binary data can be accomplished as follows:

#### Sample Code

```
" LV_XSTRING can store arbitrary binary data.
DATA lv_xstring TYPE xstring.
" LV_BASE64_ENCODING is of type STRING and contains the Base64 encoded version
" of LV_XSTRING.
DATA(lv_base64_encoding) = xco_cp=>xstring( lv_xstring
  )->as_string( xco_cp_binary=>text_encoding->base64
  )->value.
" LV_ORIGINAL_XSTRING is of type XSTRING and contains the binary data encoded
" in LV_BASE64_ENCODING
DATA(lv_original_xstring) = xco_cp=>string( lv_base64_encoding
  )->as_xstring( xco_cp_binary=>text_encoding->base64
  )->value.
```

### Using code pages

An xstring can also be converted to a string by using a code page, e.g. UTF-8:

#### Sample Code

```
DATA(lv_string) = xco_cp=>xstring( lv_xstring
  )->as_string( xco_cp_character=>code_page->utf_8
  )->value.
```

## 4.2.12.17 Metric Providers

The following objects were released for use in the ABAP environment:

Object	Description
CL_GSM_API_TEST	Convenience class to test the metric provider implementation
CX_GSM_API	Metric provider exception class
IF_GSM_API_CONSTANTS	Interface for metric provider constants
IF_GSM_API_METRIC	Interface for metric definition
IF_GSM_API_METRIC_GROUP	Interface for metric group definition
IF_GSM_API_MODEL	Interface for metric provider model definition
IF_GSM_API_PROVIDER	Interface for metric provider definition
IF_GSM_API_TEST	Interface for metric provider testing
IF_GSM_API_TYPES	Interface for metric provider type definitions

These objects are all related to the ABAP repository object called metric provider. You use metric providers as well as these released objects in ABAP Development Tools when you want to create your own metrics for health monitoring of the ABAP system.

[Proxy API for the Workflow Capability \[page 1549\]](#)

## 4.2.13 UI Development

Learn more about the different options to develop SAP Fiori applications for an OData service, where to store the application, and how to enable business users to access the application from SAP Fiori launchpad.

### Overview

You can develop SAP Fiori applications for OData services that are exposed as a UI service. See [OData Service Consumption](#).

#### Note

SAP Fiori is a design system that enables you to create business apps with a consumer-grade user experience, turning casual users into SAP experts with simple screens that run on any device. You can build apps that follow the SAP Fiori design principle using a combination of SAPUI5 and SAP Fiori elements. See [SAP Fiori](#).

SAPUI5 is a development framework that allows you to build a front-end application that follows the SAP Fiori design guidelines. SAPUI5 apps are built using HTML5, JS, XML, OData, and JSON, and are based on the Model, View, Controller (or MVC) design pattern. See [SAPUI5](#).

SAP Fiori elements is a framework that comprises the most commonly used floorplan templates. It is designed to speed up development by reducing the amount of frontend code needed to build SAP Fiori apps and to ensure UX consistency and compliance with the latest SAP Fiori design guidelines. See [SAP Fiori Elements](#).

To develop SAP Fiori applications, you can either use SAP Business Application Studio with SAP Fiori tools extensions or Microsoft Visual Studio Code (VS Code) with SAP Fiori tools extensions.

#### Note

<https://help.sap.com/docs/btp/sap-business-technology-platform/sap-business-application-studio?version=Cloud> is an SAP Business Technology Platform (SAP BTP) service that offers a modern development environment tailored for efficient development of business applications for the SAP Intelligent Enterprise. See [SAP Business Application Studio](#).

Visual Studio Code is a source-code editor provided by Microsoft for Windows, Linux, and macOS. See .

SAP Fiori tools is a set of extensions for SAP Business Application Studio and Visual Studio Code that makes developing SAP Fiori applications faster and easier. See [SAP Fiori Tools](#).

SAP Business Application Studio and VS Code support integration with Git so that you can use Git as source control system and store the code of SAP Fiori applications in remote git repositories.

#### Note

Git is a free and open source distributed version control system designed to handle everything from small to very large projects fast and efficiently.

Once you have implemented the SAP Fiori application, you can deploy it to the ABAP or Cloud Foundry environment.

You can launch the deployed apps standalone or embed them into the SAP Fiori launchpad.

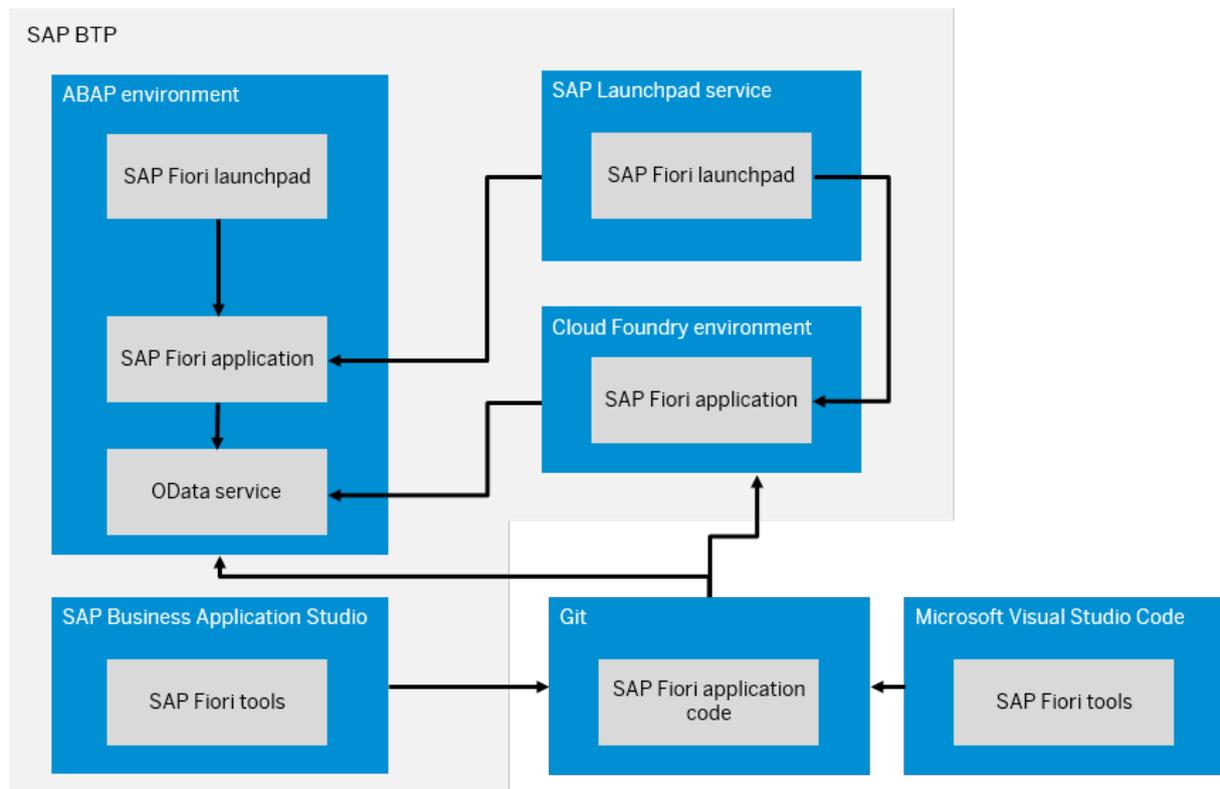

### Note

SAP Fiori launchpad is the entry point for business users to SAP Fiori apps on mobile and desktop devices. The launchpad comprises a home page where app tiles, which can display live status indicators, such as the number of open tasks, are clustered. Each tile represents a business application that the user can launch. See [SAP Fiori Launchpad - User Guide](#).

The ABAP environment comes with an embedded SAP Fiori launchpad and provides access to SAP Fiori apps that are deployed to the ABAP environment. Apps deployed to the Cloud Foundry environment can be added to a launchpad provided by the SAP Build Work Zone, standard edition. You can also add apps that are deployed to the ABAP environment to launchpads provided by the SAP Build Work Zone, standard edition. See [Integrating Content with SAP Build Work Zone, standard edition \[page 2629\]](#).

### Note

The SAP Build Work Zone, standard edition is an SAP BTP service that enables you to build a portal-like central entry point and provides enterprise-wide, efficient, secure, and role-based access to SAP and non-SAP applications. See [SAP Build Work Zone, Standard Edition](#).

## SAP Fiori Applications in the ABAP environment

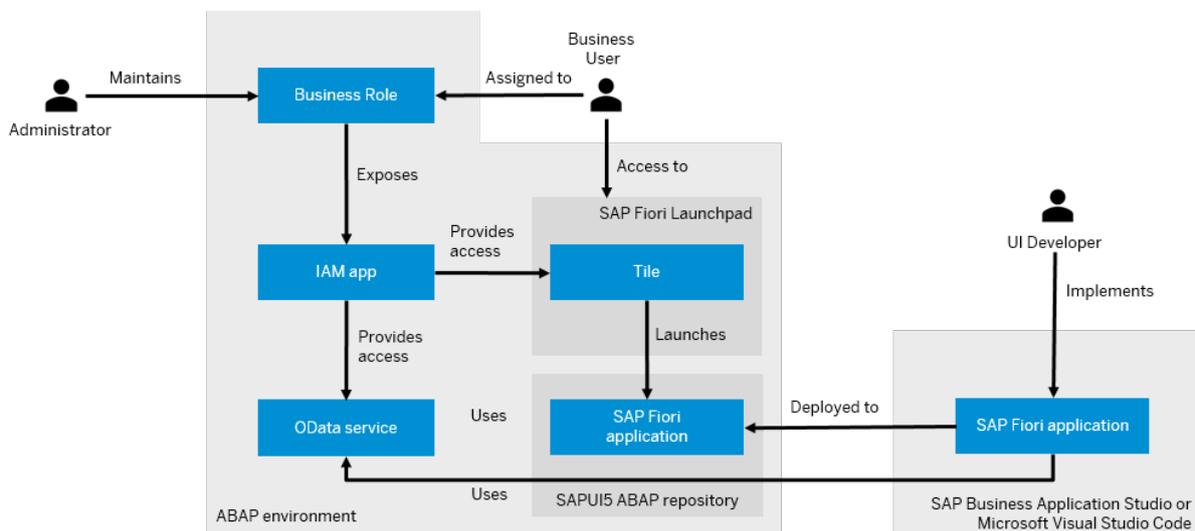

If you want to deploy an SAP Fiori application to the ABAP environment, the following users are involved:

- A UI developer implements the SAP Fiori application against the OData service and defines the tile as part of the application. Once this is done, the developer deploys the SAP Fiori application to the SAPUI5 ABAP repository.

### Note

The SAPUI5 ABAP repository is part of the ABAP environment and is the umbrella term for the single SAPUI5 repository of each application. Technically, the SAPUI5 ABAP repository is based on the Business Server Page (BSP) repository. Each SAPUI5 repository is represented by an individual BSP application. The SAPUI5 ABAP repository is also used for delivering SAPUI5 apps of the ABAP environment.

- An administrator in the ABAP environment provides access to the OData service and the tile via a business role.
- A business user that is assigned to the business role can access the tile from SAP Fiori launchpad and launch the application.

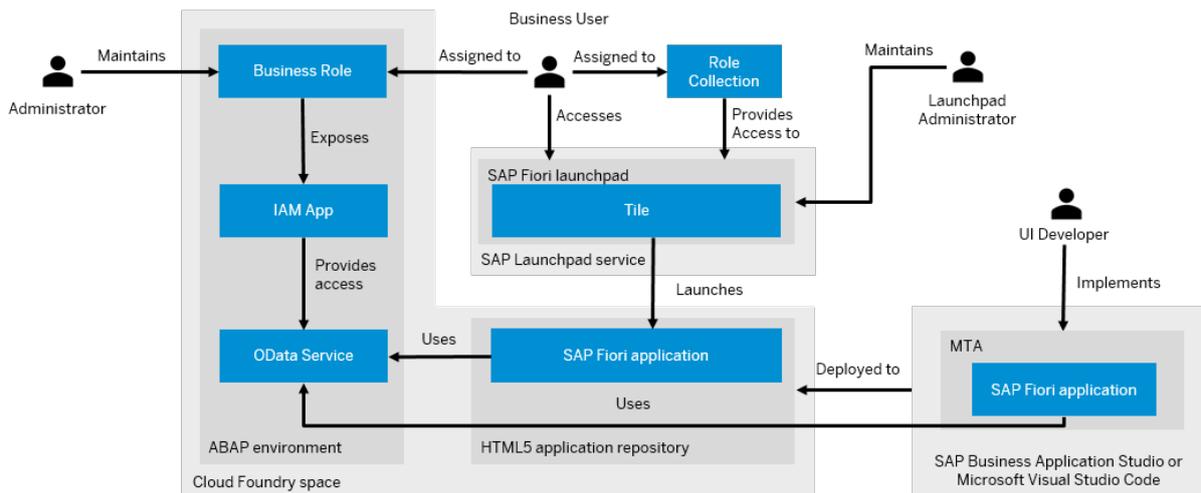

## SAP Fiori Application in the Cloud Foundry environment

If you want to deploy an SAP Fiori application to the Cloud Foundry environment, the following users are involved:

- A UI developer implements the SAP Fiori application against the OData service as part of a multi-target application (MTA).  
An MTA is logically a single application comprised of multiple parts created with different technologies, which share the same lifecycle. The developers of the MTA describe the desired result using the MTA model, which contains MTA modules, MTA resources, and interdependencies between them.
- The developer defines the tile as part of the application. Once this is done, the MTA is deployed to the Cloud Foundry space. By doing so, the SAP Fiori application of the MTA is deployed to the HTML5 application repository. The developer can deploy the MTA either manually or as part of a CI/CD pipeline. See [Continuous Integration and Delivery \(CI/CD\)](#).

The HTML5 application repository is an SAP BTP service that enables central storage of HTML5 applications' static content on the SAP BTP, Cloud Foundry environment. See [HTML5 Application Repository](#).

- An administrator in the ABAP environment provides access to the OData service via a business role. A launchpad administrator enables access to the tile via a role collection.
- A business user that is assigned to the business role and role collection can access the tile from SAP Fiori launchpad and launch the application.

[SAP Fiori Overview](#)

[Visual Studio Code](#)

[Test Automation](#)

## 4.2.13.1 SAP Fiori Applications in the ABAP Environment

When you plan to create an SAP Fiori application in the ABAP environment and want to provide this application to business users, you may want to get a better understanding of the required steps before getting started with the UI development.

## Implementing and Deploying the UI

To generate an SAP Fiori application for an OData service, you can use the Fiori Tools application generator in SAP Business Application Studio or Visual Studio Code. When generating the application, you can browse the available OData services for UI development. As part of the application implementation, you can define the tile of the application, and run the application in preview mode. The tile information is stored in the `manifest.json` file of the application.

To deploy the SAP Fiori application, you have to create a deployment configuration and provide the target package and transport request. When deploying the application to the SAPUI5 ABAP repository in the ABAP environment, the following objects are automatically created:

- A business server page (BSP) application, which stores the code of the SAP Fiori application
- An SAP Fiori launchpad app descriptor item, which contains the tile and cross navigation inbound/intent navigation for the SAP Fiori launchpad integration
- A folder in the MIME repository, which stores all MIME objects, such as graphics, icons, of the app
- A node in the Internet Communication Framework (ICF), which enables clients (browser) to access the code stored in the BSP application

The SAP Fiori launchpad app descriptor item is created from the `manifest.json` file of the SAPUI5 app, where you also have configured the tile and navigation parameters are configured. The app descriptor item is created upon deployment if you have defined the intent navigation in the `manifest.json` file. Note that only one intent navigation consisting of a semantic object and action is supported. If you change the ID of the intent, existing references from the SAP Fiori launchpad to the tile break.

You can find the BSP application and the SAP Fiori launchpad app descriptor item stored as objects in your deployment package in ABAP Development Tools for Eclipse. The folder in the MIME repository and the node in the ICF are not available in ABAP Development Tools but are listed in the transport request. Alternatively, you can use CDS view `I_CustABAPObjDirectoryEntry`.

The SAP Fiori UI is deployed in ABAP language version `ABAP for Cloud Development`, which restricts access to data sources: Data sources must be released for system-internal use in cloud development or must be in the same software component.

### ⚠ Restriction

Only OData services from your custom service binding are supported.

API services on [SAP API Business Hub](#) are not supported. They are released for external consumption only.

To discover the available OData services or run the application in preview mode, business catalog `SAP_CORE_BC_EXT_TST` has to be assigned to you. To deploy the application, business catalog `SAP_A4C_BC_DEV_UID_PC` needs to be assigned to you. Both business catalogs are contained in business role template `SAP_BR_DEVELOPER`.

## Providing Access to Business Users

After you have deployed the SAP Fiori application, you have to create an IAM app, IAM business catalog, and business role to make your application consumable for business users. This also requires adding the business service for which you've created your UI to the IAM app and assigning the automatically created SAP Fiori launchpad app descriptor item to the IAM app. When you publish the IAM app and IAM business catalog, a corresponding SAP Fiori business catalog is generated by the system. Business users that are assigned to the business role and catalog can now access the app. See [Providing Access to the SAP Fiori Application](#).

### 📌 Note

The SAP Fiori app is not yet available on the home page, which means that business users can only access it by using the [app finder](#).

## Integrating the SAP Fiori App into SAP Fiori launchpad

To make an SAP Fiori application accessible on the SAP Fiori launchpad home page of business users, you have to log on to the system as an administrator and perform the following steps:

- Enable spaces.

#### 📘 Note

This is a one-time effort.

- Create a launchpad space and page, and add the app. See [Adding Apps to a Page](#).

#### 📘 Note

The space and page need to be recorded on a customizing request.

- Assign the launchpad space to the business role you have created earlier. For users that are assigned to the business role and catalog, the space, page, and tile are displayed on the home page so that they can launch the application.

#### ⚠️ Restriction

You can't assign the tile to a group in SAP Fiori launchpad.

## Related Information

[Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#)

### 4.2.13.1.1 Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio

Get an overview about how to create and deploy an SAP Fiori application to ABAP using SAP Business Application Studio.

If you need further assistance with creating and deploying an application, check out the tutorial [Create an SAP Fiori App and Deploy it to SAP BTP, ABAP Environment](#).

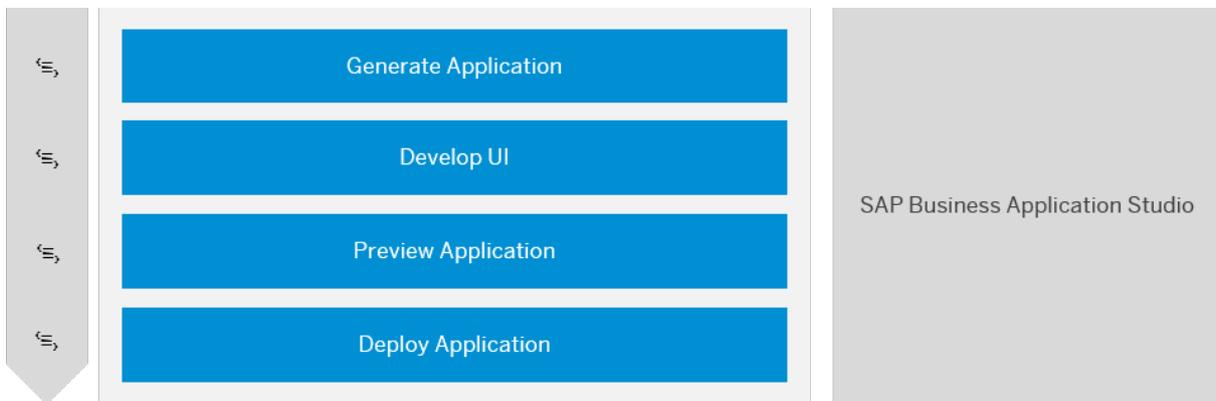

## Prerequisites

- You have set up SAP Business Application Studio. See [Setup of UI Development in SAP Business Application Studio](#).
- You have established trust by setting up a custom Identity service. See [Setup of a Custom Identity Service](#).

# 1. Generating and Deploying Your Application

## Prerequisites

- You have created a development package in ABAP Development Tools for Eclipse. See [Creating ABAP Packages](#).
- You have exposed a RAP business service as an OData service. See [Using Service Binding Editor for OData V2 Service](#).
- Business catalog `SAP_A4C_BC_DEV_UID_PC` is assigned to your user, which allows you to deploy your application.
- Business catalog `SAP_CORE_BC_EXT_TST` is assigned to your user, which allows you to preview your application and discover available OData services. See [Business Catalog for Key User Tasks](#).
- You have an open transport request.

### Legend

 Task for Developers

1. As a developer user in SAP Business Application Studio, generate an SAP Fiori application. See [Generate an Application](#).
  1. In the *Data Source and Service Selection* section of the Template Wizard, select the following values:
    - Data source: [Connect to a System](#).
    - System:
      - (Option 1) Select the destination that you have created for the SAP Business Application studio integration (`SAP_Business_Application_Studio`). See [Creating a Destination to the ABAP System for SAP Business Application Studio](#).
      - (Option 2) Select [ABAP Environment on SAP Business Technology Platform](#). From the ABAP environment drop-down menu, choose a service instance.

## Note

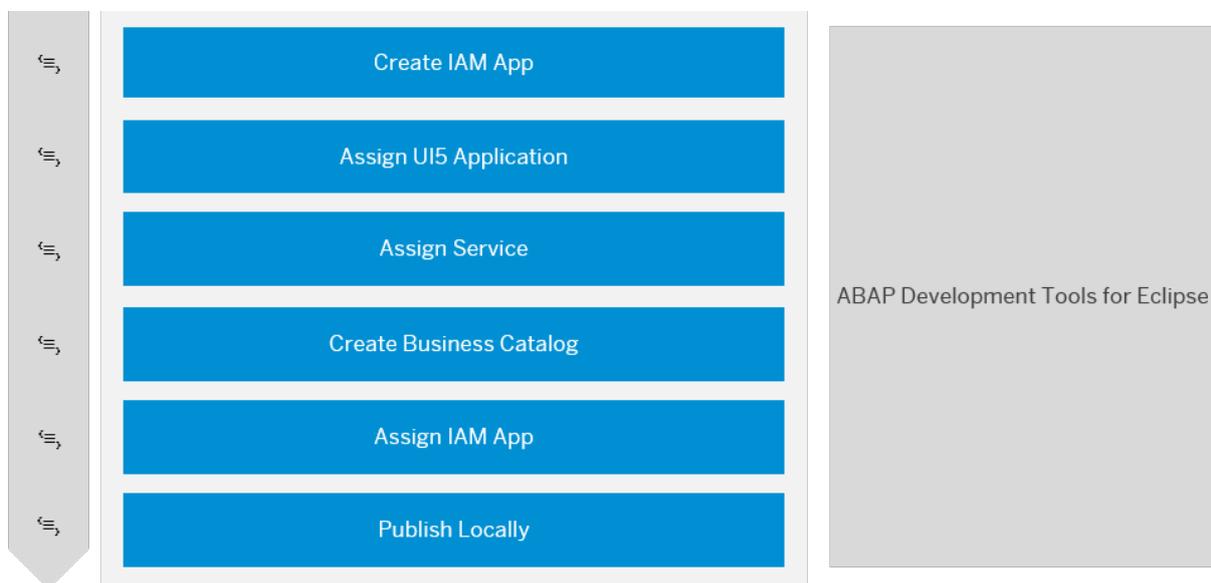

You have to log on to your Cloud Foundry space by executing command `cf login` in the terminal or by navigating to **View > Find Command > CF: Login to Cloud Foundry**. When you're prompted to enter the API endpoint, org name, and space, you can navigate to your subaccount in the SAP BTP cockpit, where you can find this information.

- Continue with choosing a service.
2. Add a deployment configuration. See section *Add deployment configuration > ABAP system* in [Additional Configuration](#).  
If you want to create your deployment configuration later, see [Generate Deployment Configuration ABAP](#).
  3. Add an SAP Fiori launchpad configuration for your UI project. See section *Add FLP configuration* in [Additional Configuration](#).  
If you want to create your FLP configuration later, see [SAP Fiori Launchpad Configuration](#).
2. Continue with the development of the UI, for example, with the help of guided development. See [Implement Features using Guided Development](#).
  3. Now you can preview the generated SAP Fiori application. See [Preview an Application](#).
  4. Deploy the SAP Fiori UI by executing command `npm run deploy` in the terminal of your project. See [Deployment to ABAP](#).

## 2. Creating and Publishing Your Identity and Access Management (IAM) App

### 📌 Prerequisite

Business catalog `SAP_A4C_BC_DEV_PC` is assigned to your user, which is required for development with ABAP Development Tools. See [Business Catalogs for Development Tasks \[page 2348\]](#).

#### Legend

☰ Task for Developers

1. To manage access to your SAP Fiori application, you have to log on as a developer in ABAP Development Tools for Eclipse to create an Identity and Access Management (IAM) application, assign a UI5 application and a service, and maintain authorizations (steps 1-3 in the figure above). See [Creating an IAM App for the Business Service](#).

2. Once you have created your IAM app, you have to create a business catalog. See [Creating a Business Catalog](#).
3. Assign your IAM app to the business catalog.
4. Publish the IAM app and business catalog locally.

## Next Step

Launch your app in SAP Fiori launchpad. See [Add Your App to SAP Fiori Launchpad](#).

## Related Information

### 4.2.13.1.2 Develop an SAP Fiori Application UI and Deploy it to ABAP Using Visual Studio Code

Get an overview about how to create and deploy an SAP Fiori application to ABAP using Visual Studio Code.

For further assistance with creating and deploying an application into SAP Fiori launchpad, see [Create a SAP Fiori App in Visual Studio Code and Deploy it to SAP BTP, ABAP Environment](#).

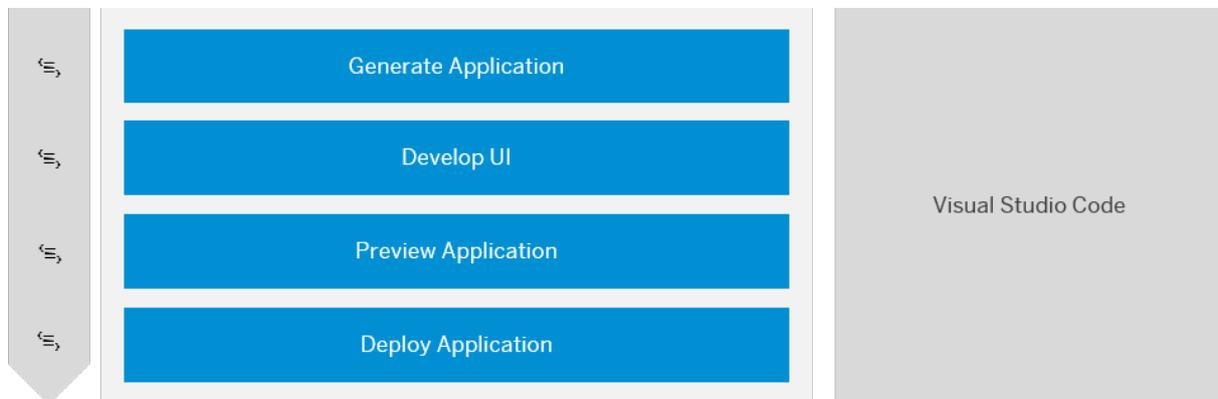

## Prerequisites

- You have installed and set up Visual Studio Code including the SAP Fiori tools extensions. See [Visual Studio Code](#).
- You have access to a RAP business service that has been exposed as an OData service. See [Using Service Binding Editor for OData V2 Service](#).
- To establish a connection with your ABAP environment system, you either have to be a space developer in the ABAP environment instance or have access to a service key in the ABAP environment instance. See [Add Space Members Using the Cockpit](#) and [Creating Service Keys](#) in the ABAP service instance.
- You have established trust by setting up a custom Identity service. See [Setup of a Custom Identity Service](#).

# 1. Generating and Deploying Your Application

## Prerequisites

- You have created a development package in ABAP Development Tools for Eclipse. See [Creating ABAP Packages](#).
- You have exposed a RAP business service as an OData service. See [Using Service Binding Editor for OData V2 Service](#).
- Business catalog `SAP_A4C_BC_DEV_UID_PC` Continue with the development of the UI, for example, with the help of guided is assigned to your user, which allows you to deploy your application.
- Business catalog `SAP_CORE_BC_EXT_TST` is assigned to your user, which allows you to preview your application and discover available OData services. See [Business Catalog for Key User Tasks](#).
- You have an open transport request.

### Legend

Task for Developers

1. As a developer user in Visual Studio Code, generate an SAP Fiori application. See [Generate an Application](#). In the *Data Source and Service Selection* section of the Template Wizard, select the following values:
  - Data source: *Connect to a System*.
  - System: *New System*
  - System type: *ABAP Environment on SAP Business Technology Platform*
  - ABAP environment definition source:
    - (Option 1) **Discover a Cloud Foundry Service**

### Note

You have to log on to your Cloud Foundry space by executing command `cf login` in the terminal or by navigating to **View** > *Find Command* > *CF: Login to Cloud Foundry*. When you're prompted to enter the API endpoint, org name, and space, you can navigate to your subaccount in the SAP BTP cockpit, where you can find this information.

- (Option 2) **Upload a Service Key File**
  - Continue with choosing a system name and service.
- In the *Project Attributes* section, add deployment configuration and FLP configuration to your UI project. See [Additional Configuration](#).

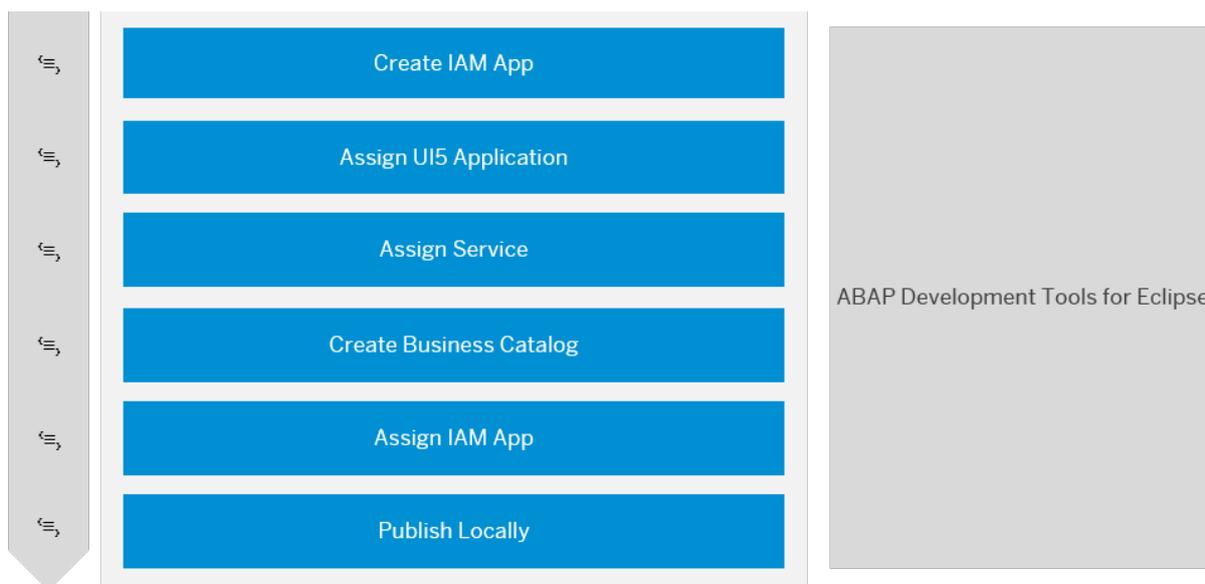

If you want to create your deployment configuration later, see [Generate Deployment Configuration ABAP](#).  
If you want to create your FLP configuration later, see [SAP Fiori Launchpad Configuration](#).

2. Continue with the development of the UI, for example, with the help of guided development. See [Implement Features using Guided Development](#).
3. Now you can preview the generated SAP Fiori application. See [Preview an Application](#).
4. Deploy the SAP Fiori UI by executing command `npm run deploy` in the terminal of your project. See [Deployment to ABAP](#).

## 2. Creating and Publishing Your Identity and Access Management (IAM) App

### 📌 Prerequisite

Business catalog `SAP_A4C_BC_DEV_PC` is assigned to your user, which is required for development with ABAP Development Tools. See [Business Catalogs for Development Tasks \[page 2348\]](#).

#### Legend

☰ Task for Developers

1. To manage access to your SAP Fiori application, you have to log on as a developer in ABAP Development Tools for Eclipse to create an Identity and Access Management (IAM) application, assign a UI5 application and a service, and maintain authorizations (steps 1-3 in the figure above). See [Creating an IAM App for the Business Service](#).
2. Once you have created your IAM app, you have to create a business catalog. See [Creating a Business Catalog](#).
3. Assign your IAM app to the business catalog.
4. Publish the IAM app and business catalog locally.

## Next Step

Launch your app in SAP Fiori launchpad. See [Add Your App to SAP Fiori Launchpad \[page 1722\]](#).

### 4.2.13.1.3 Add Your App to SAP Fiori Launchpad

Get an overview on how to add your app to SAP Fiori launchpad.

If you need further assistance with the individual steps, check out the developer tutorial [Integrate List Report into ABAP Fiori Launchpad](#).

#### Legend

-  Task for Administrators
-  Task for Business Users

1. In the SAP Fiori launchpad of your ABAP system, create a business role with the *Maintain Business Roles* app. See [Maintain Business Roles](#).
2. Assign a business catalog and business user to the business role. See [Maintain Business Users](#).
3. Create a launchpad space and page. See [Step by Step: Create a New Space and Page for a Business Role](#).

### Note

To use this app, your user must be assigned to business catalog SAP\_CORE\_BC\_UI\_FLD.

4. Enable spaces for your user. See [Enabling Spaces](#). Optionally, you can personalize and adapt the user interface of your app for all users. See [Personalizing and Adapting Apps](#).
5. As a business user, you can launch the app.

## Next Step

[Transport Your App](#)

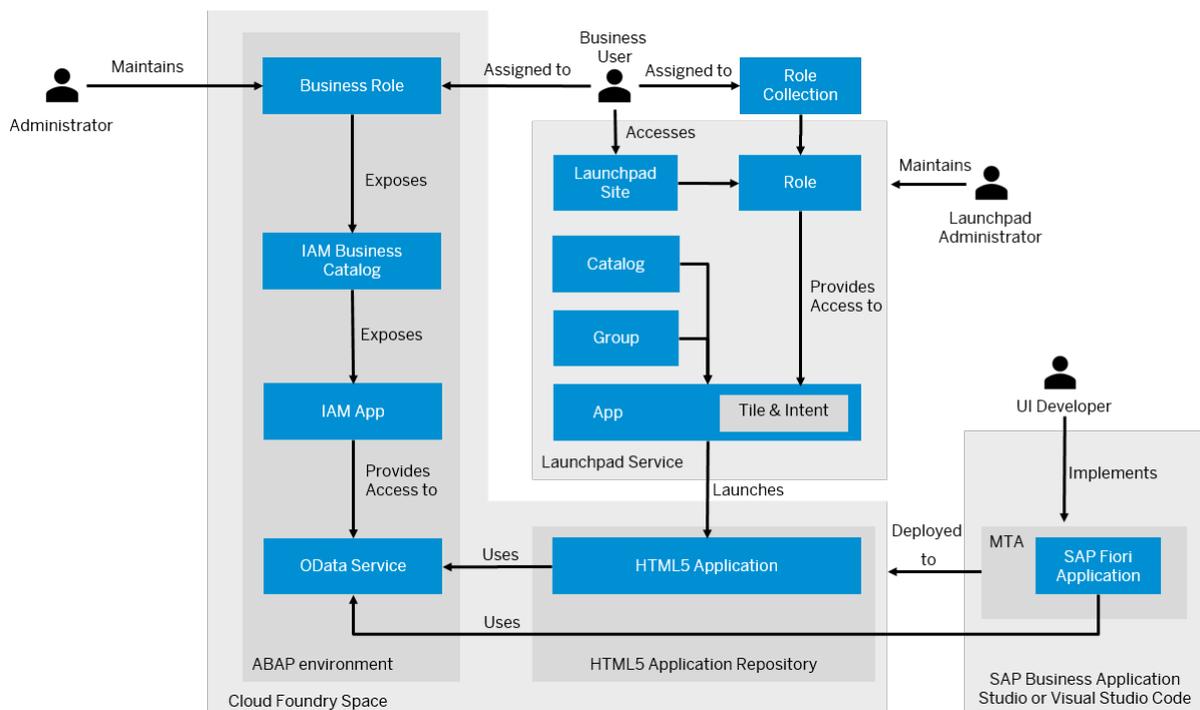

### 4.2.13.2 SAP Fiori Applications in the Cloud Foundry Environment

When you plan to create an SAP Fiori application that you have deployed to the SAP BTP, Cloud Foundry environment and want to provide this application to business users, you may want to get a better understanding of the required steps before getting started with the UI development.

#### → Recommendation

We recommend using the same UI5 version that is being used by the ABAP environment system.

To check the UI5 version in the SAP Fiori launchpad of your ABAP environment system, use command **Alt+Ctrl+Shift+P** or navigate to the user actions menu and select *About*. See [User Actions Menu](#).

## Implementing and Deploying the UI

To develop an SAP Fiori application, you can create a multitarget application using the Fiori Tools application router generator, where we recommended using the SAP-managed approuter. See [Application Router](#) and [Developing HTML5 Applications and Extensions](#).

Afterwards, you can start creating your SAP Fiori application using the Fiori Tools application generator and add it to the multitarget application (MTA). When generating the application, you can browse the available OData services for UI development. The application generation process also includes adding information for the SAP Fiori app tile in the SAP Fiori launchpad, such as a title, action, and semantic object. This information has to be defined in the project attributes of your MTA by adding an FLP configuration. Your configuration is then stored in the `manifest.json` file. Note that only one intent navigation consisting of a semantic object and action is supported. If you change the ID of the intent, existing references from the SAP Fiori launchpad to the tile break.

You can integrate the OData service of your ABAP environment into the application by specifying a corresponding route in the `xs-app.json` file. The routing can be done either by providing a destination that points to the ABAP environment instance or by specifying the service endpoint of the ABAP environment and binding the service instance. See [Configure Destinations](#) and [Binding Service Instances to Applications](#). The Fiori application generator adds a route to the `xs-app.json` file using the destination that you specify in the generator.

### Note

If you have used the Fiori Tools application generator to create your app, you have selected a destination that points to your development subaccount. Make sure that the destination in your target subaccount has the same name as the one maintained in the `xs-app.json` file.

The next step is to build the MTA project. This generates an `*.mtar` file and `mta_archives` folder.

Before deploying your UI, you should preview your application. To preview your application or discover available OData services, business catalog `SAP_CORE_BC_EXT_TST` has to be assigned to your user, which allows you to preview your application and . See [Business Catalogs for Development Tasks \[page 2348\]](#).

The final step is to create a deployment configuration and deploy the MTA to your SAP BTP, Cloud Foundry environment space, which requires the [space developer role](#). By doing so, the SAP Fiori application that you have added to the MTA gets deployed to the HTML5 application repository.

## Providing Access to Business Users

After you have deployed the SAP Fiori application, you have to create an IAM app to make your application consumable for business users. This requires assigning the business service to the IAM app. Additionally, you have to use SAP Build Work Zone, standard edition and log on as an administrator to create a role. A corresponding role collection is automatically created in the SAP BTP cockpit. This allows you to assign business users to the role collection in the SAP BTP cockpit. Being assigned to the role collection, business users can access the launchpad site and the app.

## Integrating the SAP Fiori App into SAP Fiori launchpad

To make an SAP Fiori application accessible on the SAP Fiori launchpad home page of business users, you have to assign your app to a group and catalog. See [Assign Apps to a Group and to a Catalog](#). Afterwards, you need to add content to the HTML5 apps content provider in SAP Build Work Zone, standard edition. The HTML5 apps provider reflects all the HTML5 apps that are deployed to the HTML5 app repository that is assigned to the subaccount. See [HTML5 Apps Content Provider](#) and [Integrate Apps and Shell Plugins](#).

### Related Information

[Develop an SAP Fiori Application and Deploy it to Cloud Foundry Using SAP Business Application Studio \[page 1725\]](#)

[Develop an SAP Fiori Application and Deploy it to Cloud Foundry Using Visual Studio Code \[page 1727\]](#)

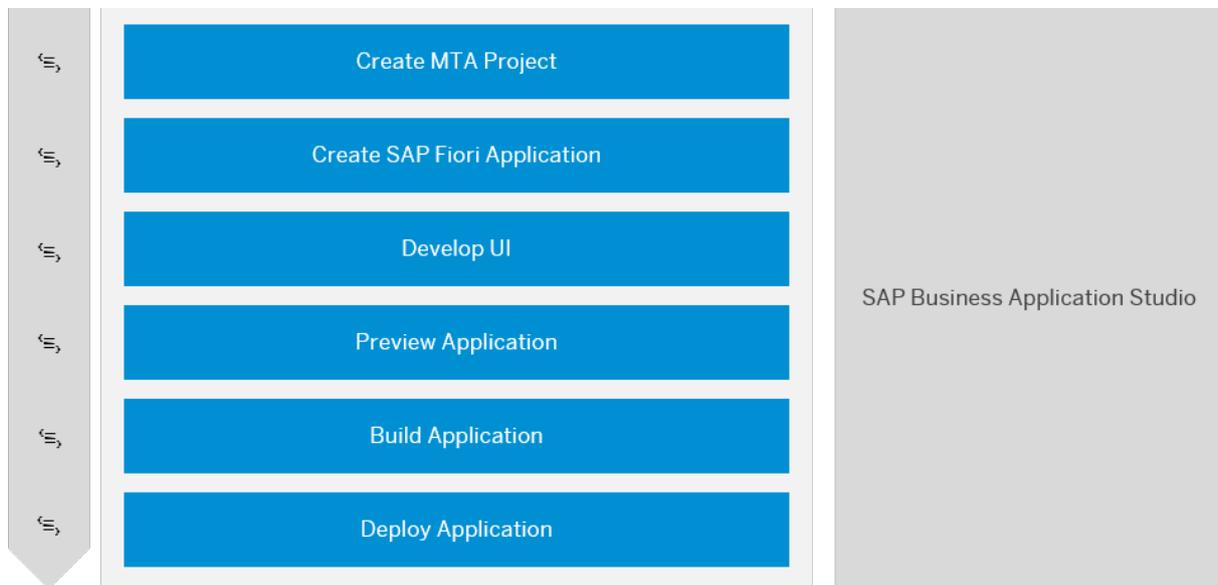

### 4.2.13.2.1 Develop an SAP Fiori Application and Deploy it to Cloud Foundry Using SAP Business Application Studio

Get an overview about how to create and deploy an SAP Fiori application to Cloud Foundry using SAP Business Application Studio.

#### Prerequisites

- A subaccount administrator has provided access to SAP Business Application Studio. See [Setup of UI Development in SAP Business Application Studio \(Optional\) \[page 175\]](#).
- A subaccount administrator has created a destination to the ABAP system to integrate SAP Business Application Studio. See [Creating a Destination to the ABAP System for SAP Business Application Studio \[page 180\]](#).
- You have created a dev space of type SAP Fiori. See [SAP Business Application Studio](#).
- You have access to a RAP business service that has been exposed as an OData service. See [Using Service Binding Editor for OData V2 Service](#).

## Generating and Deploying Your Application

### Legend

 Task for Developers

1. Create an MTA project with approuter configuration.  
To do so, use the *Fiori CF Application Router Generator*. See [Generate an MTA Deployment File](#).  
This generates an MTA project and the corresponding application router configuration.
2. With the *SAP Fiori Generator*, create an SAP Fiori application in the subfolder of the MTA file location by selecting *Fiori: Open Application Generator* from the command palette. See [Generate an Application](#) and [Add a Fiori Application to an MTA Deployment File with the Fiori Generator](#).
  - As a data source, select *Connect to a System*.
  - As a system, choose the destination to the ABAP system that has been created to integrate SAP Business Application Studio.
  - As a service, select your RAP business service that has been exposed as an OData serviceIn the *Project Attributes* section, add an SAP Fiori launchpad configuration for your UI project. See section *Add FLP configuration* in [Additional Configuration](#).  
If you want to create your FLP configuration later, see [SAP Fiori Launchpad Configuration](#).
3. Continue with the development of the UI, for example, with the help of guided development. See [Implement Features using Guided Development](#).
4. Now you can preview the generated SAP Fiori application. See [Preview an Application](#).
5. Build the application by executing command `npm run build` in the terminal of your project. See [Deployment to Cloud Foundry](#).  
This generates an `*.mtar` file and `mta_archives` folder.
6. Log on to Cloud Foundry and deploy the SAP Fiori UI to your development space by executing command `npm run deploy`. See [Deployment to Cloud Foundry](#).

### → Tip

If you can't discover an available OData service in the generator, or preview your application, check if your user is assigned to business catalog `SAP_CORE_BC_EXT_TST`. If you aren't authorized to deploy the application, check if business catalog `SAP_A4C_BC_DEV_UID_PC` is assigned to your user.

## 4.2.13.2.2 Develop an SAP Fiori Application and Deploy it to Cloud Foundry Using Visual Studio Code

Get an overview about how to create and deploy an SAP Fiori application to Cloud Foundry using Visual Studio Code (VS Code).

### Prerequisites

- You have installed and set up Visual Studio Code including the SAP Fiori tools extensions. See [Visual Studio Code](#).
- You have access to a RAP business service that has been exposed as an OData service. See [Using Service Binding Editor for OData V2 Service](#).
- To establish a connection with your ABAP environment system, you either have to be a space developer in the ABAP environment instance or have access to a service key in the ABAP environment instance. See [Add Space Members Using the Cockpit](#) and [Creating Service Keys](#) in the ABAP service instance.

## Generating and Deploying Your Application

### Legend

 Task for Developers

1. Create an MTA project with approuter configuration.  
To do so, use the *Fiori CF Application Router Generator*. See [Generate an MTA Deployment File](#).  
This generates an MTA project and the corresponding application router configuration.
2. With the *Fiori Application Generator*, create an SAP Fiori application in the subfolder of the MTA file location by selecting *Fiori: Open Application Generator* from the command palette. See [Generate an Application](#) and [Add a Fiori Application to an MTA Deployment File with the Fiori Generator](#).  
In the *Data Source and Service Selection* section of the Template Wizard, select the following values:
  - Data source: *Connect to a System*.
  - System: *New System*
  - System type: *ABAP Environment on SAP Business Technology Platform*
  - ABAP environment definition source:
    - (Option 1) **Discover a Cloud Foundry Service**

**Note**

You have to log on to your Cloud Foundry space by executing command `cf login`. When you're prompted to enter the API endpoint and org name, you can navigate to your subaccount in the SAP BTP cockpit, where you can find this information.

  - (Option 2) **Upload a Service Key File**
  - Continue with choosing a system name and service.

In the *Project Attributes section*, add an SAP Fiori launchpad configuration for your UI project. See [Add FLP Configuration](#).  
If you want to create you FLP configuration later, see [SAP Fiori Launchpad Configuration](#).
3. Continue with the development of the UI, for example, with the help of guided development. See [Implement Features using Guided Development](#).

4. Now you can preview the generated SAP Fiori application. See [Preview an Application](#).
5. Build the application by executing command `npm run build` in the terminal of your project. See [Deployment to Cloud Foundry](#).  
This generates an \*.mtar file and mta\_archives folder.
6. `npm run deploy`. See [Deployment to Cloud Foundry](#).

#### → Tip

If you can't discover an available OData service in the generator, or preview your application, check if you user is assigned to business catalog Log on to Cloud Foundry and deploy the SAP Fiori UI to your development space by executing command `SAP_CORE_BC_EXT_TST`. If you aren't authorized to deploy the application, check if business catalog `SAP_A4C_BC_DEV_UID_PC` is assigned to your user.

## Related Information

[SAP Fiori Tools](#)

[SAP Fiori Overview](#)

## 4.3 Development in the Kyma Environment

Learn more about developing applications in the Kyma environment.

### Overview

The [Kyma Environment \[page 54\]](#) enables you to build simple Functions, develop, and deploy more complex microservices, or mixtures of those, depending on your use case complexity level. Both, Functions and microservices, can act as stand-alone applications or extensions of these SAP systems:

- SAP S/4HANA
- SAP S/4HANA Cloud
- SAP S/4HANA Cloud, public edition
- SAP Field Service Management
- SAP SuccessFactors
- SAP Customer Experience systems:
  - SAP Commerce Cloud
  - SAP Cloud for Customer
  - SAP Marketing Cloud

## Language of Choice

With the Kyma environment, you can create microservices in the language of your choice and run them as containerized applications. Additionally, you can create Functions in Node.js or Python.

## Kyma Dashboard and kubectl

The Kyma environment comes with a central administration dashboard (Kyma dashboard), which allows you to deploy microservices, create Functions, and manage their configurations. You can also use it to connect SAP BTP services to your cluster and manage them using SAP BTP Service Operator, create instances of these services, and use them in your microservices or Functions.

For those who prefer to work with command-line tools, the Kyma environment also offers the Kubernetes command-line tool, kubectl.

## SAP Cloud Application Programming Model

The SAP Cloud Application Programming Model (CAP) is the recommended framework for application and service development in the Kyma environment. To learn more, see [SAP Cloud Application Programming Model \[page 107\]](#).

## Using API

The Kyma and third-party modules' APIs may vary from the least stable alpha version through a more stable beta and the most stable **vX** version (**X** being an integer). While using the alpha version, you can face issues with module upgrades, as there is no guarantee that the API will not change or won't be removed in the future. For more information, check the [Kubernetes API versioning](#) .

Run this command to get the list of the APIs, their kind, and version:

```
kubectl get crd -o custom-  
columns="KIND:.spec.names.kind,GROUP:.spec.group,VERSION:.spec.versions[*].name"
```

If an API is available in two versions, always use the version that is more stable.

## Development Tutorials

To help you get started with the development process, go through the set of tutorials that show how to [develop a full-stack application](#) in the Kyma environment. You'll create a sample containerized microservice, learn how to expose it via API, and trigger it with events. Additionally, you create Functions as well as instances of external services that you can use in your microservices and Functions.

- [Deploy MSSQL in the Kyma Environment](#)
- [Deploy a Go MSSQL API Endpoint in the Kyma Environment](#)
- [Deploy the SAPUI5 Frontend in the Kyma Environment](#)
- [Trigger a Microservice with an Event](#)
- [Use Redis in the Kyma Environment to Store and Retrieve Data](#)

## Related Information

- [Extension Samples](#)  
Kyma provides a ready-to-use project that contains sample applications. You can take advantage of them to build event- and API-based extensions in the Kyma environment using your favorite technology. These samples are implemented in multiple languages and demonstrate various Kyma environment features and use case scenarios.
- [Using SAP BTP Services in the Kyma Environment \[page 1732\]](#)  
Kyma environment allows you to extend the SAP systems to build and deploy your own applications.
- [Deploy Workloads in the Kyma Environment to Extend SAP Systems \[page 1735\]](#)  
Access the Kyma environment and start creating extensions for SAP systems using Functions.

### 4.3.1 Access a Kyma Instance Using kubectl

As an alternative to managing Kyma with a graphical user interface, Kyma dashboard, you can also use the Kubernetes command-line tool, kubectl.

## Prerequisites

You have a Kyma instance created in your subaccount of the SAP BTP cockpit.

## Context

To start using kubectl, follow these steps:

## Procedure

1. Install [kubectl oidc-login](#). Follow the original instruction from the project repository. Use the relevant commands for macOS, Linux, or Windows users.

### → Recommendation

On Windows, we recommend using the release binaries to install the kubectl oidc-login plugin. The installation of the kubectl oidc-login plugin using Chocolatey and Krew could cause issues.

2. In the SAP BTP cockpit, in your subaccount [Overview](#), go to the [Kyma Environment](#) section, and click on the [KubeconfigURL](#) link to download `kubeconfig.yaml`.
3. In the terminal, export the kubeconfig file.
  - On macOS, run:

```
export KUBECONFIG={KUBECONFIG_FILE_PATH}
```

- On Windows (PowerShell), run:

```
$ENV:KUBECONFIG=" {KUBECONFIG_FILE_PATH} "
```

## Results

Now you can manage your Kyma instance using kubectl.

### → Tip

If you authenticate in the Kyma environment with an Identity Provider using OpenID Connect, the downloaded `kubeconfig.yaml` can be used indefinitely to re-authenticate.

## Related Information

[Configure a Custom Identity Provider for Kyma \[page 2858\]](#)

## 4.3.2 Using SAP BTP Services in the Kyma Environment

With the Kyma environment, you can connect SAP BTP services to your cluster and manage them using SAP BTP Service Operator.

## Prerequisites

- The SAP BTP Operator module is added, see [Add and Delete a Kyma Module \[page 2764\]](#). Otherwise, you get the following error message: `resource mapping not found for {...}` ensure CRDs are installed first.
- For CLI interactions: `kubectl`  v1.17 or higher.

- You know the `serviceOfferingName` and `servicePlanName` for the SAP BTP service you want to connect to the Kyma cluster. You find these values in the Service Marketplace of the SAP BTP cockpit. Click on the service's tile and find *name* and *Plan*, respectively.

#### Note

You can use [SAP BTP kubectl plugin](#) to get the available services in your SAP BTP account by using the access credentials stored in the cluster. However, the plugin is still experimental.

## 4.3.2.1 Creating and Managing Services Using Kyma dashboard

Create and manage Service Instances and Service Bindings using Kyma dashboard.

### Context

Use Kyma dashboard to create and manage your resources.

### Procedure

1. In the *Namespace* view, go to *Service Management*→*Service Instances*.
2. Create Service Instance using the required service details.  
You see the status `PROVISIONED`.
3. Go to *Service Management*→*Service Bindings* and create Service Binding, choosing your instance name from the dropdown list.  
You see the status `PROVISIONED`.

### Results

You can now use a given service in your Kyma cluster.

## 4.3.2.2 Creating and Managing Services Using kubectl

Create and manage Service Instances and Service Bindings using kubectl.

### Context

Use kubectl to create and manage your resources.

### Procedure

1. Create a Service Instance:

```
kubectl create -f - <<EOF
apiVersion: services.cloud.sap.com/v1
kind: ServiceInstance
metadata:
  name: {INSTANCE_NAME}
  namespace: {NAMESPACE}
spec:
  serviceOfferingName: {NAME_FROM_SERVICE_MARKETPLACE}
  servicePlanName: {PLAN_FROM_SERVICE_MARKETPLACE}
  externalName: {INSTANCE_NAME}
EOF
```

2. To see the output, run:

```
kubectl get serviceinstances.services.cloud.sap.com {INSTANCE_NAME} -o yaml
```

You can see the status created and the message ServiceInstance provisioned successfully.

3. Create a Service Binding:

```
kubectl create -f - <<EOF
apiVersion: services.cloud.sap.com/v1
kind: ServiceBinding
metadata:
  name: {BINDING_NAME}
  namespace: {NAMESPACE}
spec:
  serviceInstanceName: {INSTANCE_NAME}
  externalName: {BINDING_NAME}
  secretName: {BINDING_NAME}
  parameters:
    key1: val1
    key2: val2
EOF
```

4. To see the output, run:

```
kubectl get servicebindings.services.cloud.sap.com {BINDING_NAME} -o yaml
```

You can see the status created and the message ServiceBinding provisioned successfully.

## Results

You can now use a given service in your Kyma cluster. To see credentials, run:

```
kubectl get secret {BINDING_NAME} -o yaml
```

## Next Steps

To clean up your resources, run:

```
kubectl delete servicebindings.services.cloud.sap.com {BINDING_NAME}
kubectl delete serviceinstances.services.cloud.sap.com {INSTANCE_NAME}
```

### 4.3.3 Deploy Workloads in the Kyma Environment to Extend SAP Systems

Access the Kyma environment and start creating extensions for SAP systems.

#### Prerequisites

- You have added the Application Connector and Serverless modules. To learn how to do it, see [Add and Delete a Kyma Module \[page 2764\]](#).
- If you want to expose and secure your workload, the default Istio and API Gateway modules must be added.
- If you want your workload to react to events, the Eventing module must be added.
- If you want to use [CloudEvents](#) , make sure that your ecosystem supports it.

#### Context

You can extend a given SAP system in the Kyma environment with workloads. There are two kinds of workloads - Functions and microservices:

- Functions are simple code snippets that are called when the Function is triggered. They implement the exact business logic you define in the code, and you don't need to worry about containerization and deployment in Kyma runtime. Because Kyma Serverless is taking care of that, using Functions is convenient and fast.
- You can also deploy your extension code as a microservice. In this variant, you must contain your microservice code in a Docker image and deploy it in Kyma runtime. You need more Kubernetes experience but get more control over the shape of your extension application, because you can separate the tasks into smaller pieces that interact with each other as loosely coupled, independently deployable units of code.

Whichever workload variant you choose, you can make it part of the SAP system extension. You can do this in two ways. Depending on your solution's needs, choose one or both of them:

- Expose your workload's API using API Rule and make it accessible to other components of your ecosystem with REST calls.
- Subscribe your workload to events emitted from the SAP systems and extend them.

### Note

Most of the linked tutorials contain steps that you can perform both on the Kyma dashboard and in the terminal after downloading the kubeconfig file with the cluster configuration.

Follow these steps to get familiar with workloads and learn how to use them.

## Procedure

1. Connect the SAP system you want to extend ([Extending SAP Solutions Using Automated Configurations](#)).
2. Choose a namespace in your cluster and create a simple Function ([Create an Inline Function](#)) or a microservice ([Create a Workload](#)).
3. If you want to expose your workload outside the cluster, read [Expose a Workload](#).

### Note

For more details on the available security options in Kyma, see [Configure Authorization \(OAuth2, JWT\)](#).

4. If you want your workload to react to events, read [Trigger the Workload with an Event](#).

To subscribe to events with Kyma, you must create a [Subscription](#) including the following parameters:

- **Application name:** The name of the external Application connected to Kyma runtime. Typically, it starts with `mp-*`. This name can be found in the UI under [Integration > Applications](#). It must be bound to the namespace.
- **Event name:** The event name depends on your CX solution:
  - [SAP Commerce Cloud](#) - for custom events, check the configuration of your [Destination Target](#) for the Kyma runtime
  - [SAP Field Service Management](#)
  - [SAP Sales Cloud / SAP Service Cloud](#) - you can check the event specification in [Event Notification Monitoring](#).
- **Event version:** **v1** for legacy events or **v2** for CloudEvents

### Caution

Your workload must be error-free, otherwise event loss could occur. If you're facing problems, check the Kyma [Troubleshooting documentation](#).

## Related Information

[Kyma: Serverless](#) 

### 4.3.4 Expose and Secure a Workload with a JSON Web Token

Learn how to expose a workload and secure it with a JSON Web Token (JWT). To get the token, create a client credentials application using SAP Cloud Identity Services - Identity Authentication.

#### Prerequisites

- You have an SAP Cloud Identity Services - Identity Authentication tenant.
- You have created an OpenID Connect Application in your Identity Authentication tenant. See [Create OpenID Connect Application for JWT Bearer Flow](#).
- You have configured a Secret for API Authentication and saved the values of Client ID and Client Secret. See [Configure Secrets for API Authentication](#).
- You have the default Istio and API Gateway modules in your cluster.
- You have a workload deployed.

#### Context

To interact with a workload that is secured using an API Rule of the JWT type, you need an access token. Follow these steps to obtain a JWT using an Identity Authentication tenant. Then, use either `kubectl` or Kyma dashboard to expose and secure your workload.

### 4.3.5 Deploy Resilient Applications in the Kyma Runtime

Kyma runtime is the SAP cloud-native Kubernetes application runtime, managed service. All SAP BTP, Kyma runtime production plans ensure high availability. To benefit from the high-availability setup, make sure the architecture and deployment of your application comply with resiliency best practices. Use the following guidelines for Kubernetes and microservice-based applications to develop a stable application. Read further to find some Istio-related resiliency tips.

#### Resilient Applications Deployed on Kubernetes

To develop resilient applications deployed on Kubernetes, use:

- Kubernetes built-in health checks. For more information, read how to [Configure Liveness, Readiness and Startup Probes](#) .
- Deployment across multiple availability zones for high availability. For more details, see the [blog post](#) .
- The [Keda module](#) or [Kubernetes autoscaling](#) to automatically adjust the number of replicas based on resource usage.
- [Rolling updates](#) to minimize downtime during application updates. If you don't provide any configuration, rolling updates are by default enabled in your SAP BTP, Kyma runtime.
- BTP backing services, such as [PostgreSQL](#) or [Object Store](#) on SAP BTP. If you have to store some application data on SAP BTP, Kyma runtime, use persistent storage to ensure data is not lost in the event of a pod failure.
- [Resource quotas](#) to prevent resource starvation and ensure fair resource allocation.
- The [Telemetry module](#) to configure a logging and monitoring solution to identify and troubleshoot issues in real time.

## Resilient Microservice-Based Applications

The [Istio module](#) and Istio traffic management features help you achieve inbuilt microservices resiliency. Moreover, to develop resilient microservice-based applications, use:

- Istio's circuit breaker and retry features to prevent service overloads and recover from service failures.
- [Distributed tracing](#) with [Istio's observability features](#) to monitor the flow of requests across microservices and identify performance and error issues by [shipping logs to SAP Cloud Logging](#) .
- The [Eventing module](#) for asynchronous communication patterns, such as messaging queues, to decouple services and reduce dependencies. See how to [Configure SAP Event Mesh for Kyma Eventing \[page 1740\]](#).
- Health check endpoints as a part of your microservice. For more details, read [Kubernetes API health endpoints](#) .
- A centralized logging and monitoring solution to identify issues across multiple microservices and quickly troubleshoot them.
- A clear and well-defined boundary in your microservice`s design to minimize the impact of failures and enable easy replacement or scaling of individual services.
- Istio's service mesh to implement mutual TLS and authorization policies to secure communication between microservices. For more details, read the [blog post](#) .
- Network resiliency using Istio's [traffic management](#) features to test how your microservices respond to various failure scenarios, such as slow or failing services.
- The [Telemetry module](#) to ship your Istio's access logs and metrics to your logging backend to monitor traffic patterns and quickly troubleshoot issues.

## 4.3.6 Choose a Backend for Kyma Eventing

The event service in Kyma runtime supports two backends: NATS and SAP Event Mesh. Learn how to set up your preferred eventing backend.

### Prerequisites

- You have added the Kyma Eventing module. See [Add and Delete a Kyma Module \[page 2764\]](#).
- If you want to use NATS, you have added the Kyma NATS module.
- If you want to use SAP Event Mesh, you have configured it for Kyma Eventing. See [Configure SAP Event Mesh for Kyma Eventing \[page 1740\]](#).

### Context

You can send and receive events in Kyma with the built-in eventing infrastructure. By default, Kyma clusters have no eventing backend defined. You must set up an eventing backend, either based on the NATS technology or SAP Event Mesh.

### Procedure

1. Log in to Kyma dashboard. The URL is in the [Overview](#) section of your subaccount.
2. Go to the `kyma-system` namespace.
3. Go to **Kyma > Eventing**, open the `eventing` resource, and choose [Edit](#).
4. Under [Backend Type](#) section, select your preferred backend.
5. If you selected [EventMesh](#), go to [Event Mesh Secret](#), and select the namespace and name of your binding.

#### → Remember

If you selected [NATS](#), make sure the Kyma NATS module is enabled.

6. Choose [Update](#).

## Results

You have set up your eventing backend for Kyma.

If you want to choose another backend, edit the `eventing` resource again, select the preferred backend, and update the resource.

You can no longer return to an empty eventing backend.

## Next Steps

Learn more about the Kyma [Eventing Module](#) and follow the [Eventing Tutorials](#).

## Related Information

[Configure SAP Event Mesh for Kyma Eventing \[page 1740\]](#)  
[SAP Event Mesh](#)

### 4.3.6.1 Configure SAP Event Mesh for Kyma Eventing

If you want to use SAP Event Mesh as backend for Kyma Eventing, you must first set up the credentials.

## Prerequisites

- The Kyma Eventing module is added to your cluster. See [Add and Delete a Kyma Module \[page 2764\]](#).
- The Kyma SAP BTP Operator module is added to your cluster.
- You are using an enterprise account.

## Procedure

1. Log in to Kyma dashboard. The URL is in the [Overview](#) section of your subaccount.
2. To generate an SAP Event Mesh Secret, select a namespace and go to [Service Management](#) > [BTP Service Instance](#).
3. Choose [Create Service Instance +](#), and enter the following information:
  - **Name** - enter or generate the name of your instance.

- *Offering Name* - type: **enterprise-messaging**.
  - *Plan Name* - type: **default**.
4. Go to the *YAML* tab, and paste the following sample `config.json` file under the `parameters` key.

```
{
  "options": {
    "management": true,
    "messagingrest": true
  },
  "rules": {
    "topicRules": {
      "publishFilter": [
        "${namespace}/*"
      ],
      "subscribeFilter": [
        "${namespace}/*"
      ]
    },
    "queueRules": {
      "publishFilter": [
        "${namespace}/*"
      ],
      "subscribeFilter": [
        "${namespace}/*"
      ]
    }
  },
  "resources": {
    "units": "10"
  },
  "version": "1.1.0",
  "emname": "${EVENT_MESH_NAME}",
  "namespace": "${EVENT_MESH_NAMESPACE}"
}
```

5. Replace `<{EVENT_MESH_NAME}>` and `<{EVENT_MESH_NAMESPACE}>` with your own values.

### Note

The `<{EVENT_MESH_NAMESPACE}>` field cannot exceed 64 characters, or begin or end with a dot or hyphen: It must follow the [SAP Event Specification](#).

6. Go to **Service Management** > **BTP Service Bindings** and choose **Create Service Binding +**.
7. Provide the name of your binding, select the name of your instance from the list, and choose **Create**.

## Results

You have set up SAP Event Mesh for Kyma Eventing.

## Next Steps

Choose SAP Event Mesh as your backend for Kyma Eventing.

## Related Information

[Choose a Backend for Kyma Eventing \[page 1739\]](#)

### 4.3.7 Function Security

When creating Functions, make sure you understand how they work to avoid potential threats.

To eliminate potential security risks when using Functions, bear in mind these few facts:

- By default, JSON Web Tokens (JWTs) issued by an OIDC-compliant identity provider do not provide the **scope** parameter for Functions. This means that if you expose your Function and secure it with a JWT, you can use the token to validate access to all Functions within the cluster as well as other JWT-protected services.
- There are no authorization policies defined that would restrict Functions' access to other resources within the Namespace. If you deploy a Function in a given Namespace, it can freely access all events and APIs of services within this Namespace.
- All administrators and regular users who have access to a specific Namespace in a cluster can also access:
  - Source code of all Functions within this Namespace
  - Internal Docker registry that contains Function images

# 5 Extensions

The extension capabilities of SAP Business Technology Platform (SAP BTP) enables developers to implement loosely coupled extension applications securely, thus implementing additional workflows or modules on top of the existing SAP cloud solution they already have.

## Overview

All standard SAP solutions are offered with customizing capabilities. Additionally, customers often have their own requirements for innovative or industry-specific extensions and the extension capabilities of SAP BTP can help them build, deploy, and operate their new functionality.

You can extend standard SAP solutions without disrupting their performance and core processes. When building extension applications, you can also benefit from the automation of the integration between the cloud platform and the extended SAP solutions.

You have the following options to extend your SAP solution:

- Extensions with automated configurations in the Cloud Foundry environment: applicable for SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors.
- Extensions with automated configurations in the Kyma environment: applicable for SAP S/4HANA Cloud, SAP Marketing Cloud, SAP SuccessFactors, SAP Cloud for Customer, SAP Commerce Cloud, and SAP Field Service Management.
- Extensions with manual configurations in the Cloud Foundry environment: applicable for SAP S/4HANA Cloud, SAP SuccessFactors, and SAP Cloud for Customer.

## Extensions with Automated Configurations

The extension capabilities of SAP BTP provide a standard way for extending SAP solutions and developing event-driven extensions and applications. This framework includes:

- Simplified, standardized and unified extensibility and configuration for the SAP solutions.
- Central catalog per customer for all connected SAP systems where data such as APIs, events, credentials and other is stored. You can benefit from business services and actionable events across end-to-end business processes.

If you have to group the systems of different SAP solutions in the same business case, you can set up the connectivity between all these systems and a global account in SAP BTP in a single formation in the SAP BTP cockpit. See [Including Systems in a Formation \[page 1763\]](#).

The following SAP solutions currently support the automated configurations:

- SAP S/4HANA Cloud
- SAP Marketing Cloud
- SAP SuccessFactors
- SAP Cloud for Customer
- SAP Commerce Cloud

- SAP Field Service Management

## Extensions with Manual Configurations

If the automated integration is not supported for your scenario, you can configure the integration manually. Using manual configurations, you can extend the following SAP solutions on SAP BTP, Cloud Foundry environment:

- SAP S/4HANA Cloud
- SAP SuccessFactors
- SAP Cloud for Customer

## Troubleshooting

To get interactive support to help troubleshoot issues related to extensions, see [Guided Answers for Extensions](#) .

## Related Information

[Extending SAP Solutions Using Automated Configurations \[page 1744\]](#)

[Extending SAP Solutions Using Manual Configurations \[page 1881\]](#)

[Guided Answers for Extensions](#) 

[Best Practices for SAP BTP: Extending Existing SAP Solutions](#)

# 5.1 Extending SAP Solutions Using Automated Configurations

The extension capabilities of SAP Business Technology Platform (SAP BTP) enables developers to implement loosely coupled extension applications securely, thus implementing additional workflows or modules on top of the existing SAP cloud solution they already have.

## Overview

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

With the automated configuration you have the following key benefits:

- A way of extending standard SAP solutions without disrupting their performance and core processes
- Frameworks that offer simplified, standardized, and unified extensibility and configuration for SAP solutions
- A central repository for solutions' APIs, events, credentials, and other data, thereby ensuring easy access to services while creating your extensions

## Process Flow

You can use the extension capabilities of SAP BTP to implement additional workflows or modules on top of your existing SAP solutions. You can extend one or more SAP solutions grouped together in a common business case. The following SAP system types are supported:

- SAP S/4HANA Cloud, public edition
- SAP Marketing Cloud
- SAP SuccessFactors
- SAP Commerce Cloud
- SAP Cloud for Customer
- SAP Field Service Management

To enable the integration, you need to:

1. Connect the corresponding SAP system with the global account.  
During the pairing process you create an integration token which is then used by the SAP system administrator to configure the integration on the SAP system side. See [Registering an SAP System \[page 1753\]](#).

### Note

You cannot migrate the registered SAP systems between global accounts.

If you want to start using another global account, you will have to register your SAP systems again.

2. Optional: Group SAP systems so that they can be extended in a business scenario at one go.  
To do so, you create a formation containing one or more different systems assigned to a common subaccount. See [Including Systems in a Formation \[page 1763\]](#).
3. Make the SAP system accessible in the subaccounts in which you want to build your extension applications.  
For systems of type SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors, configure the entitlements and assign the corresponding quota and service plans to the subaccounts where the extension applications will reside. The service plans define the access to the corresponding SAP solution APIs. See:
  - [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#)
  - [Configure the Entitlements for the SAP SuccessFactors Extensibility Service \[page 1857\]](#)For the systems of type SAP Commerce Cloud, SAP Cloud for Customer, and SAP Field Service Management, you can continue with developing your extension application.
4. For systems of type SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors, configure the communication flow for the extension application.

To be able to consume the SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors APIs, you need to create a service instance for the corresponding SAP solution system. During the creation of the service instance, you configure the communication flow between the subaccount and the corresponding SAP solution. An HTTP destination which contains the binding properties for establishing the connection is automatically generated.

After you have created the service instance, you have two options to configure the extension application's connectivity to the corresponding SAP solution:

- Consume the HTTP destination
- Bind the service instance to the extension application

## Related Information

## 5.1.1 Extensibility Concepts

When implementing your extensibility scenario, there are a couple of concepts you need to understand to be able to benefit from the functionality that SAP BTP offers.

### Systems

A system is a specific instance of an SAP or third-party solution that is manually added or auto discovered and is listed in the SAP BTP cockpit.

When you want to add functionality to your SAP or third-party solution, you start by developing an extension application and deploying it in SAP BTP. Then, to allow the application to access the SAP or third-party solution, you add the system of this solution to the [System Landscape](#) page of the SAP BTP cockpit. If the system is one of the following types, you also have to register it using a registration token:

- SAP S/4HANA Cloud
- SAP Marketing Cloud
- SAP SuccessFactors

### System Details

#### Status

The registration process can have the following status values:

- No status

The system has been added as a record to the list. You can get a registration token for it. However, the registration process on the corresponding solution's system side has not been performed or completed yet.

- **Registered**  
The registration token has been used and the automated registration process has been completed successfully. Connectivity to the system has been established and it can be used in extension business scenarios.
- **Error while Registering**  
The registration has failed.
- **Deregistering**  
A deregistration process has started. As a result, the connectivity between the system and SAP BTP is disabled and extension scenarios cannot be established. The system remains in the system landscape list and you can register it again later on.
- **Error while Deregistering**  
The deregistration has failed.
- **Removing**  
A system removal process has started in the SAP BTP cockpit. You can remove a system from the list only when this system has been deregistered. Then, you can remove the system from the [Systems](#) list completely. To register the system again, first, you must add it to the list anew, and then, initiate the registration procedure.
- **Error while Removing**  
The system removal has failed.

## Consumption Bundles, APIs, and Events

Consumption bundles group logically APIs and events intended for communication with the SAP or third-party system. This grouping means that the consumption of the APIs or the events can happen by using the same set of credentials later on. When you register a system, you can also preview the number and the content of consumption bundles that are exposed for communication with the given system.

After you add your third-party systems, you can specify the set of APIs and events in consumption bundles. A consumption bundle organizes a set of related APIs and events into a single group for consumption purposes and expresses information about how the APIs and events that it contains can be accessed. All APIs and events that are part of the same consumption bundle need to be accessible through the same set of credentials. You add the consumption bundles in [System Details](#) of the respective third-party system.

You can explore the consumption bundles, the APIs, and the events configured for your system in [System Details](#). To do that, go to the respective tab: [Consumption Bundles](#), [APIs](#), or [Events](#).

## URL

You can use the URL as an entry point to the corresponding system. Optionally, you can use it to identify duplicate systems added to the list.

## Discovery Mechanisms

There are different ways to add systems to the [System Landscape](#) page in the SAP BTP cockpit: manually or automatically. If a system of your solution is associated with your global account or through a subscription in SAP BTP cockpit associated with a given subaccount, it will appear in the list automatically. Otherwise, you have to add your system manually. Systems are added to the list in one of the following ways:

### Auto-Discovered

An auto-discovered system is a system (associated with the given global account) that has been discovered and added automatically to the list based on information of the existing system landscape. Any SAP system of the supported system types that is associated with the same customer ID, with which your global account in SAP BTP is associated, will be added automatically in the system landscape list.

### Note

If a given SAP system is missing on the [System Landscape](#) page, it may be associated with a different customer ID on the SAP BTP global account you are working in. In this case, you need to add the system manually, and then, register it.

### **Subaccount/<my-subaccount>**

Specifies that the system has been added through a subscription in SAP BTP cockpit associated with a given subaccount. The subscription has been discovered and added automatically through the subaccount.

### **Manually-Added**

Specifies that the system has been added to the list manually by the global account administrator, using the [Add System](#) button and completing the wizard. The system has been associated with the global account in SAP BTP.

### **Business Type**

When you have an auto-discovered SAP system, you can find information in the respective system details whether this system is used for test or production purposes for example. This information is loaded automatically and is presented in the [Business Type](#) field.

### **Actions**

These are the things you can do with a system:

#### **Adding**

Adding a system to the list in the [System Landscape](#) page is just the first step of the system registration process. When you have only added a system, the system is not yet registered in the global account in SAP BTP. It appears in the system landscape list as a record with empty (or initialized) status. That is, the required configuration on the system side has not been performed, and therefore, the newly added system cannot exchange or expose its technical details, metadata, APIs, or events. Only when the registration process is complete and the system is registered with SAP BTP, it can exchange the relevant information and enable the extension scenario.

#### **Registering**

When registering a system, the required configuration on the system side has been performed, and therefore, the newly added system can exchange or expose its technical details, metadata, APIs, or events. Only when the registration process is complete and the system is registered with SAP BTP, it can exchange the relevant information and enable the extension scenario.

The registration of the newly added systems is based on a registration token. The token is used for the pairing of the system and the corresponding global account. After you add a system, you can get the token in the SAP BTP cockpit. Then, you can use it to configure the integration on the corresponding system side. By using the registration token on the system side and registering the system, the system administrator allows the integration of the system with SAP BTP.

The system gets a [Registered](#) status, only when a token is issued and the registration is complete on the corresponding system side. In general, the [Registered](#) status means that the communication between

the system and SAP BTP has been established. However, depending on the system and its requirements, additional configuration might be needed for the enablement of a fully functional extension scenario. The additional configuration, depending on the system type, is outlined in the corresponding documents listed in the *Related Information* section. See [Registering an SAP System \[page 1753\]](#).

### Specifics When Registering SAP S/4HANA Cloud Systems

When you register an SAP S/4HANA Cloud system, you can automate some of the required configuration steps at a later point using communication scenario groups. The communication scenario groups are entities that are part of the registration token that you use to register your SAP S/4HANA Cloud systems and are associated with one or more communication scenarios in SAP S/4HANA Cloud.

For example, you can use the Event Mesh communication scenario group when you get the registration token for the SAP S/4HANA Cloud system. This allows the automatic enablement of the communication scenario `SAP_COM_0892` after the corresponding system is added to the formation of type *Eventing Between SAP Cloud Systems*.

You can configure the communication scenario groups when registering an SAP S/4HANA Cloud system in the SAP BTP cockpit, in [▶ System Landscape ▶ Systems ▾](#). See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

### Merging

You have added your SAP systems manually at a given point in time and you have registered them. Then, you notice that you have the exact same systems in the list in the *Systems* page only this time they are auto-discovered and are not registered. To avoid duplicates and streamline the list of systems, you can merge the auto-discovered SAP systems with your manually added systems. The logic automatically detects duplicates based on their URL and system type. Note that you can only merge auto-discovered SAP systems without assigned status in a target system that has already been registered. That is, you cannot merge registered auto-discovered systems. See [Merging SAP Systems \[page 1756\]](#).

### Deregistering

Deregistering a system means that the connectivity between this system and the global account is disabled and extension scenarios cannot be established. You can deregister a system from the *Actions* column, or from the *System Details* page that you access when selecting the system from the *System* list. See [Deregistering or Removing a System \[page 1757\]](#).

### Removing

Removing a system means that this system is no longer part of the system landscape list. To remove a system from the list, first you have to deregister it. You can remove a system from the *Actions* column, or from the *System Details* page that you access when selecting the system from the *System* list. See [Deregistering or Removing a System \[page 1757\]](#).

You can see the discovery mechanism and access all the actions related to the systems listed in the SAP BTP cockpit, in [▶ System Landscape ▶ Systems ▾](#). See [Registering an SAP System \[page 1753\]](#).

## Formations

A formation is a logical grouping of SAP or third-party systems that can be extended in a business scenario. Formations allow you to combine SAP or third-party solution systems and a subaccount in SAP BTP to simplify the connectivity setup and to provide a unified view of all components required for the implementation of your

extension scenario. To create a fully functional formation, you can use a two-step wizard. At the first step, you specify a custom formation name and assign a subaccount to it. At the second step, you can include an SAP or third-party solution system in the formation. You do this configuration once and you can change it anytime.

### Note

You can assign a subaccount to the formation during the formation creation only. While you can include or exclude systems in the formation anytime, you cannot unassign or reassign subaccounts later on. Instead, you must recreate the formation.

Extension business cases often involve extending several SAP or third-party solutions at a time. For example, for a given business case you might need to extend the functionality or the UI as follows:

- An SAP SuccessFactors system, and an SAP S/4HANA Cloud system. First, you need to configure the connectivity of each of these systems to Cloud Foundry, Kyma, or both environments. Extension applications of both solutions are part of the same business need.
- An SAP Commerce Cloud system, and an SAP S/4HANA Cloud system. Again, you first configure the connectivity of each of these systems to the Kyma environment.
- A single system of the supported SAP or third-party solutions.
- SAP or third-party systems that expose event data, which can be shared and exchanged with the systems included in the formation.

When creating a formation in the SAP BTP cockpit, you include the systems of the different SAP or third-party solutions you want to extend. If your business case features more than one system, you can use the corresponding button to include additional systems in the formation. You can start the dialog as many times and add systems to your formation as you want.

## Systems Details in a Formation

### Consumption Bundle APIs

A consumption bundle can group logically a set of APIs for communication with the SAP or third-party system.

### Consumption Bundle Events

A consumption bundle can group logically a set of events for communication with the SAP or third-party system.

## Types

The formation type defines the use case. Therefore, depending on the use case, you have different formation types. To get a list of the available formation types, see [Including Systems in a Formation \[page 1763\]](#).

## Formation Status

A formation can have the following status values:

- No status
- *Action Required*

The formation has been created but you cannot use it productively yet.

Based on the formation type and the subaccount that you specified, it might require an SAP BTP Kyma environment instance or an SAP Business Application Studio subscription. Although the SAP BTP cockpit allows you to create such a formation, to enable and make use of it, you must also create the respective instance or subscription.

- *Synchronizing*

Systems that are included in the formation are currently synchronizing in the background.

- [Error](#)

An error occurred while some of the systems that are included in the formation were synchronizing in the background.

## Actions

### Creating Formations

Create a logical grouping of the systems that you want to extend.

### Including/Excluding Systems in a Formation

Include additional systems to a given formation or exclude already included systems from a formation.

If your business case features more than one system, you can include additional systems in the formation. You can include as many systems as you want to your formation.

### Resynchronizing Systems in a Formation

When you include systems in a formation, these systems are synchronized in the background. If an error occurs, you can resynchronize these systems to restart the synchronization process. To do that, choose [Resynchronize](#) for the particular formation. You will have this action available only for formations that are in status [Error](#).

### Resetting and Resynchronizing Systems in a Formation

If you want to reconfigure the systems in a formation from scratch without excluding them, you have to choose [Reset and Resynchronize](#). You will have this action available only for formations that have no status in SAP BTP cockpit their formation type is Side-by-Side Extensibility with Kyma.

### Deleting Formations

Detach the systems, unassign the subaccount, and delete the formation at one go.

When you start a formation deletion process, first the systems are excluded from the formation, then, the subaccount is unassigned, and last, the formation is deleted from the list completely.

You can create and configure formations in the SAP BTP cockpit, in ► [System Landscape](#) ► [Formations](#) ►. See [Including Systems in a Formation \[page 1763\]](#).

## 5.1.2 Maintaining Unified Customer Landscape

### Use

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Unified Customer Landscape is a service that offers customer landscape management capabilities. The frontend representation of this service is the [System Landscape](#) page in the SAP BTP cockpit. The dedicated

[SAP S/4HANA Cloud Extensibility](#) and [SAP SuccessFactors Extensibility](#) services are also part of the Unified Customer Landscape capabilities.

## Customer Landscape Discovery

The [System Landscape](#) page of the SAP BTP cockpit gives you a visual overview of your SAP and third-party systems associated with the given global account or a subaccount. There are different ways to add systems to the [Systems](#) list in the [System Landscape](#) page: manually or automatically. If a system of your solution is associated with your global account or through a subscription in SAP BTP cockpit associated with a given subaccount, it will appear in the list automatically. Otherwise, you have to add your system manually. Systems are added to the list in one of the following ways:

- **Auto-Discovered**  
An auto-discovered system is a system (associated with the given global account) that has been discovered and added automatically to the list based on information of the existing system landscape. Any SAP system of the supported system types that is associated with the same customer ID, with which your global account in SAP BTP is associated, will be added automatically in the system landscape list.
- **Subaccount/<my-subaccount>**  
Specifies that the system has been added through a subscription in SAP BTP cockpit associated with a given subaccount. The subscription has been discovered and added automatically through the subaccount.
- **Manually-Added**  
Specifies that the system has been added to the list manually by the global account administrator, using the [Add System](#) button and completing the wizard. The system has been associated with the global account in SAP BTP.  
See [Registering an SAP System \[page 1753\]](#).

## Integration and Extensibility

Unified Customer Landscape also helps you integrate and extend your SAP S/4HANA, SAP Ariba, SAP SuccessFactors, and other SAP and third-party systems in one single experience.

In the SAP BTP cockpit, you get a comprehensive overview of all your systems associated with your customer ID. These systems can be registered or auto discovered. They are conveniently listed as a record in the [Systems](#) list. Moreover, Unified Customer Landscape lets you integrate one or more systems in a common business case by including these systems in a formation.

See:

- [Including Systems in a Formation \[page 1763\]](#)
- [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#)
- [Extending SAP Marketing Cloud in the Cloud Foundry and Kyma Environment \[page 1843\]](#)
- [Extending SAP SuccessFactors in the Cloud Foundry and Kyma Environment \[page 1851\]](#)
- [Extending SAP Customer Experience Products in the Kyma Environment \[page 1877\]](#)

## 5.1.3 Registering an SAP System

To connect an SAP system with a global account in SAP BTP, you first need to register the system.

### Prerequisites

- You are a global account administrator, or you are a system landscape administrator of the global account where you want to register your SAP system. See [Working with Role Collections \[page 2087\]](#).
- Before adding your system, make sure it's not already auto-discovered and listed automatically in the [Systems](#) list.

### Context

#### ⓘ Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Adding a system to the list in the [System Landscape](#) page is just the first step of the system registration process. When you have only added a system, the system is not yet registered in the SAP BTP global account. That is, the required configuration on the system side has not been performed, and therefore, the newly added system cannot exchange or expose its technical details, metadata, APIs, or events. Only when the registration process is complete and the system is registered with SAP BTP, it can exchange the relevant information and enable the extension scenario.

If your system is associated with the given global account, this system is discovered and added automatically to the [Systems](#) list based on information of the existing system landscape. Any SAP system of the supported system types that is associated with the same customer ID, with which your global account in SAP BTP is associated, will be auto-discovered.

#### ⓘ Note

If a given SAP system is missing on the [System Landscape](#) page, it may be associated with a different customer ID on the SAP BTP global account you are working in. In this case, you need to add the system manually, and then, register it.

#### ⓘ Note

You cannot migrate the registered SAP systems between global accounts.

If you want to start using another global account, you will have to register your SAP systems again.

The registration of the newly added systems is based on a registration token. The token is used for the pairing of the system and the corresponding global account. After you add a system, you can get the token in the SAP BTP cockpit. Then, you can use it to configure the integration on the corresponding system side. By using the registration token on the system side and registering the system, the system administrator allows the integration of the system with SAP BTP.

When you add a system, it appears in the system landscape list as a record with empty (or initialized) status. The system gets a *Registered* status, only when a token is issued and the registration is complete on the corresponding system side. In general, the *Registered* status means that the communication between the system and SAP BTP has been established. However, depending on the system and its requirements, additional configuration might be needed for the enablement of a fully functional extension scenario. The additional configuration, depending on the system type, is outlined in the corresponding documents listed in the *Related Information* section.

#### Note

When registering SAP systems of the same type, you can have up to 1000 tokens per global account ready to be used. Tokens that are already used to register an SAP system are not included in this number.

This means that you cannot have more than 1000 systems in the Systems list of the same type with an empty status and generated token that is not used yet.

The registration process has the following states displayed in the cockpit:

- No status displayed in the *Status* column - the registration token for an SAP system has been created but the registration on the respective SAP system side has not been performed or completed yet.
- *Registered* - the registration token for systems of type SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors has been used and the automated registration process has been successfully completed. The systems of these types can be assigned to a formation on the *Formations* page in the cockpit. All other system types are registered without a registration token and can be assigned to a formation.
- *Error while Registering* - the registration has failed.

#### Note

If a system is in status *Error while Registering*, delete it and register it again.

If the registration error persists, report a case in one of the following components depending on the system type:

- SAP SuccessFactors - BC-NEO-EXT-SF
- SAP S/4HANA Cloud - BC-NEO-EXT-S4C
- All other system types - BC-CP-MP

#### Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► *System Landscape* ► *Systems* ►.
2. On the *Systems* page, choose *Add System*.

### 📘 Note

Before adding your system, make sure it's not already auto-discovered and listed automatically in the [Systems](#) list. Some of the SAP systems have additional configurations described in dedicated procedures. See:

- [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#)
- [Register an SAP Marketing Cloud System in a Global Account in SAP BTP \[page 1847\]](#)
- [Register an SAP SuccessFactors System in a Global Account in SAP BTP \[page 1853\]](#)
- [Register an SAP Customer Experience System \[page 1878\]](#)

3. In the *Add System* wizard:
  - a. Enter a name for the system you want to register.

### 📘 Note

Use only printable ASCII characters.

### → Tip

We recommend that you indicate the type of the system when specifying the system name. For example, `<mysystem>-commerce-cloud`. This helps you identify the system type when assigning systems to a formation.

- b. In the *Type* dropdown list, select the system type.
- c. Choose *Add*.
- d. Choose *Get Token*.

The system generates the registration token.
- e. Copy the registration token. You need the token to complete the integration on the respective SAP solution system side.
- f. Close the wizard.

## Results

The system has been added as a record to the list on the [Systems](#) page in the SAP BTP cockpit and a token for connecting the corresponding SAP solution with the global account in SAP BTP has been generated.

### 📘 Note

Registration tokens have different validity periods that depend on the system type. For more information about token expiry, see the corresponding documentation at the [Related Links](#) section.

## Next Steps

- Use the registration token to complete the registration on the respective SAP system side. See:

- [Trigger the Registration in the SAP S/4HANA Cloud Tenant \[page 1785\]](#)
- [Trigger the Registration in the SAP Marketing Cloud Tenant \[page 1850\]](#)
- [Register an SAP SuccessFactors System in a Global Account in SAP BTP \[page 1853\]](#)
- You can optionally assign the system to a formation on the *Formations* page, as follows:
  - Systems of type *SAP Commerce Cloud*, *SAP Cloud for Customer*, and *SAP Field Service Management* can be assigned to a formation directly before the integration is complete on the respective SAP Customer Experience (SAP CX) system side. However, to enable the API access, you first need to complete the integration.
  - For systems of type *SAP S/4HANA Cloud* and *SAP SuccessFactors*, you first need to configure the integration on the respective SAP system side. See [Including Systems in a Formation \[page 1763\]](#).
- If you no longer need it, you can deregister or remove the system depending on its status. See [Deregistering or Removing a System \[page 1757\]](#).

## Related Information

[Extending SAP Marketing Cloud in the Cloud Foundry and Kyma Environment \[page 1843\]](#)

[Extending SAP SuccessFactors in the Cloud Foundry and Kyma Environment \[page 1851\]](#)

[Extending SAP Customer Experience Products in the Kyma Environment \[page 1877\]](#)

### 5.1.3.1 Merging SAP Systems

Merging the SAP systems allows you to reduce the duplicate systems in the list. You can merge auto-discovered SAP systems without assigned status in a target system that has already been registered.

#### Prerequisites

- You are a global account administrator, or you are a system landscape administrator of the global account where you want to deregister or remove your SAP system. See [Working with Role Collections \[page 2087\]](#).
- You have registered the target SAP system. See [Registering an SAP System \[page 1753\]](#).

#### Context

The logic of the SAP BTP cockpit enables it to discover SAP systems across your landscape and add them automatically on the *Systems* page. If you have already added these systems manually at a given point in time and you have registered them, the auto-discovered systems might create duplicate entries in the list. To avoid duplicates and streamline the list of systems, you can merge the auto-discovered SAP systems with your

manually added systems. The logic automatically detects duplicates based on their URL and system type. Note that you can only merge auto-discovered SAP systems without assigned status in a target system that has already been registered. That is, you cannot merge registered auto-discovered systems.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#) ▾.
2. On the [Systems](#) page, find the auto-discovered SAP system you want to merge.
3. Under the [Actions](#) column, choose the [Merge system](#) button.

Alternatively, you can choose the system from the list to open the [System Details](#) view, and then, choose the [Merge System](#) button on the top-right corner.

The [Merge System](#) dialog opens.

4. In the [Target System](#) dropdown menu, find and select the SAP system, in which you want to merge your system.
5. Choose [Merge](#).

## Results

The auto-discovered system has been merged in the target system. That is, all individual properties of the system were recorded in the target system and the common properties were preserved. At the end, the duplicate (auto-discovered) system has been removed as a record from the list on the [Systems](#) page in the SAP BTP cockpit.

### 5.1.3.2 Deregistering or Removing a System

When you no longer need the system to be paired with your global account, you can deregister or remove it depending on its status.

## Prerequisites

- You are a global account administrator, or you are a system landscape administrator of the global account where you want to deregister or remove your system. See [Working with Role Collections \[page 2087\]](#).
- You have added your system as a record to the list on the [Systems](#) page. See [Registering an SAP System \[page 1753\]](#).

## Context

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Deregistering an SAP or third-party system means that the connectivity between this system and the global account is disabled and extension scenarios cannot be established, while removing a system means that this system is no longer part of the system landscape list. You can deregister or remove a system from the [Actions](#) column, or from the [System Details](#) page that you access when selecting the system from the system landscape list.

The deregistration and the removal processes have the following states displayed in the cockpit:

- **Deregistering** - a deregistration process has started. As a result, the connectivity between the SAP or third-party system and SAP BTP is disabled and extension scenarios cannot be established. The system remains in the system landscape list and you can register it again later on. Once a system is registered, you can deregister it only after removing it from all entitlement configurations and formations it takes part in.
- **Error while Deregistering** - the deregistration has failed. Try to deregister the system again. If the problem persists, you have to report a case in one of the components mentioned below.
- **Removing** - a system removal process has started in the SAP BTP cockpit. As a result, the SAP or third-party system is deregistered, and then, it is removed from the system landscape list completely. To register the system again, first, you must add it to the list anew, and then, initiate the registration procedure. Once a system is registered, you can only remove it if you first deregister it.
- **Error while Removing** - the system removal has failed. Try to deregister the system again. If the problem persists, you have to report a case in one of the components mentioned below.

### Note

If the deregistration, or removal errors persist, report a case in one of the following components depending on the system type:

- SAP SuccessFactors - BC-NEO-EXT-SF
- SAP S/4HANA Cloud - BC-NEO-EXT-S4C
- All other system types - BC-CP-MP

## Procedure

1. In the cockpit, navigate to your global account, and then choose [System Landscape](#) [Systems](#).
2. On the [Systems](#) page, select the SAP or third-party system you want to deregister or remove.
  - To deregister a system, choose [\(Deregister system\)](#) from the [Actions](#) column, or choose [Deregister System](#) from the [System Details](#) page that you access when selecting the system from the system landscape list.  
You can deregister only registered systems.

- To remove a system, choose  (*Remove system*) from the *Actions* column, or choose *Remove System* from the *System Details* page that you access when selecting the system from the system landscape list.

Before removing a system from the list, first you have to check all configurations that this system is part of, such as entitlements and formations. Then, you have to deregister it and after that you will be able to remove it from the *Systems* page. If you try to remove a system before deregistering it, a dialog will appear and will ask you to deregister the system first.

#### Note

You can only remove manually added systems. Depending on their discovery mode the systems that are added to the list either are *Manually added* (registered manually by following the procedure in the prerequisites), or *Auto-discovered* (added to the list automatically, based on information of the existing system landscape), or part of the *Subaccount/<my-subaccount>* (automatically added, based on the information of the SAP BTP subaccount).

You cannot remove *Auto-discovered* systems from the list.

## Results

The system has been deregistered or removed as a record from the list on the *Systems* page in the SAP BTP cockpit.

## 5.1.4 Registering Third-Party Systems

To connect a third-party systems, for example a Google system, with a global account in SAP BTP, you first need to register this system.

### Prerequisites

You are a global account administrator, or you are a system landscape administrator of the global account where you want to register your third-party system. See [Working with Role Collections \[page 2087\]](#).

### Context

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

You add a third-party system to the list in the [System Landscape](#) page. At this point you provide all the required details for this system: its type, provider, URL, and system ID. For third-party systems, this also completes the registration process and you have your third-party system registered with SAP BTP.

When you have this system added in the [Systems](#) list, you can select it and open its system details. There, you specify in the consumption bundles the APIs, and the events. A consumption bundle organizes a set of related APIs and events into a single group for consumption purposes and expresses information about how the APIs and events that it contains can be accessed. All APIs and events that are part of the same consumption bundle need to be accessible through the same set of credentials.

#### 📘 Note

You cannot migrate the registered third-party systems between global accounts.

If you want to start using another global account, you will have to register your systems again.

#### 📘 Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. In the cockpit, navigate to your global account, and then choose [System Landscape](#) [Systems](#).
2. On the [Systems](#) page, choose [Add System](#).
3. In the [Add System](#) wizard:
  - a. Enter a name for the system you want to register.

#### 📘 Note

Use only printable ASCII characters.

#### → Tip

We recommend that you indicate the type of the system when specifying the system name. For example, `<mysystem>-google-workspace`.

- b. In the [Type](#) dropdown list, select [Other System Type](#).
  - c. In the [System Type Name](#) field, enter the type of your system. This is a user-defined type of the system you want to add. For example, [Workspace](#).
  - d. In the [Provider](#) field, enter the provider of your system. For example, [Google](#).
  - e. In the [URL](#) field, enter the URL of your system.
  - f. In the [System ID](#) field, enter the unique identifier of the added system that is used in its own domain.
  - g. Choose [Add](#).
4. Find this system in the [Systems](#) list and open its system details. Choose [Add Consumption Bundle](#) and fill in the following properties:
    - [Consumption Bundle Name](#): add a meaningful name

- *Description*:
  - *Credentials Type*: choose between OAuth and Basic
    - If you choose *OAuth*, fill in these properties:
      - *Client ID*
      - *Client Secret*
      - *URL*: this is the token URL, that is used for obtaining OAuth tokens through the client ID and the client secret.
    - If you choose *Basic*, fill in these properties:
      - *User*
      - *Password*
5. Choose *Add*. Open the consumption bundle from the list.
  6. If you want to add APIs, choose *Add API* and fill in the following properties:
    - *API Name*: add a meaningful name.
    - *Description*: this field is optional.
    - *URL*
    - *Specification*: this is the file containing the specification. The file format depends on the specification type. For OpenAPI, you can use YAML and JSON. For OData, you can use JSON and XML.
    - *Type*: this is the type of the specification. The API specification type can be OpenAPI or OData.
  7. If you want to add events, choose *Add Event* and fill in the following properties:
    - *Event Name*: add a meaningful name.
    - *Description*: this field is optional.
    - *Specification*: this is the file containing the specification. The file format can be JSON and YAML.
    - *Type*: this is the type of the specification. The event specification type can be only AsyncAPI.

## Results

The system has been added as a record to the list on the [Systems](#) page in the SAP BTP cockpit and you have added the respective APIs or events.

If you no longer need it, you can remove the system depending on its status. See [Deregistering or Removing a System \[page 1757\]](#).

## 5.1.5 Declaring System APIs and Events as Dependencies for Business Scenarios

### Prerequisites

You have a system of type *Other System Type* or *CAP Application* listed in the *System Landscape* page of your global account in SAP BTP. See [Registering Third-Party Systems \[page 1759\]](#).

### Context

For certain formation types, systems of type *Other System Type* or *CAP Application* that are part of the *System Landscape* page may need to describe their runtime dependencies so other systems can comply with these dependencies to be able to interact with these systems in a common scenario. See [Enabling Events Exchange Between SAP Cloud Systems \[page 1772\]](#).

The integration dependency includes a list of requirements, which point out which API and event resources are involved. Each requirement describes one aspect and can be used to express alternatives using OR conditions for achieving the same outcome.

To add the necessary API and event resources to an integration dependency, systems use the Open Resource Discovery standard. The Open Resource Discovery standard is about adding missing or common high-level information and standardizing the discovery aspects. See [Why ORD](#) .

Every integration dependency has the following properties:

- Name: a human-readable name that does not exceed 255 characters. For example, **Integration Dependency to realize Customer Order data product**.
- Description: a plain text that does not exceed 255 characters. For example, **SAP S/4HANA Cloud, our next generation cloud ERP suite designed for in-memory computing**.
- Version: the version is assigned automatically when adding a new integration dependency.

#### Note

If you add a new integration dependency using the same name as an existing integration dependency, the version of the new integration dependency will be automatically increased. Then, in the given system, there will be two integration dependencies with the same name and different versions.

Integration dependencies contain aspects. An aspect contains a set of APIs and/or events of a system that define the dependencies other systems need to comply with to be able to be part of an integration scenario together.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#) ►.
2. On the [Systems](#) page, select the system to which you want to add an integration dependency and open its system details.
3. In the [Integration Dependencies](#) tab, choose [Add](#).
4. Define a name and a description for the new integration dependency. Choose [Next Step](#).

### Note

The version is assigned automatically when adding a new integration dependency. If you add a new integration dependency using the same name as an existing integration dependency, the version of the new integration dependency will be automatically increased.

5. Define a name and a description for the first aspect and add more if necessary. Choose [Next Step](#).
6. Add at least one API or event to each aspect and choose [Review](#).
7. Check if all the aspects are configured properly and choose [Add](#).

### Note

Once you add an integration dependency to a system, you can no longer edit it and add or delete aspects, APIs or events. You can only delete an integration dependency.

## 5.1.6 Including Systems in a Formation

You can include various SAP systems into a formation and thus combine diverse SAP solutions into an extended business scenario.

### Prerequisites

- You are a global account administrator, or you are a system landscape administrator. See [Working with Role Collections \[page 2087\]](#).
- The SAP solution systems that you want to include to a formation must be added at the [Systems](#) list in the [System Landscape](#) page. See [Registering an SAP System \[page 1753\]](#).

### Context

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

A formation is a logical grouping of SAP systems that can be extended in a business scenario. Formations allow you to combine SAP solution systems and a subaccount in SAP BTP to simplify the connectivity setup and to provide a unified view of all components required for the implementation of your extension scenario. To create a fully functional formation, you can use a two-step wizard. At the first step, you specify a custom formation name and assign a subaccount to it. At the second step, you can include an SAP solution system in the formation. You do this configuration once and you can change it anytime.

### Note

You can assign a subaccount to the formation during the formation creation only. While you can include or exclude systems in the formation anytime, you cannot unassign or reassign subaccounts later on. Instead, you must recreate the formation.

Extension business cases often involve extending several SAP solutions at a time. For example, for a given business case you might need to extend the functionality or the UI as follows:

- An SAP SuccessFactors system, and an SAP S/4HANA Cloud system. First, you need to configure the connectivity of each of these systems to Cloud Foundry, Kyma, or both environments. Extension applications of both solutions are part of the same business need.
- An SAP Commerce Cloud system, and an SAP S/4HANA Cloud system. Again, you first configure the connectivity of each of these systems to the Kyma environment.
- A single system of the supported SAP solutions.
- SAP systems that expose event data, which can be shared and exchanged with the systems included in the formation.

When creating a formation in the SAP BTP cockpit, you include the systems of the different SAP solutions you want to extend. If your business case features more than one SAP solution system, you can use the corresponding button to include additional systems in the formation. You can start the dialog as many times and add systems to your formation as you want.

A formation can have the following status values:

- **No status**  
The formation has been added as a record to the list and all registered systems are included successfully.
- **Action Required**  
The formation has been created but you cannot use it productively yet. Based on the formation type and the subaccount that you specified, it might require an SAP BTP Kyma environment instance or an SAP Business Application Studio subscription. Although the SAP BTP cockpit allows you to create such a formation, to enable and make use of it, you must also create the respective instance or subscription.
- **Synchronizing**  
Systems that are included in the formation are currently synchronizing in the background.
- **Error**  
An error occurred while some of the systems that are included in the formation were synchronizing in the background. In this case, report an incident in the `BC-CP-MP` component.

When you include systems in a formation, these systems are synchronized in the background. If an error occurs, you can resynchronize these systems to restart the synchronization process. To do that, choose **Resynchronize** for the particular formation. You will have this action available only for formations that are in status **Error**.

If you want to reconfigure the systems in a formation from scratch without excluding them, you have to choose [Reset and Resynchronize](#). You will have this action available only for formations that have no status in SAP BTP cockpit and their formation type is Side-by-Side Extensibility with Kyma.

### Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. Open the SAP BTP cockpit and navigate to your global account.
2. Choose [System Landscape](#) > [Formations](#).
3. Choose [Create Formation](#).

The [Create Formation](#) dialog opens. There, in a wizard, you can create a formation and include one or more SAP systems to it.

4. On the [General Information](#) step of the wizard, enter the following information:
  - a. Enter a unique formation name.

The formation name can contain lowercase or uppercase Latin letters, numbers, hyphens, spaces, or underscores only. The name must start and end with an alphanumeric character.

- b. Specify a type for the formation.

The formation type defines the use case. Therefore, depending on the use case, you can specify one of the following formation types:

Formation Type	Description
<a href="#">Side-by-Side Extensibility with Kyma</a>	Formations of type <a href="#">Side-by-Side extensibility with Kyma</a> enable business scenarios that involve extending the functionality of several SAP systems at a time with SAP BTP Kyma environment instance.  See <a href="#">Enabling Side-by-Side Extensibility with Kyma [page 1768]</a> .
<a href="#">Developing with SAP Business Application Studio</a>	Formations of type <a href="#">Developing with SAP Business Application Studio</a> enable connectivity between given SAP systems of type <a href="#">SAP S/4HANA Cloud</a> from the <a href="#">System Landscape</a> page of SAP BTP cockpit and the SAP Business Application Studio, you must create a formation of the corresponding type and include the SAP S/4HANA Cloud systems in it.  See <a href="#">Enabling System Landscape for SAP Business Application Studio [page 1768]</a> .

Formation Type	Description
<i>Integration with SAP Build</i>	<p>Formations of type <i>Integration with SAP Build</i> enable connectivity between given SAP systems of type <i>SAP S/4HANA Cloud</i> from the <i>System Landscape</i> page of SAP BTP cockpit and SAP Build, you must create a formation of the corresponding type and include the SAP S/4HANA Cloud systems in it.</p> <p>See <a href="#">Enabling System Landscape for SAP Build [page 1770]</a>.</p>
<i>Eventing Between SAP Cloud Systems</i>	<p>Formations of type <i>Eventing Between SAP Cloud Systems</i> enable end-to-end communication flow of events between the SAP systems that are included in the given formation. As the name of the formation suggests, the systems transmit information about events using SAP Event Broker. To be able to exchange such events information, the SAP systems must be also visible and configurable in the SAP Event Broker user interface. The formation makes the systems visible in SAP Event Broker, however, it requires a subscription to SAP Event Broker in the corresponding SAP BTP subaccount first.</p> <p>See <a href="#">Enabling Events Exchange Between SAP Cloud Systems [page 1772]</a>.</p>
<i>Integration with SAP Ariba Buying</i>	<p>Formations of type <i>Integration with SAP Ariba Buying</i> set up SAP Ariba Buying with SAP S/4HANA Cloud on SAP BTP.</p> <p>See <a href="#">Enabling SAP Ariba Buying [page 1774]</a>.</p>
<i>Integration with SAP Start</i>	<p>Formations of type <i>Integration with SAP Start</i> set up SAP Start with SAP S/4HANA Cloud on SAP BTP.</p> <p>See <a href="#">Enabling SAP Start [page 1775]</a>.</p>
<i>Data Ingestion for Industry Cloud Solutions</i>	<p>Formations of type <i>Data Ingestion for Industry Cloud Solutions</i> set systems that support data ingestion and are part of the industry cloud solutions published by SAP and SAP BTP.</p> <p>See <a href="#">Enabling Data Ingestion for Industry Cloud Solutions [page 1777]</a>.</p>

Depending on the type, a list of systems that can be included in this formation is loaded at the following step of the wizard.

- c. Specify a subaccount that you want to associate with the formation.

All systems that you include in the formation will be available and can be managed in the respective application or runtime in this subaccount.

#### Note

Based on the formation type and the subaccount that you specified in the newly created formation, it might require an SAP BTP Kyma environment instance. Although the SAP BTP cockpit allows you to create such a formation, to enable and make use of it, you must also create an SAP BTP Kyma environment instance for the corresponding SAP BTP subaccount.

5. Choose *Next Step*.
6. On the *Include Systems* step, select one or more systems that you want to include in the newly created formation, and then, choose *Next Step*.

The wizard prefilters the systems that were added to the *Systems* tab and are valid for the formation type that you specified at the previous step.

7. On the *Review* step, double check your entries before you create the formation.

If you want to make any changes, either you can edit the corresponding section directly, or use the *Previous* button.

8. Choose *Create*.
9. Optionally, you can include additional systems to the newly created formation, by choosing *Include System*.

On the systems list that opens, select a system, and then, choose *Include*.

## Results

For systems of type SAP Commerce Cloud, SAP Cloud for Customer, and SAP Field Service Management, the access to the corresponding solution's APIs has been enabled. After you have created a formation, you can edit it and change the included systems. The status of each system depends on whether you have registered that system in the global account.

#### Note

When you delete a formation, several activities are performed at one go. First, the systems are excluded from the formation. Then, the subaccount is unassigned. Finally, the formation is deleted from the formations list completely.

To restore a deleted formation, first you must create it anew, and then, include all of its systems again, one by one.

## Next Steps

For the systems of type SAP S/4HANA Cloud, SAP Marketing Cloud, and SAP SuccessFactors and a formation using the Cloud Foundry environment, or the Kyma environment, to be able to consume the respective APIs, you need to continue with assigning the required entitlements and creating a service instance.

- SAP S/4HANA Cloud, and SAP Marketing Cloud:
  1. [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#)
  2. [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#)
- SAP SuccessFactors:
  1. [Configure the Entitlements for the SAP SuccessFactors Extensibility Service \[page 1857\]](#)
  2. [Create a Service Instance to Consume the SAP SuccessFactors HXM Suite OData API \[page 1858\]](#)

### 5.1.6.1 Enabling Side-by-Side Extensibility with Kyma

#### ⓘ Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

You want to extend the functionality on top of your existing SAP solution because your specific business needs require it. You also want to use the SAP BTP Kyma environment. You can build an extension application that contains your business logic and UI changes and deploy it in SAP BTP Kyma runtime. For the users of your SAP solution, this change will be seamless, it will look as if it's part of the original functionality. At the same time, you can use the extension capabilities of SAP BTP to implement the additional workflows or modules. This is called side-by-side extensibility with Kyma.

To enable the side-by-side extensibility with Kyma for your SAP solution, you have to create an SAP BTP Kyma environment instance in your subaccount in SAP BTP. Then, you have to connect the corresponding SAP system with the global account in SAP BTP. Use the automated configurations for the following SAP solutions:

- [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#)
- [Extending SAP Marketing Cloud in the Cloud Foundry and Kyma Environment \[page 1843\]](#)
- [Extending SAP SuccessFactors in the Cloud Foundry and Kyma Environment \[page 1851\]](#)
- [Extending SAP Customer Experience Products in the Kyma Environment \[page 1877\]](#)

Finally, you can create a formation of type *Side-by-Side Extensibility with Kyma* where you can include one or more SAP systems depending on your use case.

### 5.1.6.2 Enabling System Landscape for SAP Business Application Studio

#### ⓘ Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

A registered SAP S/4HANA Cloud system in the SAP BTP cockpit can expose consumption bundles that contain APIs and events. You can easily discover and consume the APIs exposed by the SAP S/4HANA Cloud systems in your system landscape when you develop and extend applications on SAP BTP, Cloud Foundry environment, using SAP Business Application Studio. To do this, first you need to enable connectivity between your system landscape in SAP BTP cockpit and SAP Business Application Studio. The integration

requires performing several configuration steps starting with configuration on a global account level, and then, configuration on a subaccount level.

The following procedure outlines the steps you need to perform to consume the APIs of registered SAP S/4HANA Cloud systems within the SAP Business Application Studio.

1. Add and then register an SAP system of type *SAP S/4HANA Cloud* in the *System Landscape* page of SAP BTP cockpit.  
To expose information about its APIs and events and show this information on the *System Landscape* page, an SAP system of type *SAP S/4HANA Cloud* must be registered in the SAP BTP cockpit. Only when registered, the system communicates information about its APIs and other technical details across the landscape. See [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#).
2. Create a formation of type *Developing with SAP Business Application Studio* and include the SAP S/4HANA Cloud systems you want to expose in SAP Business Application Studio.

### Note

In the formation type *Developing with SAP Business Application Studio*, you can include only SAP systems of type *SAP S/4HANA Cloud*.

To enable connectivity between given SAP systems of type *SAP S/4HANA Cloud* from the *System Landscape* page of SAP BTP cockpit and the SAP Business Application Studio, you must create a formation of the corresponding type and include the SAP S/4HANA Cloud systems in it. See [Including Systems in a Formation \[page 1763\]](#).

3. Create a destination and make sure it has the corresponding system and consumption bundle properties.
  - Create a destination manually.  
You can create the destination manually via the SAP Destination service page in SAP BTP cockpit by specifying one of the following additional properties variants in it.

Additional Properties (variant 1)	Additional Properties (variant 2)	Description
x-correlation-id	x-correlation-id	The property identifies the consumption bundle and its APIs that are exposed by the SAP S/4HANA Cloud system. The destination also provides the required credentials to consume the bundle and use it for further development in the SAP Business Application Studio.
x-system-id	x-system-name	Properties that uniquely identify the local tenant of the registered SAP S/4HANA Cloud system.
x-system-type	x-system-base-url	

All of the required properties of a given SAP S/4HANA Cloud system are accessible in the corresponding *System Details* section on the *System Landscape* page. See [Create a Destination \[page 854\]](#) and [Configuring the Extension Application's Connectivity to SAP S/4HANA Cloud \[page 1885\]](#).

- Create a destination automatically.  
Alternatively, the destination can be created automatically. You can do this, by creating a service instance of the SAP S/4HANA Cloud Extensibility service after you register an SAP S/4HANA Cloud

system. See [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#) and [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#).

4. Create an SAP Business Application Studio subscription.  
To work with the SAP Business Application Studio, you must subscribe the subaccount to its application. See [Subscribe to SAP Business Application Studio](#).

## Next Steps

Develop applications on SAP BTP, Cloud Foundry environment using SAP Business Application Studio and the system landscape.

When you enable the connectivity, the SAP S/4HANA Cloud systems and their APIs are accessible in the SAP Business Application Studio. Next you can use the APIs to develop new or extend the existing functionality with the help of SAP Business Application Studio. See [Unified Customer Landscape Service Provider](#).

### 5.1.6.3 Enabling System Landscape for SAP Build

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

A registered SAP S/4HANA Cloud system in the SAP BTP cockpit can expose consumption bundles that contain APIs and events. You can easily discover and consume the APIs exposed by the SAP S/4HANA Cloud systems in your system landscape when you develop and extend applications on SAP BTP, Cloud Foundry environment, using SAP Build. To do this, first you need to enable connectivity between your system landscape in SAP BTP cockpit and SAP Build. The integration requires performing several configuration steps starting with configuration on a global account level, and then, configuration on a subaccount level.

The following procedure outlines the steps you need to perform to consume the APIs of registered SAP S/4HANA Cloud systems within SAP Build.

1. Add and then register an SAP system of type *SAP S/4HANA Cloud* in the *System Landscape* page of SAP BTP cockpit.  
To expose information about its APIs and events and show this information on the *System Landscape* page, an SAP system of type *SAP S/4HANA Cloud* must be registered in the SAP BTP cockpit. Only when registered, the system communicates information about its APIs and other technical details across the landscape. See [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#).
2. Create a formation of type *Integration with SAP Build* and include the SAP S/4HANA Cloud systems you want to expose in SAP Build.

#### Note

In the formation type *Integration with SAP Build*, you can include only SAP systems of type *SAP S/4HANA Cloud*.

To enable connectivity between given SAP systems of type *SAP S/4HANA Cloud* from the *System Landscape* page of SAP BTP cockpit and SAP Build, you must create a formation of the corresponding type and include the SAP S/4HANA Cloud systems in it. See [Including Systems in a Formation \[page 1763\]](#).

3. Create a destination and make sure it has the corresponding system and consumption bundle properties.
  - Create a destination manually.  
You can create the destination manually via the SAP Destination service page in SAP BTP cockpit by specifying one of the following additional properties variants in it.

Additional Properties (variant 1)	Additional Properties (variant 2)	Description
x-correlation-id	x-correlation-id	The property identifies the consumption bundle and its APIs that are exposed by the SAP S/4HANA Cloud system. The destination also provides the required credentials to consume the bundle and use it for further development in SAP Build.
x-system-id	x-system-name	Properties that uniquely identify the local tenant of the registered SAP S/4HANA Cloud system.
x-system-type	x-system-base-url	

All of the required properties of a given SAP S/4HANA Cloud system are accessible in the corresponding *System Details* section on the *System Landscape* page. See [Create a Destination \[page 854\]](#) and [Configuring the Extension Application's Connectivity to SAP S/4HANA Cloud \[page 1885\]](#).

- Create a destination automatically.  
Alternatively, the destination can be created automatically. You can do this, by creating a service instance of the SAP S/4HANA Cloud Extensibility service after you register an SAP S/4HANA Cloud system. See [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment \[page 1778\]](#) and [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#).
4. Create an SAP Build subscription.

## Next Steps

Develop applications on SAP BTP, Cloud Foundry environment using SAP Build and the system landscape.

When you enable the connectivity, the SAP S/4HANA Cloud systems and their APIs are accessible in SAP Build. Next you can use the APIs to develop new or extend the existing functionality with the help of SAP Build.

## Related Information

[SAP Build Process Automation: Using SAP Systems](#)

## 5.1.6.4 Enabling Events Exchange Between SAP Cloud Systems

### Use

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Systems that are included in *Eventing Between SAP Cloud Systems* formations on the *System Landscape* page of the SAP BTP cockpit can publish and consume events. The process of publishing and consuming events is in fact an exchange of event information across the customer system landscape and is driven by the system formations on the one hand side and the SAP Event Broker on the other.

#### Note

By creating a formation of type *Eventing Between SAP Cloud Systems*, you understand that there may be event distribution charges incurred if you exceed the free quota limit when using SAP Event Broker. To learn more about usage and consumption costs, see [Usage and Consumption Costs](#).

When creating *Eventing Between SAP Cloud Systems* formations, keep in mind the following rules:

- Every system can be included in at most one *Eventing Between SAP Cloud Systems* formation.

The following procedure outlines the steps you need to perform to enable the exchange of events across the systems within the system landscape.

### Prerequisites

- You are a global account administrator, or you are a system landscape administrator. See [Working with Role Collections \[page 2087\]](#).
- You have subscribed to SAP Event Broker application. See [Subscribing to SAP Event Broker Application](#).

### Procedure

1. In the *System Landscape* page of the SAP BTP cockpit, in the *Systems* list, browse the already added systems in your customer system landscape or manually add and register any missing systems. The customer landscape features systems that are added to the list in one of the following ways:
  - *Auto-discovered*  
An auto-discovered system is a system (associated with the given global account) that has been discovered and added automatically to the list based on information of the existing system landscape. Any SAP system of the supported system types that is associated with the same customer ID, with

which your global account in SAP BTP is associated, will be added automatically in the system landscape list.

- **Subaccount/<my-subaccount>**  
A subscription in SAP BTP cockpit associated with a given subaccount. The subscription has been discovered and added automatically through the subaccount. Check the value of the *Discovery* column to see the subaccount where your system is subscribed.
- **Manually added**  
Specifies that the system has been added to the list manually by the global account administrator, using the *Add System* button and completing the wizard. The system has been associated with the global account in SAP BTP.

#### Note

If a given SAP system is missing on the *System Landscape* page, it may be associated with a different customer ID on the SAP BTP global account you are working in. In this case, you need to add the system manually, and then, register it.

See [Registering an SAP System \[page 1753\]](#).

2. Create a formation of type *Eventing Between SAP Cloud Systems* and include the relevant systems in it.
  1. Add any name that helps you identify your formation.
  2. In the *Formation Type* dropdown menu, select *Eventing Between SAP Cloud Systems*.
  3. In the *Subaccount* dropdown menu, select the subaccount where SAP Event Broker is subscribed.

#### Note

The subaccount where SAP Event Broker is subscribed can only be part of one formation in a global account.

SAP systems can only be added to one formation of type *Eventing Between SAP Cloud Systems* in a global account.

4. Select the systems that you want to include in the formation.
5. Review your selections and create the formation.

## Next Steps

When the formation is created, navigate to the SAP Event Broker application and enable the event subscriptions. See [Enabling SAP Event Subscriptions](#).

## Remove a System from the Formation

If you want to remove an SAP system from a formation of type *Eventing Between SAP Cloud Systems*, make sure that all active event subscriptions are disabled first in SAP Event Broker. You can check your subscriptions in the SAP Event Broker application on the *Subscriptions* page. See [Disabling SAP Event Subscriptions](#).

## 5.1.6.5 Enabling SAP Ariba Buying

### Use

#### 📘 Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

SAP Ariba Buying offers procurement users a unique buying experience through a guided process. SAP Ariba Buying provides buyers an easy process to shop for items. Buyers can search for, view and purchase items that are available in the connected shopping sites, or request items from suppliers. SAP Ariba Buying also helps buyers to track their purchase requests.

To set up SAP Ariba Buying with SAP S/4HANA Cloud on SAP BTP you need to have all the necessary systems included in a formation of type *Integration with SAP Ariba Buying* in the *System Landscape* page of the SAP BTP cockpit.

When creating *Integration with SAP Ariba Buying* formations, keep in mind the following rules:

- SAP S/4HANA Cloud systems can be included in at most one *Integration with SAP Ariba Buying* formation.
- Only SAP S/4HANA Cloud systems that are registered with *All Communication Scenarios* or *Integration with SAP Ariba Buying* communication scenario group can be part of a *Integration with SAP Ariba Buying* formation. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

### Prerequisites

- You are a global account administrator, or you are a system landscape administrator. See [Working with Role Collections \[page 2087\]](#).
- You have an Identity Authentication tenant. See [Identity Authentication: Initial Setup](#).
- (Optional: if you are using the *Set Up SAP Ariba Buying* booster in the SAP BTP cockpit, this step will be automatically done by the booster.) Check that you have a system of type *SAP Ariba Buying* in the *Systems* list. This system is added through a subscription in SAP BTP cockpit associated with a given subaccount. The subscription has been discovered and added automatically through the subaccount. To have a system of type *SAP Ariba Buying* in the *Systems* list, you need to:
  - You have subscribed to SAP Ariba Buying. See [Get a Subscription to SAP Ariba Buying](#).
  - You have subscribed to the services required for SAP Ariba Buying. See [Subscribe to Services Required for SAP Ariba Buying](#).
- Check that you have a system of type *SAP S/4HANA Cloud* in the *Systems* list in the *System Landscape* page. This system is auto-discovered because it is associated with your global account and has been discovered and added automatically to the list based on information of the existing system landscape.

#### 📘 Note

If you don't find your system of type *SAP S/4HANA Cloud* in the *Systems* list, add this system manually. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

- Register the SAP S/4HANA Cloud system in the *Systems* list in the *System Landscape* page. When you register an SAP S/4HANA Cloud system, use the *Integration with SAP Ariba Buying* communication scenario group when you get the registration token for the SAP S/4HANA Cloud system. This allows the automatic enablement of the communication scenarios `SAP_COM_0545` and `SAP_COM_0A00` after the corresponding system is added to the formation of type *Integration with SAP Ariba Buying*. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

## Procedure

If you have SAP Ariba Buying set up in your subaccount in SAP BTP, follow these steps to configure the integration between SAP Ariba Buying and SAP S/4HANA Cloud using a formation of type *Integration with SAP Ariba Buying*.

If you want to have the end-to-end setup automatically, including creating the formation, use the *Set Up SAP Ariba Buying* booster in the SAP BTP cockpit to guide you through the steps to configure SAP Ariba Buying in your subaccount and integrate it with SAP S/4HANA Cloud.

1. In the *Systems* list, find the systems of type *SAP Ariba Buying* and *SAP S/4HANA Cloud* that you want to include in a formation.
2. Create a formation of type *Integration with SAP Ariba Buying* and include the relevant systems in it.
  1. Add any name that helps you identify your formation.
  2. In the *Formation Type* dropdown menu, select *Integration with SAP Ariba Buying*.
  3. Select the *SAP Ariba Buying* and *SAP S/4HANA Cloud* systems that you want to include in the formation.
  4. Review your selections and create the formation.

## Next Steps

When the formation is created, you have SAP Ariba Buying set up with SAP S/4HANA Cloud on SAP BTP.

### 5.1.6.6 Enabling SAP Start

#### Use

##### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

SAP Start is a predefined central entry point for accessing SAP cloud business solutions that are integrated with it, such as SAP S/4HANA Cloud

To set up SAP Start with SAP S/4HANA Cloud on SAP BTP you need to have all the necessary systems included in a formation of type *Integration with SAP Start* in the *System Landscape* page of the SAP BTP cockpit.

When creating *Integration with SAP Start* formations, keep in mind the following rules:

- SAP Start systems can be included in at most one *Integration with SAP Start* formation.
- At most one SAP Start system can be included in an *Integration with SAP Start* formation.
- Only SAP S/4HANA Cloud systems that are registered with *All Communication Scenarios* or *Integration with SAP Start* communication scenario group can be part of a *Integration with SAP Start* formation. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

## Prerequisites

- Integration with SAP You are a global account administrator, or you are a system landscape administrator. See [Working with Role Collections \[page 2087\]](#).
- You have an Identity Authentication tenant. See [Identity Authentication: Initial Setup](#).
- (Optional: if you are using the *Set Up SAP Start* booster in the SAP BTP cockpit, this step will be automatically done by the booster.) Check that you have a system of type *SAP Start* in the *Systems* list. This system is added through a subscription in SAP BTP cockpit associated with a given subaccount. The subscription has been discovered and added automatically through the subaccount.
- Check that you have a system of type *SAP S/4HANA Cloud* in the *Systems* list in the *System Landscape* page. This system is auto-discovered because it is associated with your global account and has been discovered and added automatically to the list based on information of the existing system landscape.

### Note

If you don't find your system of type *SAP S/4HANA Cloud* in the *Systems* list, add this system manually. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

- Register the SAP S/4HANA Cloud system in the *Systems* list in the *System Landscape* page. When you register an SAP S/4HANA Cloud system, use the *Integration with SAP Start* communication scenario group when you get the registration token for the SAP S/4HANA Cloud system. This allows the automatic enablement of the communication scenario `SAP_COM_0647` after the corresponding system is added to the formation of type *Integration with SAP Start*. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

## Procedure

If you have SAP Start set up in your subaccount in SAP BTP, follow these steps to configure the integration between SAP Start and SAP S/4HANA Cloud using a formation of type *Integration with SAP Start*.

If you want to have the end-to-end setup automatically, including creating the formation, use the *Set Up SAP Start* booster in the SAP BTP cockpit to guide you through the steps to configure SAP Start in your subaccount and integrate it with SAP S/4HANA Cloud.

1. In the *Systems* list, find the systems of type *SAP Start* and *SAP S/4HANA Cloud* that you want to include in a formation.

2. Create a formation of type *Integration with SAP Start* and include the relevant systems in it.
  1. Add any name that helps you identify your formation.
  2. In the *Formation Type* dropdown menu, select *Integration with SAP Start*.
  3. Select the *SAP Start* and *SAP S/4HANA Cloud* systems that you want to include in the formation.
  4. Review your selections and create the formation.

## Next Steps

When the formation is created, you have SAP Start set up with SAP S/4HANA Cloud on SAP BTP. Then, set up SAP Task Center. See [Post-Setup Tasks](#).

### 5.1.6.7 Enabling Data Ingestion for Industry Cloud Solutions

SAP's industry cloud provides specialized industry-focused solutions to help you optimize, extend, and transform your core business processes. Developed by SAP and SAP partners and based on SAP Business Technology Platform (SAP BTP), industry cloud solutions integrate with SAP S/4HANA Cloud and SAP Business Network. They help you take advantage of the latest industry-relevant innovations and extend existing capabilities in an efficient way. For a list of all industry cloud solutions published by SAP, see [SAP Store](#).

Data ingestion for industry cloud solutions allows supported industry cloud solutions to consume data from a shared data foundation instead of integrating with the source systems individually. This helps to simplify solution implementation, increase operational visibility, and improve data quality. For a list of all industry cloud solutions published by SAP that support data ingestion, see [Data Integration Overview](#).

To set up on SAP BTP systems that support data ingestion and are part of the industry cloud solutions published by SAP, you need to include them in a formation of type *Data Ingestion for Industry Cloud Solutions*. When you create a new formation of type *Data Ingestion for Industry Cloud Solutions*, a system of type *Data Ingestion for Industry Cloud Solutions* is automatically added to the *Systems* list and included in this formation.

When creating *Data Ingestion for Industry Cloud Solutions* formations, keep in mind the following rules:

- Only systems that are part of the industry cloud solutions, support data ingestion, and are provisioned from SAP for Me can be included in formations of type *Data Ingestion for Industry Cloud Solutions*.
- System that is part of the industry cloud solutions published by SAP are included in at most one *Data Ingestion for Industry Cloud Solutions* formation when creating this formation.
- System of type *Data Ingestion for Industry Cloud Solutions* is automatically registered and included in the *Data Ingestion for Industry Cloud Solutions* formation.
- System of type *Data Ingestion for Industry Cloud Solutions* cannot be excluded from the *Data Ingestion for Industry Cloud Solutions* formation. Once you delete this formation, the *Data Ingestion for Industry Cloud Solutions* system is automatically deleted.

## Prerequisites

You are a global account administrator, or you are a system landscape administrator. See [Working with Role Collections \[page 2087\]](#).

## Procedure

1. In the *System Landscape* page of the SAP BTP cockpit, in the *Systems* list, browse the already added systems that are part of the industry cloud solutions published by SAP in your customer system landscape.
2. Create a formation of type *Data Ingestion for Industry Cloud Solutions* and include the relevant systems in it.
  1. Add any name that helps you identify your formation.
  2. In the *Formation Type* dropdown menu, select *Data Ingestion for Industry Cloud Solutions*.
  3. Select the systems that you want to include in the formation.
  4. Review your selections and create the formation.

## Related Information

[Data Integration Overview](#)

## 5.1.7 Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment

Extend SAP S/4HANA Cloud with extension applications running on the cloud platform using automated integration configuration.

## Overview

### Note

The SAP S/4HANA Cloud Extensibility service is available for the EU-only access regions for feature set B global accounts. See [Regions](#).

EU Access is not available for feature set A global accounts for the SAP S/4HANA Cloud Extensibility service.

### Note

This documentation refers to SAP S/4HANA Cloud Public Edition. See [Introduction to the Universe of SAP S/4HANA Cloud Public Edition](#).

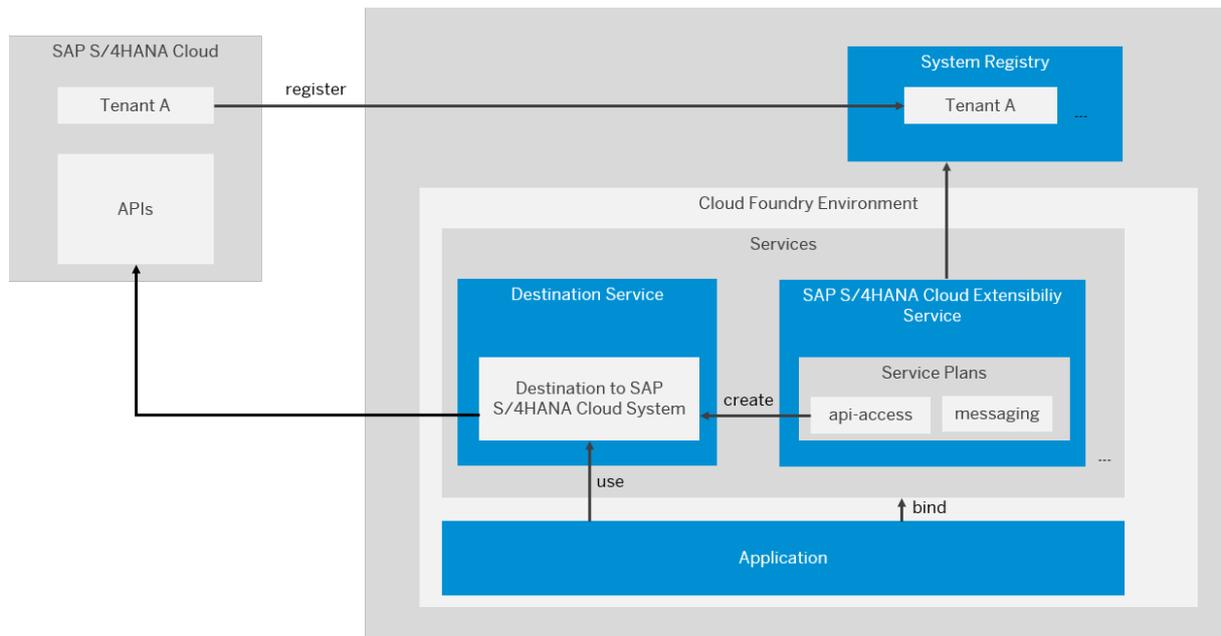

The extension capabilities of SAP BTP offer a standard way for extending SAP S/4HANA Cloud and developing event-driven extensions and applications.

You can extend SAP S/4HANA Cloud without disrupting its performance and core processes. When building extension applications, you can also benefit from the automation of the integration between the cloud platform and SAP S/4HANA Cloud.

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

The following graphic provides a high-level overview of the integration between the cloud platform and SAP S/4HANA Cloud:

## Process Flow

To integrate the cloud platform and SAP S/4HANA Cloud so that you can build extension applications, you need to:

**Process Step**

**Related Documentation**

1. Connect the SAP S/4HANA Cloud system you want to extend with the corresponding global account in SAP BTP.

[Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#)

During the pairing process you create an registration token which is then used by the SAP S/4HANA Cloud system tenant administrator to configure the integration on the SAP S/4HANA Cloud system side.

**Note**

You cannot migrate the registered SAP S/4HANA Cloud systems between global accounts.

If you want to start using another global account, you will have to register your SAP S/4HANA Cloud systems again.

2. Make the SAP S/4HANA Cloud system accessible in the SAP BTP subaccounts in which you want to build your extension applications.

[Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#)

To do so, you configure the entitlements and assign the corresponding quota and service plans to the subaccounts where the extension applications will reside for the system you registered in the previous step.

## Process Step

## Related Documentation

3. Configure the communication flow.

You have the following options:

- Consume the SAP S/4HANA Cloud APIs (inbound connection) or consume APIs exposed by the extension application from SAP S/4 HANA Cloud (outbound connection). To do so, you create a service instance of the *SAP S/4HANA Cloud Extensibility* service using the *api-access* service plan.

For communication arrangements with inbound connections, an HTTP destination on a subaccount level is automatically generated in this subaccount during the service instance creation. It contains all instance binding properties which are sufficient to establish connection to the SAP S/4HANA Cloud system. When creating the service instance, you configure the communication arrangement and the authentication type for the connection.

The following authentication scenarios for SAP S/4HANA Cloud are supported:

- Basic Authentication (inbound and outbound connections)
- OAuth 2.0 SAML Bearer Assertion (inbound connections)
- OAuth 2.0 Client Credentials (outbound Connections)
- No Authentication (outbound connections)

Both predefined and custom communication scenarios are supported.

- Enable the consumption of SAP S/4HANA Cloud events.  
If you want to create event-based extensions for SAP S/4HANA Cloud using the SAP Event Mesh, you have to create a service instance of the *SAP S/4HANA Cloud Extensibility* service using the *messaging* service plan.
- A combination of both

- [Creating a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#)
- [Enable the Consumption of SAP S/4HANA Cloud Events \[page 1809\]](#)

## Related Information

[Cloud Management Tools - Feature Set Overview](#)

### 5.1.7.1 Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP

To connect an SAP S/4HANA Cloud Public Edition system with a global account in SAP BTP, you need to register the system in the corresponding global account.

#### Prerequisites

- See [Registering an SAP System \[page 1753\]](#).
- You are an administrator of the global account where you want to register your SAP S/4HANA Cloud system.
- To configure the integration on the SAP S/4HANA Cloud system side, you need to be an administrator of the SAP S/4HANA Cloud tenant.

#### Context

##### ⓘ Note

This documentation refers to SAP S/4HANA Cloud Public Edition. See [Introduction to the Universe of SAP S/4HANA Cloud Public Edition](#).

The registration process is based on a registration token that is used for the pairing of the SAP S/4HANA Cloud system and the corresponding global account. You create the token in the global account, and then the tenant administrator of the respective SAP S/4HANA Cloud system uses the token to start the automated registration process on the SAP S/4HANA Cloud system side.

##### ⓘ Note

When registering SAP S/4HANA Cloud systems, you can have up to 1000 tokens per global account ready to be used. Tokens that are already used to register an SAP S/4HANA Cloud system are not included in this number.

This means that you cannot have more than 1000 systems in the [Systems](#) list of type SAP S/4HANA Cloud with an empty status and generated token that is not used yet.

##### ⓘ Note

You cannot migrate the registered SAP S/4HANA Cloud systems between global accounts.

If you want to start using another global account, you will have to register your SAP S/4HANA Cloud systems again.

The registration process has the following states displayed in the cockpit:

- No status displayed in the *Status* column - the registration token for an SAP system has been created but the registration on the respective SAP solution system side has not been performed or completed.
- *Registered* - the registration token has been used and the automated registration process has been successfully completed. The system can be assigned to a formation on the *Formations* page in the cockpit.
- *Error while Registering* - the registration has failed. Remove the system and then add it to the *Systems* list and try to register it again
- *Deregistering* - a deregistration process has started in the SAP BTP cockpit. As a result, the connection between the SAP solution system and the global account in SAP BTP is removed. The system remains in the list and you can register it again later on.  
Once a system is registered, you can deregister it only after removing it from all entitlement configurations and formations it takes part in.

#### ⓘ Note

You will not be able to deregister a system if its status is one of the following:

- *Error while Registering*
  - *Deregistering*
- *Error while Deregistering* - the deregistration has failed. Try to deregister the system again. If the problem persists, you have to report a case in the BC-NEO-EXT-S4C component.
  - *Removing* - a system removal process has started in the SAP BTP cockpit. As a result, the link between the SAP solution and SAP BTP is destroyed and the system is removed from the list. To register the system again, first you must add it to the list anew, and then initiate the registration procedure.  
Once a system is registered, you can only remove it if you first deregister it.

#### ⓘ Note

You will not be able to remove a system if its status is one of the following:

- *Registered*  
You first need to deregister the system.
  - *Deregistering*
  - *Error while Deregistering*  
Try to deregister the system again.
- *Error while Removing* - the system removal has failed. Try to deregister the system again. If the problem persists, you have to report a case in the BC-NEO-EXT-S4C component.

#### ⓘ Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#) ▾.
2. On the [Systems](#) page, choose [Add System](#).

- a. Enter a name for the system you want to register.

### Note

Use only printable ASCII characters.

### Tip

We recommend that you indicate the type of the system when specifying the system name. For example, **<mysystem>-S/4HANA-cloud**. This helps you identify the system type when assigning systems to a formation.

- b. In the [Type](#) dropdown list, select [SAP S/4HANA Cloud](#).
- c. Choose [Add](#).
- d. In the [Communication Scenario Groups](#) dropdown menu, select one of the following options:
  - [All Communication Scenarios](#): to create any of the communication scenarios in SAP S/4HANA Cloud.
  - [Eventing Between SAP Cloud Systems](#): to allow the automatic enablement of the `SAP_COM_0892` communication scenario in SAP S/4HANA Cloud.
  - [Integration with SAP Ariba Buying](#): to allow the automatic enablement of the `SAP_COM_0545` and `SAP_COM_0A00` communication scenarios in SAP S/4HANA Cloud.
  - [Integration with SAP Start](#): to allow the automatic enablement of the `SAP_COM_0647` communication scenario in SAP S/4HANA Cloud.
- e. Choose [Get Token](#).

The system generates the registration token.

- f. Copy the registration token and send it to the tenant administrator for the respective SAP S/4HANA Cloud system. You need it for configuring the integration on the extended SAP S/4HANA Cloud system side.

You can also get the registration token later, once the system appears in the list on the [Systems](#) page.

The registration token is valid for 7 days after it has been generated. When a token is not used within its validity period, it is no longer valid and cannot be used for registering an SAP S/4HANA Cloud system. If the validity of the token expires before you use it to configure the integration on the SAP S/4HANA Cloud system side and complete the registration, you need to get a new token. You can then copy it and use it to complete the registration.

### Note

A registration token can be used only once, for registering a single SAP S/4HANA Cloud system.

- g. Close the wizard.

The SAP S/4HANA Cloud system appears in the list of systems on the [Systems](#) page. Its [Status](#) field is empty because the registration process is not yet completed.

3. Start the automated registration process on the SAP S/4HANA Cloud system side. To do so, proceed as described in as described in [Trigger the Registration in the SAP S/4HANA Cloud Tenant \[page 1785\]](#).

### Note

You can register a system with the same name only once per global account. Once you have started a registration process for a system with a specified name you can no longer register a system with the same name and connect it with the same global account, unless you delete the corresponding extension in the *Maintain Extensions on SAP BTP* in the SAP S/4HANA Cloud tenant. If the registration process fails, you need to delete the failed extension from the SAP S/4HANA Cloud tenant and create a new integration token in the cockpit for the corresponding system to be able to start the automated registration process again.

4. Check the status of the registration process. To do so, in the cockpit navigate to your global account, and on the *Systems* page, check if the status of the SAP S/4HANA Cloud system has changed to *Registered*.  
If you are already on the *Systems* page, refresh the page to check if the status has changed.

## Next Steps

[Trigger the Registration in the SAP S/4HANA Cloud Tenant \[page 1785\]](#)

## Related Information

[Registering an SAP System \[page 1753\]](#)

[Deregistering or Removing a System \[page 1757\]](#)

### 5.1.7.1.1 Trigger the Registration in the SAP S/4HANA Cloud Tenant

Use this procedure to trigger the registration process for an SAP S/4HANA Cloud system that you want to pair with your global account in SAP BTP.

## Prerequisites

You are an SAP S/4HANA Cloud tenant administrator.

## Procedure

1. Log on to the SAP S/4HANA Cloud tenant, go to *Home, Communication Management* tab and then choose the *Maintain Extensions on SAP BTP* tile.

2. In the *Maintain Extensions on SAP BTP* screen, in the *Extensions* section, choose *New*.
3. In the *Integration Token* field, enter the content of the registration token from the SAP BTP cockpit.
4. Choose *Save*. A new entry in the table appears with status *Enabling*.
5. After the integration has finished successfully, you can refresh the table.

The status of the integration should have changed to *Enabled*.

## 5.1.7.2 Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service

Configure the required entitlements to make the APIs of the registered SAP S/4HANA Cloud system accessible in your subaccount in which your extension applications will reside.

### Prerequisites

- You are an administrator of the global account in SAP BTP.
- The subaccount is in the SAP BTP, Cloud Foundry environment with enabled Cloud Foundry, or Kyma, or both capabilities.
- You have registered an SAP S/4HANA Cloud system. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

### Context

An entitlement is your right to provision and consume a resource. In other words, the entitlement is the respective service plan, *api-access* or *messaging*, that you're entitled to use. Depending on feature set you are using, you need to follow different steps to configure the entitlements. See [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

### Procedure

1. In the SAP BTP cockpit, navigate to your global account.
2. Depending on the feature set you are using, you need to follow different steps to configure the entitlements.
  - For feature set A, follow these steps:
    1. In the navigation area, choose **Entitlements** **Subaccount Assignments**.
    2. Select your subaccount from the drop down menu, choose *Go*, and then choose *Configure Entitlements*.

#### → Tip

If your global account contains more than 20 subaccounts, choose  to open up the value help dialog. There you can filter subaccounts by role, environment and region to make your selection easier and faster. You can only select a maximum of 50 subaccounts at once.

- If you are using feature set B, you have to:
  1. In the navigation area, choose [Entitlements](#) > [Entity Assignments](#) .
  2. On the [Entity Assignments](#) screen, select your subaccount in the [Select Entities](#) field.
  3. Choose [Go](#), and then choose [Configure Entitlements](#).
- 3. Choose [Add Service Plans](#), and then select the [SAP S/4HANA Cloud Extensibility](#) service.

#### Note

To have the [SAP S/4HANA Cloud Extensibility](#) service in the list, you need to have registered at least one SAP S/4HANA Cloud system.

4. In the [Available Service Plans](#) area, select the system you have registered and the required service plans, and then choose [Add Service Plan](#).

#### Note

For more information about the available service plans for SAP S/4HANA Cloud Extensibility service, see [Supported Service Plans for SAP S/4HANA Cloud \[page 1838\]](#).

## Related Information

[Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)

### 5.1.7.3 Create a Service Instance to Consume the SAP S/4HANA Cloud APIs

To enable the integration of your extension applications with the SAP S/4HANA Cloud system you have registered in the SAP BTP global account, and to configure the communication flow, you create a service instance of the SAP S/4HANA Cloud Extensibility service.

## Prerequisites

For a communication flow with SAML Bearer Assertion authentication, you must:

- Configure Single-Sign On (SSO). See [Single Sign-On Configuration](#).
- Protect your application. See [Configure Application Authentication](#).

## Context

In both Cloud Foundry and Kyma environments, you consume services by creating a service instance. Service instances are created using a specific service plan.

To allow applications running on SAP BTP to consume SAP S/4HANA Cloud APIs, you need to create a service instance of the SAP S/4HANA Cloud Extensibility service using the *api-access* service plan.

### Note

These service plans have been deprecated:

- [sap\\_com\\_0109](#)
- [sap\\_com\\_0009](#)
- [sap\\_com\\_0008](#)

However, you can still enable these communication scenarios using the *api-access* service plan:

- *Sales Order Integration (SAP\_COM\_0109)*: allows you to integrate your extension applications with sales order processing in SAP S/4HANA Cloud. For more information, see [https://api.sap.com/api/API\\_SALES\\_ORDER\\_SRV/overview](https://api.sap.com/api/API_SALES_ORDER_SRV/overview).
- *Product Integration (SAP\_COM\_0009)*: enables you to replicate product master data from client system to SAP S/4HANA system. For more information, see <https://api.sap.com/api/PRODUCTMDMBULKREPLICATEREQUEST/overview>.
- *Business Partner, Customer and Supplier Integration (SAP\_COM\_0008)*: allows you to consume the Business Partner API which enables you to create, read, update, and delete master data related to Business Partners, Suppliers, and Customers in an SAP S/4HANA system. For more information, see [https://api.sap.com/api/API\\_BUSINESS\\_PARTNER/overview](https://api.sap.com/api/API_BUSINESS_PARTNER/overview).

For a sample JSON for these communication scenarios, see [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).

The *api-access* service plan define the access to the corresponding SAP S/4HANA Cloud APIs. It supports both predefined and custom communication scenarios for consuming the SAP S/4HANA Cloud APIs and integrating your extension applications. See:

- [Supported Service Plans for SAP S/4HANA Cloud \[page 1838\]](#)
- [Custom Communication Scenarios](#)

You create the service instance in your subaccount with the respective environment enabled. When creating the service instance, you configure the connectivity by specifying the required configurations in a JSON format. The following authentication scenarios are supported for the communication flow between the extension application and SAP S/4HANA Cloud:

- Basic Authentication (inbound and outbound connections)
- OAuth 2.0 Client Credentials (outbound connections)
- OAuth 2.0 SAML Bearer Assertion (inbound connections)  
To communicate with SAP S/4HANA Cloud the extension application can use Principal Propagation which is done using OAuth 2.0 SAML Bearer Assertion flows. Principal Propagation means you forward the identity of the logged-in cloud users when accessing or updating data in the SAP S/4HANA Cloud system. This is useful in scenarios where you need to have restricted data access based on the logged-in user from your extension. Or, you want to ensure only users with the right permissions are able to update the system via extensions deployed in SAP BTP.

To use this authentication scenario, you first need to configure single-sign on (SSO) with the Identity Authentication service and protect your application. See [Single Sign-On Configuration](#).

- Client Certificate Authentication (inbound and outbound connections)
- OAuth2mTLS (outbound connections)

Depending on whether you are using Cloud Foundry or Kyma environment, you have to follow different steps to create an SAP S/4HANA Cloud Extensibility service instance:

- [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Cloud Foundry Environment \[page 1789\]](#)
- [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1792\]](#)

## Related Information

[Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#)

### 5.1.7.3.1 Create an SAP S/4HANA Cloud Extensibility Service Instance in the Cloud Foundry Environment

#### Prerequisites

- Before creating an SAP S/4HANA Cloud Extensibility service instance in the Cloud Foundry environment, see [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#).
- Have enabled Cloud Foundry environment for your subaccount. See [Enable Environment or Create Environment Instance \[page 1986\]](#).
- Have registered an SAP S/4HANA Cloud system. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).
- Have configured the entitlements to the SAP S/4HANA Cloud Extensibility service. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

#### Context

To consume the SAP S/4HANA Cloud APIs (inbound connection) or consume APIs exposed by the extension application from SAP S/4HANA Cloud (outbound connection), you create an SAP S/4HANA Cloud Extensibility service instance. When creating the service instance, you configure the communication arrangement and the authentication type for the connection.

For communication arrangements with inbound connections, a destination on a subaccount level with the same name as the service instance name is automatically created in this subaccount. It contains all instance binding properties which are sufficient to establish connection to the SAP S/4HANA Cloud system.

### Note

Make sure that you don't already have a destination with the same name as the service instance. If you do, you will not be able to create the service instance.

### Note

Multitenant applications, that this subaccount is subscribed to, can access the destination and connect to the SAP S/4HANA Cloud system without binding to the created service instance.

See [Developing Multitenant Business Applications in the Cloud Foundry Environment](#).

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount in which you want to create a service instance.
2. In the navigation area, choose **Services** > **Service Marketplace** .
- All services available to you appear.
3. To enable the integration with an SAP S/4HANA Cloud system that you have registered in SAP BTP global account, choose **SAP S/4HANA Cloud Extensibility**.
4. In the **SAP S/4HANA Cloud Extensibility** page, choose **Create**.
5. In the **New Instance or Subscription** wizard:
  - a. In the **Service** dropdown list, ensure you have selected the **SAP S/4HANA Cloud Extensibility** service.
  - b. In the **Plan** dropdown list, select the **api-access** service plan.
  - c. In the **Runtime Environment** dropdown list, select **Cloud Foundry**.
  - d. In the **Space** dropdown list, select your space. If you haven't create a space yet, you can do it at this point.
  - e. In the **System Name** dropdown list, select the SAP S/4HANA Cloud system you have registered.
  - f. In the **Instance Name** field, enter a name for your instance. Choose **Next**.
  - g. To define the communication arrangement and the authentication type for the API access, specify a JSON file or specify parameters in the JSON format. If you decide to define the communication arrangement and the authentication type later on, you have to delete this service instance and create it again. Choose **Next**.

For more information about the structure of the JSON file, see [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).
  - h. Choose **Create**.

After you have created the service instance:

- The newly created instance appears in the list of instances in the **Instance and Subscriptions** page.
- An HTTP destination on a subaccount level with the same name as the service instance name is automatically generated in this subaccount.

Alternatively, you can use the Cloud Foundry Command Line Interface (cf CLI) to create the service instance using the technical name of the SAP S/4HANA Cloud Extensibility service which is **s4-hana-cloud**.

For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface](#).

#### Note

You can use the cf CLI to troubleshoot if the creation of the service instance fails. To do that, use this command in the cf CLI:

```
cf service <service_instance_name>
```

## Next Steps

After you have created the service instance:

- The newly created instance appears in the list of instances in the *Instance and Subscriptions* page.
- An HTTP destination on a subaccount level with the same name as the service instance name is automatically generated in this subaccount.

Alternatively, you can use the Cloud Foundry Command Line Interface (cf CLI) to create the service instance using the technical name of the SAP S/4HANA Cloud Extensibility service which is **s4-hana-cloud**.

For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface](#).

#### Note

You can use the cf CLI to troubleshoot if the creation of the service instance fails. To do that, use this command in the cf CLI:

```
cf service <service_instance_name>
```

After creating the *SAP S/4HANA Cloud Extensibility* service instance, you have the following options for configuring the connectivity for your extension application:

- Bind the instance to an application, and it will be assigned an access URL and credentials to the corresponding API. For more information about binding applications to service instances, see [Binding Service Instances to Applications](#) in the SAP BTP documentation.
- Consume the automatically generated destination.  
To consume the destination, you use the destination service. You can either consume the Destination service directly, or configure the application router to consume it.

#### Note

The name of the destination is the same as the name of the service instance you have created.

- For more information about consuming the destination service using the application router, see [Application Routes and Destinations](#).
- For more information about consuming the destination service directly, see [Consuming the Destination Service \(Cloud Foundry Environment\)](#).

## 5.1.7.3.2 Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment

### Prerequisites

- Before creating an SAP S/4HANA Cloud Extensibility service instance in the Kyma environment, see [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#).
- Have the Kyma environment enabled for the subaccount you are using. See [Create the Kyma Instance \[page 2749\]](#).
- Configure the roles in the Kyma environment. See [Assign Roles in the Kyma Environment \[page 2766\]](#).
- The SAP BTP Operator module is enabled. See [Add and Delete a Kyma Module \[page 2764\]](#)
- Have the entitlements of the SAP S/4HANA Cloud Extensibility service configured. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

### Context

To consume the SAP S/4HANA Cloud APIs (inbound connection) or consume APIs exposed by the extension application from SAP S/4HANA Cloud (outbound connection), you create an SAP S/4HANA Cloud Extensibility service instance. When creating the service instance, you configure the communication arrangement and the authentication type for the connection.

For communication arrangements with inbound connections, a destination on a subaccount level with the same name as the service instance name is automatically created in this subaccount. It contains all instance binding properties which are sufficient to establish connection to the SAP S/4HANA Cloud system.

#### Note

Make sure that you don't already have a destination with the same name as the service instance. If you do, you will not be able to create the service instance.

### Procedure

1. Navigate to the subaccount for which you want to create an SAP S/4HANA Cloud Extensibility service instance.
2. On the subaccount [Overview](#) page, in the [Kyma Environment](#) section, open the Kyma dashboard.
3. Choose [Namespaces](#) from the left-hand side navigation and open the namespace in which you want to create a service instance.
4. Choose [▶ Service Management ▶ Service Instances ▶](#) from the left-hand side navigation.
5. In the [Service Instances](#) page, choose [Create Service Instance](#) in the upper right-hand corner. A new dialog opens.

6. Choose the *Simple* tab and fill in the following fields:
  - Give a meaningful name of the new SAP S/4HANA Cloud Extensibility service instance.
  - In the *Offering Name* field, enter **s4-hana-cloud**, which is the technical name of the SAP S/4HANA Cloud Extensibility service.
  - In the *Plan Name* field, enter **api-access**.
7. Choose the *YAML* tab.

To define the communication arrangement and the authentication type for the API access, specify in *parameters*: in the *spec*: section, the parameters listed in this YAML file: [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).

For specific examples, see [Communication Arrangement YAML File - Examples \[page 1805\]](#).
8. Choose *Create*.

## Next Steps

After creating the *SAP S/4HANA Cloud Extensibility* service instance, you must bind the instance to an application, and it will be assigned an access URL and credentials to the corresponding API. See [Using SAP BTP Services in the Kyma Environment \[page 1732\]](#).

### 5.1.7.3.3 Communication Arrangement JSON/YAML File - Properties

Learn how to construct a JSON or YAML file for the SAP S/4HANA Cloud APIs, including parameters such as system name, communication arrangement, authentication type, communication system, outbound services, and additional properties. It also provides guidelines and rules for each property.

## Context

To construct the JSON file for the Cloud Foundry environment or the YAML file for the Kyma environment for the SAP S/4HANA Cloud APIs you want to use, you can use these parameters. To access the specific documentation of these APIs, see [SAP S/4HANA Cloud APIs at SAP API Business Hub](#).

The information that you need to construct the JSON or the YAML file is available in the Display Communication Scenario application in the corresponding SAP S/4HANA Cloud system. It contains information such as scenario details and properties, and supported inbound and outbound authentication methods. See [Display Communication Scenarios](#).

For specific sample JSON files, see [Communication Arrangement JSON File - Examples \[page 1801\]](#).

For specific sample YAML files, see [Communication Arrangement YAML File - Examples \[page 1805\]](#).

## Properties

Parameter	Description
systemName	<p>The name of the system you have registered in SAP BTP global account.</p> <div><p><b>Note</b></p><p>The system must be in status <i>Registered</i>.</p></div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>Required: Yes</li></ul>
communicationArrangement	<p>Represents a communication arrangement in SAP S/4HANA Cloud.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>Required: Yes</li></ul>
communicationArrangementName	<p>A <code>communicationArrangement</code> property.</p> <p>Meaningful name of the communication arrangement that will be created for the SAP S/4HANA Cloud tenant.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>Allowed characters: [a-zA-Z0-9_-]</li><li>Max length: 80</li><li>Required: Yes</li></ul>
scenarioId	<p>A <code>communicationArrangement</code> property.</p> <p>The ID of the SAP S/4HANA Cloud communication scenario.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>Required: Yes</li><li>Allowed characters: [A-Z0-9_]</li><li>Pattern: <b>SAP_COM_&lt;number&gt;</b></li></ul>

Parameter	Description
inboundAuthentication	<p>A communicationArrangement property.</p> <p>The authentication type for the SAP S/4HANA Cloud API access.</p>

**Note**

Currently, the following authentication methods are supported:

- Basic Authentication
- SAML Bearer Assertion Authentication

**Note**

The generated X.509 certificate that is used to configure the trust between the cloud platform and SAP S/4HANA Cloud system expires two years after you have created the instance.

- Client Certificate Authentication

**Rules/Guidelines**

- Required: Yes, if there is no outboundAuthentication defined
- Allowed values: OAuth2SAMLBearerAssertion, BasicAuthentication, and ClientCertificateAuthentication

Parameter	Description
outboundAuthentication	<p>A <code>communicationArrangement</code> property.</p> <p>The type of the authentication used by SAP S/4HANA Cloud to call SAP BTP APIs.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>Currently, the following authentication methods are supported:</p> <ul style="list-style-type: none"> <li>• Basic Authentication</li> <li>• OAuth 2.0 Client Credentials</li> <li>• No Authentication</li> <li>• OAuth2mTLS</li> <li>• Client Certificate Authentication</li> </ul> </div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: Yes, if there is no <code>inboundAuthentication</code> defined</li> <li>• Allowed values: <code>BasicAuthentication</code>, <code>OAuth2ClientCredentials</code>, <code>NoAuthentication</code>, <code>OAuth2mTLS</code>, and <code>ClientCertificateAuthentication</code></li> </ul>
communicationSystem	<p>A <code>communicationArrangement</code> property.</p> <p>This represents the <i>Communication System</i> view of the communication arrangement.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> </ul>
communicationSystemHostname	<p>A <code>communicationSystem</code> property.</p> <p>The URL of the remote system hosting the APIs that will be consumed in case the scenario contains outbound communication. For SAP S/4HANA Cloud extensions on SAP BTP, this is the URL of the extension application running on SAP BTP.</p> <p>This is equivalent to <a href="#">▶ Technical Data ▶ General ▶ Host Name ▶</a> in the <i>Communication System</i> view.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: Yes, if <code>communicationArrangement</code> is specified.</li> </ul>

Parameter	Description
port	<p>A <code>communicationSystem</code> property.</p> <p>The port for outbound calls to the remote system hosting the APIs that will be consumed in case the scenario contains outbound communication.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No If not specified, the default <code>443</code> port is used for the communication.</li> <li>Type: String</li> <li>Allowed values: positive integer [<code>1-65535</code>]</li> </ul>
oAuthAuthEndpoint	<p>A <code>communicationSystem</code> property.</p> <p>The OAuth authorization endpoint of the remote OAuth service in case the communication scenario contains outbound communication. This is equivalent to <a href="#">Technical Data &gt; OAuth 2.0 Settings &gt; Auth. Endpoint</a> in the <i>Communication System</i> view.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
oAuthTokenEndpoint	<p>A <code>communicationSystem</code> property.</p> <p>The OAuth token endpoint. This is equivalent to <a href="#">Technical Data &gt; OAuth 2.0 Settings &gt; Token Endpoint</a> in the <i>Communication System</i> view.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
outboundCommunicationUser	<p>A <code>communicationSystem</code> property.</p> <p>The communication user used for outbound authentication. This is equivalent to an entry under the <i>Users for Outbound Communication</i> table in the <i>Communication System</i> view in the SAP S/4HANA Cloud system.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px; margin: 10px 0;"> <p><b>Note</b></p> <p>Currently, only users with authentication method <i>User Name and Password</i> are supported.</p> </div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>

Parameter	Description
username	<p>An <code>outboundCommunicationUser</code> property.</p> <p>The username of the communication user.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if the <code>outboundCommunicationUser</code> property is specified.</li> </ul>
password	<p>An <code>outboundCommunicationUser</code> property.</p> <p>The password of the communication user.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if the <code>outboundCommunicationUser</code> property is specified.</li> </ul>
outboundServices	<p>A <code>communicationArrangement</code> property.</p> <p>A list of outbound service objects.</p> <p>This is equivalent to the <i>Outbound Services</i> section in the SAP S/4HANA Cloud <i>Communication Arrangement</i> view.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
outboundService	<p>An <code>outboundServices</code> object.</p> <p>A specific outbound service object.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
id	<p>An <code>outboundService</code> property.</p> <p>The id of the outbound service. It must match the <i>Outbound Service ID</i> displayed in the SAP S/4HANA Cloud system.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if the <code>outboundServices</code> property is specified.</li> </ul> <div data-bbox="850 1711 1394 1872" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>When you specify the <code>id</code> property of the outbound service, you can skip the <code>name</code> property.</p> </div>

Parameter	Description
name	<p>An <code>outboundService</code> property.</p> <p>The name of the outbound service. It must be an exact match of the name displayed in the SAP S/4HANA Cloud system.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if the <code>outboundServices</code> property is specified, and the <code>id</code> property is not specified.</li> </ul> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>If the <code>id</code> property is specified, the <code>name</code> property is not required.</p> </div>
urlPath	<p>An <code>outboundService</code> property.</p> <p>This is equivalent to the <code>Path</code> field in the SAP S/4HANA Cloud system. It is used to configure the API path in the outbound service URL.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
isServiceActive	<p>An <code>outboundService</code> property.</p> <p>This is equivalent to the <code>Service Status</code> checkbox in the SAP S/4HANA Cloud system. In some communication scenarios, some outbound services must be disabled. You can achieve that by setting this parameter to <code>false</code>.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> <li>Default value: <code>true</code></li> </ul>
attributes	<p>An <code>outboundService</code> parameter.</p> <p>A list of attribute objects.</p> <p>This is equivalent to the <code>Additional Properties</code> section of the outbound service.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>

Parameter	Description
attribute	<p>An <code>attributes</code> object.</p> <p>A specific attribute object. Represents an additional property in the outbound service.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
name	<p>An <code>attribute</code> property.</p> <p>The name of the additional property of the outbound service. It is equivalent to the <i>Technical Property Name</i> column in the <i>Additional Properties</i> section in the Display Communication Scenarios app in the SAP S/4HANA Cloud system. See <a href="#">Display Communication Scenarios</a>.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if an <code>attribute</code> object is specified.</li> </ul>
value	<p>An <code>attribute</code> property.</p> <p>Enter value for the additional property of the outbound service.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if an <code>attribute</code> object is specified.</li> </ul>
attributes	<p>A <code>communicationArrangement</code> parameter.</p> <p>A list of attribute objects.</p> <p>This is equivalent to the <i>Additional Properties</i> section of the communication arrangement in SAP S/4HANA Cloud.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
attribute	<p>An <code>attributes</code> object.</p> <p>A specific attribute object. Represents an additional property in the communication arrangement.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>

Parameter	Description
name	<p>An attribute property.</p> <p>It is equivalent to the <i>Technical Property Name</i> section in the <i>Additional Properties</i> table in the Display Communication Scenarios application in the SAP S/4HANA Cloud system. See <a href="#">Display Communication Scenarios</a>.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if an attribute object is specified for communicationArrangement.</li> </ul>
value	<p>An attribute property.</p> <p>Enter a value for the additional property of the communication arrangement.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: Yes, if an attribute object is specified for communicationArrangement.</li> </ul>

### 5.1.7.3.4 Communication Arrangement JSON File - Examples

The examples in this section will help you to create the service JSON descriptor used for defining the communication arrangement and the authentication type for the SAP S/4HANA Cloud API access.

The information that you need to create the JSON file is available in the *Display Communication Scenario* app in the corresponding SAP S/4HANA Cloud system. It contains information such as scenario details and properties, and supported inbound and outbound authentication methods. See [Display Communication Scenarios](#).

#### Note

The purpose of these examples is just to give you an idea how you construct your JSON file. For more details of the properties of these JSON files, see [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).

## Example of Enabling Communication Scenario of Type Basic Authentication

This is an example of a JSON file for a communication arrangement with an inbound connection with *Basic Authentication* and an outbound connection with *Basic Authentication*.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "communicationArrangementName": "INBOUND_COMMUNICATION_ARRANGEMENT",
    "scenarioId": "SAP_COM_0008",
    "inboundAuthentication": "BasicAuthentication",
    "outboundAuthentication": "BasicAuthentication",
    "outboundServices": [
      {
        "id": "DEBMAS_IDOC",
        "isServiceActive": false
      },
      {
        "id": "CREMAS_IDOC",
        "isServiceActive": false
      },
      {
        "id": "ADRMAS_IDOC",
        "isServiceActive": false
      },
      {
        "id": "ADR3MAS_IDOC",
        "isServiceActive": false
      },
      {
        "id": "ADR2MAS_IDOC",
        "isServiceActive": false
      },
      {
        "id": "CO_MDG_BP_RPLCTRQ_SPRX",
        "isServiceActive": false
      },
      {
        "id": "CO_MDG_BP_RELATIONSHIP_OUT_SPRX",
        "isServiceActive": false
      },
      {
        "id": "CO_MDG_BP_RPLCTCO_SPRX",
        "isServiceActive": false
      },
      {
        "id": "CO_MDG_BP_RELATIONSHIP_CNF_OUT_SPRX",
        "isServiceActive": false
      }
    ],
    "communicationSystem": {
      "communicationSystemHostname": "default.com",
      "outboundCommunicationUser": {
        "username": "DefaultUser",
        "password": "DefaultPassword"
      }
    }
  }
}
```

## Example of Enabling Communication Scenario of Type OAuth2ClientCredentials

This is an example of a JSON file for a communication arrangement with an outbound connection with authentication type *OAuth2ClientCredentials*.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "outboundAuthentication": "OAuth2ClientCredentials",
    "communicationArrangementName": "0219_ARRANGEMENT",
    "scenarioId": "SAP_COM_0219",
    "communicationSystem": {
      "communicationSystemHostname": "default.com",
      "oAuthAuthEndpoint": "oauth.com/oauth/authorize",
      "oAuthTokenEndpoint": "oauth.com/oauth/token",
      "outboundCommunicationUser": {
        "username": "DefaultUser",
        "password": "DefaultPassword"
      }
    }
  }
}
```

## Example for Enabling Communication Scenario of Type OAuth2SAMLBearerAssertion

This is an example of a JSON file for a communication arrangement with an inbound connection with *OAuth2SAMLBearerAssertion* and an outbound connection with *NoAuthentication*.

To communicate with SAP S/4HANA Cloud the extension application can use Principal Propagation which is done using OAuth 2.0 SAML Bearer Assertion flows. Principal Propagation means you forward the identity of the logged-in cloud users when accessing or updating data in the SAP S/4HANA Cloud system.

This is useful in scenarios where you need to have restricted data access based on the logged-in user from your extension. Or, you want to ensure only users with the right permissions are able to update the system via extensions deployed in SAP BTP, Cloud Foundry runtime.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "scenarioId": "SAP_COM_0213",
    "communicationArrangementName": "0213_ARRANGEMENT",
    "inboundAuthentication": "OAuth2SAMLBearerAssertion",
    "communicationSystem": {
      "communicationSystemHostname": "default.com"
    }
  }
}
```

## Example for Enabling Communication Scenario of Type NoAuthentication

This is an example of a JSON file for a communication arrangement with an outbound connection with authentication type *NoAuthentication*.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "outboundAuthentication": "NoAuthentication",
    "communicationArrangementName": "0215_ARRANGEMENT",
    "scenarioId": "SAP_COM_0215",
    "outboundServices": [
      {
        "id": "SAP_COM_0215_0001_REST",
        "isServiceActive": true
      }
    ],
    "communicationSystem": {
      "communicationSystemHostname": "default.com"
    }
  }
}
```

## Example for Enabling Communication Scenario of Type Client Certificate Authentication with Inbound Connection

This is an example of a JSON file for a communication arrangement with an inbound connection with authentication type *ClientCertificateAuthentication*.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "scenarioId": "SAP_COM_0724",
    "communicationArrangementName": "CommunicationArrangementName",
    "inboundAuthentication": "ClientCertificateAuthentication"
  }
}
```

## Example for Enabling Communication Scenario of Type Client Certificate Authentication with Outbound Connection

This is an example of a JSON file for a communication arrangement with an outbound connection with authentication type *ClientCertificateAuthentication*.

```
{
  "systemName": "DEMO",
  "communicationArrangement": {
    "communicationArrangementName": "CommunicationArrangementName",
    "scenarioId": "SAP_COM_0047",
    "outboundAuthentication": "ClientCertificateAuthentication",
    "communicationSystem": {
      "communicationSystemHostname": "default.com"
    }
  }
}
```

```
}  
}  
}
```

## Example for Enabling Communication Scenario of Type OAuth2mTLS

This is an example of a JSON file for a communication arrangement with an outbound connection with authentication type *OAuth2mTLS*.

```
{  
  "systemName": "DEMO",  
  "communicationArrangement": {  
    "outboundAuthentication": "OAuth2mTLS",  
    "communicationArrangementName": "CommunicationArrangementName",  
    "scenarioId": "SAP_COM_0080",  
    "communicationSystem": {  
      "communicationSystemHostname": "default.com",  
      "oAuthAuthEndpoint": "oauth.com/oauth/authorize",  
      "oAuthTokenEndpoint": "oauth.com/oauth/token",  
      "outboundCommunicationUser": {  
        "username": "DefaultUser"  
      }  
    }  
  }  
}
```

### 5.1.7.3.5 Communication Arrangement YAML File - Examples

The examples in this section will help you to create the service YAML descriptor used for defining the communication arrangement and the authentication type for the SAP S/4HANA Cloud API access.

The information that you need to create the YAML file is available in the [Display Communication Scenario](#) app in the corresponding SAP S/4HANA Cloud system. It contains information such as scenario details and properties, and supported inbound and outbound authentication methods. See [Display Communication Scenarios](#).

#### Note

The purpose of these examples is just to give you an idea how you construct your YAML file. For more details of the properties of these YAML files, see [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).

## Example of Enabling Communication Scenario of Type Basic Authentication

This is an example of a YAML file for a communication arrangement with an inbound connection with *Basic Authentication* and an outbound connection with *Basic Authentication*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      communicationArrangementName: INBOUND_COMMUNICATION_ARRANGEMENT
      scenarioId: SAP_COM_0008
      inboundAuthentication: BasicAuthentication
      outboundAuthentication: BasicAuthentication
      outboundServices:
        - id: DEBMAS_IDOC
          isServiceActive: false
        - id: CREMAS_IDOC
          isServiceActive: false
        - id: ADRMAS_IDOC
          isServiceActive: false
        - id: ADR3MAS_IDOC
          isServiceActive: false
        - id: ADR2MAS_IDOC
          isServiceActive: false
        - id: CO_MDG_BP_RPLCTRQ_SPRX
          isServiceActive: false
        - id: CO_MDG_BP_RELATIONSHIP_OUT_SPRX
          isServiceActive: false
        - id: CO_MDG_BP_RPLCTCO_SPRX
          isServiceActive: false
        - id: CO_MDG_BP_RELATIONSHIP_CNF_OUT_SPRX
          isServiceActive: false
    communicationSystem:
      communicationSystemHostname: default.com
      outboundCommunicationUser:
        username: DefaultUser
        password: DefaultPassword
```

## Example of Enabling Communication Scenario of Type OAuth2ClientCredentials

This is an example of a YAML file for a communication arrangement with an outbound connection with authentication type *OAuth2ClientCredentials*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      outboundAuthentication: OAuth2ClientCredentials
      communicationArrangementName: 0219_ARRANGEMENT
      scenarioId: SAP_COM_0219
    communicationSystem:
      communicationSystemHostname: default.com
```

```
oAuthAuthEndpoint: oauth.com/oauth/authorize
oAuthTokenEndpoint: oauth.com/oauth/token
outboundCommunicationUser:
  username: DefaultUser
  password: DefaultPassword
```

## Example for Enabling Communication Scenario of Type OAuth2SAMLBearerAssertion

This is an example of a YAML file for a communication arrangement with an inbound connection with *OAuth2SAMLBearerAssertion* and an outbound connection with *NoAuthentication*.

To communicate with SAP S/4HANA Cloud the extension application can use Principal Propagation which is done using OAuth 2.0 SAML Bearer Assertion flows. Principal Propagation means you forward the identity of the logged-in cloud users when accessing or updating data in the SAP S/4HANA Cloud system.

This is useful in scenarios where you need to have restricted data access based on the logged-in user from your extension. Or, you want to ensure only users with the right permissions are able to update the system via extensions deployed in SAP BTP, Kyma runtime.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      communicationArrangementName: 0213_ARRANGEMENT
      scenarioId: SAP_COM_0213
      inboundAuthentication: OAuth2SAMLBearerAssertion
    communicationSystem:
      communicationSystemHostname: default.com
```

## Example for Enabling Communication Scenario of Type NoAuthentication

This is an example of a YAML file for a communication arrangement with an outbound connection with authentication type *NoAuthentication*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      communicationArrangementName: 0215_ARRANGEMENT
      scenarioId: SAP_COM_0215
      outboundAuthentication: NoAuthentication
    outboundServices:
      - id: SAP_COM_0215_0001_REST
        isServiceActive: true
    communicationSystem:
      communicationSystemHostname: default.com
```

## Example for Enabling Communication Scenario of Type Client Certificate Authentication with Inbound Connection

This is an example of a YAML file for a communication arrangement with an inbound connection with authentication type *ClientCertificateAuthentication*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      communicationArrangementName: CommunicationArrangementName
      scenarioId: SAP_COM_0724
      inboundAuthentication: ClientCertificateAuthentication
```

## Example for Enabling Communication Scenario of Type Client Certificate Authentication with Outbound Connection

This is an example of a YAML file for a communication arrangement with an outbound connection with authentication type *ClientCertificateAuthentication*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
  parameters:
    systemName: DEMO
    communicationArrangement:
      communicationArrangementName: CommunicationArrangementName
      scenarioId: SAP_COM_0018
      outboundAuthentication: ClientCertificateAuthentication
    outboundServices:
      - id: CO_MSM_PROJECT_ERPCREATE_REQUE_SPRX
        isServiceActive: true
      - id: CO_MSM_PROJECT_ERPUPDATE_REQUE_SPRX
        isServiceActive: false
      - id: CO_MSM_PROJECT_ERPBY_IDQUERY_R_SPRX
        isServiceActive: false
    communicationSystem:
      communicationSystemHostname: default.com
```

## Example for Enabling Communication Scenario of Type OAuth2mTLS

This is an example of a YAML file for a communication arrangement with an outbound connection with authentication type *OAuth2mTLS*.

```
spec:
  externalName: ''
  serviceOfferingName: s4-hana-cloud
  servicePlanName: api-access
```

```

parameters:
  systemName: DEMO
  communicationArrangement:
    communicationArrangementName: CommunicationArrangementName
    scenarioId: SAP_COM_0080
    outboundAuthentication: OAuth2mTLS
    outboundServices:
      - id: SAP_COM_0080_0001_REST
        isServiceActive: true
  communicationSystem:
    communicationSystemHostname: default.com
    oAuthAuthEndpoint: oauth.com/oauth/authorize
    oAuthTokenEndpoint: oauth.com/oauth/token
    outboundCommunicationUser:
      username: DefaultUser

```

## 5.1.7.4 Enable the Consumption of SAP S/4HANA Cloud Events

To create event-based extensions for SAP S/4HANA Cloud you need to set up the messaging between the SAP S/4HANA Cloud system and the SAP Event Mesh.

### Prerequisites

- You have registered an SAP S/4HANA Cloud tenant in the global account in SAP BTP. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).

### Context

To consume SAP S/4HANA Cloud events, you need to configure the connectivity between SAP Event Mesh and the SAP S/4HANA Cloud tenant. To do so, you need to create and configure service instances for both SAP S/4HANA Cloud Extensibility service and SAP Event Mesh.

When you create a service instance in a subaccount, an event bus for this subaccount is created. All service instances in a subaccount point to the same event bus and are nothing else but clients providing access credentials for the event bus. You configure the clients using JSON descriptors. Each client has its own name which can be configured with the `emname` parameter in the JSON descriptor file. Thus, the client is identified with a human readable name instead of a GUID. The name of each client must be unique. As all of the clients point to the same event bus, they must have different namespaces in which to publish events. Each namespace must be unique per subaccount. Each client should publish only in its own unique namespace.

### Communication flow

The SAP S/4HANA Cloud Extensibility service instance is the client which creates the SAP S/4HANA Cloud integration and provides the credentials for the SAP S/4HANA Cloud system so that the SAP S/4HANA Cloud system can send events to that event bus. The purpose of this client is to send messages to a topic. It sends messages to the namespace which was configured while creating the service instance of S/4HANA Cloud

Extensibility service. See [Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File \[page 1817\]](#)

The SAP Event Mesh service instance is the client which receives the events. This service instance must have a different name and a different namespace than the ones configured for the SAP S/4HANA Cloud extensibility service instance. Since the purpose of this client is to receive messages from a different client the rules have to take care of that. So, for the SAP Event Mesh service instance, you need to configure the subscribe filter to the SAP S/4HANA Cloud Extensibility service instance. See [Define SAP Event Mesh Service Descriptor JSON/YAML File \[page 1830\]](#).

After both instances are created and configured, you can create the topic-to-queue subscription. To do so, you first create a queue in the client that refers to the SAP Event Mesh service instance and then subscribe the topic of the namespace of the SAP S/4HANA Cloud Extensibility service to that queue. See [Manage Queues](#) in the SAP Event Mesh documentation

The service instance of SAP Event Mesh is the client which consumes the message and should be bound to the extension application.

## Procedure

To configure the connectivity between SAP Event Mesh and the SAP S/4HANA Cloud tenant so that SAP S/4HANA Cloud events can be produced and then consumed by applications running on SAP BTP, you need to perform the following tasks:

1. Add the required quotas to your subaccount as follows:
  1. Assign the *messaging* SAP S/4HANA Cloud Extensibility service plan to the subaccount in SAP BTP you want to pair with the SAP S/4HANA Cloud tenant. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

### Note

You can use the service plan on regions where the SAP Event Mesh service is available.

### Note

The *messaging* service plan enables the *Enterprise Eventing Integration (SAP\_COM\_0092)* communication scenario which allows you to consume SAP S/4HANA Cloud events and create event-based extensions.

This service plan has been renamed from *sap\_com\_0092*.

2. Assign the required number of SAP Event Mesh instances to the subaccount in SAP BTP that you want to pair with the SAP S/4HANA Cloud tenant. See [Configure the Entitlements for SAP Event Mesh \[page 1811\]](#).
2. Configure the connectivity between SAP Event Mesh and the SAP S/4HANA Cloud tenant, and then configure event topics for the channel inside SAP S/4HANA Cloud tenant. See [Set Up the Connectivity Between Event Mesh and the SAP S/4HANA Cloud Tenant \[page 1812\]](#).
3. Enable the SAP Event Mesh for your subaccount in SAP BTP, create a queue that is specific to your application, and then subscribe this queue to the channel topic that the SAP S/4HANA Cloud tenant uses to produce events. See [Enable the SAP Event Mesh Service for Your Subaccount in SAP BTP \[page 1826\]](#).

## Related Information

[What Is SAP Event Mesh?](#)

### 5.1.7.4.1 Configure the Entitlements for SAP Event Mesh

To be able to consume SAP S/4HANA Cloud events, you need to configure the entitlements for SAP Event Mesh for the subaccount in SAP BTP.

#### Context

The *messaging* service plan connects SAP S/4HANA Cloud tenant to SAP Event Mesh for the subaccount where the SAP Event Mesh service entitlement is configured. This SAP Event Mesh service instance allows you to consume events from SAP S/4HANA Cloud.

You need to configure the entitlements for the SAP Event Mesh service to create an SAP Event Mesh service instance. Then, you bind this service instance to an application to consume events from this application.

#### Procedure

1. In SAP BTP cockpit, navigate to the global account that contains the subaccount in which you want to make your SAP system accessible.
  2. In the navigation area, choose *Entitlements*. Then, depending on the feature set you are using, you have to follow different steps. See [Cloud Management Tools — Feature Set Overview \[page 111\]](#).
    - If you are using feature set A, you have to:
      1. In the navigation area, choose ► *Entitlements* ► *Subaccount Assignments* ▾.
      2. Select your subaccount from the drop down menu, choose *Go*, and then choose *Configure Entitlements*.
- Tip

If your global account contains more than 20 subaccounts, choose  to open up the value help dialog. There you can filter subaccounts by role, environment and region to make your selection easier and faster. You can only select a maximum of 50 subaccounts at once.
- If you are using feature set B, you have to:
    1. In the navigation area, choose ► *Entitlements* ► *Entity Assignments* ▾.
    2. On the *Entity Assignments* screen, select your subaccount in the *Select Entities* field.
    3. Choose *Go*, and then choose *Configure Entitlements*.
  3. Choose *Add Service Plans*, and then select the *SAP Event Mesh* service.

4. In the *Available Service Plans* area, select the system you have registered and the *default* service plan, and then choose *Add Service Plan*.
5. Choose *Save*.

## Related Information

[Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#)

### 5.1.7.4.2 Set Up the Connectivity Between Event Mesh and the SAP S/4HANA Cloud Tenant

#### Overview

To configure the connectivity between the SAP S/4HANA Cloud tenant and SAP Event Mesh and to enable the exchange of credentials between the two systems, you first need to create an *SAP S/4HANA Cloud Extensibility* service instance with service plan *messaging*. For more information about the *messaging* service plan, see [Supported Service Plans for SAP S/4HANA Cloud \[page 1838\]](#).

When creating this service instance, you create the required configurations in both the SAP S/4HANA Cloud tenant and the Event Mesh system associated with the subaccount in SAP BTP, so that events can flow. Depending on the SAP BTP environment, to create an *SAP S/4HANA Cloud Extensibility* service instance, you have to choose one of the following options:

- [Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment \[page 1813\]](#)
- [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1815\]](#)

After you have created the *SAP S/4HANA Cloud Extensibility* service instance, either in the Cloud Foundry or Kyma environment, you need to configure event topics for the channel inside the SAP S/4HANA Cloud tenant, and then you need to create an SAP Event Mesh service instance, respectively in the Cloud Foundry or Kyma environment, for the application to consume SAP S/4HANA Cloud events. You do this in a dedicated JSON file that you add either when creating the service instance, or after that. To construct this JSON file, see [Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File \[page 1817\]](#).

## Process Flow

Process Step	Related Documentation
1. Create an SAP S/4HANA Cloud Extensibility service instance with service plan messaging.	<ul style="list-style-type: none"><li>• <a href="#">Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment [page 1813]</a></li><li>• <a href="#">Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment [page 1815]</a></li></ul>
2. Define a dedicated JSON file that you add either when creating the SAP S/4HANA Cloud Extensibility service instance, or after that.	<a href="#">Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File [page 1817]</a>
3. Configure event topics for the channel inside SAP S/4HANA Cloud tenant.	<a href="#">Configure Event Topics in SAP S/4HANA Cloud [page 1825]</a>

### 5.1.7.4.2.1 Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment

Use this procedure to configure the communication between SAP S/4HANA Cloud and SAP Event Mesh.

#### Prerequisites

- Before creating an SAP S/4HANA Cloud Extensibility service instance in the Cloud Foundry environment, see [Create a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#).
- Have enabled Cloud Foundry environment for your subaccount. See [Enable Environment or Create Environment Instance \[page 1986\]](#).
- Have registered an SAP S/4HANA Cloud system. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP \[page 1782\]](#).
- Have configured the entitlements to the SAP S/4HANA Cloud Extensibility service. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

#### Context

To configure the connectivity between the SAP S/4HANA Cloud tenant and Event Mesh and to enable the exchange of credentials between the two systems, you first need to create an [SAP S/4HANA Cloud Extensibility](#) service instance with service plan messaging. For more information about the messaging service plan, see [Supported Service Plans for SAP S/4HANA Cloud \[page 1838\]](#).

When creating this service instance, you create the required configurations in both the SAP S/4HANA Cloud tenant and the Event Mesh system associated with the subaccount in SAP BTP, so that events can flow.

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount in which you want to create a service instance.
2. In the navigation area, choose **Services** > **Service Marketplace** .  
All services available to you appear.
3. To enable the integration with an SAP S/4HANA Cloud system that you have registered in the global account in SAP BTP, choose [SAP S/4HANA Cloud Extensibility](#).
4. In the [SAP S/4HANA Cloud Extensibility](#) page, choose **Create**.
5. In the *New Instance or Subscription* wizard:
  - a. In the *Service* dropdown list, ensure you have selected the [SAP S/4HANA Cloud Extensibility](#) service.
  - b. In the *Plan* dropdown list, select the *messaging* service plan.
  - c. In the *Runtime Environment* dropdown list, select *Cloud Foundry*.
  - d. In the *Space* dropdown list, select your space. If you haven't create a space yet, you can do it at this point.
  - e. In the *System Name* dropdown list, select the SAP S/4HANA Cloud system you have registered.
  - f. In the *Instance Name* field, enter a name for your instance. Choose **Next**.
  - g. Specify a JSON file or specify parameters in the JSON format to define the communication arrangement for the communication scenario *Enterprise Eventing Integration (SAP\_COM\_0092)* in the SAP S/4HANA Cloud tenant and to configure the parameters for the Enterprise Messaging service. If you decide to define the communication arrangement later on, you have to delete this service instance and create it again. Choose **Next**.

For more information about the structure of the JSON file, see [Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File \[page 1817\]](#).

- h. Choose **Create**.

The newly created instance appears in the list of instances in the *Instance and Subscriptions* page.

Alternatively, you can create the instance using cf CLI. To do so, execute the following command

```
cf create-service s4-hana-cloud messaging emsconnect -c '{"systemName":
"<system_name>","communicationArrangement": {"communicationArrangementName":
"<communication_arrangement_name>","attributes": [{"name": "Channel","value":
"<channel_name>"}, {"name": "Description","value": "<short_description>"},
{"name": "Topic Space","value": "<topic_to_be_used_by_events>"},
{"name": "QoS","value": "<quality_of_service>"}, {"name":
"Reconnect Attempts","value": "<number_of_reconnect_attempts>"},
{"name": "Reconnect wait time(sec)","value":
"<time_before_trying_to_reconnect>"}]},{"ems": {"parameters":
{"emname": "enterprise_messaging_client_name","namespace": "enterprise-
messaging_client_namespace":{"options": {"<required_options>"},"rules":
{"<required_rules>}}}'
```

For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface](#).

### Note

You can use the cf CLI to troubleshoot if the creation of the service instance fails. To do that, use this command in the cf CLI:

```
cf service <service_instance_name>
```

## Next Steps

[Configure Event Topics in SAP S/4HANA Cloud \[page 1825\]](#)

### 5.1.7.4.2 Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment

Use this procedure to configure the communication between SAP S/4HANA Cloud and SAP Event Mesh in the Kyma environment.

## Prerequisites

In the SAP BTP cockpit, you have assigned the `messaging` SAP S/4HANA Cloud service plan to the subaccount you want to pair with the SAP S/4HANA Cloud tenant. See [Configure the Entitlements for the SAP BTP Subaccount \[page 1786\]](#).

## Context

To configure the connectivity between an SAP S/4HANA Cloud tenant and Event Mesh and to enable the exchange of credentials between the two systems, you first need to create an SAP S/4HANA Cloud Extensibility service instance with `messaging` service plan in the Kyma dashboard. For more information about the `messaging` service plan, see [Supported Service Plans for SAP S/4HANA Cloud \[page 1838\]](#).

When creating this service instance, you create the required configurations in both the SAP S/4HANA Cloud tenant and the Event Mesh system associated with the subaccount in SAP BTP, so that the events can flow from one system to the other.

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount for which you want to create an SAP S/4HANA Cloud Extensibility service instance.
2. On the subaccount *Overview* page in the *Kyma Environment* section, open the Kyma dashboard.
3. Navigate to the *default* namespace from the drop-down list in the top navigation.
4. Choose **► Service Management ► BTP Service Instances ►** from the left-hand side navigation.
5. In the *Service Instances* page, choose *Create Service Instance* in the upper right-hand corner. A new dialog opens.
6. Choose the *Simple* tab and fill in the following fields:

- Give a meaningful name of the new SAP S/4HANA Cloud Extensibility service instance.
  - In the *Offering Name* field, enter **s4-hana-cloud**, which is the technical name of the SAP S/4HANA Cloud Extensibility service.
  - In the *Plan Name* field, enter **messaging**.
7. Choose the *YAML* tab.

In *parameters*: in the *spec*: section, specify the parameters to define the communication arrangement for the communication scenario *Enterprise Eventing Integration (SAP\_COM\_0092)* in the SAP S/4HANA Cloud tenant and to configure the parameters for the Event Mesh service. Make sure you include at least these two required parameters: `systemName` and `emClientId`. The parameters are listed in this YAML file: [Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File \[page 1817\]](#).
  8. Choose *Create*.

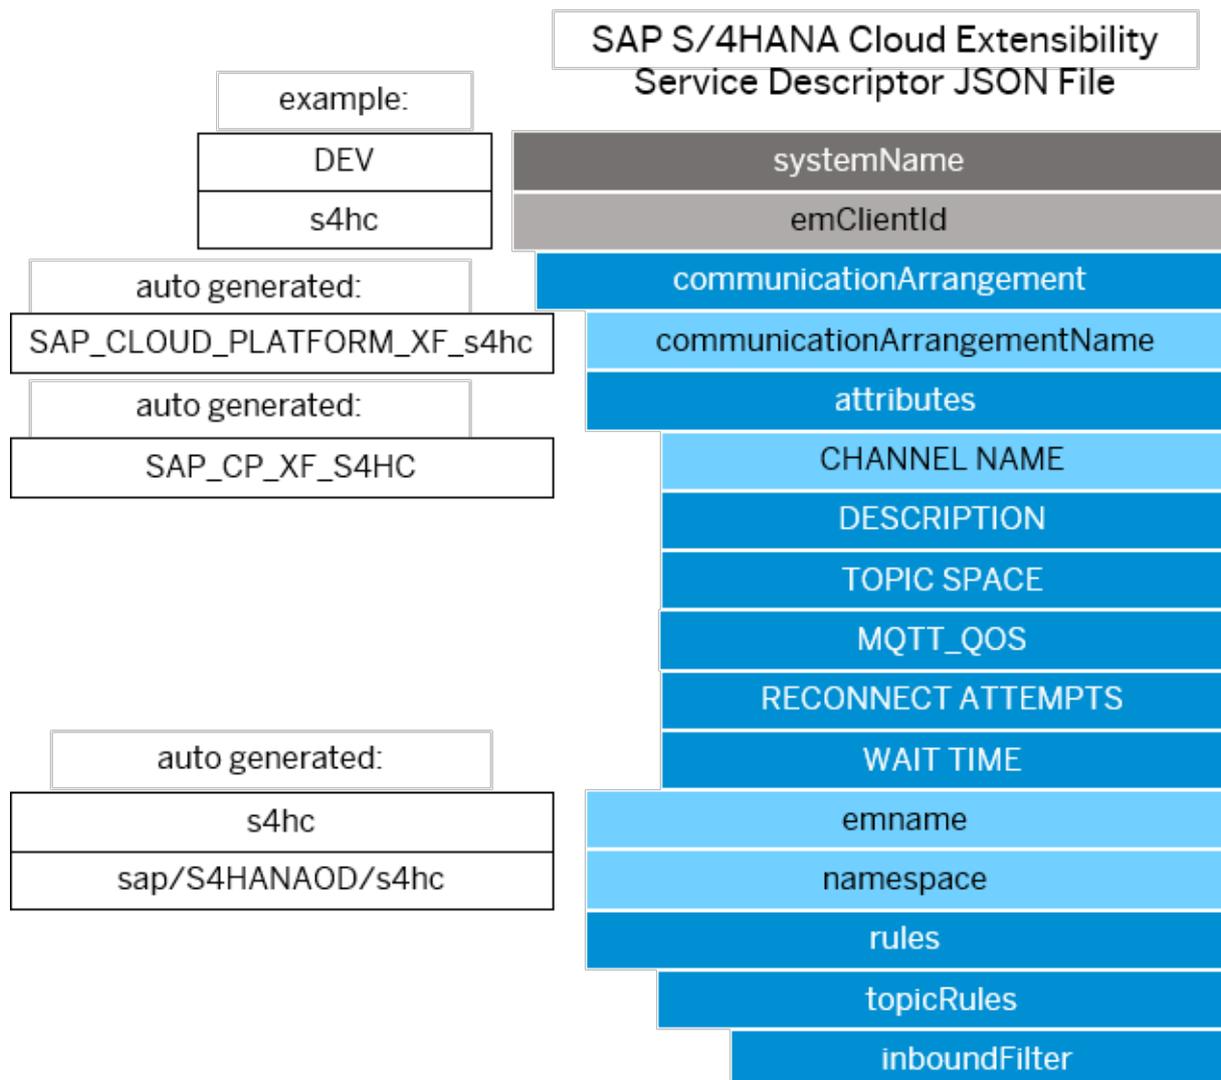

## Next Steps

After creating the SAP S/4HANA Cloud Extensibility service instance with the `messaging` plan, a respective messaging client is created for you in the `sap/s4hanaod/{emClientId}` namespace of the Event Mesh service. As the next step, you must relate the two clients (SAP S/4HANA Cloud Extensibility and Event Mesh) in the Kyma dashboard. To do this, create an instance of the Event Mesh service with the details of the automatically created Event Mesh namespace. Follow the steps in [Create an SAP Event Mesh Service Instance in the Kyma Environment \[page 1828\]](#).

### 5.1.7.4.2.3 Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File

The SAP S/4HANA Cloud Extensibility service descriptor defines details of a message client and needs to be provided when provisioning new SAP S/4HANA Cloud Extensibility service instances with service plan messaging.

#### Procedure

**Legend:**

- Required property
- Required property whose value is used to generate automatically the values of a set of optional properties
- Optional property
- Optional property whose value is generated automatically based on the value of a required property. If specified, overrides the automatically generated one

Define the SAP S/4HANA Cloud Extensibility service descriptor in a JSON structure for the Cloud Foundry environment and in a YAML structure for the Kyma environment. It has to contain two sections:

- For the parameters needed to activate the communication arrangement for the communication scenario *Enterprise Eventing Integration (SAP\_COM\_0092)* in the SAP S/4 HANA Cloud tenant. There are only two required parameters, *emClientId* and *systemName*. The rest of the parameters are automatically generated. However, you can still provide the optional parameters in the descriptor to override the automatically generated values.
- For the parameters for configuring the SAP Event Mesh service. If this section is not explicitly added to the JSON/YAML file, the values of its parameters are automatically generated based on the values of the *emClientId* and *systemName* parameters.

Parameters required to activate the communication arrangement in SAP S4/HANA Cloud tenant

Parameter	Description
systemName	<p>The name of the system you have registered in the global account in SAP BTP.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: Yes</li> <li>• The name must be the same as the one you have used when registering the SAP S/4HANA Cloud system during the pairing process.</li> </ul>
emClientId	<p>Using default patterns, it generates <b>communication arrangement name, channel name, emname, and namespace</b>, when these parameters are not explicitly provided. The default values are described in the table below containing the parameters required to configure SAP Event Mesh service.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin: 10px 0;"> <p><b>Note</b></p> <p>The values of the emname and namespace parameters must be the same as the values of the emname and namespace parameters in the SAP Event Mesh service descriptor. See <a href="#">Define SAP Event Mesh Service Descriptor JSON/YAML File [page 1830]</a>.</p> </div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: Yes</li> <li>• Allowed characters: <b>[a-zA-Z0-9]</b></li> <li>• Maximum length: 4</li> </ul>
communicationArrangement	<p>Defines the communication arrangement for the SAP S4/HANA Cloud tenant.</p>

Parameter	Description
communicationArrangementName	<p>A communicationArrangement property.</p> <p>The name of the communication arrangement for the SAP S/4HANA Cloud tenant.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: [a-zA-Z0-9_-]</li> <li>• Maximum length: 80</li> <li>• Default value: <b>"SAP_CLOUD_PLATFORM_XF_&lt;emClientId&gt;"</b></li> </ul>
attributes	<p>A communicationArrangement property.</p> <p>Defines the configuration properties for the communication arrangement.</p> <p>The name of the property is equivalent to the <i>Technical Property Name</i> column in the properties table in the Display Communication Scenarios app in the SAP S/4HANA Cloud system. See <a href="#">Display Communication Scenarios</a>.</p>
CHANNEL NAME	<p>An attributes property.</p> <p>The name of the communication channel.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: [A-Z0-9_-]</li> <li>• Default value: <b>"SAP_CP_XF_&lt;emclientId&gt;"</b></li> </ul> <div data-bbox="847 1368 1394 1527" style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px;"> <p><b>Note</b></p> <p>Have in mind that the <b>&lt;emclientId&gt;</b> will be automatically capitalized.</p> </div> <ul style="list-style-type: none"> <li>• Must be unique within the SAP S/4 HANA Cloud tenant.</li> </ul>

Parameter	Description
DESCRIPTION	<p>An <code>attributes</code> property.</p> <p>Short description.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Maximum length: 60</li> <li>• Allowed characters: <code>[a-zA-Z0-9_-]</code></li> <li>• Default value: <b>"Integration with Enterprise Messaging for EM Client: &lt;emclientId&gt;"</b></li> </ul>
TOPIC_SPACE	<p>An <code>attributes</code> property.</p> <p>The identifier for the events that originate from the same source. This is the topic that the events should use.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Maximum length: 24</li> <li>• Allowed characters: <code>[a-zA-Z0-9//]</code></li> <li>• Contains exactly three segments, for example <code>a/b/c</code>.</li> <li>• Default value: <b>"sap/S4HANAOD/&lt;emclientId&gt;"</b></li> <li>• The <code>subscribeFilter</code> in the SAP Event Mesh configuration must be use the topic space as a prefix.</li> </ul>
MQTT_QOS	<p>An <code>attributes</code> property.</p> <p>Defines the quality of service.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed values: <b>0, 1</b></li> </ul> <p>QoS=<b>0</b>, at most once delivery. The message is delivered according to the capabilities of the underlying network. No response is sent by the receiver and no retry is performed by the sender. The message arrives at SAP Event Mesh either once or not at all.</p> <p>QoS=<b>1</b>, at least once delivery. This quality of service ensures that the message arrives at SAP Event Mesh at least once.</p> <ul style="list-style-type: none"> <li>• Default value: <b>1</b></li> </ul>

Parameter	Description
RECONNECT_ATTEMPTS	<p>An <code>attributes</code> property.</p> <p>The number of attempts the Enterprise Event Enablement framework tries to reestablish the connection if the connection is lost.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Default value: <b>0</b></li> <li>• If no value is entered or the entered value is 0, the framework tries to connect until connection is established. If the connection is not established after reaching reconnect attempts, the communication arrangement and the underlying channel is deactivated.</li> </ul>

WAIT_TIME	<p>An <code>attributes</code> property.</p> <p>Specifies the time (in seconds) for which the Enterprise Event Enablement framework waits before trying to reconnect. If the attempts fail, framework increases the wait time until the reconnect wait time (1800 seconds) is reached.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Default value: <b>10</b></li> </ul>
-----------	---

Parameters required to configure SAP Event Mesh service

Parameter	Description
emname	<p>Specifies the name of the SAP Event Mesh client. It is used by SAP Event Mesh to identify clients.</p> <p><b>Rules/Guidelines:</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: <b>[a-zA-Z0-9_-]</b></li> <li>• Maximum length: 100</li> <li>• Default value: <b>&lt;emClientId&gt;</b></li> <li>• It is unique within a subaccount.</li> </ul>

Parameter	Description
namespace	<p>Namespace for the message client.</p> <p><b>Rules/Guidelines:</b> The namespace in the SAP Event Mesh configuration must be the same as the first three segments of the topic space in the configuration of the communication arrangement in SAP S4/HANA Cloud tenant.</p> <p><b>Rules/Guidelines:</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: [a-zA-Z0-9//]</li> <li>• Maximum length: 24</li> <li>• It is unique within a subaccount</li> <li>• Contains exactly three segments, for example a/b/c.</li> <li>• Default value: "sap/S4HANAOD/&lt;emclientId&gt;"</li> </ul>
rules	<p>Defines the access privileges of the message client.</p> <p><b>Guidelines/Rules:</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• In order to allow access to a queue or a topic the namespace of the corresponding owner client has to be added. The placeholder <code>{ namespace }</code> can be used instead of the defined namespace.</li> </ul>
topicRules	<p>A <code>rules</code> attribute.</p> <p><b>Guidelines/Rules:</b></p> <ul style="list-style-type: none"> <li>• Type: object</li> </ul>
inboundFilter	<p>A <code>topicRules</code> attribute.</p> <p>Defines if a client (publisher/producer) is allowed to send messages to the defined topics.</p> <p><b>Guidelines/Rules:</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: [a-zA-Z#?/]</li> <li>• Type: array</li> <li>• Default value: <code>{ namespace }/#</code></li> <li>• Example values: <code>{ namespace }/foo/bar</code>, <code>{ namespace }/#</code>.</li> </ul>

Parameter	Description
resources	<p>A collection of messaging resources such as queues, connections, and so on, required for a message client.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: No</li> </ul>
units	<p>A <code>resources</code> attribute.</p> <p>Specify this value in the service descriptor to allocate messaging resources based a specific business scenario. See <a href="#">Syntax for Service Descriptor</a>.</p> <p><b>Guidelines/Rules:</b></p> <ul style="list-style-type: none"> <li>Required: No</li> <li>Allowed values: <b>10-50</b></li> <li>Type: attribute</li> <li>Default value: <b>10</b></li> </ul>

## JSON File Example

In this example, only the required properties are provided.

```
{
  "systemName": "DEV",
  "emClientId": "s4hc"
}
```

This descriptor is equivalent to:

### Note

All properties can be overridden explicitly.

```
{
  "systemName": "DEV",
  "emClientId": "s4hc",
  "communicationArrangement": {
    "communicationArrangementName": "SAP_CLOUD_PLATFORM_XF_s4hc",
    "attributes": [
      {
        "name": "CHANNEL_NAME",
        "value": "SAP_CP_XF_S4HC"
      },
      {
        "name": "DESCRIPTION",
        "value": "Integration with Enterprise Messaging for EM Client: s4hc"
      },
      {
        "name": "TOPIC SPACE",
        "value": "sap/S4HANAOD/s4hc"
      }
    ]
  }
}
```

```

    {
      "name": "MQTT_QOS",
      "value": "1"
    },
    {
      "name": "RECONNECT_ATTEMPTS",
      "value": "0"
    },
    {
      "name": "WAIT_TIME",
      "value": "10"
    }
  ]
},
"ems": {
  "parameters": {
    "emname": "s4hc",
    "namespace": "sap/S4HANAOD/s4hc",
    "rules": {
      "topicRules": {
        "inboundFilter": [
          "${namespace}/#"
        ]
      }
    },
    "resources": {
      "units": "10"
    }
  }
}
}
}
}

```

## YAML File Example

In this example, only the required properties are provided.

```

parameters:
  systemName: DEV
  emClientId: s4hc

```

This descriptor is equivalent to:

```

## 5.1.7.4.2.4 Configure Event Topics in SAP S/4HANA Cloud

Configure event topics for the channel inside the SAP S/4HANA Cloud tenant.

### Prerequisites

You have created the SAP S/4HANA Cloud Extensibility service instance in the Cloud Foundry or Kyma environment. See:

- [Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment \[page 1813\]](#)
- [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1815\]](#)

### Context

After you have created the SAP S/4HANA Cloud Extensibility service instance, you need to configure event topics for the channel inside the SAP S/4HANA Cloud tenant, and then you need to create an SAP Event Mesh service instance for the application to consume SAP S/4HANA Cloud events.

### Procedure

Configure event topics for the channel inside SAP S/4HANA Cloud tenant. Use the channel you have specified in SAP S/4HANA Cloud Extensibility service descriptor JSON file when configuring the parameters for the communication arrangement in SAP S4/HANA Cloud tenant.

As an example, you can use the `sap/s4/beh/businesspartner/v1/BusinessPartner/Changed/v1` outbound topic.

## Next Steps

Create an SAP Event Mesh service instance in the Cloud Foundry or the Kyma environment. See:

- [Create an SAP Event Mesh Service Instance in the Cloud Foundry Environment \[page 1827\]](#)
- [Create an SAP Event Mesh Service Instance in the Kyma Environment \[page 1828\]](#)

### 5.1.7.4.3 Enable the SAP Event Mesh Service for Your Subaccount in SAP BTP

#### Prerequisites

- You have created the `SAP S/4HANA Cloud Extensibility` service instance in the Cloud Foundry or Kyma environment. See:
  - [Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment \[page 1813\]](#)
  - [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1815\]](#)
- You have configured event topics for the channel inside SAP S/4HANA Cloud tenant. See [Configure Event Topics in SAP S/4HANA Cloud \[page 1825\]](#).

#### Overview

To enable the SAP Event Mesh for your subaccount in SAP BTP, you have to create an instance of the SAP Event Mesh service with service plan `default`. This instance will specify the details of the namespace that you created in SAP Event Mesh for the SAP S/4HANA Cloud Extensibility service instance with the `messaging` plan. This way, you are setting up a contract between SAP Event Mesh and the Cloud Foundry, or the Kyma environment, and connect them to enable seamless event flow from the given SAP S/4HANA Cloud tenant.

Depending on the SAP BTP environment, to create an SAP Event Mesh service instance, you have to choose one of these:

- [Create an SAP Event Mesh Service Instance in the Cloud Foundry Environment \[page 1827\]](#)
- [Create an SAP Event Mesh Service Instance in the Kyma Environment \[page 1828\]](#)

Define the details of your message client in SAP Event Mesh as parameters in a dedicated JSON file. To map the message client to the client defined in the SAP S/4HANA Cloud JSON file, in the SAP Event Mesh JSON file, you must include the `subscribeFilter` parameter which specifies the `sap/s4hanaod/{emClientId}` namespace you created for the SAP S/4 HANA Cloud Extensibility instance of the `messaging` plan. For more information about the structure of the JSON file, see [Define SAP Event Mesh Service Descriptor JSON/YAML File \[page 1830\]](#).

## Process Flow

Process Step	Related Documentation
1. Create an SAP Event Mesh service instance with service plan default.	<ul style="list-style-type: none"><li>• <a href="#">Create an SAP Event Mesh Service Instance in the Cloud Foundry Environment [page 1827]</a></li><li>• <a href="#">Create an SAP Event Mesh Service Instance in the Kyma Environment [page 1828]</a></li></ul>
2. Define a dedicated JSON file that you add either when creating the SAP Event Mesh service instance, or after that.	<a href="#">Define SAP Event Mesh Service Descriptor JSON/YAML File [page 1830]</a>
3. Create a queue in the message client that refers to the SAP Event Mesh service instance and then subscribe the topic of the namespace of the SAP S/4HANA Cloud Extensibility service to that queue.	<a href="#">Create Queues and Subscribe to Them [page 1836]</a>

### 5.1.7.4.3.1 Create an SAP Event Mesh Service Instance in the Cloud Foundry Environment

Use this procedure to enable the SAP Event Mesh service for the subaccount where your extension application will reside.

#### Context

To enable the SAP Event Mesh service for your subaccount in SAP BTP, you have to go through the following steps.

#### Procedure

1. Prepare a JSON file that contains details of a message client. See [Define SAP Event Mesh Service Descriptor JSON/YAML File \[page 1830\]](#).
2. Create an SAP Event Mesh service instance for the application to consume SAP S/4HANA Cloud events.
  - a. In the SAP BTP cockpit, navigate to the space in which you want to create a service instance.
  - b. In the navigation area, choose **Services** > **Service Marketplace**, and then choose **Event Mesh** in the **Service Marketplace** panel.
  - c. From the **Event Mesh** service tile, choose **Create** and follow the steps in the wizard to subscribe to the service.
  - d. In the **New Instance or Subscription** wizard:

1. In the *Service* dropdown list, select *Event Mesh*.
2. In the *Plan* dropdown list select the *default* service plan.
3. In the *Runtime Environment* dropdown list, select *Cloud Foundry*.
4. In the *Space* dropdown list, select your Cloud Foundry space.
5. In the *Instance Name* field, enter a name for your instance. Choose *Next*.
6. Specify the JSON file you prepared in **Step 1**. Choose *Next*.
7. Review and verify the instance details, and choose *Create*.

## Next Steps

[Create Queues and Subscribe to Them \[page 1836\]](#)

### 5.1.7.4.3.2 Create an SAP Event Mesh Service Instance in the Kyma Environment

Use this procedure to enable the SAP Event Mesh service for the subaccount where your extension application will reside.

## Prerequisites

- In the SAP BTP cockpit, you have assigned the `messAGING` SAP S/4HANA Cloud Extensibility service plan to the SAP BTP subaccount that you want to pair with the SAP S/4HANA Cloud tenant. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).
- In the Kyma dashboard, you have created the SAP S/4HANA Cloud Extensibility service instance with the `messAGING` plan. See [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1815\]](#).
- In the SAP BTP cockpit, you have assigned the `default` SAP Event Mesh service plan to the SAP BTP subaccount that you want to pair with the SAP S/4HANA Cloud tenant. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

## Context

In the Kyma dashboard, create an instance of the SAP Event Mesh service. This instance will specify the details of the namespace that you created in SAP Event Mesh for the SAP S/4HANA Cloud Extensibility service instance with the `default` plan. This way, you are setting up a contract between SAP Event Mesh and the Kyma environment, and connect them to enable seamless event flow from the given SAP S/4HANA Cloud tenant to Kyma.

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount for which you want to create an SAP Event Mesh service instance.
2. On the subaccount *Overview* page in the *Kyma Environment* section, open the Kyma dashboard.
3. Navigate to the *default* namespace from the drop-down list in the top navigation.
4. Choose **► Service Management ► BTP Service Instances ►** from the left-hand side navigation.
5. In the *Service Instances* page, choose *Create Service Instance* in the upper right-hand corner. A new dialog opens.
6. Choose the *Simple* tab and fill in the following fields:
  - Give a meaningful name of the new SAP Event Mesh service instance.
  - In the *Offering Name* field, enter **enterprise-messaging**, which is the technical name of the SAP Event Mesh service.
  - In the *Plan Name* field, enter **default**.
7. Choose the *YAML* tab.

In *parameters:* in the *spec:* section, specify the parameters to define the details of your message client in the SAP Event Mesh service. You must include the `subscribeFilter` parameter which specifies the `sap/s4hanaod/{emClientId}` namespace you created for the SAP S/4 HANA Cloud Extensibility instance of the messaging plan in SAP Event Mesh. For more information about the structure of the YAML file, see [Define SAP Event Mesh Service Descriptor JSON/YAML File \[page 1830\]](#).

8. Choose *Create*.

## Results

Once the service instance is provisioned, you can see it under **► Service Management ► Instances ►** in the left-hand side navigation of the Kyma dashboard.

## Next Steps

[Create Queues and Subscribe to Them \[page 1836\]](#)

### 5.1.7.4.3.3 Define SAP Event Mesh Service Descriptor JSON/YAML File

The SAP Event Mesh service descriptor defines details of a message client and needs to be provided when provisioning new SAP Event Mesh service instances with service plan `default`.

#### Prerequisites

- You have created an SAP S/4HANA Cloud Extensibility service instance with defined SAP S/4HANA Cloud Extensibility descriptor. See [Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File \[page 1817\]](#).
- Get to know the additional parameters you can have in the SAP Event Mesh service descriptor. In this page only the parameters that are related to this use case are described. See [Syntax for Service Descriptor in SAP Event Mesh documentation](#).

#### Context

You set up service instance of the SAP Event Mesh service to receive the events which are sent by the SAP S/4HANA Cloud Extensibility service. In the JSON file for the Cloud Foundry environment and in the YAML file for the Kyma environment, this service instance needs to be created with a different `emname` as well as a different `namespace`. The rule set here is important as each client should only publish in its own namespace. Since this message client's purpose is to receive messages from a different client, the rules of the `subscribeFilter` for topics need to take care of that. So the value of the message client defined in the SAP Event Mesh JSON/YAML file has to be configured to have the value of the `subscribeFilter` to be the same as the value of the `namespace` of the other client defined in the SAP S/4HANA Cloud Extensibility JSON/YAML file.

After both message clients are set up, you have to create a queue in the message client which refers to the SAP Event Mesh service instance. You can name the queue as you like and it will be created in the namespace of the client. This queue can now be subscribed to the topic configured **step 7** in the [Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment \[page 1813\]](#) page. This topic is defined in the namespace of the S/4HANA Cloud Extensibility service descriptor, for example `sap/S4HANAOD/s4hc/myTopic`.

The service instance of SAP Event Mesh is the message client which consumes the messages and should be bound to the actual application. These are the important aspects of the whole configuration:

- When creating a service instance of the SAP S/4HANA Cloud Extensibility service:
  - Use unique `emname` per subaccount
  - Use unique namespace per subaccount, for example `a/b/c`
- When creating a service instance of the SAP Event Mesh service:
  - Use unique `emname` per subaccount
  - Use unique namespace per subaccount, for example `d/e/f`
  - Use the namespace defined in the SAP S/4HANA Cloud Extensibility JSON/YAML file and put it in the `subscribeFilter` parameter

JSON:

### Sample Code

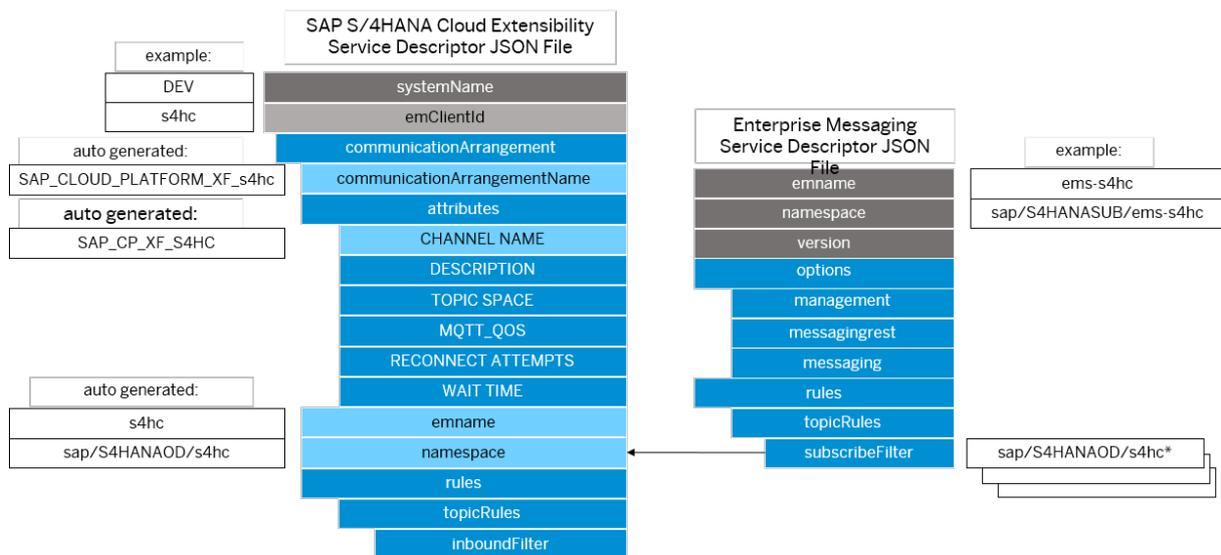

```
"subscribeFilter": [
  "a/b/c/*",
  "${namespace}/*"
]
```

YAML:

### Sample Code

```
subscribeFilter:
- a/b/c/*
- "${namespace}/*"
```

- Create queue for this client
- Subscribe this queue to the topic defined in the namespace of the SAP S/4HANA Cloud Extensibility JSON/YAML file

#### Legend:

- Required property
- Required property whose value is used to generate automatically the values of a set of optional properties
- Optional property
- Optional property whose value is generated automatically based on the value of a required property. If specified, overrides the automatically generated one

## Procedure

Define the JSON file for the SAP Event Mesh service instance following the requirements for the properties and their values listed below:

Parameter	Description
emname	<p>Specifies the name of the SAP Event Mesh client. It is used by SAP Event Mesh to identify clients.</p> <div data-bbox="821 622 1401 913"><p><b>Note</b></p><p>The emname parameter in this descriptor must be unique per subaccount, so it must have the different value than the emname parameter in the SAP S/4HANA Cloud service descriptor. See <a href="#">Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File [page 1817]</a>.</p></div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>• Required: Yes</li><li>• Allowed characters: [a-zA-Z0-9_-]</li><li>• Max length: 100</li></ul> <p><b>Rules/Guidelines:</b> It is unique within a subaccount.</p>
version	<p>It specifies the version of the service descriptor.</p> <div data-bbox="821 1227 1401 1384"><p><b>Note</b></p><p>The version parameter is optional when you use the deprecated syntax. See <a href="#">Syntax for Service Descriptor</a>.</p></div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>• Required: Yes</li><li>• Allowed value: 1.1.0</li></ul>

Parameter	Description
namespace	<p>Namespace for the messaging client.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>The <code>namespace</code> parameter in this descriptor must be unique per subaccount, so it must have the different value than the <code>namespace</code> parameter in the SAP S/4HANA Cloud service descriptor. See <a href="#">Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File [page 1817]</a>.</p> </div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: Yes</li> <li>• Allowed characters: [a-zA-Z0-9//]</li> <li>• Max length: 24</li> <li>• It is unique within a subaccount</li> <li>• Contains exactly three segments, for example <code>d/e/f</code>.</li> </ul>
options	<p>Defines the access channels for the message client.</p>
management	<p>An <code>options</code> attribute.</p> <p>Enables/disables the usage of the management REST APIs.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Default: false</li> <li>• Allowed values: true   false</li> </ul>
<ul style="list-style-type: none"> <li>• <code>messagingrest</code></li> </ul>	<p>An <code>options</code> attribute.</p> <p>Enables/Disables the usage of the messaging REST APIs.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Default: false</li> <li>• Allowed values: true   false</li> </ul>
messaging	<p>An <code>options</code> attribute.</p> <p>Enables/disables the usage of the messaging gateway.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Default: true</li> <li>• Allowed values: true   false</li> </ul>

Parameter	Description
rules	<p>Defines the access privileges of the messaging client.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Required: true</li> <li><b>Guidelines/Rules:</b> In order to allow access to a queue or a topic, the namespace of the corresponding owner client has to be added. The placeholder <code>{namespace}</code> can be used instead of the defined namespace.</li> </ul>
topicRules	<p>A <code>rules</code> attribute.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Type: Object</li> </ul>
subscribeFilter	<p>A <code>topicRules</code> attribute.</p> <p>Filters from which topics a client (receiver) is allowed to receive messages.</p> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>Type: Array</li> <li>Allowed characters: <code>[a-zA-Z*?/]</code></li> <li>Default: no default</li> <li>Example values: <code>#{namespace}/foo/bar/*</code>, <code>#{namespace}/*</code>.</li> </ul> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>The <code>namespace</code> part of the value must be specified exactly as the <code>namespace</code> value of the SAP S/4HANA Cloud Extensibility service descriptor JSON File described in <a href="#">Define SAP S/4HANA Cloud Extensibility Service Descriptor JSON/YAML File [page 1817]</a>.</p> </div>

## JSON File Example

```
{
  "emname": "ems-s4hc",
  "namespace": "sap/S4HANAOD/ems-s4hc",
  "version": "1.1.0",
  "options": {
    "management": true,
    "messagingrest": true,
    "messaging": true
  },
  "rules": {
```

```

    "queueRules": {
      "subscribeFilter": [
        "${namespace}/*"
      ]
    },
    "topicRules": {
      "subscribeFilter": [
        "${namespace}/*",
        "sap/S4HANAOD/s4hc/*"
      ]
    }
  }
}

```

## YAML File Example

```

spec:
  externalName: ''
  serviceOfferingName: enterprise-messaging
  servicePlanName: default
  parameters:
    emname: ems-s4hc
    namespace: sap/S4HANAOD/ems-s4hc
    version: 1.1.0
  options:
    management: true
    messagingrest: true
    messaging: true
  rules:
    queueRules:
      subscribeFilter:
        - "${namespace}/*"
    topicRules:
      subscribeFilter:
        - "${namespace}/*"
        - sap/S4HANAOD/s4hc/*

```

## 5.1.7.4.3.4 Create Queues and Subscribe to Them

### Prerequisites

You have created the SAP S/4HANA Cloud Extensibility service instance in the Cloud Foundry or Kyma environment. See:

- [Create an SAP S/4HANA Extensibility Service Instance in the Cloud Foundry Environment \[page 1813\]](#)
- [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Kyma Environment \[page 1815\]](#)

You have created the SAP Event Mesh service instance in the Cloud Foundry or Kyma environment. See:

- [Create an SAP Event Mesh Service Instance in the Cloud Foundry Environment \[page 1827\]](#)
- [Create an SAP Event Mesh Service Instance in the Kyma Environment \[page 1828\]](#)

### Context

After both instances are created and configured, you can create the topic-to-queue subscription. To do so, you first create a subscription to SAP Event Mesh with plan `standard`. Then, create a queue in the client that refers to the SAP Event Mesh service instance and then subscribe the topic of the namespace of the SAP S/4HANA Cloud Extensibility service to that queue.

#### Note

You can subscribe to the SAP Event Mesh service once per subaccount.

### Procedure

1. Create a subscription to SAP Event Mesh.
  - a. In the SAP BTP cockpit, navigate to the space in which you want to create a service instance.
  - b. In the navigation area, choose **Services** > **Service Marketplace**, and then choose **Event Mesh** in the **Service Marketplace** panel.
  - c. From the **Event Mesh** service tile, choose **Create** and follow the steps in the wizard to subscribe to the service.
  - d. In the **New Instance or Subscription** wizard:
    1. In the **Service** dropdown list, select **Event Mesh**.
    2. In the **Plan** dropdown list, select the **standard** service plan. Choose **Create**.
2. Assign the necessary roles to your user.
  - a. In the SAP BTP cockpit, navigate to your subaccount.

- b. In the navigation area, choose ► [Security](#) ► [Trust Configuration](#) ▾, and then choose [SAP ID Service](#) in the [Trust Configuration](#) panel.
  - c. On the [Role Collection Assignment](#) page, enter the e-mail of your user in the empty field and choose [Show Assignments](#). Then, choose [Assign Role Collection](#).
  - d. In the [Assign Role Collection](#) wizard, select the following role collections:
    - [Enterprise Messaging Administrator](#)
    - [Enterprise Messaging Developer](#)
    - [Enterprise Messaging Display](#)
    - [Enterprise Messaging Subscription Administrator](#)
  - e. Choose [Assign Role Collection](#).
3. Open the SAP Event Mesh application.
    - a. In the SAP BTP cockpit, navigate to the space in which you want to create a service instance.
    - b. In the navigation area, choose ► [Services](#) ► [Instances and Subscriptions](#) ▾.
    - c. In the [Subscriptions](#) tab, choose the [Event Mesh](#) application.
    - d. From the [Event Mesh](#) page, choose [Go to Application](#) and open the SAP Event Mesh application.

#### 🕒 Note

If you are using the sample JSON files when creating the SAP S/4HANA Extensibility and the Event Mesh service instances, you should see 2 message clients in the SAP Event Mesh application, [s4hc](#) and [ems-s4hc](#).

4. Create a queue that is specific to your application.
  - a. Open the message client created when creating the Event Mesh service instance. For example, choose the [ems-s4hc](#) tile.
  - b. Choose the [Queues](#) tab in the message client page and then choose [Create Queue](#).
  - c. Enter a queue name. Note that in the blue field of the [Create a New Queue](#) wizard, the final queue name is displayed. For example, if you write **my-queue** in the [Queue Name](#) field, the final queue name would be [sap/S4HANAOD/ems-s4hc/my-queue](#). Choose [Create](#).
5. Subscribe this queue to the channel topic that SAP S/4HANA Cloud tenant uses to produce events.
  - a. From the [Actions](#) of your newly created queue, select [Queue Subscriptions](#).
  - b. In the [Topic](#) field, enter the topic you configured in the SAP S/4HANA Cloud tenant. For example, `sap/S4HANAOD/s4hc/ce/sap/s4/beh/businesspartner/v1/BusinessPartner/Changed/v1`.
  - c. Choose [Add](#).

## 5.1.7.5 Supported Service Plans for SAP S/4HANA Cloud

The following service plans are available for subaccounts in SAP BTP paired with an SAP S/4HANA Cloud tenant.

### api-access

This service plan enables all communication scenarios, both predefined and custom, which allow you to consume SAP S/4HANA Cloud APIs and integrate your extension applications with the respective SAP S/4HANA Cloud functionality.

- To access the specific documentation of these APIs, see [SAP S/4HANA Cloud APIs at SAP Business Accelerator Hub](#).
- For more information about SAP S/4HANA Cloud communication scenarios see:
  - [Communication Management](#)
  - [Custom Communication Scenarios](#)

#### Note

These service plans have been deprecated:

- [sap\\_com\\_0109](#)
- [sap\\_com\\_0009](#)
- [sap\\_com\\_0008](#)

However, you can still enable these communication scenarios using the [api-access](#) service plan:

- *Sales Order Integration (SAP\_COM\_0109)*: allows you to integrate your extension applications with sales order processing in SAP S/4HANA Cloud. For more information, see [https://api.sap.com/api/API\\_SALES\\_ORDER\\_SRV/overview](https://api.sap.com/api/API_SALES_ORDER_SRV/overview).
- *Product Integration (SAP\_COM\_0009)*: enables you to replicate product master data from client system to SAP S/4HANA system. For more information, see <https://api.sap.com/api/PRODUCTMDMBULKREPLICATEREQUEST/overview>.
- *Business Partner, Customer and Supplier Integration (SAP\_COM\_0008)*: allows you to consume the Business Partner API which enables you to create, read, update, and delete master data related to Business Partners, Suppliers, and Customers in an SAP S/4HANA system. For more information, see [https://api.sap.com/api/API\\_BUSINESS\\_PARTNER/overview](https://api.sap.com/api/API_BUSINESS_PARTNER/overview).

For a sample JSON for these communication scenarios, see [Communication Arrangement JSON/YAML File - Properties \[page 1793\]](#).

### messaging

This service plan enables the *Enterprise Eventing Integration (SAP\_COM\_0092)* communication scenario which allows you to consume SAP S/4HANA Cloud events and create event-based extensions.

### Note

This service plan has been renamed from `sap_com_0092`.

## 5.1.7.6 Configuring Backup

You can back up and restore the destination and the trust configuration settings for the integration between the SAP S/4HANA Cloud and the global account in SAP BTP.

You can back up and restore the following configuration settings:

- The HTTP destination configured during the creation of the SAP S/4HANA Cloud Extensibility service instance. For more, see [Export Destinations](#).
- Your subaccount X.509 certificates. For more information, see [Set up Trust Between Systems](#)
- Your subaccount-specific IdP metadata.  
To download your SAP SuccessFactors IdP SAML 2.0 metadata, in the SAP BTP cockpit, navigate to [Connectivity > Destinations > Download IdP Metadata](#).
- Your identity provider configurations.  
You can back up identity provider configurations with the Identity Provider Management API. For more information see: [Identity Provider Management](#) API.

## 5.1.7.7 Auditing and Logging Information

Here you can find a list of the events that are logged by SAP S/4HANA Cloud Extensibility service. To retrieve the audit logs stored for SAP S/4HANA Cloud Extensibility create a support ticket in component BC-NEO-EXT-S4C.

Events written in audit logs

Event grouping	What events are logged	How to identify related log events	Additional information
Creating an integration	Start creating integration	<ul style="list-style-type: none"> <li>• "type": "s4Integration"</li> <li>• "attributes": [{"name": &lt;object_name&gt;, "new": &lt;integration_details&gt;}]</li> <li>• "status": "BEGIN"</li> </ul>	<p>Event that signifies an integration of a global account with an SAP S/4HANA Cloud system has been started. The log contains integration details such as the SAP S/4HANA Cloud tenant host name and ID, the Identity Authentication tenant ID, the integration ID, and other.</p> <p>The customDetails attribute contains the SAP S/4HANA Cloud user ID of the user who has triggered the integration process.</p>
	Created integration	<ul style="list-style-type: none"> <li>• "type": "s4Integration"</li> <li>• "attributes": [{"name": &lt;object_name&gt;, "new": &lt;integration_details&gt;}]</li> <li>• "status": "END"</li> </ul>	<p>Event that signifies an integration of a global account with an SAP S/4HANA Cloud system has been completed. The log contains integration details such as the SAP S/4HANA Cloud tenant host name and ID, the Identity Authentication tenant ID, the integration ID, and other.</p> <p>The customDetails attribute contains the SAP S/4HANA Cloud user ID of the user who has triggered the integration process.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	Delete integration	<ul style="list-style-type: none"> <li>• "type": "s4Integration"</li> <li>• "attributes": [ {"name": &lt;object_name&gt;, "old": &lt;integration_details&gt; } ]</li> <li>• "status": "BEGIN"</li> </ul>	<p>Event that signifies a deletion of an integration of a global account with an SAP S/4HANA Cloud system has been triggered. The log contains integration details such as the SAP S/4HANA Cloud tenant host name and ID, the Identity Authentication tenant ID, the integration ID, and other.</p> <p>The <code>customDetails</code> attribute contains the SAP S/4HANA Cloud user ID of the user who has triggered the deletion process.</p>
	Deleted integration	<ul style="list-style-type: none"> <li>• "type": "s4Integration"</li> <li>• "attributes": [ {"name": &lt;object_name&gt;, "old": &lt;integration_details&gt; } ]</li> <li>• "status": "END"</li> </ul>	<p>Event that signifies a deletion of an integration of a global account with an SAP S/4HANA Cloud system has been completed. The log contains integration details such as the SAP S/4HANA Cloud tenant host name and ID, the Identity Authentication tenant ID, the integration ID, and other.</p> <p>The <code>customDetails</code> attribute contains the SAP S/4HANA Cloud user ID of the user who has triggered the deletion process.</p>
Setting up the connectivity	Start creating connectivity configuration	<ul style="list-style-type: none"> <li>• "type": "s4Configuration"</li> <li>• "attributes": [ {"name": &lt;object_name&gt;, "new": &lt;connection_details&gt; } ]</li> <li>• "status": "BEGIN"</li> </ul>	<p>Event that signifies a creation of a service instance of the SAP S/4HANA Cloud Extensibility service has been triggered. The log contains details such as the global account ID, the subaccount ID, the communication arrangement, and the authentication mechanism.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	Created connectivity configuration	<ul style="list-style-type: none"> <li>"type": "s4Configuration"</li> <li>"attributes": [{"name": &lt;object_name&gt;, "old": &lt;connection_details&gt;}</li> <li>"status": "BEGIN"</li> </ul>	Event that signifies a creation of a service instance of the SAP S/4HANA Cloud Extensibility service has been completed. The log contains details such as the global account ID, the subaccount ID, the communication arrangement, and the authentication mechanism.
	Start deleting connectivity configuration	<ul style="list-style-type: none"> <li>"type": "s4Configuration"</li> <li>"attributes": [{"name": &lt;object_name&gt;, "old": &lt;connection_details&gt;}</li> <li>"status": "BEGIN"</li> </ul>	Event that signifies the deletion of a service instance of the SAP S/4HANA Cloud Extensibility service has been started. The log contains details such as the global account ID, the subaccount ID, the communication arrangement, and the authentication mechanism.
	Deleted connectivity configuration	<ul style="list-style-type: none"> <li>"type": "s4Configuration"</li> <li>"attributes": [{"name": &lt;object_name&gt;, "old": &lt;connection_details&gt;}</li> <li>"status": "END"</li> </ul>	Event that signifies the deletion of a service instance of the SAP S/4HANA Cloud Extensibility service has been completed. The log contains details such as the global account ID, the subaccount ID, the communication arrangement, and the authentication mechanism.

The following information is described in the table columns:

- [Event grouping](#) - Events that are logged with a similar format or are related to the same entities.
- [What events are logged](#) - Description of the security or data protection and privacy related event that is logged.
- [How to identify related log events](#) - Search criteria or key words, that are specific for a log event that is created along with the logged event.
- [Additional information](#) - Any related information that can be helpful.

## 5.1.7.8 Accessibility Features in SAP S/4HANA Cloud Extensibility Service

To optimize your experience of SAP S/4HANA Cloud Extensibility service, SAP Business Technology Platform (SAP BTP) provides features and settings that help you use the software efficiently.

### Note

SAP S/4HANA Cloud Extensibility service runs on the SAP BTP cockpit. For this reason, accessibility features for SAP BTP cockpit also apply. See the accessibility documentation for SAP BTP cockpit on SAP Help Portal at [Accessibility Features in SAP BTP cockpit \[page 1937\]](#).

For more information on screen reader support and keyboard shortcuts, see [Accessibility for End Users](#).

## 5.1.8 Extending SAP Marketing Cloud in the Cloud Foundry and Kyma Environment

### Overview

### Note

The SAP S/4HANA Cloud Extensibility service is available for the EU-only access regions for feature set B global accounts. See [Regions](#).

EU Access is not available for feature set A global accounts for the SAP S/4HANA Cloud Extensibility service.

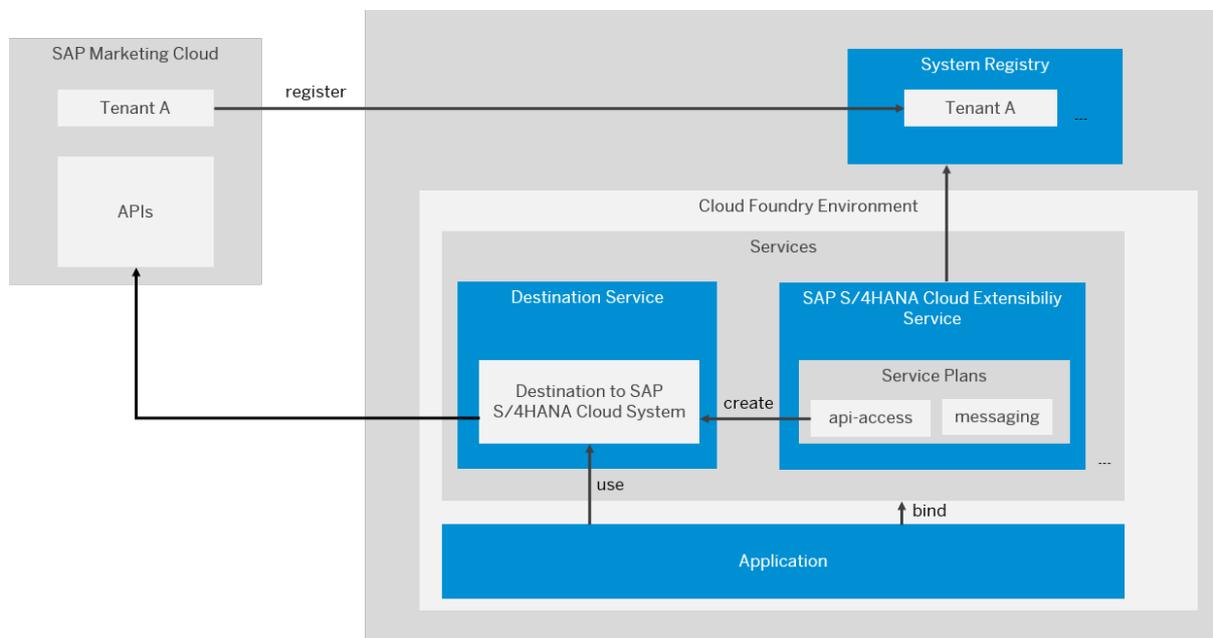

SAP BTP offers a standard way for extending SAP solutions.

You can extend SAP Marketing Cloud in the Cloud Foundry or the Kyma environment without disrupting the performance and the core processes. When building extension applications, you can also benefit from the automation of the integration between the cloud platform and SAP Marketing Cloud.

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

The following graphic provides a high-level overview of the integration between the cloud platform SAP Marketing Cloud:

## Process Flow

To integrate SAP BTP and SAP Marketing Cloud so that you can build extension applications, you have to use the SAP S/4HANA Cloud Extensibility service. All the steps are the same from the SAP BTP side. You register an SAP Marketing Cloud system in the SAP BTP cockpit. Then, you take the generated token and use it to configure the connectivity on the SAP Marketing Cloud side. These are the tasks you need to follow:

Integrating SAP BTP and SAP Marketing Cloud

### Process Step

1. Connect the SAP Marketing Cloud system you want to extend with the corresponding global account in SAP BTP.

During the pairing process you create an registration token which is then used by the SAP Marketing Cloud system tenant administrator to configure the integration on the SAP Marketing Cloud system side.

### Related Documentation

[Register an SAP Marketing Cloud System in a Global Account in SAP BTP \[page 1847\]](#)

### Note

You cannot migrate the registered SAP Marketing Cloud systems between global accounts.

If you want to start using another global account, you will have to register your SAP Marketing Cloud systems again.

## Process Step

## Related Documentation

---

2. Make the SAP Marketing Cloud system accessible in the subaccounts in SAP BTP in which you want to build your extension applications.

[Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#)

To do so, you configure the entitlements and assign the corresponding quota and service plans to the subaccounts where the extension applications will reside for the system you registered in the previous step.

---

## Process Step

## Related Documentation

3. Configure the communication flow.

You have the following options:

- Consume the SAP Marketing Cloud APIs (inbound connection) or consume APIs exposed by the extension application from SAP S/4 HANA Cloud (outbound connection). To do so, you create a service instance of the [SAP S/4HANA Cloud Extensibility](#) service using the [api-access](#) service plan.

During the service instance creation an HTTP destination on a subaccount level is automatically generated in this subaccount. It contains all instance binding properties which are sufficient to establish connection to the SAP Marketing Cloud system. When creating the service instance, you configure the communication arrangement and the authentication type for the connection. The following authentication scenarios for SAP Marketing Cloud are supported:

- Basic Authentication (inbound and outbound connections)
- OAuth 2.0 SAML Bearer Assertion (inbound connections)
- OAuth 2.0 Client Credentials (outbound Connections)
- No Authentication (outbound connections)

Both predefined and custom communication scenarios are supported.

- Enable the consumption of SAP Marketing Cloud events.

If you want to create event-based extensions for SAP Marketing Cloud using the SAP Enterprise Messaging service, you have to create a service instance of the [SAP S/4HANA Cloud Extensibility](#) service using the [messaging](#) service plan.

- A combination of both

- [Creating a Service Instance to Consume the SAP S/4HANA Cloud APIs \[page 1787\]](#)
- [Enable the Consumption of SAP S/4HANA Cloud Events \[page 1809\]](#)

## 5.1.8.1 Register an SAP Marketing Cloud System in a Global Account in SAP BTP

To connect an SAP Marketing Cloud system with a global account in SAP BTP, you need to register the system in the corresponding global account.

### Prerequisites

- See [Registering an SAP System \[page 1753\]](#)
- You are an administrator of the global account where you want to register your SAP Marketing Cloud system.
- To configure the integration on the SAP Marketing Cloud system side, you need to be an administrator of the SAP Marketing Cloud tenant.

### Context

The registration process is based on a registration token that is used for the pairing of the SAP Marketing Cloud system and the corresponding global account. You create the token in the global account, and then the tenant administrator of the respective SAP Marketing Cloud system uses the token to start the automated registration process on the SAP Marketing Cloud system side.

#### Note

When registering SAP Marketing Cloud systems, you can have up to 1000 tokens per global account ready to be used. Tokens that are already used to register an SAP Marketing Cloud system are not included in this number.

This means that you cannot have more than 1000 systems in the [Systems](#) list of type SAP Marketing Cloud with an empty status and generated token that is not used yet.

The registration process has the following states displayed in the cockpit:

- No status displayed in the [Status](#) column - the registration token for an SAP system has been created but the registration on the respective SAP solution system side has not been performed or completed.
- [Registered](#) - the registration token has been used and the automated registration process has been successfully completed. The system can be assigned to a formation on the [Formations](#) page in the cockpit.
- [Error while Registering](#) - the registration has failed. Remove the system and then add it to the [Systems](#) list and try to register it again
- [Deregistering](#) - a deregistration process has started in the SAP BTP cockpit. As a result, the connection between the SAP solution system and the global account in SAP BTP is removed. The system remains in the list and you can register it again later on.  
Once a system is registered, you can deregister it only after removing it from all entitlement configurations and formations it takes part in.

### Note

You will not be able to deregister a system if its status is one of the following:

- [Error while Registering](#)
- [Deregistering](#)

- [Error while Deregistering](#) - the deregistration has failed. Try to deregister the system again. If the problem persists, you have to report a case in the `BC-NEO-EXT-S4C` component..
- [Removing](#) - a system removal process has started in the SAP BTP cockpit. As a result, the link between the SAP solution and SAP BTP is destroyed and the system is removed from the list. To register the system again, first you must add it to the list anew, and then initiate the registration procedure. Once a system is registered, you can only remove it if you first deregister it.

### Note

You will not be able to remove a system if its status is one of the following:

- [Registered](#)  
You first need to deregister the system.
- [Deregistering](#)
- [Error while Deregistering](#)

- [Error while Removing](#) - the system removal has failed. Try to deregister the system again. If the problem persists, you have to report a case in the `BC-NEO-EXT-S4C` component.

### Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

### Note

You cannot migrate the registered SAP Marketing Cloud systems between global accounts.

If you want to start using another global account, you will have to register your SAP Marketing Cloud systems again.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#) ►.
2. On the [Systems](#) page, choose [Add System](#).
  - a. Enter a name for the system you want to register.

### Note

Use only printable ASCII characters.

### → Tip

We recommend that you indicate the type of the system when specifying the system name. For example, `<mysystem>-S/4HANA-cloud`. This helps you identify the system type when assigning systems to a formation.

- b. In the *Type* dropdown list, select *SAP Marketing Cloud*.
- c. Choose *Add*.
- d. Choose *Get Token*.

The system generates the registration token.

- e. Copy the registration token and send it to the tenant administrator for the respective SAP Marketing Cloud system. You need it for configuring the integration on the extended SAP Marketing Cloud system side.

You can also get the registration token later, once the system appears in the list on the *Systems* page.

The registration token is valid for 7 days after it has been generated. When a token is not used within its validity period, it is no longer valid and cannot be used for registering an SAP Marketing Cloud system. If the validity of the token expires before you use it to configure the integration on the SAP Marketing Cloud system side and complete the registration, you need to get a new token. You can then copy it and use it to complete the registration.

### 📌 Note

A registration token can be used only once, for registering a single SAP Marketing Cloud system.

- f. Close the wizard.

The SAP Marketing Cloud system appears in the list of systems on the *Systems* page. Its *Status* field is empty because the registration process is not yet completed.

3. Start the automated registration process on the SAP Marketing Cloud system side. To do so, proceed as described in as described in [Trigger the Registration in the SAP Marketing Cloud Tenant \[page 1850\]](#).

### 📌 Note

You can register a system with the same name only once per global account. Once you have started a registration process for a system with a specified name you can no longer register a system with the same name and connect it with the same global account, unless you delete the corresponding extension in the *Maintain Extensions on SAP BTP* in the SAP Marketing Cloud tenant. If the registration process fails, you need to delete the failed extension from the SAP Marketing Cloud tenant and create a new registration token in the cockpit for the corresponding system to be able to start the automated registration process again.

4. Check the status of the registration process. To do so, in the cockpit navigate to your global account, and on the *Systems* page, check if the status of the SAP Marketing Cloud system has changed to *Registered*.

If you are already on the *Systems* page, refresh the page to check if the status has changed.

## Next Steps

[Trigger the Registration in the SAP Marketing Cloud Tenant \[page 1850\]](#)

## Related Information

[Registering an SAP System \[page 1753\]](#)

[Deregistering or Removing a System \[page 1757\]](#)

### 5.1.8.1.1 Trigger the Registration in the SAP Marketing Cloud Tenant

Use this procedure to trigger the registration process for an SAP Marketing Cloud system that you want to pair with your global account in SAP BTP.

#### Prerequisites

You are an SAP Marketing Cloud tenant administrator.

#### Procedure

1. Log on to the SAP Marketing Cloud tenant, go to *Home, Communication Management* tab and then choose the *Maintain Extensions on SAP BTP* tile.
2. In the *Maintain Extensions on SAP BTP* screen, in the *Extensions* section, choose *New*.
3. In the *Integration Token* field, enter the content of the registration token from the SAP BTP cockpit.
4. Choose *Save*. A new entry in the table appears with status *Enabling*.
5. After the integration has finished successfully, you can refresh the table.

The status of the integration should have changed to *Enabled*.

## Process Flow

To integrate SAP BTP and SAP SuccessFactors so that you can build extension applications, you need to perform the following tasks:

Integrating SAP BTP and SAP SuccessFactors

Process Step	Related Documentation
<p>1. Connect the SAP SuccessFactors system that you want to extend with the corresponding global account in SAP BTP.</p> <p>During the pairing process you create a registration token which is then used by the SAP SuccessFactors system tenant administrator to configure the integration on the SAP SuccessFactors system side.</p>	<p><a href="#">Register an SAP SuccessFactors System in a Global Account in SAP BTP [page 1853]</a>.</p> <div><p><b>Note</b></p><p>You cannot migrate the registered SAP SuccessFactors systems between global accounts.</p><p>If you want to start using another global account, you will have to register your SAP SuccessFactors systems again.</p></div>

<p>5. If you have performed an automated instance refresh or your cloud operators have performed a manual instance refresh, you need to restore some of the extension configuration settings.</p>	<a href="#">Restore Configuration Settings After an Instance Refresh [page 1870]</a>

## 5.1.9.1 Register an SAP SuccessFactors System in a Global Account in SAP BTP

To connect an SAP SuccessFactors system with a global account in SAP BTP, you need to register the system in the corresponding global account.

### Prerequisites

- See [Registering an SAP System \[page 1753\]](#).
- You are an administrator of the global account where you want to register your SAP SuccessFactors system.
- You have a dedicated SAP SuccessFactors company instance.
- You have a user with permissions to access *Extension Center* in SAP SuccessFactors Admin Center that include:

- *Admin Access to MDF OData API* permission from the *Metadata Framework* category
- *Create Integration with SAP BTP* permission from the *Manage Extensions on SAP BTP* category

To assign these permissions to your user, you might need the help of an administrator.

To get a user with the respective permissions, follow these steps:

1. Make sure you have an access to the SAP SuccessFactors Admin Center. See [Permission to Access Admin Center](#).
2. Add your user to an already existing group or create a new dedicated group and add your user. See [Creating Dynamic Permission Groups](#).
3. Use an already existing role or create a new dedicated role. See [Creating Permission Roles](#).
4. Assign the respective permissions to your role. See [Assigning Permissions to a Role](#).
5. Add your role to the dedicated group. See [Assigning Roles to Groups](#).
6. To fully activate the permissions, log out and log in again to the SAP SuccessFactors company instance.

## Context

The registration process is based on a registration token that is used for the pairing of the SAP SuccessFactors company and the corresponding global account in SAP BTP. You create the token in the global account, and then start the automated registration process on the SAP SuccessFactors company side using this token.

### Note

When registering SAP SuccessFactors systems, you can have up to 1000 tokens per global account ready to be used. Tokens that are already used to register an SAP SuccessFactors system are not included in this number.

This means that you cannot have more than 1000 systems in the [Systems](#) list of type SAP SuccessFactors with an empty status and generated token that is not used yet.

The registration process has the following states displayed in the cockpit:

- No status displayed in the [Status](#) column - the registration token for an SAP system has been created but the registration on the respective SAP solution system side has not been performed or completed.
- [Registered](#) - the registration token has been used and the automated registration process has been successfully completed. The system can be assigned to a formation on the [Formations](#) page in the cockpit.
- [Error while Registering](#) - the registration has failed. Remove the system and then add it to the [Systems](#) list and try to register it again
- [Deregistering](#) - a deregistration process has started in the SAP BTP cockpit. As a result, the connection between the SAP solution system and the global account in SAP BTP is removed. The system remains in the list and you can register it again later on.  
Once a system is registered, you can deregister it only after removing it from all entitlement configurations and formations it takes part in.
- [Error while Deregistering](#) - the deregistration has failed. Try to deregister the system again. If the problem persists, you have to report a case in the `BC-NEO-EXT-SF` component.
- [Removing](#) - a system removal process has started in the SAP BTP cockpit. As a result, the link between the SAP solution and SAP BTP is destroyed and the system is removed from the list. To register the system again, first you must add it to the list anew, and then initiate the registration procedure.  
Once a system is registered, you can only remove it if you first deregister it.

### Note

You will not be able to remove a system if its status is one of the following:

- [Registered](#)  
You first need to deregister the system.
  - [Deregistering](#)
  - [Error while Deregistering](#)  
Try to deregister the system again.
- [Error while Removing](#) - the system removal has failed. Try to deregister the system again. If the problem persists, you have to report a case in the `BC-NEO-EXT-SF` component.

### Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. In the SAP BTP cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#).
2. On the [Systems](#) page, choose [Add System](#).
  - a. Enter a name for the system you want to register.

### Note

Use only printable ASCII characters.

### Tip

We recommend that you indicate the type of the system when specifying the system name. For example, `<mysystem>-SuccessFactors`. This helps you identify the system type when assigning systems to a formation.

- b. In the [Type](#) dropdown list, select SAP SuccessFactors.
- c. Choose [Add](#).
- d. Choose [Get Token](#).

The system generates the registration token.
- e. Copy the registration token and send it to the tenant administrator for the respective SAP SuccessFactors system. You need it for configuring the integration on the extended SAP SuccessFactors system side.

You can also get the registration token later, once the system appears in the list on the [Systems](#) page.

The registration token is valid for 7 days after it has been generated. When a token is not used within its validity period, it is no longer valid and cannot be used for registering an SAP SuccessFactors system. If the validity of the token expires before you use it to configure the integration on the SAP SuccessFactors system side and complete the registration, you need to get a new token. You can then copy it and use it to complete the registration.

### Note

A token can be used only once, for registering a single SAP SuccessFactors system.

- f. Close the wizard.

The SAP SuccessFactors system appears in the list of systems on the [Systems](#) page. Its [Status](#) field is empty because the registration process is not yet completed.
3. Start the automated integration process on the SAP SuccessFactors company side:

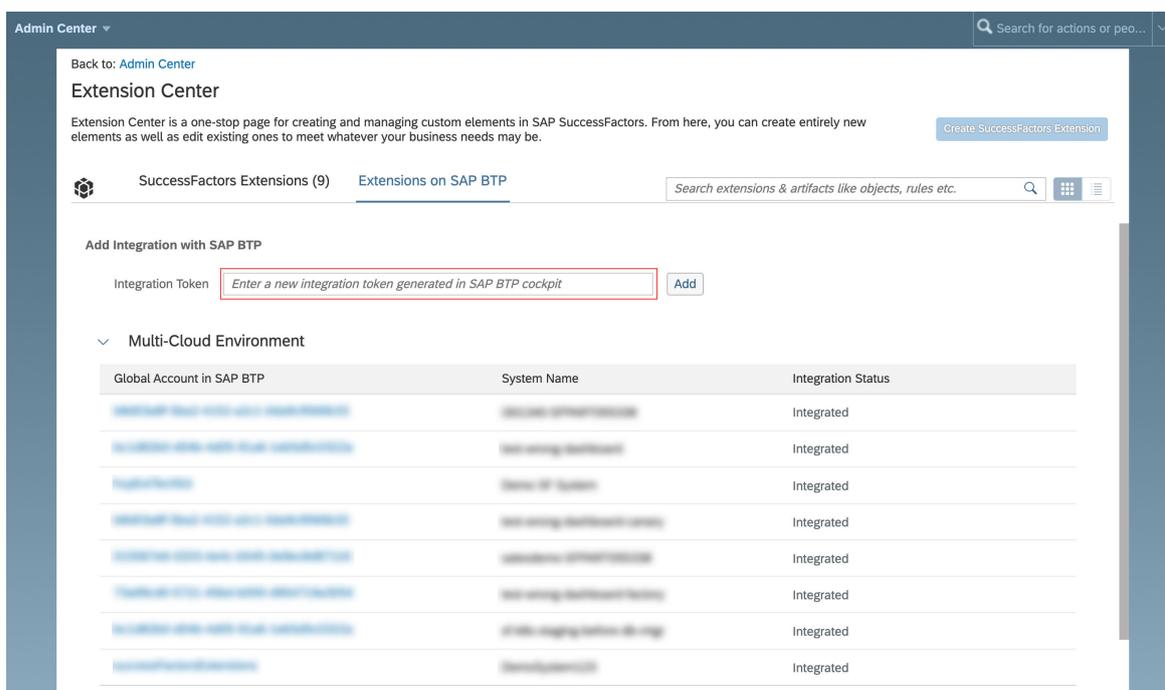

### Note

If you do not have permissions to access the Extension Center for the corresponding SAP SuccessFactors system, you need to send the registration token to a user with such permissions who will configure the integration on the SAP SuccessFactors system side. For the requires permissions, check the prerequisites.

1. In SAP SuccessFactors [Admin Center](#), navigate to [Extension Center](#).

- On the *Extensions on SAP BTP* tab page, navigate to the *Add Integration with SAP BTP* screen area, and paste the registration token in the *Integration Token* input field.
- Choose *Add*.

The system appears in the integration list in the *Multi-Cloud Environment* screen area, and the status of the integration is displayed in the *Integration Status* column. To refresh the status of the process, choose the *Check Status* icon. Wait for the integration to finish.

- In the cockpit, check the status of the registration process. To do so, navigate to your global account, and on the *Systems* page, check if the status of the SAP System has changed to *Registered*.

If you are already on the *Systems* page, refresh the page to check if the status has changed.

### Note

You can register a system only once with the same name per global account.

### Note

You cannot migrate the registered SAP SuccessFactors systems between global accounts.

If you want to start using another global account, you will have to register your SAP SuccessFactors systems again.

## Related Information

[Registering an SAP System \[page 1753\]](#)

[Deregistering or Removing a System \[page 1757\]](#)

## 5.1.9.2 Configure the Entitlements for the SAP SuccessFactors Extensibility Service

Configure the required entitlements to make the SAP SuccessFactors HXM Suite OData APIs of the registered SAP SuccessFactors system accessible in your subaccount in which your extension applications will reside.

### Prerequisites

- You are an administrator of the global account in SAP BTP.
- The subaccount is in the SAP BTP, Cloud Foundry environment with enabled Cloud Foundry, or Kyma, or both capabilities.
- You have registered an SAP SuccessFactors system. See [Register an SAP SuccessFactors System in a Global Account in SAP BTP \[page 1853\]](#).

### Context

An entitlement is your right to provision and consume a resource. In other words, the entitlement is the *api-access* service plan that you're entitled to use, and the *sso-configuration* service plan that allows you to register an assertion consumer service in SAP SuccessFactors automatically.

Depending on feature set you are using, you need to follow different steps to configure the entitlements. See [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

### Procedure

1. In the SAP BTP cockpit, navigate to your global account.
2. Depending on the feature set you are using, you need to follow different steps to configure the entitlements.
  - For feature set A, follow these steps:
    1. In the navigation area, choose **Entitlements** > **Subaccount Assignments**.
    2. Select your subaccount from the drop down menu, choose **Go**, and then choose **Configure Entitlements**.

#### → Tip

If your global account contains more than 20 subaccounts, choose  to open up the value help dialog. There you can filter subaccounts by role, environment and region to make your selection easier and faster. You can only select a maximum of 50 subaccounts at once.

- If you are using feature set B, you have to:

1. In the navigation area, choose **Entitlements > Entity Assignments**.
  2. On the *Entity Assignments* screen, select your subaccount in the *Select Entities* field.
  3. Choose *Go*, and then choose *Configure Entitlements*.
3. Choose *Add Service Plans*, and then select the *SAP SuccessFactors Extensibility* service.

#### Note

To have the *SAP SuccessFactors Extensibility* service in the list, you need to have registered at least one SAP SuccessFactors system.

4. In the *Available Service Plans* area, select the system you have registered and the *api-access* and *sso-configuration* service plans, and then choose *Add 2 Service Plans*.

## Related Information

[Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)

### 5.1.9.3 Create a Service Instance to Consume the SAP SuccessFactors HXM Suite OData API

To enable the integration of your extension applications with the SAP SuccessFactors system you have registered in the global account in SAP BTP, you first need to create a service instance of the corresponding service.

## Context

In both Cloud Foundry and Kyma environment, you consume services by creating a service instance. Service instances are created using a specific service plan.

To allow applications running on SAP BTP to consume SAP SuccessFactors HXM Suite OData APIs, you need to create a service instance of the SAP SuccessFactors Extensibility service using the *api-access* service plan.

You create the service instance in your subaccount with the respective environment enabled. When creating the service instance, you configure the authentication type for the communication by specifying the required configurations in a JSON format. SAP BTP supports the following authentication scenarios for SAP SuccessFactors:

- OData access with OAuth 2.0 SAML bearer assertion  
To use this authentication type, you must protect your application. See [Adding Authentication and Authorization \[page 465\]](#).
- OData access with OAuth 2.0 SAML bearer assertion with technical user

The process for creating a service instance depends on the environment you are using:

- For Cloud Foundry environment, see [Create an SAP SuccessFactors Extensibility Service Instance in the Cloud Foundry Environment \[page 1859\]](#).
- For Kyma environment, see [Create an SAP SuccessFactors Extensibility Service Instance in the Kyma Environment \[page 1861\]](#).

### 5.1.9.3.1 Create an SAP SuccessFactors Extensibility Service Instance in the Cloud Foundry Environment

To enable the integration of your extension applications with the SAP SuccessFactors system you have registered in the global account in SAP BTP, you first need to create a service instance of the corresponding service.

#### Prerequisites

- You have registered an SAP SuccessFactors system. See [Register an SAP SuccessFactors System in a Global Account in SAP BTP \[page 1853\]](#).
- Before creating an SAP SuccessFactors Extensibility service instance in the Cloud Foundry environment, see [Create a Service Instance to Consume the SAP SuccessFactors HXM Suite OData API \[page 1858\]](#).
- Have enabled Cloud Foundry environment for your subaccount. See [Enable Environment or Create Environment Instance \[page 1986\]](#).
- Have configured the entitlements to the SAP SuccessFactors Extensibility service. See [Configure the Entitlements for the SAP SuccessFactors Extensibility Service \[page 1857\]](#).

#### Context

In the Cloud Foundry environment, you consume services by creating a service instance. Service instances are created using a specific service plan. The services are offered in the Service Marketplace, from which you can create service instances to provision the reserved resources.

To allow applications running on SAP BTP to consume SAP SuccessFactors HXM Suite OData APIs, you need to create a service instance of the SAP SuccessFactors Extensibility service using the *api-access* service plan.

You create the service instance in a space of your subaccount. When creating the service instance, you configure the authentication type for the communication by specifying the required configurations in a JSON format. SAP BTP supports the following authentication scenarios for SAP SuccessFactors:

- OData access with OAuth 2.0 SAML bearer assertion  
To use this authentication type, you must protect your application. See [Authentication for Applications](#).
- OData access with OAuth 2.0 SAML bearer assertion with technical user

During the creation of the service instance, a destination on a subaccount level with the same name as the service instance name is automatically created in this subaccount. It contains all instance binding properties which are sufficient to establish connection to the SAP SuccessFactors system.

### Note

Make sure that you don't already have a destination with the same name as the service instance. If you do, you will not be able to create the service instance.

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount in which you want to create a service instance.
2. In the navigation area, choose **Services** > **Service Marketplace**.
- All services available to you appear.
3. To enable the integration with an SAP SuccessFactors system that you have registered in SAP BTP global account, choose *SAP SuccessFactors Extensibility*.
4. In the *SAP SuccessFactors Extensibility* page, choose *Create*.
5. In the *New Instance or Subscription* wizard:
  - a. In the *Service* dropdown list, ensure you have selected the *SAP SuccessFactors Extensibility* service.
  - b. In the *Plan* dropdown list, select the *api-access* service plan.
  - c. In the *Runtime Environment* dropdown list, select *Cloud Foundry*.
  - d. In the *Space* dropdown list, select your space. If you haven't create a space yet, you can do it at this point.
  - e. In the *System Name* dropdown list, select the SAP SuccessFactors system you have registered.
  - f. In the *Instance Name* field, enter a name for your instance. Choose *Next*.
  - g. (Optional) To define a technical user the access to the SAP SuccessFactors HXM Suite API, specify a JSON file or specify parameters in the JSON format. If you decide to add a technical user later on, you have to delete this service instance and create it again. Choose *Next*.

For more information about the structure of the JSON file, see [API Access Configuration JSON File \[page 1863\]](#).

  - h. Choose *Create*.

## Results

After you have created the service instance:

- The newly created instance appears in the list of instances in the *Instance and Subscriptions* page.
- An HTTP destination on a subaccount level with the same name as the service instance name is automatically generated in this subaccount.

Alternatively, you can use the Cloud Foundry Command Line Interface (cf CLI) to create the service instance using the technical name of the SAP SuccessFactors Extensibility service which is **sap-successfactors-extensibility**.

For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface](#).

#### Note

You can use the cf CLI to troubleshoot if the creation of the service instance fails. To do that, use this command in the cf CLI:

```
cf service <service_instance_name>
```

## Next Steps

After creating the *SAP SuccessFactors Extensibility* service instance, you have the following options for configuring the connectivity for your extension application:

- Bind the instance to an application, and it will be assigned an access URL and credentials to the corresponding API. For more information about binding applications to service instances, see [Binding Service Instances to Applications](#).
- Consume the automatically generated destination.  
To consume the destination, you use the Destination service. You can either consume the Destination service directly, or configure the application router to consume it.

#### Note

The name of the destination is the same as the name of the service instance you have created.

- For more information about consuming the destination service using the application router, see [Application Routes and Destinations](#).
- For more information about consuming the destination service directly, see [Consuming the Destination Service \(Cloud Foundry Environment\)](#).

## 5.1.9.3.2 Create an SAP SuccessFactors Extensibility Service Instance in the Kyma Environment

### Prerequisites

- Before creating an SAP SuccessFactors Extensibility service instance in the Kyma environment, see [Create a Service Instance to Consume the SAP SuccessFactors HXM Suite OData API \[page 1858\]](#).
- Have the Kyma environment enabled for the subaccount you are using. See [Create the Kyma Instance \[page 2749\]](#).
- Configure the roles in the Kyma environment. See [Assign Roles in the Kyma Environment \[page 2766\]](#).
- The SAP BTP Operator module is enabled. See [Add and Delete a Kyma Module \[page 2764\]](#)

- Have the entitlements of the SAP SuccessFactors Extensibility service configured. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service \[page 1786\]](#).

## Context

During the creation of the service instance, a destination on the subaccount level with the same name as the service instance name is automatically created in this subaccount. It contains all instance binding properties which are sufficient to establish connection to the SAP SuccessFactors system.

### Note

Make sure that you don't already have a destination with the same name as the service instance. If you do, you will not be able to create the service instance.

## Procedure

1. Navigate to the subaccount for which you want to create an SAP SuccessFactors Extensibility service instance.
2. On the subaccount *Overview* page, in the *Kyma Environment* section, open the Kyma dashboard.
3. Choose *Namespaces* from the left-hand side navigation and open the namespace in which you want to create a service instance.
4. Choose **▶ Service Management ▶ Service Instances ▶** from the left-hand side navigation.
5. In the *Service Instances* page, choose *Create Service Instance* in the upper right-hand corner. A new dialog opens.
6. Choose the *Advanced* tab and fill in the following fields:
  - Give a meaningful name of the new SAP SuccessFactors Extensibility service instance.
  - In the *Offering Name* field, enter **sap-successfactors-extensibility**, which is the technical name of the SAP SuccessFactors Extensibility service.
  - In the *Plan Name* field, enter **api-access**.
  - Expand *Instance Parameters*.  
To define the authentication type for the API access, specify the parameters listed in this JSON file: [API Access Configuration JSON File \[page 1863\]](#).
7. Choose *Create*.

## Next Steps

After creating the *SAP SuccessFactors Extensibility* service instance, you have to bind the instance to an application, and it will be assigned an access URL and credentials to the corresponding API. See [Using SAP BTP Services in the Kyma Environment \[page 1732\]](#).

### 5.1.9.3.3 API Access Configuration JSON File

Use the authentication type JSON descriptor to define the authentication type for the inbound connectivity to the SAP SuccessFactors HXM Suite OData API.

Parameter	Description
systemName	<p>The name of the system you have registered in a global account in SAP BTP.</p> <div data-bbox="804 618 1394 734"><p><b>Note</b></p><p>The system must be in status <i>Registered</i>.</p></div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"><li>• Required: Yes</li></ul>

Parameter	Description
technicalUser	<p>The name of the technical user for consuming the SAP SuccessFactors HXM Suite OData API without a logged-in user.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>This property specifies the <i>systemUser</i> property in the destination that is created as a result of creating the SAP SuccessFactors Extensibility service instance.</p> <p>The <i>systemUser</i> is deprecated and will be removed soon. We recommend that you work on behalf of specific (named) users instead of working with a technical user.</p> <p>As an alternative for technical user communication, we strongly recommend that you use the Mutual Transport Layer Security (mTLS) protocol. See <a href="#">Using Mutual Transport Layer Security (mTLS) [page 1910]</a>.</p> </div> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>📄 Note</b></p> <p>The technical user can be any user with the respective permissions. These permissions depend on the use case and the API you want to access. To find out which permission you need to assign to the technical user, go to <a href="#">SAP Business Accelerator Hub</a>, find the SAP SuccessFactors API you want to access and from the <i>Overview</i> tab go to the <i>Documentation</i> section and open the <a href="#">help.sap.com</a> link. There you find the right information for each API.</p> </div> <p><b>Rules/Guidelines</b></p> <ul style="list-style-type: none"> <li>• Required: No</li> <li>• Allowed characters: [a-zA-Z0-9_-]</li> <li>• Max length: 100</li> </ul>

## Example

```
{
  "systemName": "MY_SYSTEM",
  "technicalUser": "technicalonboarder"
}
```

## 5.1.9.4 Configure Single Sign-On Between a Subaccount in SAP BTP and SAP SuccessFactors

Use this procedure to configure the single sign-on (SSO) between SAP BTP and the SAP SuccessFactors system.

### Prerequisites

You have the *UI and Role Administrator* role assigned to your user. See [Security Administration: Managing Authentication and Authorization \[page 2012\]](#).

### Context

The authentication to SAP SuccessFactors applications is restricted to the authorized users. The identification of a user is verified by the identity provider, as specified by SAML 2.0. The Identity Authentication service stores a list of all users that are allowed to access the SAP SuccessFactors system along with their credentials. The integration between the SAP SuccessFactors and the identity provider is based on a trust configuration. When a user attempts to access SAP SuccessFactors for the first time, the system redirects the user to the identity provider for identification. From then on, the user session is kept active, and the user is no longer prompted for credentials when trying to use the SAP SuccessFactors application. This is called single sign-on (SSO).

To ensure the required security for accessing the applications, you need to configure the single sign-on between the subaccount in SAP BTP and the SAP SuccessFactors system using a SAML identity provider. The single sign-on requires both solutions to be configured as trusted SAML service providers for the identity provider, and at the same time, the identity provider to be configured as trusted identity provider for the two solutions.

If you have an account in the Cloud Foundry environment, you need to set up the single sign-on (SSO) according to this environment.

### Procedure

1. [Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#).
2. [Configure the Subaccount as a Trusted Service Provider in SAP SuccessFactors \[page 1866\]](#).

## 5.1.9.4.1 Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP

Use this procedure to set up the trust configuration of the subaccount in SAP BTP and add SAP SuccessFactors as an identity provider.

### Procedure

1. Download SAML metadata from the SAP SuccessFactors system.
  - a. Go to `https://<sap_successfactors_system>/idp/samlmetadata?company=<company_id>&cert=sha2` where:
    - `<sap_successfactors_system>` is the hostname of your SAP SuccessFactors system
    - `<company_id>` is the ID of your SAP SuccessFactors company
  - b. When you are prompted, save the file on your local file system and change its extension to **.xml**.
2. Register the SAP SuccessFactors identity provider in the SAP BTP cockpit.
  - a. Open the cockpit and navigate to your subaccount.
  - b. Choose **Security > Trust Configuration**.
  - c. Choose **New Trust Configuration**.
  - d. To upload the SAML metadata you downloaded in step 1, choose **Upload**. Browse to the XML file you saved and select it. Some of the fields are automatically filled in.
  - e. In the **Name** field, enter a meaningful name for the trust configuration.
  - f. Save the changes.
3. Make the trust configuration to the SAP SuccessFactors identity provider the only configuration that is active.

## 5.1.9.4.2 Configure the Subaccount as a Trusted Service Provider in SAP SuccessFactors

To configure the subaccount as a trusted service provider in SAP SuccessFactors, you have to create an SAP SuccessFactors Extensibility service instance using the *sso-configuration* service plan.

### Prerequisites

- [Register an SAP SuccessFactors System in a Global Account in SAP BTP \[page 1853\]](#)
- [Configure the Entitlements for the SAP SuccessFactors Extensibility Service \[page 1857\]](#)
- [Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#)

## Context

### Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

With the SAP SuccessFactors Extensibility service instance using the *sso-configuration* service plan, you can create automatically an assertion consumer service in SAP SuccessFactors for the subaccount in which this service instance is created and a logout URL for each extension application you have deployed in SAP BTP that is extending the functionality of the registered SAP SuccessFactors system. To create an assertion consumer service, you either go to the SAP SuccessFactors Provisioning and create these assertion consumer services manually, or create them automatically in the SAP BTP cockpit via an SAP SuccessFactors Extensibility service instance using the *sso-configuration* service plan without logging in to the Provisioning. If you want to create an assertion consumer service in the Provisioning manually, see:

- [Register the Assertion Consumer Service of the Subaccount in SAP BTP in SAP SuccessFactors \[page 1899\]](#)
- [Register the Assertion Consumer Service for Every Extension Application in SAP SuccessFactors \[page 1900\]](#)

To create an assertion consumer service automatically, you create an SAP SuccessFactors Extensibility service instance of plan *sso-configuration* providing all the necessary information in a JSON file. You can have only one service instance of plan *sso-configuration* per subaccount.

In the JSON file you provide, in the *systemName* parameter, you specify the SAP SuccessFactors system where you want the assertion consumer services to be created. Then, you automatically get an assertion consumer service for the subaccount where the service instance is created and assertion consumer services for each logout URL you provided.

If you want to add or delete assertion consumer services with logout URLs, you have to update the SAP SuccessFactors Extensibility service instance of plan *sso-configuration* and provide a JSON file with the respective information. Before updating the service instance, you have the option to view the JSON that was previously passed.

When updating the service instance:

- All the new assertion consumer services with logout URLs will be created in SAP SuccessFactors.
- All the assertion consumer services with logout URLs that were previously created but are not part of the new JSON file will be deleted.
- All the assertion consumer services with logout URLs that were previously created and are part of the new JSON file will be recreated.

When you delete the SAP SuccessFactors Extensibility service instance of plan *sso-configuration*, all the assertion consumer services with logout URLs created by this service instance will also be deleted.

### Note

You cannot bind the service instance of *sso-configuration* service plan.

## Procedure

1. In the SAP BTP cockpit, navigate to the subaccount in which you want to create a service instance.
2. In the navigation area, choose ► [Services](#) ► [Service Marketplace](#) 🗒.

All services available to you appear.

3. To enable the integration with an SAP SuccessFactors system that you have registered in the global account, choose [SAP SuccessFactors Extensibility](#).
4. In the [SAP SuccessFactors Extensibility](#) page, choose [Create](#).
5. In the [New Instance or Subscription](#) wizard:
  - a. In the [Service](#) dropdown list, ensure you have selected the [SAP SuccessFactors Extensibility](#) service.
  - b. In the [Plan](#) dropdown list, select the [sso-configuration](#) service plan.
  - c. In the [Runtime Environment](#) dropdown list, select [Other](#).
  - d. In the [System Name](#) dropdown list, select the SAP SuccessFactors system you have registered.
  - e. In the [Instance Name](#) field, enter a name for your instance. Choose [Next](#).
  - f. To configure the assertion consumer service of the subaccount and the respective applications, specify a JSON file or specify parameters in a JSON format. You can also do this later on. Choose [Next](#).

### 📘 Note

The content of the JSON file must be up to 5120 characters without spaces.

For more information about the structure of the JSON file, see [Single Sign-On Configuration JSON File \[page 1868\]](#).

- g. Choose [Create](#).

## Results

You have the assertion consumer services created in SAP SuccessFactors and have the SSO between your subaccount in SAP BTP and your SAP SuccessFactors system.

You can check the assertion consumer services. To do so, go to the [Admin Center](#) of your SAP SuccessFactors company and in the [Search](#) field, enter [Authorized SP Assertion Consumer Service Settings](#). This is a read-only information that allows you to verify if all the assertion consumer services that you need are created.

### 5.1.9.4.3 Single Sign-On Configuration JSON File

Use the single sign-on (SSO) configuration JSON file to define the assertion consumer services in SAP SuccessFactors for the subaccount in SAP BTP and for each extension application you have deployed in SAP BTP that is extending the SAP SuccessFactors system functionality.

### 📘 Note

The content of the JSON file must be up to 5120 characters without spaces.

Parameter	Description
systemName	<p>The name of the system you have registered in the global account in SAP BTP</p> <p><b>Rules/Guidelines</b></p> <p>The name must be the same as the one defined during the system registration in the global account. See <a href="#">Register an SAP SuccessFactors System in a Global Account in SAP BTP [page 1853]</a>.</p> <p><b>Note</b></p> <p>The system must be in status <i>Registered</i>.</p>
logoutURLs	<p>(Optional) This is a list of the logout URLs. A logout URL is the absolute URL that corresponds to the URL of the application router with the appended value of the <code>LogoutEndpoint</code> property. See <a href="#">logout [page 404]</a>.</p> <p><b>Note</b></p> <p>Make sure that the value of the <code>LogoutMethod</code> property is set to <b>GET</b> in the <code>xs-app.json</code> file.</p> <p><b>Note</b></p> <p>The <code>SameSite</code> attribute of the <code>Set-Cookie</code> HTTP response header needs to be set to <code>None</code> so that the cookies are sent in all responses to both first-party and cross-origin requests. You also need to set the <code>Secure</code> attribute, because it requires a secure context/HTTPS. See <a href="#">Environment Variables [page 429]</a>.</p> <p><b>Note</b></p> <p>If you don't specify the <code>logoutURLs</code> parameter, only an assertion consumer service for the subaccount in SAP BTP will be created.</p>

### Sample Code

```
{
  "systemName": "MY_SYSTEM",
  "logoutURLs": [ "https://my-first-site.com/logout", "https://my-second-site.com/logout" ]
}
```

## 5.1.9.5 Restore Configuration Settings After an Instance Refresh

After an instance refresh, you must restore some of your extension integration artifacts and configuration settings for the SAP SuccessFactors target company.

### Prerequisites

- You have a dedicated SAP SuccessFactors company instance.
- You have a registered SAP SuccessFactors system in your global account in SAP BTP.
- You have performed the instance refresh with the [Instance Refresh](#) tool or your cloud operators have performed an instance refresh manually.

### Context

In SAP SuccessFactors, instance refresh is a procedure in which the data and the settings of a source company instance are copied into another company instance. During the instance refresh the data of the target company instance is deleted and replaced by the data of the source company instance. Therefore, after an instance refresh, if the target company has been integrated with a global account in SAP BTP, the extension integration configuration settings and artifacts in the target company are overwritten by the configuration settings and data coming from the source company.

You can trigger the instance refresh automatically with the [Instance Refresh](#) tool or your cloud operators can trigger it manually.

If you have performed an instance refresh with the [Instance Refresh](#) tool, the OAuth clients, and the Assertion Consumer Services (ACS) created by the cloud platform are recreated. In [Provisioning](#), the [Extension Management Configuration](#) page displays the integration details for the target system.

#### Note

The OAuth clients are assigned new IDs. This does not affect the configuration settings.

However, if you have the following artifacts, you must reconfigure them in the SAP SuccessFactors target company instance:

- Custom home page tiles
- Permission roles
- Permission groups

#### Note

After a manual instance refresh, no artifacts are reconfigured. If you want to restore the integration settings for the target company instance, you need to recreate the [SAP SuccessFactors Extensibility](#) service instance.

## Procedure

To restore the configuration settings after an instance refresh, proceed as follows:

- After an automated instance refresh:
  1. If you have configured custom home page tiles in the target company instance, reconfigure them. See [Custom Home Page Tiles](#).
  2. If you have configured permission roles and permission groups, you need to reconfigure them. See [What Are Role-Based Permissions?](#).
- After a manual instance refresh:
  1. For SAP SuccessFactors, Second Half 2021 Release or later, proceed as follows:
    1. Recreate the *SAP SuccessFactors Extensibility* service instance. See [Create a Service Instance to Consume the SAP SuccessFactors HXM Suite OData API \[page 1858\]](#).
    2. If you have configured permission roles and permission groups, you need to reconfigure them. See [Custom Home Page Tiles](#).
    3. Reconfigure the permission roles and permission groups. See [What Are Role-Based Permissions?](#).

## Results

You have restored the extension integration artifacts and configuration setting of the target company instance.

### 5.1.9.6 Auditing and Logging Information

Here you can find a list of the events that are logged by SAP SuccessFactors Extensibility service. To retrieve the audit logs stored for SAP SuccessFactors Extensibility create a support ticket in component BC-NEO-EXT-SF.

Events written in audit logs

Event grouping	What events are logged	How to identify related log events	Additional information
Creating an integration	Start of create-integration process	<ul style="list-style-type: none"> <li>• "type": "integration"</li> <li>• "attributes": [{"name": "&lt;object_name&gt;", "new": "&lt;integration_details&gt;"}]</li> <li>• "status": "BEGIN"</li> </ul>	<p>Event that signifies an integration of a global account with an SAP SuccessFactors system has been started.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>
	End of create-integration process	<ul style="list-style-type: none"> <li>• "success": true</li> <li>• "type": "integration"</li> <li>• "attributes": [{"name": "&lt;object_name&gt;", "new": "&lt;integration_details&gt;"}]</li> <li>• "status": "END"</li> </ul>	<p>Event that signifies an integration of a global account with an SAP SuccessFactors system has been completed.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	Failure of create-integration process	<ul style="list-style-type: none"> <li>• "success": true</li> <li>• "type": "integration"</li> <li>• "attributes": [{"name": "&lt;object_name&gt;", "new": "&lt;integration_details&gt;"}]</li> <li>• "status": "END"</li> </ul>	<p>Event that signifies an integration of a global account with an SAP SuccessFactors system could not be completed.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>
	Start of delete-integration	<ul style="list-style-type: none"> <li>• "type": "integration"</li> <li>• "attributes": [{"name": "&lt;object_name&gt;", "old": "&lt;integration_details&gt;"}]</li> <li>• "status": "BEGIN"</li> </ul>	<p>Event that signifies a deletion of the integration of a global account with an SAP SuccessFactors system has been triggered.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	End of delete-integration	<ul style="list-style-type: none"> <li>"success": true</li> <li>"type": "integration"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "old": "&lt;integration_details&gt;"}]</li> <li>"status": "END"</li> </ul>	<p>Event that signifies a deletion of the integration of a global account with an SAP SuccessFactors system has been completed.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>
	Failure of delete-integration	<ul style="list-style-type: none"> <li>"success": false</li> <li>"type": "integration"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "old": "&lt;integration_details&gt;"}]</li> <li>"status": "END"</li> </ul>	<p>Event that signifies a deletion of the integration of a global account with an SAP SuccessFactors system could not be completed.</p> <p>The customDetails attribute contains details such as the issuer of the integration token, the global account ID, the name of the SAP SuccessFactors system and the SAP SuccessFactors company ID, the SAP SuccessFactors host name, and other.</p>
Setting up the connectivity	Start of create-inbound-connection process	<ul style="list-style-type: none"> <li>"type": "inboundConnection"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "new": "&lt;connection_details&gt;"}]</li> <li>"status": "BEGIN"</li> </ul>	<p>Event that signifies a creation of a service instance of the SAP SuccessFactors Extensibility service has been triggered.</p> <p>The customDetails attribute contains details such as the subaccount ID, the global account ID, SAP SuccessFactors host name, and other.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	End of create-inbound-connection process	<ul style="list-style-type: none"> <li>"type": "inboundConnection"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "new": "&lt;connection_detail_s&gt;"}]</li> <li>"status": "END"</li> </ul>	<p>Event that signifies a creation of a service instance of the SAP SuccessFactors Extensibility service has been completed.</p> <p>The customDetails attribute contains details such as the subaccount ID, the global account ID, SAP SuccessFactors host name, and other.</p>
	Start of delete-inbound-connection	<ul style="list-style-type: none"> <li>"type": "inboundConnection"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "old": "&lt;connection_detail_s&gt;"}]</li> <li>"status": "BEGIN"</li> </ul>	<p>Event that signifies the deletion of a service instance of the SAP SuccessFactors Extensibility service has been started.</p> <p>The customDetails attribute contains details such as the subaccount ID, the global account ID, SAP SuccessFactors host name, and other.</p>
	End of delete-inbound-connection	<ul style="list-style-type: none"> <li>"success": true</li> <li>"type": "inboundConnection"</li> <li>"attributes": [{"name": "&lt;object_name&gt;", "old": "&lt;connection_detail_s&gt;"}]</li> <li>"status": "END"</li> </ul>	<p>Event that signifies the deletion of a service instance of the SAP SuccessFactors Extensibility service has been completed.</p> <p>The customDetails attribute contains details such as the subaccount ID, the global account ID, SAP SuccessFactors host name, and other.</p>

Event grouping	What events are logged	How to identify related log events	Additional information
	Failure of delete-inbound-connection	<ul style="list-style-type: none"> <li>"success": false</li> <li>"type": "inboundConnection"</li> <li>"attributes": [ {"name": "&lt;object_name&gt;", "old": "&lt;connection_details&gt;"</li> <li>"status": "END"</li> </ul>	<p>Event that signifies the deletion of a service instance of the SAP SuccessFactors Extensibility service could not be completed.</p> <p>The <code>customDetails</code> attribute contains details such as the subaccount ID, the global account ID, SAP SuccessFactors host name, and other.</p>

The following information is described in the table columns:

- [Event grouping](#) - Events that are logged with a similar format or are related to the same entities.
- [What events are logged](#) - Description of the security or data protection and privacy related event that is logged.
- [How to identify related log events](#) - Search criteria or key words, that are specific for a log event that is created along with the logged event.
- [Additional information](#) - Any related information that can be helpful.

## Related Information

[Audit Logging in the Cloud Foundry Environment](#)

### 5.1.9.7 Configuring Backup

You can back up and restore the destination and the trust configuration settings for the integration between the SAP SuccessFactors system and the global account in SAP BTP.

You can back up the following configuration settings:

- The HTTP destination configured during the creation of the SAP SuccessFactors Extensibility service instance. For more, see [Export Destinations](#).
- Your subaccount X.509 certificates. For more information, see [Set up Trust Between Systems](#)
- Your SAP SuccessFactors IdP SAML 2.0 metadata.  
To download your SAP SuccessFactors IdP SAML 2.0 metadata, in the SAP BTP cockpit, navigate to [Connectivity > Destinations > Download IdP Metadata](#).
- Your identity provider configurations.  
You can back up identity provider configurations with the Identity Provider Management API. For more information see: [Identity Provider Management](#) API.

## 5.1.9.8 Accessibility Features in SAP SuccessFactors Extensibility Service

To optimize your experience of SAP SuccessFactors Extensibility service, SAP Business Technology Platform (SAP BTP) provides features and settings that help you use the software efficiently.

### Note

SAP SuccessFactors Extensibility service runs on the SAP BTP cockpit. For this reason, accessibility features for SAP BTP cockpit also apply. See the accessibility documentation for SAP BTP cockpit on SAP Help Portal at [Accessibility Features in SAP BTP cockpit \[page 1937\]](#).

For more information on screen reader support and keyboard shortcuts, see [Accessibility for End Users](#).

## 5.1.10 Extending SAP Customer Experience Products in the Kyma Environment

You can configure the integration between SAP BTP and SAP Customer Experience automatically to extend SAP Customer Experience products with applications running on the cloud platform.

### Overview

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

SAP BTP offers a standard way for extending SAP solutions.

You can extend SAP Customer Experience products in SAP BTP, Kyma runtime without disrupting the performance and the core processes. You can build extension applications for SAP Commerce Cloud, SAP Field Management, and SAP Cloud for Customer. When building extension applications, you can also benefit from the automation of the integration between the cloud platform and SAP Customer Experience.

### Process Flow

To integrate SAP BTP and SAP Customer Experience products so that you can build extension applications, you need to perform the following tasks:

Process Step	Related Documentation
<p>1. Add the <a href="#">Application Connector module</a>, and connect the SAP Customer Experience system you want to extend with the corresponding global account in SAP BTP.</p> <p>During the registration process you create an integration token which is then used in the SAP Customer Experience system for configuring the integration on the SAP Customer Experience side.</p>	<p><a href="#">Register an SAP Customer Experience System [page 1878]</a></p>
<p>2. Configure the integration on SAP Customer Experience side.</p> <p>To do so, you pair the integration token with your SAP Customer Experience system.</p>	<ul style="list-style-type: none"> <li>For an SAP Commerce Cloud system, see <b>steps 2-7</b> in <a href="#">Retrieving Client Certificate</a>.</li> <li>For an SAP Field Service Management system, see <a href="#">SAP BTP Extensions</a>.</li> <li>For an SAP Cloud for Customer system, see <a href="#">SAP BTP Extensions &gt; Step 2 Configuration in SAP Cloud for Customer Event Notifications</a> in <a href="#">Configure an Event Notification</a>.</li> </ul>
<p>3. Assign the SAP Customer Experience system to a formation to enable the API access to the corresponding SAP Customer Experience product's APIs.</p>	<p><a href="#">Including Systems in a Formation [page 1763]</a></p>
<p>4. Call a registered external service using Central Application Gateway URL.</p>	<p><a href="#">Call a registered external service from Kyma</a></p>

## Related Information

[Getting Started in the Kyma Environment \[page 204\]](#)

[Development in the Kyma Environment \[page 1729\]](#)

[Administration and Operations in the Kyma Environment \[page 2747\]](#)

### 5.1.10.1 Register an SAP Customer Experience System

Register an SAP Customer Experience system to connect it with a global account in SAP BTP.

#### Prerequisites

- See [Registering an SAP System \[page 1753\]](#).
- You are an administrator of the global account where you want to register your SAP Customer Experience system.

- To configure the integration on the SAP Customer Experience system side, you need to be an administrator of the SAP Customer Experience tenant.

## Context

The registration process is based on a registration token that is used for the pairing of the SAP Customer Experience system and the corresponding global account. You create the token in the global account, and then the tenant administrator of the respective SAP Customer Experience system uses the token to start the automated registration process on the SAP Customer Experience system side.

The registration process has the following states displayed in the cockpit:

- No status displayed in the *Status* column - the registration token for an SAP system has been created but the registration on the respective SAP solution system side has not been performed or completed.
- *Registered* - the registration token has been used and the automated registration process has been successfully completed. The system can be assigned to a formation on the *Formations* page in the cockpit.
- *Error while Registering* - the registration has failed. Remove the system and then add it to the *Systems* list and try to register it again
- *Deregistering* - a deregistration process has started in the SAP BTP cockpit. As a result, the connection between the SAP solution system and the global account in SAP BTP is removed. The system remains in the list and you can register it again later on.  
Once a system is registered, you can deregister it only after removing it from all entitlement configurations and formations it takes part in.
- *Error while Deregistering* - the deregistration has failed. Try to deregister the system again. If the problem persists, you have to report a case in the BC-CP-MP component.
- *Removing* - a system removal process has started in the SAP BTP cockpit. As a result, the link between the SAP solution and SAP BTP is destroyed and the system is removed from the list. To register the system again, first you must add it to the list anew, and then initiate the registration procedure.  
Once a system is registered, you can only remove it if you first deregister it.

### Note

You will not be able to remove a system if its status is one of the following:

- *Registered*  
You first need to deregister the system.
  - *Deregistering*
  - *Error while Deregistering*  
Try to deregister the system again.
- *Error while Removing* - the system removal has failed. Try to deregister the system again. If the problem persists, you have to report a case in the BC-CP-MP component.

### Note

When registering a system or creating a formation, the data you provide in the given input fields is not encrypted with your customer managed key. The data you enter is only encrypted at rest.

## Procedure

1. In the cockpit, navigate to your global account, and then choose ► [System Landscape](#) ► [Systems](#) 🗑️.
2. On the [Systems](#) page, choose [Add System](#).
  - a. Enter a name for the system you want to register.

### Note

Use only printable ASCII characters.

### Tip

We recommend that you indicate the type of the system when specifying the system name. For example, `<mysystem>-S/4HANA-cloud`. This helps you identify the system type when assigning systems to a formation.

- b. In the [Type](#) dropdown list, select the system type.

The following SAP Customer Experience systems are supported:

- SAP Commerce Cloud
- SAP Field Service Management
- SAP Cloud for Customer

- c. Choose [Add](#).
- d. Choose [Get Token](#).

The system generates the registration token.

- e. Copy the registration token and send it to the tenant administrator for the respective SAP Customer Experience system. You need it for configuring the integration on the extended SAP Customer Experience system side.

You can also get the registration token later, once the system appears in the list on the [Systems](#) page.

The integration token is valid for 10 minutes after it has been generated. When a token is not used within its validity period, it is no longer valid and cannot be used for registering a system. If the validity of the token expires before you use it to configure the integration on the SAP Customer Experience system side and complete the registration, you need to get a new token. You can then copy it and use it to complete the registration.

### Note

A registration token can be used only once, for registering a single SAP Customer Experience system.

- f. Close the wizard.

The SAP Customer Experience system appears in the list of systems on the [Systems](#) page. Its [Status](#) field is empty because the registration process is not yet completed.

3. (Recommended) Follow the steps in [Including Systems in a Formation \[page 1763\]](#) before proceeding with the registration on the SAP Customer Experience side.
4. Configure the integration on the SAP Customer Experience system side. See [Extending SAP Customer Experience Products in the Kyma Environment \[page 1877\]](#).

5. Check the status of the registration process. To do so, in the cockpit navigate to your global account, and in the [Systems](#) panel, check if the status of the SAP Customer Experience system has changed to [Registered](#).

If you are already in the [Systems](#) panel, refresh the page to check if the status has changed.

## Results

Once you use the integration token to connect your SAP Customer Experience system, all of the exposed services and events are propagated to the Kyma runtime.

## Related Information

[Deregistering or Removing a System \[page 1757\]](#)

## 5.2 Extending SAP Solutions Using Manual Configurations

If your scenario requires a configuration setup that is not included in the automated extension configurations, you can optionally configure the integration between SAP BTP and your SAP solution manually.

### Note

Use the manual configuration process only if your scenario is not included in the automated configurations with SAP BTP. See [Extending SAP Solutions Using Automated Configurations \[page 1744\]](#).

If you configure the integration between SAP BTP and your SAP solution manually, you will not be able to benefit from any of the automations provided in the automated configurations.

## Process Flow

When configuring the integration between the cloud platform and an SAP solution manually, you need to perform the following tasks:

1. Configure the extension subaccount. To do so, you configure the trust between the extended SAP solution and the cloud platform.
2. Install and configure the extension application.

## Supported SAP Solutions

Using manual configurations, you can extend the following SAP solutions on SAP BTP, Cloud Foundry environment:

- SAP S/4HANA Cloud. See [Extending SAP S/4HANA Cloud in the Cloud Foundry Environment Manually \[page 1882\]](#).
- SAP SuccessFactors. See [Extending SAP SuccessFactors in the Cloud Foundry Environment Manually \[page 1897\]](#).
- SAP Cloud for Customer. See [Extending SAP Cloud for Customer in the Cloud Foundry Environment Manually \[page 1914\]](#).

### 5.2.1 Extending SAP S/4HANA Cloud in the Cloud Foundry Environment Manually

This section guides you through the configuration tasks that you need to perform to enable the SAP BTP, Cloud Foundry environment for developing extension applications for your SAP S/4HANA Cloud tenant.

#### Process Flow

##### Note

Use the manual configuration steps only if your scenario is not covered by the automated process with SAP BTP. If you configure the integration between the cloud platform and SAP S/4HANA Cloud manually, you may not be able to benefit from any automations.

You have to configure the cloud platform extension integration with SAP S/4HANA Cloud to enable the use of applications running on top of the platform from SAP S/4HANA Cloud.

These are the steps you need to follow:

1. Set up the extension subaccount in SAP BTP by configuring the single sign-on. See [SAP BTP Extension Onboarding for SAP S/4HANA Cloud \[page 1883\]](#).
2. Configure the extension application and create the respective destination in the SAP BTP cockpit. See [Extension Application Configuration \[page 1884\]](#).

## 5.2.1.1 SAP BTP Extension Onboarding for SAP S/4HANA Cloud

The SAP BTP, Cloud Foundry environment extension onboarding enables the integration between the cloud platform and SAP S/4HANA Cloud. This allows the SAP S/4HANA Cloud side-by-side extension applications to run on top of the cloud platform.

The Identity Authentication service provides authentication, single sign-on, and on-premise integration. The Identity Authentication service is closely integrated with SAP BTP, and it is offered as part of the platform.

The authentication to SAP S/4HANA Cloud applications is restricted to the authorized users. The identification of a user is verified by the identity provider, as specified by SAML 2.0. The Identity Authentication service stores a list of all users that are allowed to access the service provider (SAP S/4HANA Cloud) along with their credentials. The integration between the SAP S/4HANA Cloud and the Identity Authentication service is based on a trust configuration. When a user attempts to access SAP S/4HANA Cloud for the first time, the system redirects the user to the identity provider for identification. From then on, the user session is kept active, and the user is no longer prompted for credentials when trying to use the SAP S/4HANA Cloud application. This is called single sign-on (SSO).

To ensure the required security for accessing the applications, you need to configure the single sign-on between the SAP BTP subaccount and the SAP S/4HANA Cloud tenant using a SAML identity provider, for example Identity Authentication service. The single sign-on requires both solutions to be configured as trusted SAML service providers for the Identity Authentication service, and at the same time, the Identity Authentication service to be configured as trusted identity provider for the two solutions.

### Note

You own an SAP S/4HANA Cloud tenant with an Identity Authentication tenant configured. You need to use the same Identity Authentication tenant for your subaccount in SAP BTP.

### 5.2.1.1.1 Configure Single Sign-On with the Identity Authentication Service

To use the SAML 2.0 bearer assertion authentication for the communication flow between the extension application and SAP S/4HANA Cloud, you need to configure single-sign on (SSO).

If you have an account in the SAP BTP, Cloud Foundry environment, you need to set up the single sign-on (SSO) according to this environment. The single sign-on requires both solutions, the cloud platform and SAP S/4HANA Cloud, to be configured as trusted SAML service providers for the Identity Authentication service, and at the same time, the Identity Authentication service to be configured as trusted identity provider for the two solutions. See [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).

## 5.2.1.2 Extension Application Configuration

Use this procedure to configure the authentication flow between the extension application and the SAP S/4HANA Cloud system.

When configuring the extension application and you have a subaccount in the SAP BTP, Cloud Foundry environment, you have to set up the connectivity from the subaccount to the SAP S/4HANA Cloud tenant. To do that, you can use different authentication methods: Basic, Client Certificate, or SAML Bearer Assertion.

### Related Information

[Configure Application Authentication \[page 1884\]](#)

[Configuring the Extension Application's Connectivity to SAP S/4HANA Cloud \[page 1885\]](#)

## 5.2.1.2.1 Configure Application Authentication

Use this procedure to configure the application with which you want to extend your SAP S/4HANA Cloud system.

### Prerequisites

- Have the Cloud Foundry command line interface (cf CLI) downloaded and installed. See [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- Have Node.JS including its NPM Packager Manager installed. See <https://nodejs.org/en/> .

### Context

You need your own application router that connects your extension application to the centrally provided user account and authentication (UAA) service. This means that you need to deploy an approuter as part of your application that manages the user authentication for you.

The approuter has these main functions:

- Handles authentication for all apps of the application
- Serves static resources
- Performs route mapping (URL mapping)
- In case of multitenancy, it derives the tenant information from the URL and provides it to the extended services for the Authorization and Trust Management service to redirect the authentication request to the tenant-specific identity provider. See [SAP Authorization and Trust Management Service \[page 2778\]](#).

## Procedure

1. To set up the application router as part of your application, execute the following command in cf CLI:

```
npm config set @sap:registry=https://registry.npmjs.org
```

2. Create a service instance of the Authorization and Trust Management service. See [Creating Service Instances \[page 231\]](#).
3. Add an application router. See [Application Router and Destination](#)
4. Update the extension application by using the `cf push` command in the cf CLI.
5. Verify that there is an authentication for your application and access the application using the approuter URL.
  - a. Get the url of the approuter using the `cf apps` command.
  - b. Enter the approuter URL in a browser.
  - c. You are redirected to the Identity Authentication service that you have already configured. See [Configure Single Sign-On with the Identity Authentication Service \[page 1883\]](#).
  - d. After a successful login, you will get redirected to the welcome page of you extension application if you have defined one.

### 5.2.1.2.2 Configuring the Extension Application's Connectivity to SAP S/4HANA Cloud

Use this procedure to set up the connectivity between the extension application on SAP BTP and the SAP S/4HANA Cloud system.

To set up the connectivity from a subaccount in SAP BTP to an SAP S/4HANA Cloud tenant, you need to create HTTP destinations in the SAP BTP cockpit. These destinations provide data communication via HTTP protocol.

When creating an HTTP destination, you can use different authentication types for access control:

#### Basic Authentication

Using authentication method you need to provide username and password. When configuring the HTTP destination in the cockpit, the username and password must correspond to the communication user in the SAP S/4HANA Cloud tenant.

See [Using Basic Authentication \[page 1886\]](#).

#### Client Certificate Authentication

##### ⓘ Note

Available only for the manual configuration.

To configure a client certificate authentication, you need a client certificate signed by a trusted certificate authority (CA). You upload the public key when creating a communication user in the SAP S/4HANA Cloud tenant, and then, you add the corresponding keystore to the HTTP destination in the SAP BTP cockpit.

See [Using Client Certificate Authentication \[page 1889\]](#).

## SAML Bearer Assertion Authentication

You can use the SAML Bearer assertion flow for consuming OAuth-protected resources. Users are authenticated by using SAML against the configured trusted identity providers. The SAML assertion is then used to request an access token from an OAuth authorization server. This access token must be added as an Authorization header with value *Bearer <access token>* in all HTTP requests to the OAuth-protected resources.

See [Using SAML Bearer Assertion Authentication \[page 1892\]](#).

## Related Information

[Authentication for Java Resource Servers](#)

[Consuming the Destination Service \(Cloud Foundry Environment\)](#)

### 5.2.1.2.2.1 Using Basic Authentication

#### Context

To be able to use Basic authentication, you need to configure both SAP S/4HANA Cloud and SAP BTP sides.

#### 5.2.1.2.2.1.1 Set Up SAP S/4HANA Cloud Side

#### Context

From the SAP S/4HANA Cloud side you need to maintain the communication settings to configure the connectivity between SAP S/4HANA Cloud and SAP BTP.

## Procedure

1. Create a communication user. See [Maintain Communication Users](#).

For the basic authentication, you need to provide a password when defining the required credentials.

2. Create a communication system. See [Maintain Communication Systems](#).
  - a. Log into the SAP Fiori launchpad in the SAP S/4HANA Cloud system.
  - b. Select the *Communication Systems* tile.
  - c. Choose *New* to create a new system.
  - d. Enter a system ID and a system name.
  - e. Choose *Create*.
  - f. Enter information about SAP BTP in the *Technical Data* section.
  - g. Choose + (Add) under *User for Inbound Communication*.
  - h. In the dialog box that appears, select *User Name and Password* from the *Authentication Method* drop-down list.

The username corresponds to the communication user.

- i. Choose *OK* to confirm.
  - j. Choose *Save*.
3. Create a communication arrangement and select a communication scenario. See [Maintain Communication Arrangements](#).

## Related Information

[Communication Management](#)

### 5.2.1.2.2.1.2 Set Up SAP BTP Side

## Prerequisites

You have logged into the SAP BTP SAP BTP cockpit from the SAP BTP landing page for your subaccount.

## Procedure

1. In the cockpit, navigate to your subaccount.
2. Choose  [Connectivity](#)  [Destinations](#)  in the navigation panel.

- Choose *New Destination* and fill in the following properties:

Parameter	Value
Name	Enter a meaningful name.
Type	<b>HTTP</b>
Description	(Optional) Enter a meaningful description.
URL	The service URL from the communication arrangement.
Proxy Type	<b>Internet</b>
Authentication	<b>BasicAuthentication</b>
User	The name of the communication user you have in the SAP S/4HANA Cloud tenant.
Password	The password for the communication user.

- (Optional) If you are using SAP Business Application Studio to develop your application, you have to specify another set of additional properties. See [What is SAP Business Application Studio](#).

In the *Additional Properties*, choose *New Property* to define the following properties related to the SAP Business Application Studio:

Parameter	Value
WebIDEUsage	Specify this property with value <b>odata_gen</b> to consume an OData service in your application.
WebIDEEnabled	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
HTML5.DynamicDestination	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
product.name	<b>SAP S/4HANA Cloud</b> The type of the SAP System for which you create this HTTP destination.
communicationScenarioID	The ID of the communication scenario.

- 
- 
- 
- 
- 
- Select the *Use default JDK truststore* checkbox.
- Save your entries.

## Related Information

[Consuming the Destination Service \(Cloud Foundry Environment\)](#)

## 5.2.1.2.2.2 Using Client Certificate Authentication

### Context

To be able to use client certificate authentication, you need to configure both SAP S/4HANA Cloud and SAP BTP sides.

### 5.2.1.2.2.2.1 Set Up SAP BTP Side

#### Prerequisites

You have logged into the SAP BTP cockpit from the SAP BTP landing page for your subaccount.

#### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose ► [Connectivity](#) ► [Destinations](#) ▾.
3. Choose [Certificates](#) and then choose [Generate Certificate](#) to generate the certificate for this subaccount.
4. In the [Generate new certificate](#) wizard:
  - In the [Certificate File Name](#) field, enter a name for the certificate.
  - In the [File Name Extension](#) dropdown menu, select the type of keystore you want to use, for example [PEM](#) or [p12](#).

#### Note

If you use SAP Cloud SDK to develop a JavaScript application, check the supported keystore types at [SAP Cloud SDK: Keystore Configuration](#) ↗ .

- (Optional) In the [Certificate Validity Time Unit](#) dropdown menu, select whether you want to set a validity for the certificate in days, months, or years.
  - (Optional) In the [Certificate Validity Value](#) specify the validity of the certificate.
  - (Optional) Select the [Enable automatic renewal](#) checkbox.
  - Choose [Generate Certificate](#) and then choose [Cancel](#) to close the wizard.
5. Choose ► [Connectivity](#) ► [Destinations](#) ▾ in the navigation panel.
  6. Choose [New Destination](#) and fill in the following properties:

Parameter	Value
Name	Enter a meaningful name.
Type	<b>HTTP</b>
Description	(Optional) Enter a meaningful description.
URL	The service URL from the communication arrangement.  Make sure you use the HTTPS protocol, otherwise the <i>ClientCertificateAuthentication</i> option would not appear in the <i>Authentication</i> dropdown list.  For example, <a href="https://yourSAPS4HANACloudTenant-api.s4hana.ondemand.com">https://yourSAPS4HANACloudTenant-api.s4hana.ondemand.com</a> .
Proxy Type	<b>Internet</b>
Authentication	<b>ClientCertificateAuthentication</b>
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>Once you have selected this option, the system displays the <a href="#">Upload and Delete Certificate</a> link.</p> </div>
Key Store Location	Select the certificate you have generated in step 4 for the destinations in your subaccount in SAP BTP.

7. Save the destination.
8. (Optional) If you are using SAP Business Application Studio to develop your application, you have to specify another set of additional properties. See [What is SAP Business Application Studio](#).

In the *Additional Properties*, choose *New Property* to define the following properties related to the SAP Business Application Studio:

Parameter	Value
WebIDEUsage	Specify this property with value <b>odata_gen</b> to consume an OData service in your application.
WebIDEEEnabled	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
HTML5.DynamicDestination	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
product.name	<b>SAP S/4HANA Cloud</b>  The type of the SAP System for which you create this HTTP destination.
communicationScenarioID	The ID of the communication scenario.

9. Choose [Export](#) to download the certificate you have generated and assigned to this destination.
10. Open the keystore file in an editor of your choice and extract the certificate chain from the keystore. For example:
  - If you are using the [PEM](#) keystore type:
    1. Decode the [.pem](#) file from Base64 format and create a new decoded [cert.pem](#) file.
    2. Open the [cert.pem](#) file and delete the section between the lines `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----` including these lines. Save the file.
  - If you are using the [p12](#) keystore type:
    1. Decode the [.p12](#) file from Base64 format and create a new decoded [keystore.p12](#) file. For example, for Unix operating systems, use the command: `cat <your-file>.p12 | base64 --decode > keystore.p12`.
    2. Extract the certificate chain from the [keystore.p12](#) file and copy the result in a new [cert.pem](#) file. For example, for Unix operating systems, use the command: `openssl pkcs12 -info -in keystore.p12 -nokeys -out cert.pem`.
    3. Open the [cert.pem](#) file and clean [bag](#) attributes.

## Related Information

[Managing Destinations](#)

### 5.2.1.2.2.2 Set Up SAP S/4HANA Cloud Side

#### Context

To use client certificate authentication, you proceed with creating and configuring the communication settings in the SAP S/4HANA Cloud tenant. To do that, you have to:

#### Procedure

1. Use the client certificate signed by a trusted certificate authority (CA) in [.pem](#) format you have generated in the [Set Up SAP BTP Side \[page 1889\]](#) page.
2. Create a communication user and upload the public key. See [Maintain Communication Users](#).
3. Create a communication system and add the communication user as [User for Inbound Communication](#) with an authentication method SSL Client Certificate.
  - a. Log in the SAP Fiori launchpad in the SAP S/4HANA Cloud system.
  - b. Select the [Communication Systems](#) tile.

- c. Choose *New* to create a new system.
- d. Enter a system ID and a system name.
- e. Choose *Create*.
- f. Enter information about SAP BTP in the *Technical Data* section.
- g. Choose + (Add) under *User for Inbound Communication*.
- h. In the dialog box that appears, select *SSL Client Certificate* from the *Authentication Method* drop-down list.

The username corresponds to the communication user.

- i. Choose *OK* to confirm.
  - j. Choose *Save*.
4. Create a communication arrangement using an existing or create a new scenario that supports client certificate authentication. See [Maintain Communication Arrangements](#).

You can use the already created communication system. The settings in the *Inbound Communication* section are filled in automatically. Save the value from the *URL* field, you will need it when creating a destination in the subaccount in SAP BTP.

5. Copy the URL of the newly created communication arrangement, and get back to the SAP BTP cockpit. Navigate to your extension subaccount in the Cloud Foundry environment. Choose ► [Connectivity](#) ► [Destinations](#) and find the destination you have created in the *Set Up SAP BTP Side* section. Make sure the URL you have set up in the destination is the same as the URL you have for the communication arrangement.

## 5.2.1.2.2.3 Using SAML Bearer Assertion Authentication

### Prerequisites

You have configured single-sign on (SSO) with the Identity Authentication service. See [Configure Single Sign-On with the Identity Authentication Service \[page 1883\]](#).

### Context

To be able to use SAML Bearer Assertion authentication, you need to configure both SAP S/4HANA Cloud and SAP BTP sides.

### Related Information

[SAML Bearer Assertion Authentication](#)

## 5.2.1.2.2.3.1 Upload Your Key-Pair Keystore in SAP BTP

To use SAML Bearer Assertion authentication for the communication between your extension application and the SAP S/4HANA Cloud system, you first need to upload your key-pair keystore in SAP BTP on subaccount level.

### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose ► [Connectivity](#) ► [Destinations](#) ►.
3. Choose ► [Certificates](#) ► [Upload Certificate](#) ►.
4. Browse to the keystore file.

#### Note

You can only use JKS, PFX and P12 files. The keystore file must contain exactly one key pair entry.

The keystore file containing your key pair entry is added.

### Related Information

[Use Destination Certificates](#)

## 5.2.1.2.2.3.2 Set Up SAP S/4HANA Cloud Side

### Context

From the SAP S/4HANA Cloud side you need to maintain the communication settings to configure the connectivity between SAP S/4HANA Cloud and SAP BTP.

#### Note

Make sure you have assigned the appropriate business catalogs to the propagated business users in the SAP S/4HANA Cloud tenant.

## Procedure

1. Create a communication user. See [Maintain Communication Users](#).

For the SAML Bearer Assertion authentication, you need to provide a password when defining the required credentials.

2. Create a communication system. See [Maintain Communication Systems](#).

- a. Log into the SAP Fiori launchpad in the SAP S/4HANA Cloud system.
- b. Select the *Communication Systems* tile.
- c. Choose *New* to create a new system.
- d. Enter a system ID and a system name.
- e. Choose *Create*.
- f. In the *Technical Data* section, in the *Host Name* field, enter the URL of the Cloud Foundry application or service required by your scenario or consult your scenario configuration guide.

For example, the URL for an application deployed in SAP BTP in the Cloud Foundry environment is `https://<application_route>.cfapps.<location>.hana.ondemand.com`. Where:

- The domain depends on your location, in the European region for example, the domain is [cfapps.eu10.hana.ondemand.com](#)
  - The application route is the single point of entry of an application. To view the application route, you can use the `cf apps` or `cf routes` cf CLI command.
- g. Enable the OAuth Identity Provider by checking the box under *OAuth 2.0 Identity Provider*.
  - h. Upload the public key contained in the keystore file you have have uploaded in your subaccount in SAP BTP. See [Upload Your Key-Pair Keystore in SAP BTP \[page 1893\]](#).
  - i. In the *Provider Name* field, enter a unique provider name. For example, you can enter the value of the CN field of your public key.
  - j. Choose + (Add) under *User for Inbound Communication*.
  - k. In the dialog box that appears, select *User Name and Password* from the *Authentication Method* drop-down list.

The username corresponds to the communication user.

- l. Choose *OK* to confirm.
  - m. Choose *Save*.
3. Create a communication arrangement and select a communication scenario. See [Maintain Communication Arrangements](#).

### Note

When you have the communication arrangement created, choose *OAuth 2.0 Details*. Copy and save locally the fields and their values. You will need them when setting up the destination in the SAP BTP cockpit.

## 5.2.1.2.2.3.3 Set Up SAP BTP Side

### Prerequisites

You have logged into the SAP BTP cockpit from the SAP BTP landing page for your subaccount.

### Procedure

1. In the cockpit, navigate to your subaccount.
2. Choose ► [Connectivity](#) ► [Destinations](#) ► in the navigation panel.
3. Create an HTTP destination.

To enable principal propagation, create an [OAuth2SAMLBearerAssertion](#) HTTP destination and configure its settings as follows:

1. Configure the basic settings:

Parameter	Value
Name	Enter a meaningful name.
Type	<b>HTTP</b>
Description	(Optional) Enter a meaningful description.
URL	The service URL from the communication arrangement. <div data-bbox="863 1429 1394 1547"><b>Note</b> Make sure you use the HTTPS protocol.</div>
Proxy Type	<b>Internet</b>
Authentication	<b>OAuth2SAMLBearerAssertion</b>
Key Store Location	In the dropdown list, select the key-pair keystore file you have uploaded in <a href="#">Upload Your Key-Pair Keystore in SAP BTP [page 1893]</a> .
Key Store Password	The password for the keystore. <div data-bbox="863 1832 1394 1980"><b>Note</b> The password for the keystore must be the same as the one for the key pair entry in the keystore file.</div>

Parameter	Value
Audience	The URL of your SAP S/4HANA Cloud account. To get it, log on to your SAP S/4HANA Cloud account. Select the profile picture and then choose <i>Settings</i> and copy the value from the <i>Server</i> field.
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>Make sure you use the HTTPS protocol.</p> </div>
Client Key	The name of the communication user you have in the SAP S/4HANA Cloud tenant.
Token Service URL	This is the <i>Token Service URL</i> from the <i>OAuth 2.0 Details</i> in the communication arrangement. See <a href="#">Set Up SAP S/4HANA Cloud Side [page 1893], step 3</a> .
Token Service User	The name of the communication user you have in the SAP S/4HANA Cloud tenant.
Token Service Password	The password for the communication user.
System User	This parameter is not used, leave the field empty.

2. Configure the required additional property. To do so, in the *Additional Properties* panel, choose *New Property*, and enter the following property:

Parameter	Value
authnContextClassRef	<b>urn:oasis:names:tc:SAML:2.0:ac:classes:X509</b>
assertionIssuer	Issuer of the SAML assertion.  Enter the provider name you have specified when creating the communication system in SAP S/4HANA Cloud. See <a href="#">Set Up SAP S/4HANA Cloud Side [page 1893]</a> .

3. (Optional) If you are using SAP Business Application Studio to develop your application, you have to specify another set of additional properties. See [What is SAP Business Application Studio](#). In the *Additional Properties*, choose *New Property* to define the following properties related to the SAP Business Application Studio:

Parameter	Value
WebIDEUsage	Specify this property with value <b>odata_gen</b> to consume an OData service in your application.

Parameter	Value
WebIDEEEnabled	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
HTML5.DynamicDestination	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
product.name	<b>SAP S/4HANA Cloud</b> The type of the SAP System for which you create this HTTP destination.
communicationScenarioID	The ID of the communication scenario.

1. Select the *Use default JDK truststore* checkbox.
4. Save your entries.

## Related Information

[Consuming the Destination Service \(Cloud Foundry Environment\)](#)

## 5.2.2 Extending SAP SuccessFactors in the Cloud Foundry Environment Manually

This section guides you through the configuration tasks that you need to perform to enable the SAP BTP, Cloud Foundry environment for developing extension applications for your SAP SuccessFactors system.

### Process Flow

You have to configure the cloud platform extension integration with SAP SuccessFactors to enable the use of applications running on top of the platform from SAP SuccessFactors.

These are the steps you need to follow:

1. [Configuring the Subaccount in SAP BTP for SAP SuccessFactors \[page 1898\]](#)
2. [Installing and Configuring SAP SuccessFactors Extension Applications for Cloud Foundry Environment \[page 1902\]](#)

## 5.2.2.1 Configuring the Subaccount in SAP BTP for SAP SuccessFactors

Use this procedure to configure the Single-Sign On (SSO) between a subaccount in SAP BTP and the SAP SuccessFactors system.

The authentication to SAP SuccessFactors applications is restricted to the authorized users. The identification of a user is verified by the identity provider, as specified by SAML 2.0. The Identity Authentication service stores a list of all users that are allowed to access the SAP SuccessFactors system along with their credentials. The integration between the SAP SuccessFactors and the identity provider is based on a trust configuration. When a user attempts to access SAP SuccessFactors for the first time, the system redirects the user to the identity provider for identification. From then on, the user session is kept active, and the user is no longer prompted for credentials when trying to use the SAP SuccessFactors application. This is called single sign-on (SSO).

To ensure the required security for accessing the applications, you need to configure the single sign-on between the subaccount and the SAP SuccessFactors system using a SAML identity provider. The single sign-on requires both solutions to be configured as trusted SAML service providers for the identity provider, and at the same time, the identity provider to be configured as trusted identity provider for the two solutions.

If you have an account in the SAP BTP, Cloud Foundry environment, you need to set up the single sign-on (SSO) according to this environment.

### Related Information

[Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#)

[Register the Assertion Consumer Service of the Subaccount in SAP BTP in SAP SuccessFactors \[page 1899\]](#)

### 5.2.2.1.1 Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP

Use this procedure to set up the trust configuration of the subaccount in SAP BTP and add SAP SuccessFactors as an identity provider.

#### Procedure

1. Download SAML metadata from the SAP SuccessFactors system.
  - a. Go to `https://<sap_successfactors_system>/idp/samlmetadata?company=<company_id>&cert=sha2` where:
    - `<sap_successfactors_system>` is the hostname of your SAP SuccessFactors system
    - `<company_id>` is the ID of your SAP SuccessFactors company

- b. When you are prompted, save the file on your local file system and change its extension to **.xml**.
2. Register the SAP SuccessFactors identity provider in the SAP BTP cockpit.
  - a. Open the cockpit and navigate to your subaccount.
  - b. Choose ► **Security** ► **Trust Configuration** ►.
  - c. Choose **New Trust Configuration**.
  - d. To upload the SAML metadata you downloaded in step 1, choose **Upload**. Browse to the XML file you saved and select it. Some of the fields are automatically filled in.
  - e. In the **Name** field, enter a meaningful name for the trust configuration.
  - f. Save the changes.
3. Make the trust configuration to the SAP SuccessFactors identity provider the only configuration that is active.

## 5.2.2.1.2 Register the Assertion Consumer Service of the Subaccount in SAP BTP in SAP SuccessFactors

You need to register the assertion consumer service of the subaccount as an authorized assertion consumer service in Provisioning of SAP SuccessFactors.

### Prerequisites

[Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#)

### Procedure

1. Download the service provider SAML metadata file from the SAP BTP cockpit.
  - a. Go to your subaccount and choose ► **Security** ► **Trust Configuration** ►.
  - b. Choose **SAML Metadata** to download an XML file that contains the SAML 2.0 metadata describing SAP BTP as a service provider.
  - c. Open the XML file in a text editor and copy the following values:
    - The value of the `Location` attribute of the `AssertionConsumerService` element with the `HTTP-POST` binding of the XML file: this is the value of the Assertion Consumer Service.
    - The value of the `Location` attribute of the `SingleLogoutService` element with the `HTTP-POST` binding of the XML file: this is the value of the logout URL.
    - The value of the `EntityID` attribute of `EntityDescriptor` element of the XML file: this is the value of the Audience URL.
2. Log in to SAP SuccessFactors Provisioning for your SAP SuccessFactors system using the following link:
 

```
https://<sap_successfactors_system>/provisioning_login
```

 where `<sap_successfactors_system>` is the hostname of your SAP SuccessFactors system.

3. Go to your company and choose *Authorized SP Assertion Consumer Service Settings* under the *Service Provider Settings* section.
4. Choose *Add another Service Provider ACS* and fill in the following fields:

Field	Value
<i>Assertion Consumer Service</i>	This is the value of the <code>Location</code> attribute of the <code>AssertionConsumerService</code> element with the HTTP-POST binding you copied in <b>step 1</b> .
<i>Logout URL</i>	This is the value of the <code>Location</code> attribute of the <code>SingleLogoutService</code> element with the HTTP-POST binding you copied in <b>step 1</b> .
<i>Audience Url</i>	This is the value of the <code>EntityID</code> attribute of <code>EntityDescriptor</code> element you copied in <b>step 1</b> .
<i>Application Name</i>	Select <i>SAP Business Technology Platform</i> from the drop-down list.
<i>SHA-256 Certificate</i>	Select the checkbox if it is not automatically selected when specifying the <i>Application Name</i> value.

5. Choose *Save*.

### 5.2.2.1.3 Register the Assertion Consumer Service for Every Extension Application in SAP SuccessFactors

#### Prerequisites

##### Note

This procedure is required only if you use SAP BTP, Cloud Foundry environment.

1. [Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#)
2. [Register the Assertion Consumer Service of the Subaccount in SAP BTP in SAP SuccessFactors \[page 1899\]](#)

## Procedure

1. Log in to SAP SuccessFactors Provisioning for your SAP SuccessFactors system using the following link:  
`https://<sap_successfactors_system>/provisioning_login`  
where `<sap_successfactors_system>` is the hostname of your SAP SuccessFactors system.
2. Go to your company and choose *Authorized SP Assertion Consumer Service Settings* under the *Service Provider Settings* section.
3. Choose *Add another Service Provider ACS* and fill in the following fields:

### Note

If you are using more than one application router for your extension applications in your subaccount, repeat this step for every application router.

Field	Value
<i>Assertion Consumer Service</i>	This is the absolute URL that corresponds to the URL of the application router. See <a href="#">Application Router [page 377]</a> .
<i>Logout URL</i>	This is the absolute URL that corresponds to the URL of the application router with the appended value of the <code>logoutEndpoint</code> property. See <a href="#">logout [page 404]</a> .
	<h3>Note</h3> <p>Make sure that the value of the <code>logoutMethod</code> property is set to <b>GET</b> in the <code>xs-app.json</code> file.</p>
	<h3>Note</h3> <p>The <code>SameSite</code> attribute of the <code>Set-Cookie</code> HTTP response header needs to be set to <code>None</code> so that the cookies are sent in all responses to both first-party and cross-origin requests. You also need to set the cookie <code>Secure</code> attribute, because it requires a secure context/HTTPS. See <a href="#">Environment Variables [page 429]</a>.</p>
<i>Application Name</i>	Select <i>SAP Business Technology Platform</i> from the drop-down list.
<i>SHA-256 Certificate</i>	Select the checkbox if it is not automatically selected when specifying the <i>Application Name</i> value.

4. Choose *Save*.

## 5.2.2.2 Installing and Configuring SAP SuccessFactors Extension Applications for Cloud Foundry Environment

Use this procedure to configure the authentication of the applications with which you want to extend your SAP SuccessFactors systems and to install and configure them in SAP BTP, Cloud Foundry environment.

To use OAuth 2.0 for authentication, you will first need to register your OAuth client in the SAP SuccessFactors system, and set up the permissions required for this registration. Then, you can register your OAuth client application.

You can also use the mutual transport layer security (mTLS) when configuring the extension application's connectivity to SAP SuccessFactors.

### Related Information

[Configuring Application Authentication \[page 1902\]](#)

[Configuring the Extension Application's Connectivity to SAP SuccessFactors \[page 1905\]](#)

### 5.2.2.2.1 Configuring Application Authentication

Use this procedure to configure the authentication of the applications with which you want to extend your SAP SuccessFactors systems.

### Prerequisites

You have the Cloud Foundry command line interface (cf CLI) downloaded and installed. See [Download and Install the Cloud Foundry Command Line Interface](#).

### Context

You need your own application router that connects your extension application to the centrally provided user account and authentication (UAA) service. This means that you need to create an application with an application router and configure it to route the requests to your extension application. Thus, the application router manages the user authentication for you.

#### Note

For Node.js extension applications, you can optionally deploy the application router as part of your extension application.

## Procedure

1. Create an xsuaa service instance. See [Create a Service Instance from the xsuaa Service](#).
2. Bind the xsuaa service instance you have created to the extension application. See: [Bind the xsuaa Service Instance to the Application](#).
3. Create an application with an application router and configure it to forward the requests to your extension application. See [Configure Application Router](#) .
4. Verify that there is an authentication for your extension application and access the application using the application router URL.
  - a. Get the URL of the application router using the `cf apps` command.
  - b. Enter the application router URL in a browser.
  - c. You are redirected to the SAP SuccessFactors identity provider that you have already configured. See [Configure SAP SuccessFactors as a Trusted Identity Provider in SAP BTP \[page 1866\]](#).
  - d. After a successful login, you will get redirected to the welcome page of you extension application if you have defined one.

## Related Information

[Establish Trust and Federation with UAA Using Any SAML Identity Provider \[page 2039\] Authentication for Applications](#)

### 5.2.2.2.1.1 Establish Trust Between the Identity Authentication Service and SAP BTP

Use this procedure to configure the SAP BTP trust settings and add the Identity Authentication tenant as an identity provider.

## Context

The Identity Authentication service is closely integrated with SAP BTP, and it is offered as part of most of the cloud platform packages. For those packages the trust between the subaccount in SAP BTP and Identity Authentication service is configured automatically and the tenant for the Identity Authentication service is set up by default, once you have a partner or customer subaccount. However, you can manually configure the trust and set up the Identity Authentication tenant if your scenario requires it.

## Procedure

1. In the Identity Authentication tenant, access the administration console by using the console's URL. You need to use another browser, or incognito session of the same browser.

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

You can also get the URL from the Identity Authentication tenant registration e-mail.

2. You have to save the metadata of your Identity Authentication tenant on your local file system as an XML file. You can either find the tenant at `https://<tenant ID>.accounts.ondemand.com/saml2/metadata` or access it via **Applications & Resources > Tenant Settings > SAML 2.0 Configuration**. Then choose the [Download Metadata File](#) link. You will need this metadata in **Step 5**.
3. Open the SAP BTP cockpit and select the region in which your subaccount is hosted. Select the global account that contains your subaccount, and then choose the tile of your subaccount. For more information about regions, see [Regions and Hosts](#).
4. Choose **Security > Trust Configuration**.
5. Choose [New Trust Configuration](#) and fill in the required fields:
  - a. In the [Metadata](#) field, upload the metadata file you have downloaded from the Identity Authentication tenant in **step 2**. All the required fields are automatically filled in.
  - b. In the [Name](#) field, enter a meaningful name of your choice.
  - c. Choose [Save](#).

6. In the cockpit, download the service provider SAML metadata file. Open the link `https://<subaccount_subdomain>.authentication.<region_host>/saml/metadata`, where:
  - `<subaccount_subdomain>` is part of the subaccount details in the cockpit.
  - `<region_host>` is the API endpoint without `api.cf..` See [Regions and Hosts](#).

When you are prompted, save the XML file on your local file system. This file contains the SAML 2.0 metadata describing SAP BTP as a service provider.

You will need this metadata in **Step 11**.

7. In the Identity Authentication tenant, access the administration console by using the console's URL. You need to use another browser, or incognito session of the same browser.

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

You can also get the URL from the Identity Authentication tenant registration e-mail.

8. Choose **Applications & Resources > Applications**.
9. Choose the [+Add](#) button on the left-hand panel, and enter the name of your subaccount.
10. Choose [Save](#).
11. Configure the SAML 2.0 trust with subaccount as a service provider. To do so, proceed as follows:
  - a. On the left-hand side, choose the newly created application, and then choose [Trust](#).
  - b. Choose [SAML 2.0 Configuration](#).
  - c. Upload the metadata XML file of your subaccount that you have downloaded in **Step 6**.

On service provider metadata upload, the fields are populated with the parsed data from the XML file.
  - d. Save the configuration settings.

## Results

The trust will be established automatically upon registration on both the subaccount in SAP BTP and Identity Authentication tenant side.

## Related Information

[ID Federation with a Identity Authentication Tenant](#)

### 5.2.2.2.2 Configuring the Extension Application's Connectivity to SAP SuccessFactors

Use this procedure to configure the connectivity between your extension application the SAP SuccessFactors system.

#### Using OAuth Client with SAML Bearer Assertion Authentication

To be able to make calls to the SAP SuccessFactors OData APIs with user propagation, you need to create a destination with SAML Bearer Assertion authentication in the SAP BTP cockpit on a subaccount level. You also need to create an OAuth client in the SAP SuccessFactors system.

See [Using OAuth Client with SAML Bearer Assertion Authentication \[page 1906\]](#).

#### Using Mutual Transport Layer Security Protocol

You can also use the mutual transport layer security (mTLS) when configuring the extension application's connectivity to SAP SuccessFactors.

See [Using Mutual Transport Layer Security \(mTLS\) \[page 1910\]](#).

## 5.2.2.2.2.1 Using OAuth Client with SAML Bearer Assertion Authentication

### Context

To be able to make calls to the SAP SuccessFactors OData APIs with user propagation, you need to create a destination with SAML Bearer Assertion authentication in the SAP BTP cockpit on a subaccount level. You also need to create an OAuth client in the SAP SuccessFactors system.

### Procedure

1. [Download the X509 Certificate in SAP BTP \[page 1906\]](#).
2. [Create an OAuth Client in SAP SuccessFactors \[page 1907\]](#).
3. [Create an HTTP Destination Using SAML 2.0 Bearer Assertion Authentication \[page 1907\]](#).
4. [Consume the Destination \[page 1909\]](#).

### Related Information

[SAP Authorization and Trust Management Service \[page 2778\]](#)  
[Consuming the Destination Service \(Cloud Foundry Environment\)](#)

## 5.2.2.2.2.1.1 Download the X509 Certificate in SAP BTP

### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose **► Connectivity ► Destinations**.
3. Choose [Download Trust](#) to get the certificate for this subaccount and save it on your local file system.
4. Open the certificate in a text editor and copy the content between `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----`.

## 5.2.2.2.1.2 Create an OAuth Client in SAP SuccessFactors

### Procedure

1. In the SAP SuccessFactors system, go to [Admin Center](#) and search for **OAuth**. Choose [Manage OAuth2 Client Applications](#) from the search results.
2. Choose [Register Client Application](#).
3. In the [Application Name](#), choose a descriptive name for the client of your choice.
4. In the [Application URL](#) field, enter the URL of the extension application.
5. In the [X.509 Certificate](#) field, paste the content between `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` of the certificate you downloaded in the [Download the X509 Certificate in SAP BTP](#), step 4.
6. Choose [Register](#) to save the OAuth client.

## 5.2.2.2.1.3 Create an HTTP Destination Using SAML 2.0 Bearer Assertion Authentication

You create an HTTP destination to be able to make calls to the SAP SuccessFactors HXM Suite OData APIs using SAML 2.0 Bearer Assertion authentication.

### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose [Connectivity](#) > [Destinations](#).
3. Choose [New Destination](#) and fill in the following properties:

Property	Value
<a href="#">Name</a>	Enter a name for the destination.  For example, <code>sap_hcmcloud_core_odata</code> .
<a href="#">Type</a>	HTTP
<a href="#">URL</a>	Enter the URL of the SAP SuccessFactors OData API you want to consume. For a list of the API Endpoint URL for the SAP SuccessFactors environments, see <a href="#">About HXM Suite OData APIs</a> .

Property	Value
<i>Proxy Type</i>	Internet
<i>Authentication</i>	OAuth2SAMLBearerAssertion
<i>Audience</i>	www.successfactors.com
<i>AuthnContextClassRef</i>	<b>urn:oasis:names:tc:SAML:2.0:ac:classes:PreviousSession</b>
<i>Client Key</i>	Enter the API Key of the OAuth client you created in SAP SuccessFactors.
<i>Token Service URL</i>	<p>Enter the API Endpoint URL for the SAP SuccessFactors instance followed by <b>/oauth/token</b>. For example, <b>https://apisalesdemo2.successfactors.eu/oauth/token</b>.</p> <p>For a list of the API Endpoint URL for the SAP SuccessFactors environments, see <a href="#">About HXM Suite OData APIs</a>.</p>

4. In the *Additional Properties*, choose *New Property* to define the following properties:

Property	Value
<i>apiKey</i>	Enter the API Key of the OAuth client you created in SAP SuccessFactors.
<b>(Deprecated)</b> <i>SystemUser</i>	<p>The technical user for an OData access with SAML 2.0 Bearer Assertion authentication with technical user.</p> <p>Specify a value for this setting if you want to configure OData access with SAML 2.0 Bearer Assertion authentication with technical user.</p> <div style="border: 1px solid orange; padding: 10px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>This property is deprecated and will be removed soon. We recommend that you work on behalf of specific (named) users instead of working with a technical user.</p> <p>As an alternative for technical user communication, we strongly recommend that you use the Mutual Transport Layer Security (mTLS) protocol. See <a href="#">Using Mutual Transport Layer Security (mTLS) [page 1910]</a>.</p> </div>
<i>companyId</i>	The ID of your SAP SuccessFactors company.

Property	Value
<i>nameIdFormat</i>	<p><b>urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified</b> if the user ID will be propagated to SAP SuccessFactors application</p> <p>or</p> <p><b>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</b> if the user email will be propagated to SAP SuccessFactors.</p>

- (Optional) If you are using SAP Business Application Studio to develop your application, you have to specify another set of additional properties. See [What is SAP Business Application Studio](#).

In the *Additional Properties*, choose *New Property* to define the following properties related to the SAP Business Application Studio:

Property	Value
<i>WebIDEUsage</i>	Specify this property with value <b>odata_gen</b> to consume an OData service in your application.
<i>WebIDEEnabled</i>	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
<i>HTML5.DynamicDestination</i>	If your application does not run on Cloud Foundry, you have to establish a connection to an external system by setting this property to <b>true</b> .
<i>product.name</i>	<p><b>SAP SuccessFactors</b></p> <p>The type of the SAP System for which you create this HTTP destination.</p>

- Save the changes.

## 5.2.2.2.1.4 Consume the Destination

### Context

To consume the destination you have created, you use the Destination service. You can either consume the Destination service directly, or configure the application router to consume it.

- For more information about consuming the destination service using the application router, see [Application Routes and Destinations](#).

- For more information about consuming the destination service directly, see [Consuming the Destination Service \(Cloud Foundry Environment\)](#).

## 5.2.2.2.2 Using Mutual Transport Layer Security (mTLS)

### Context

The transport layer security (TLS) protocol encrypts the connection between client and server, following the TLS specification. When using mutual TLS, both the TLS client and the TLS server authenticate each other through X.509 certificates.

Mutual Transport Layer Security (mTLS) is considered more secure than the combination of client ID and client secret. When using mTLS, no secret is shared between the calling application in SAP BTP and SAP SuccessFactors.

#### Note

After setting up the mTLS, when sending requests to SAP SuccessFactors, you have to use an additional header in the HTTP call. The header is `successfactors-companyid` and its value is the SAP SuccessFactors company ID. See [SAP SuccessFactors API Reference Guide \(OData V2\): Headers](#).

To specify the `successfactors-companyid` header, select one of the following options:

- Provide the `successfactors-companyid` header in the source code of the extension application.
- If you use approuter with a destination, select one of the following:
  - Provide a custom code extension in the approuter. See [Extension API of the Application Router \[page 451\]](#).
  - Configure an additional property in the destination. For example, `URL.headers.<header-name>`. See <https://www.npmjs.com/package/@sap/approuter#destination-service> .

Follow these steps to enable mTLS when configuring the extension application's connectivity to SAP SuccessFactors.

### Procedure

1. [Generate X509 Certificate in SAP BTP \[page 1911\]](#).
2. [Create an HTTP Destination Using Client Certificate Authentication \[page 1912\]](#).
3. [Create the X509 Certificate Mapping in SAP SuccessFactors \[page 1913\]](#).

## 5.2.2.2.2.1 Generate X509 Certificate in SAP BTP

### Context

Before creating the HTTP destination, you have to generate an X509 certificate for your subaccount. Then, when creating the HTTP destination, you will be able to select it as a key store location.

### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose ► [Connectivity](#) ► [Destinations](#) ▾.
3. Choose [Certificates](#) and then choose [Generate Certificate](#) to generate the certificate for this subaccount.
4. In the [Generate new certificate](#) wizard:
  - In the [Certificate File Name](#) field, enter a name for the certificate.
  - In the [File Name Extension](#) dropdown menu, select the type of keystore you want to use, for example [PEM](#) or [p12](#).

#### Note

If you use SAP Cloud SDK to develop a JavaScript application, check the supported keystore types at [SAP Cloud SDK: Keystore Configuration](#) ➔ .

- In the [Certificate Common Name](#) field, enter the name of the technical user for consuming the SAP SuccessFactors HXM Suite OData API.

#### Note

The technical user can be any user with the respective permissions. These permissions depend on the use case and the API you want to access. To find out which permission you need to assign to the technical user, go to [SAP API Business Hub](#) ➔, find the SAP SuccessFactors API you want to access and from the [Overview](#) tab go to the [Documentation](#) section and open the [help.sap.com](#) link. There you find the right information for each API.

- (Optional) In the [Certificate Validity Time Unit](#) dropdown menu, select whether you want to set a validity for the certificate in days, months, or years.
- (Optional) In the [Certificate Validity Value](#) specify the validity of the certificate.
- (Optional) Select the [Enable automatic renewal](#) checkbox.
- Choose [Generate Certificate](#) and then choose [Cancel](#) to close the wizard.

## 5.2.2.2.2.2 Create an HTTP Destination Using Client Certificate Authentication

### Context

You have to create an HTTP destination to be able to make calls to the SAP SuccessFactors HXM Suite OData APIs using Client Certificate authentication.

### Procedure

1. In the SAP BTP cockpit, navigate to your extension subaccount in the Cloud Foundry environment.
2. Choose ► [Connectivity](#) ► [Destinations](#) ▾.
3. Choose [New Destination](#) and fill in the following properties:

Property	Value
<i>Name</i>	Enter a name for the destination. For example, <code>sap_hcmcloud_core_odata</code> .
<i>Type</i>	HTTP
<i>URL</i>	Enter the URL of the SAP SuccessFactors OData API you want to consume with <code>cert.</code> before <code>successfactors.com</code> . For a list of the API Endpoint URL for the SAP SuccessFactors environments, see <a href="#">List of SAP SuccessFactors API Servers</a> . For example, <code>https://api8sales.cert.successfactors.com</code> .
<i>Proxy Type</i>	Internet
<i>Authentication</i>	ClientCertificateAuthentication
<i>Key Store Location</i>	Select the certificate you have generated for the destinations in your subaccount in SAP BTP. See <a href="#">Generate X509 Certificate in SAP BTP [page 1911]</a> .

4. Save the changes.
5. Choose [Export](#) to download the certificate you have generated and assigned to this destination.
6. Save the ZIP file to your local system and extract the keystore file.
7. Open the keystore file in an editor of your choice and extract the certificate chain from the keystore. For example:

- If you are using the *PEM* keystore type:
  1. Decode the *.pem* file from Base64 format and create a new decoded *cert.pem* file.
  2. Open the *cert.pem* file and delete the section between the lines `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----` including these lines. Save the file.
- If you are using the *p12* keystore type:
  1. Decode the *.p12* file from Base64 format and create a new decoded *keystore.p12* file. For example, for Unix operating systems, use the command: `cat <your-file>.p12 | base64 --decode > keystore.p12`.
  2. Extract the certificate chain from the *keystore.p12* file and copy the result in a new *cert.pem* file. For example, for Unix operating systems, use the command: `openssl pkcs12 -info -in keystore.p12 -nokeys -out cert.pem`.
  3. Open the *cert.pem* file and clean *bag* attributes.

#### Note

Using this modified PEM file, you will create the X509 certificate mapping in SAP SuccessFactors. See [Create the X509 Certificate Mapping in SAP SuccessFactors \[page 1913\]](#).

## 5.2.2.2.2.3 Create the X509 Certificate Mapping in SAP SuccessFactors

### Prerequisites

Have set up the *Access to X509 Certificates* permission required to create X509 certificate mappings in the Security Center. See [Setting Up Permissions for Security Center](#).

### Procedure

1. In the SAP SuccessFactors system, go to *Admin Center* and search for **Security Center**.
2. Choose the *X.509 Public Certificate Mapping* tile.
3. Choose *Add*.
4. Fill in the following parameters:
  - In the *Configuration Name* field, enter a meaningful name for your X509 certificate mapping.
  - In the *Integration Name* dropdown menu, select *Business Technology Platform*.
  - In the *Certificate File* field, upload the certificate you have downloaded and edited when creating the HTTP destination in the SAP BTP cockpit. See [Create an HTTP Destination Using Client Certificate Authentication \[page 1912\]](#).

- In the *Login Name* field, enter the same technical user for consuming the SAP SuccessFactors HXM Suite OData API you have used when creating the HTTP destination in SAP BTP cockpit. See [Create an HTTP Destination Using Client Certificate Authentication \[page 1912\]](#).
5. Choose *Save*.

## 5.2.3 Extending SAP Cloud for Customer in the Cloud Foundry Environment Manually

This section guides you through the configuration tasks that you need to perform to enable the SAP BTP, Cloud Foundry environment for developing extension applications for your SAP Cloud for Customer system.

### Process Flow

You have to configure the cloud platform extension integration with SAP Cloud for Customer to enable the use of applications running on top of the platform from SAP Cloud for Customer.

#### 1. Authentication and Principal Propagation

A single sign-on configuration between SAP Cloud for Customer and the cloud platform and the principal propagation enablement ensure the secure and consistent access for the extension solutions. If your solution requires system-to-system data access, with no user propagation, you can implement it using a user with Basic authentication and no principal propagation.

##### → Tip

We recommend that you use SSO and OData access with principal propagation, to ensure that the data is accessed on behalf of the proper authorized user.

#### Implementation with SSO and principal propagation

When your scenario requires SSO and principal propagation, the SAP Cloud for Customer system and the subaccount in SAP BTP (where the extension application is deployed or subscribed) have to trust each other and use one and the same identity provider. For more information, see [Configuring Single Sign-On on Cloud Foundry Environment \[page 1915\]](#).

#### Implementation without SSO and principal propagation

If your scenario does not require SSO, principal propagation, or UI integration, you use a dedicated user and create an HTTP destination with Basic Authentication to configure the connectivity. For more information, see [Create and Configure the HTTP Destination \[page 1931\]](#).

#### 2. Connectivity Between SAP BTP and SAP Cloud for Customer

When your extension application needs to do read and write operations from/to the SAP Cloud for Customer system, you have to configure the connectivity to enable the use of SAP Cloud for Customer OData APIs. You need such connectivity to be established also when you want to embed the UIs of the extension solution into the SAP Cloud for Customer user interface.

The connectivity configuration steps are required on both systems and can be implemented with the following options depending on the security mechanisms for protecting the connectivity:

### Using OAuth

#### Note

- On the SAP Cloud for Customer side:
  - [Configure OAuth Identity Provider in SAP Cloud for Customer \[page 1930\]](#)
  - [Configure the OAuth Client for OData Access \[page 1930\]](#)
- On the SAP BTP side:
  - Create an HTTP destination with OAuthSAMLBearerAssertion for authentication method. For more details, see [Create and Configure the HTTP Destination \[page 1931\]](#).

### Using Basic Authentication

- On SAP Cloud for Customer side:
  - (If not available) Create a technical user with permissions to access the required SAP Cloud for Customer OData APIs and use it for the HTTP destination configuration when you choose Basic authentication for protecting the connectivity.
- On the SAP BTP side:
  - Create an HTTP destination with Basic authentication using the credentials of a technical user in the SAP Cloud for Customer system. For more details, see [Create and Configure the HTTP Destination \[page 1931\]](#).

## 3. User Interface Integration

The extension capabilities of the cloud platform allow developers to embed the user interface of the new solution in the SAP Cloud for Customer screens and this way to offer seamless end-user experience.

The UI integration is via the HTML mashups of the SAP Cloud for Customer solution. For more details how to create an HTML mashup for your new extension solution and how to make it visible in the SAP Cloud for Customer screens, see [Add Mashups on Screens](#).

### 5.2.3.1 Configuring Single Sign-On on Cloud Foundry Environment

You can configure the cloud platform extension integration with SAP Cloud for Customer to enable the use of applications running on top of the platform from SAP Cloud for Customer.

## Using SAP BTP

The SAP BTP service provides authentication, Single Sign-On, and on-premise integration. The SAP BTP service is closely integrated with SAP BTP, and it is offered as part of the platform.

To ensure the required security for accessing the extension applications, you need to configure the Single Sign-On between the extension subaccount in SAP BTP and the SAP Cloud for Customer tenant using a SAML

identity provider, for example SAP BTP. The Single Sign-On requires both solutions to be configured as trusted SAML service providers for the SAP BTP service and on the other side the SAP BTP service to be configured as trusted identity provider for the two solutions.

In this scenario, the authentication to SAP Cloud for Customer extension applications is restricted to the authorized users. The identity of a user is verified by the identity provider, as specified by SAML 2.0. The identity provider, (SAP BTP), stores a list of all users that are allowed to access the service provider (SAP Cloud for Customer) along with their credentials. The integration between the SAP Cloud for Customer and the SAP BTP is based on trust configuration. When a user attempts to access SAP Cloud for Customer for the first time, the system redirects the user to the identity provider for identification. From then on, the user session is kept active, and the user is no longer prompted for credentials when he or she, for example, tries to use the extension application. This is called Single Sign-On (SSO).

## Using Third-Party Identity Provider

You can use a third-party identity provider (which means a different from SAP BTP) as well to ensure the required security for your landscape. In this case you also need to perform a few configuration tasks on all the sides - SAP BTP, SAP Cloud for Customer, and the identity provider that you are using.

## Related Information

[Configuring Single Sign-On Using Identity Authentication \[page 1916\]](#)

[Configuring Single Sign-On Using Third-Party Identity Provider \[page 1927\]](#)

### 5.2.3.1.1 Configuring Single Sign-On Using Identity Authentication

To ensure the required security for your landscape you need to perform a few configuration tasks on all the sides - SAP BTP, Identity Authentication and SAP Cloud for Customer.

## Context

The following procedure describes how to configure Identity Authentication and SAP Cloud for Customer to use the authentication and Single Sign-On capabilities based on the industry standard SAML 2.0. You can also find information about how to configure the trust between Identity Authentication and the subaccount in the SAP BTP, Cloud Foundry environment, in case it is not configured by default.

## Procedure

1. Configure the trust settings between Identity Authentication and your SAP Cloud for Customer system. For more information, see [Setting Up Trust Between Identity Authentication and SAP Cloud for Customer \[page 1917\]](#).

### Note

If you already have a SAP Cloud for Customer system with existing users, you need to define these users in the Identity Authentication service as well. To do that, export as a CSV file the users of your company employees from your SAP Cloud for Customer system and import it into Identity Authentication.

2. Configure the SAP BTP trust settings and add the tenant of Identity Authentication available for your company as a SAML identity provider. For more information, see [Setting Up Trust Between Identity Authentication and SAP BTP \[page 1926\]](#).

## 5.2.3.1.1.1 Setting Up Trust Between Identity Authentication and SAP Cloud for Customer

To use Identity Authentication as a common identity provider between SAP BTP, Cloud Foundry environment and SAP Cloud for Customer, first you need to configure it for the SAP Cloud for Customer system.

## Procedure

1. Configure the Identity Authentication.
2. Configure SAP Cloud for Customer.
3. Configure an application's Home URL.

### 5.2.3.1.1.1.1 Configuring Identity Authentication

Use this procedure to configure the service provider (SAP Cloud for Customer) in the Identity Authentication tenant and to define the identity federation.

## Procedure

1. Get the service provider metadata XML file. To do so, you download the metadata XML file of your SAP Cloud for Customer system:
  - a. Log on to your SAP Cloud for Customer system as an administrator.

- b. Select ► [ADMINISTRATOR](#) ► [Common Tasks](#) ► and then choose [Configure Single Sign-On](#).
  - c. On the [CONFIGURE SINGLE SIGN-ON](#) screen, navigate to ► [MY SYSTEM](#) ► [GENERAL](#) ► [Download Metadata](#) ►.
  - d. Choose the [SP Metadata](#) link, to download the SAP Cloud for Customer metadata XML file. Save it locally on your file system to import in later on in the Identity Authentication.
2. Create a custom application to use it as a SAML2.0 service provider. Access the tenant's administration console for Identity Authentication by using the console's URL.

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

You can also get the URL from the Identity Authentication tenant registration e-mail.

- a. Choose ► [Applications & Resources](#) ► [Applications](#) ► from the menu on the left.
- b. Choose the [+Add](#) button on the left hand panel, and enter the name of your SAP Cloud for Customer system.

#### Note

The name of the application is displayed on the login and registration pages.

- c. Choose [Save](#).

The system creates an application and adds it to the list of applications.

3. Configure the SAML 2.0 trust with SAP Cloud for Customer as a service provider. In the tenant's administration console for Identity Authentication, execute the following steps:
  - a. On the left-hand side, choose the newly created application, and then choose [Trust](#).
  - b. Choose [SAML 2.0 Configuration](#).
  - c. Upload the metadata XML file of your SAP Cloud for Customer system that you have downloaded in **Step 1**.

On service provider metadata upload, the fields are populated with the parsed data from the XML file.

- d. Save the configuration settings.
4. Configure the identity federation on Identity Authentication. To do so, proceed as follows:
    - a. In the tenant's administration console for Identity Authentication, choose your SAP Cloud for Customer application, and navigate to ► [Trust](#) ► [Name ID Attribute](#) ►, and then select [Login Name](#).

This is the profile attribute that Identity Authentication sends to the application as a name ID. The application then uses this attribute to identify the user. You should select the attribute expected by your SAP Cloud for Customer system as a valid user.

#### Note

E-mail is not supported by the SAP Cloud for Customer system.

- b. Save your selection.

## 5.2.3.1.1.1.2 Configuring SAP Cloud for Customer

Configure the Single Sign-On (SSO) to Identity Authentication in the SAP Cloud for Customer system.

### Procedure

1. Get the identity provider metadata XML file. To do so:
  - a. Use the following URL to access the metadata for the Identity Authentication tenant:  
`https://<tenant ID>.accounts.ondemand.com/saml2/metadata.`
  - b. Save the content of the page locally on your file system as an XML file.
2. Log on to your SAP Cloud for Customer system as an administrator.
3. Choose ► **ADMINISTRATOR** ► *Common Tasks* ► and then choose *Configure Single Sign-On*.
4. On the **CONFIGURE SINGLE SIGN-ON** screen, choose the **IDENTITY PROVIDER** tab.
5. Choose *New Identity Provider*.
6. Browse and open the metadata XML file that you have downloaded in **Step 1**. By importing the metadata, the system automatically uploads the required signature certificate and encryption certificate.  
  
The new identity provider is activated and displayed in the *Trusted Identity Provider* list.
7. Once you have configured your identity provider, activate SSO in your SAP Cloud for Customer system. To do so, choose *Activate Single Sign-On*, and then choose *OK*.
8. To save your settings, choose *Save* in the upper left-hand corner.

## 5.2.3.1.1.1.3 Configuring the Application's Home URL

You can configure the *Home URL* of an application in the administration console for Identity Authentication.

### Context

Home URL is the URL that the user is redirected to after being authenticated. Initially, the *Home URL* for an application is not configured in the administration console for Identity Authentication. Once the URL has been set, you can change it.

#### → Remember

*Home URL* is necessary when you import new users in Identity Authentication. Identity Authentication needs to send activation e-mails to the new users and the home URL has to be mentioned in the e-mails. To access the application, the users have to activate their user accounts. For more information see [Importing or Updating SAP Cloud for Customer Users in Identity Authentication \[page 1923\]](#).

To configure the *Home URL*, proceed as follows:

## Procedure

1. Access the tenant's administration console for Identity Authentication by using the console's URL.

### Note

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

*Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation e-mail with a URL in it. This URL contains the *tenant ID*.

2. Choose **Applications & Resources** > **Applications** from the menu on the left.

This operation opens a list of the applications.

3. Choose the application that you want to edit.

### Note

Type the name of the application in the search field to filter the list items, or choose the application from the list on the left.

If you do not have a created application in your list, you can create one. For more information, see [Create a New Application](#).

4. Select the *Home URL* anchor text.

### Note

You get the Home URL from the SAP Cloud for Customer system:

- Log on to your SAP Cloud for Customer system as an administrator.
- Choose **ADMINISTRATOR** > **Common Tasks** and then choose *Configure Single Sign-On*.
- In the *Single Sign-On URL Handling* section, copy and save the URL from the *SSO URL* field. If this URL starts with uppercase *HTTPS* protocol, replace it with **https**.

- If you are configuring the URL for the first time, type the address in the pop-up dialog that appears.
- If you are editing the URL, choose *Edit* from the list item, and type the new address in the pop-up dialog.

5. Save your changes.

Once the application has been updated, the system displays the message `Application <name of application> updated`.

## 5.2.3.1.1.2 Uploading Users to Identity Authentication

When you configure the Identity Authentication service as the SAML identity provider for your SAP Cloud for Customer system, you have to make sure that all users from SAP Cloud for Customer will have an identity

record in the Identity Authentication service. For this purpose, you have to export the user details in a CSV file format and then use this CSV file to import these users into the Identity Authentication tenant of your company that will be used as the identity provider.

## Context

To upload the users of your SAP Cloud for Customer company into Identity Authentication, you export the user base and import it into Identity Authentication in CSV format.

## Procedure

1. Export the SAP Cloud for Customer users and save the data in CSV format. For more information, see [Exporting SAP Cloud for Customer Users \[page 1921\]](#).
2. Import the users (user names and user IDs) in the Identity Authentication tenant with the CSV file you have exported from your SAP Cloud for Customer system. For more information, see [Importing or Updating SAP Cloud for Customer Users in Identity Authentication \[page 1923\]](#).

### 5.2.3.1.1.2.1 Exporting SAP Cloud for Customer Users

Use this procedure to export SAP Cloud for Customer users and save the user data in CSV format.

## Context

You need to export the users from the SAP Cloud for Customer system, adapt the data and save it in CSV format so that you can import the data in the Identity Authentication tenant and thus allow your company employees to authenticate with their corporate credentials.

### Note

It is mandatory to have an e-mail for every user that you replicate from the SAP Cloud for Customer system in your Identity Authentication tenant.

Although in the SAP Cloud for Customer system having an e-mail for a user is not obligatory, you need to have this e-mail as a parameter when you export the users and import them in your subaccount in SAP BTP.

The CSV file with the SAP Cloud for Customer user data must contain the following columns:

- `status`
- `loginName`
- `mail`

- firstName
- lastName

## Procedure

1. Log on to your SAP Cloud for Customer system as an administrator.
2. Open the *Business Users* view. To do so, choose **ADMINISTRATOR** > **GENERAL SETTINGS** > *Business Users*.
3. To export the users, choose **Export** > **To Microsoft Excel®**.

The system exports the users in a Microsoft Excel® spreadsheet. The spreadsheet contains the following columns: *User Locked*, *Password Locked*, *User ID*, *Name*, *Technical ID*. The spreadsheet does not contain a column with the user e-mails and the user status.

4. Modify the spreadsheet as follows:
  - a. Remove the superfluous data and leave only the *User ID* and *Name* columns.
  - b. Rename the *User ID* column to **loginName** and split the *Name* column to **firstName** and **lastName** columns.

The data in the *loginName* stays the same, while the names from the former *Name* columns are split in the following way: first names go to the *firstName* column and last names go to the *lastName* column.

- c. Insert a new column before the *loginName* column and name it **status**. The status can be **active** or **inactive**.
- d. Insert a new column between *loginName* and *firstName* and name it **mail**.

Go to the SAP Cloud for Customer system. To get the e-mail of a user, select the user. The e-mail is displayed on the *General Data* tab page.

### Note

- The *status*, *loginName*, *mail* and *firstName* columns must be with a string value of up to 32 characters. The *lastName* column must be with a string value of up to 64 characters.
- The names in the *mail* and *loginName* columns must be unique.
- You cannot change the e-mail of an existing user.
- The *status* column defines whether the user is still active in the system and is able to work with any tenant applications. When a user is deleted, it is rendered inactive.

- e. Save the file in CSV format.

After you have modified and saved your file, you should have a CSV file with the following columns and similar data.

status	loginName	mail	firstName	lastName
active	EID00001	michael.adams@example.com	Michael	Adams

status	loginName	mail	firstName	lastName
active	EID00002	julie.armstrong@example.com	Julie	Armstrong
active	EID00003	donna.moore@example.com	Donna	Moore

## 5.2.3.1.1.2.2 Importing or Updating SAP Cloud for Customer Users in Identity Authentication

As a tenant administrator of the Identity Authentication, you can import new users or update existing ones for a specific application with a CSV file, and send activation e-mails to the users that have not received activation e-mails for that application so far.

### Prerequisites

- You are assigned the [Manage Applications](#) and [Manage Users](#) roles. For more information about how to assign administrator roles, see [Edit Administrator Authorizations](#).
- You have configured the trust between Identity Authentication tenant and the SAP Cloud for Customer system. For more information see [Setting Up Trust Between Identity Authentication and SAP Cloud for Customer \[page 1917\]](#).

#### Note

You need the metadata to configure the trust between the service provider and Identity Authentication, which is in the role of identity provider.

### Context

By importing new users with a CSV file, you create user profiles without passwords in Identity Authentication. As a result, the users receive e-mails with instructions how to activate their user accounts. After the users set their passwords, they can log on to the application for which they were imported. Based on the user access configuration of the application, the users can log on to other applications connected with the tenant in Identity Authentication.

#### Note

When a new application is created in the Identity Authentication tenant, the default value for user access is internal and you have to keep it like this. If you decide to change the user access to private for your subaccount in SAP BTP or for the SAP Cloud for Customer system, you have to make sure you import the users into that application. For more details, see

In addition to the new user import, you can specify existing users in the imported CSV file. You thus define the users to be updated in Identity Authentication.

The CSV file contains these columns *status*, *loginName*, *mail*, *firstName*, *lastName*. These columns are mandatory and they must always have values.

The *status*, *loginName*, *mail* and *firstName* columns must be with a string value of up to 32 characters. The *lastName* column must be with a string value of up to 64 characters.

The names in the *mail* and *loginName* columns must be unique.

### ⚠ Caution

You cannot change the e-mail of an existing user.

The *status* column defines whether the user is still active in the system and is able to work with any tenant applications. When a user is deleted, it is rendered inactive.

### 🔗 Example

status	loginName	mail	firstName	lastName
active	EID00001	michael.adams@example.com	Michael	Adams
active	EID00002	julie.armstrong@example.com	Julie	Armstrong
active	EID00003	donna.moore@example.com	Donna	Moore

To import users for an application into Identity Authentication, and to send activation e-mails, proceed as follows:

## Procedure

1. Access the tenant's administration console for Identity Authentication by using the console's URL.

### 📘 Note

The URL has the `https://<tenant ID>.subaccounts.ondemand.com/admin` pattern.

*Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation e-mail with a URL in it. This URL contains the *tenant ID*.

2. Choose the *Import Users* tile.

This operation opens the *Import Users* page.

3. Choose the application that you want to edit. This is the application you created in [Setting Up Trust Between Identity Authentication and SAP Cloud for Customer \[page 1917\]](#).

### Note

Type the name of the application in the search field to filter the list items, or choose the application from the list on the left.

If you do not have a created application in your list, you can create one. For more information, see [Setting Up Trust Between Identity Authentication and SAP Cloud for Customer \[page 1917\]](#).

4. Choose the *Browse...* button and specify the location of the CSV file.

### Note

Use a file smaller than 100 KB and with an extension `.csv`. If your file is 100 KB or larger, you have to import the user information in iterations with smaller size files.

5. Choose the *Import* button.

If the operation is successful, the system displays the message `Users imported or updated`.

6. Choose the one of the following options:

Option	Description
<b>Do nothing</b>	The users are imported or updated for the selected application, but they will not receive activation e-mails. The activation e-mails will be sent when you choose <a href="#">Send E-Mails</a> > <a href="#">Send</a> .
<b>Repeat steps 2 to 5</b>	The users are imported or updated for the selected application, but they will not receive activation e-mails. The activation e-mails will be sent when you choose <a href="#">Send E-Mails</a> > <a href="#">Send</a> .
<b>Choose</b> <a href="#">Send E-Mails</a> > <a href="#">Send</a>	This will send activation e-mails to all users that are imported for the selected application, but have not received activation e-mails so far.

### Note

The *Send* button is inactive if *Home URL* or SAML 2.0 configuration of the application is missing. You can only import users, but you cannot send activation emails.

You need the *Home URL* configured for the specific application to be able to send the activation e-mails to the imported new users. For more information, see [Configuring the Application's Home URL \[page 1919\]](#).

To access the application, the users have to activate their user accounts by following the link they receive in the e-mails.

## 5.2.3.1.1.3 Setting Up Trust Between Identity Authentication and SAP BTP

Use this procedure to configure the SAP BTP, Cloud Foundry environment trust settings and to add the tenant of Identity Authentication registered for your current SAP user as an identity provider.

### Context

Identity Authentication is closely integrated with SAP BTP, and it is offered as part of most of the cloud platform packages. For those packages the trust between the subaccount in SAP BTP and Identity Authentication is configured automatically and the tenant for Identity Authentication is set up by default, once you have a partner or customer subaccount. However, you can manually configure the trust and set up the Identity Authentication tenant if your scenario requires it.

### Procedure

1. In the Identity Authentication tenant, access the administration console by using the console's URL. You need to use another browser, or incognito session of the same browser.

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

You can also get the URL from the Identity Authentication tenant registration e-mail.

2. You have to save the metadata of your Identity Authentication tenant on your local file system as an XML file. You can either find the tenant at `https://<tenant ID>.accounts.ondemand.com/saml2/metadata` or access it via **Applications & Resources > Tenant Settings > SAML 2.0 Configuration**. Then choose the *Download Metadata File* link. You will need this metadata in **Step 5**.
3. Open the SAP BTP cockpit and select the region in which your subaccount is hosted. Select the global account that contains your subaccount, and then choose the tile of your subaccount. For more information about regions, see [Regions and API Endpoints Available for the Cloud Foundry Environment \[page 20\]](#).
4. Choose **Security > Trust Configuration**.
5. Choose *New Trust Configuration* and fill in the required fields:
  - a. In the *Metadata* field, upload the metadata file you have downloaded from the Identity Authentication tenant in **step 2**. All the required fields are automatically filled in.
  - b. In the *Name* field, enter a meaningful name of your choice.
  - c. Choose *Save*.
6. In the cockpit, download the service provider SAML metadata file. Open the link `https://<subaccount_subdomain>.authentication.<region_host>/saml/metadata` where:
  - `<subdomain>` is part of the subaccount details in the cockpit.
  - `<region_host>` is the API endpoint without `api.cf..` See [Regions and Hosts](#).

When you are prompted, save the XML file on your local file system. This file contains the SAML 2.0 metadata describing SAP BTP as a service provider.

You will need this metadata in **Step 11**.

7. In the Identity Authentication tenant, access the administration console by using the console's URL. You need to use another browser, or incognito session of the same browser.

The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

You can also get the URL from the Identity Authentication tenant registration e-mail.

8. Choose **► Applications & Resources ► Applications ▾**.
9. Choose the **+Add** button on the left-hand panel, and enter the name of your subaccount.
10. Choose **Save**.
11. Configure the SAML 2.0 trust with the subaccount as a service provider. To do so, proceed as follows:
  - a. On the left-hand side, choose the newly created application, and then choose **Trust**.
  - b. Choose **SAML 2.0 Configuration**.
  - c. Upload the metadata XML file of your subaccount that you have downloaded in **Step 6**.

On service provider metadata upload, the fields are populated with the parsed data from the XML file.
  - d. Save the configuration settings.

## Related Information

[Identity Authentication Get Started with Identity Authentication](#)  
[ID Federation with an Identity Authentication Tenant](#)

### 5.2.3.1.2 Configuring Single Sign-On Using Third-Party Identity Provider

To ensure the required security for your landscape you need to perform a few configuration tasks on all the sides - SAP BTP, SAP Cloud for Customer, and the identity provider that you are using (if this provider is different from Identity Authentication, for which there is a dedicated section).

## Procedure

1. Set up trust between your identity provider and SAP Cloud for Customer system.

See [Configure Your Solution for Single Sign-On](#).
2. Set up trust between your identity provider and SAP BTP.

See [Identity Federation](#).

## 5.2.3.2 Configuring the Extension Application

When configuring the extension application, you have to set up the connectivity from the subaccount in the SAP BTP, Cloud Foundry environment to the SAP Cloud for Customer system.

### Related Information

[Configure Application Authentication \[page 1928\]](#)

[Configuring the Extension Application Connectivity to SAP Cloud for Customer APIs \[page 1929\]](#)

### 5.2.3.2.1 Configure Application Authentication

#### Prerequisites

- Have the Cloud Foundry command line interface (cf CLI) downloaded and installed. See [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- Have Node.JS including its NPM Packager Manager installed. See <https://nodejs.org/en/> .

#### Context

You need your own application router that connects your extension application to the centrally provided user account and authentication (UAA) service. This means that you need to deploy an approuter as part of your application that manages the user authentication for you.

The approuter has these main functions:

- Handles authentication for all apps of the application
- Serves static resources
- Performs route mapping (URL mapping)
- In case of multitenancy, it derives the tenant information from the URL and provides it to the extended services for the Authorization and Trust Management service to redirect the authentication request to the tenant-specific identity provider. See [SAP Authorization and Trust Management Service \[page 2778\]](#).

## Procedure

1. To set up the application router as part of your application, execute the following command in cf CLI:

```
npm config set @sap:registry=https://registry.npmjs.org
```

2. Create a service instance of the Authorization and Trust Management service. See [Creating Service Instances \[page 231\]](#).
3. Add an application router. See [Application Router and Destination](#)
4. Update the extension application by using the `cf push` command in the cf CLI.
5. Verify that there is an authentication for your application and access the application using the approuter URL.
  - a. Get the url of the approuter using the `cf apps` command.
  - b. Enter the approuter URL in a browser.
  - c. You are redirected to the Identity Authentication service that you have already configured. See [Setting Up Trust Between Identity Authentication and SAP Cloud for Customer \[page 1917\]](#).
  - d. After a successful login, you will get redirected to the welcome page of you extension application if you have defined one.

### 5.2.3.2.2 Configuring the Extension Application Connectivity to SAP Cloud for Customer APIs

To set up the connectivity from a subaccount in SAP BTP to an SAP Cloud for Customer system, you need to create HTTP destinations in the SAP BTP cockpit. These destinations provide data communication via HTTP protocol.

You can use the SAML Bearer assertion flow for consuming OAuth-protected resources. Users are authenticated by using SAML against the configured trusted identity providers. The SAML assertion is then used to request an access token from an OAuth authorization server. This access token must be added as an Authorization header with value *Bearer <access token>* in all HTTP requests to the OAuth-protected resources.

These are the steps you need to follow:

1. [Configure OAuth Identity Provider in SAP Cloud for Customer \[page 1930\]](#)
2. [Configure the OAuth Client for OData Access \[page 1930\]](#)
3. [Create and Configure the HTTP Destination \[page 1931\]](#)

## Related Information

[Authentication for Java Resource Servers](#)

[Consuming the Destination Service \(Cloud Foundry Environment\)](#)

## 5.2.3.2.2.1 Configure OAuth Identity Provider in SAP Cloud for Customer

You need to add the SAP BTP service provider as a trusted OAuth identity provider.

### Procedure

1. Log on to the SAP BTP cockpit, and configure the settings as follows:
  - a. Navigate to your extension subaccount in the Cloud Foundry environment.
  - b. Choose ► [Connectivity](#) ► [Destinations](#) ▾.
  - c. Choose [Download Trust](#) to get the certificate for this subaccount and save it on your local file system.
  - d. Open the certificate in a text editor, copy the content between -----BEGIN CERTIFICATE----- and -----END CERTIFICATE-----, and save it in a file with the following format `<subaccount>_signing.cer`, where `<subaccount>` is the *Subaccount Name* from the *Subaccount Information* of your subaccount.
2. Log on to your SAP Cloud for Customer system as an administrator. Go to ► [ADMINISTRATOR](#) ► [Common Tasks](#) ▾. Choose ► [Configure OAuth 2.0 Identity Provider](#) ► [New OAuth2.0 Provider](#) ▾, and configure the settings as follows:
  - In the *Issuing Entity Name* field, enter `cfapps.<region_host>/<subaccountID>`. You go to the SAP BTP cockpit, navigate to the subaccount, go to *Overview* and:
    - For the `<region_host>`, copy the API endpoint from the *Cloud Foundry* section, and remove the `https://api.cf.`
    - For the `<subaccountID>`, copy the ID from the *Subaccount Details* section.For example, `cfapps.eu10.hana.ondemand.com/12345678-1234-1234-1234-1234578`.
  - From the *Primary Signing Certificate* field, browse the `<subaccount>_signing.cer` file that you saved on **step 1d**.
  - Select the *E-Mail Address* checkbox.
3. Choose [Submit](#).

## 5.2.3.2.2.2 Configure the OAuth Client for OData Access

In SAP Cloud for Customer, use this procedure to configure the OAuth client for OData access to SAP Cloud for Customer OData APIs.

### Procedure

1. Log on to your SAP Cloud for Customer system as an administrator. Go to ► [ADMINISTRATOR](#) ► [OAUTH2.0 CLIENT REGISTRATION](#) ▾.

2. Choose [New](#).
3. Specify a client secret, description, and token lifetime (in seconds). For example, 3600 seconds.
4. In the *Issuer Name* field, use the dropdown list to specify the identity provider that you created in the document [Configure OAuth Identity Provider in SAP Cloud for Customer \[page 1930\]](#).
5. Copy the entry in the *Client ID* field. You will need it later when creating the HTTP destination with OAuth authentication required for the connectivity to the SAP Cloud for Customer OData APIs.
6. In the *Scope* list, select the *UIWC:CC\_HOME* scope.
7. Choose [Save and Close](#).

## Next Steps

On the SAP BTP side configure the HTTP destination required to create an HTTP client for the OData API, and thus ensure the connectivity to SAP Cloud for Customer. For more information, see [Create and Configure the HTTP Destination \[page 1931\]](#).

## Related Information

[Configuring OAuth 2.0](#)

### 5.2.3.2.2.3 Create and Configure the HTTP Destination

## Prerequisites

You have logged into the SAP BTP cockpit from the landing page for your subaccount.

## Procedure

1. In the cockpit, navigate to your subaccount.
2. Choose [Connectivity](#) [Destinations](#) in the navigation panel.
3. Create an HTTP destination.

To enable principal propagation, create an *OAuth2SAMLBearerAssertion* HTTP destination and configure its settings as follows:

1. Configure the basic settings:

Parameter	Value
Name	Enter a meaningful name.
Type	<b>HTTP</b>
Description	(Optional) Enter a meaningful description.
URL	<b>https:// &lt;my_SAP_Cloud_for_Customer_system_name&gt;.crm.ondemand.com/sap/c4c/odata/v1/c4codataapi</b>
Proxy Type	<b>Internet</b>
Authentication	<b>OAuth2SAMLBearerAssertion</b>
Audience	Go to the SAP Cloud for Customer administration view, then navigate to <i>Configure Single Sign-On</i> under <i>General Settings</i> and copy the value from the <i>Local Service Provider</i> field.
Client Key	Client ID  Paste the entry you have copied from the <i>Client ID</i> field when configuring the OAuth client. For more information, see <a href="#">Configure the OAuth Client for OData Access [page 1930]</a> .
Token Service URL	<b>https:// &lt;my_SAP_Cloud_for_Customer_system_name&gt;.crm.ondemand.com/sap/bc/sec/oauth2/token</b>
Token Service User	Client ID  Paste the entry you have copied from the <i>Client ID</i> field when configuring the OAuth client. For more information, see <a href="#">Configure the OAuth Client for OData Access [page 1930]</a> .
Token Service Password	Client secret  Paste the entry you have copied from the <i>Client Secret</i> field when configuring the OAuth client. For more information, see <a href="#">Configure the OAuth Client for OData Access [page 1930]</a> .

2. Configure the required additional property. To do so, in the *Additional Properties* panel, choose *New Property*, and enter the following property:

### Note

You map the application users with the respective users in SAP Cloud for Customer using their email. Thanks to this mapping, you don't necessarily need to have a common identity provider between SAP BTP and SAP Cloud for Customer.

Parameter	Value
<code>authnContextClassRef</code>	<code>urn:none</code>
<code>nameIdFormat</code>	<code>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</code>
<code>scope</code>	Scope ID entries separated by space.  Paste the entry you have copied from the Client ID field when configuring the OAuth client. For more information, see <a href="#">Configure the OAuth Client for OData Access [page 1930]</a> .  Example: <code>UIWC:CC_HOME</code>
<code>userIdSource</code>	email

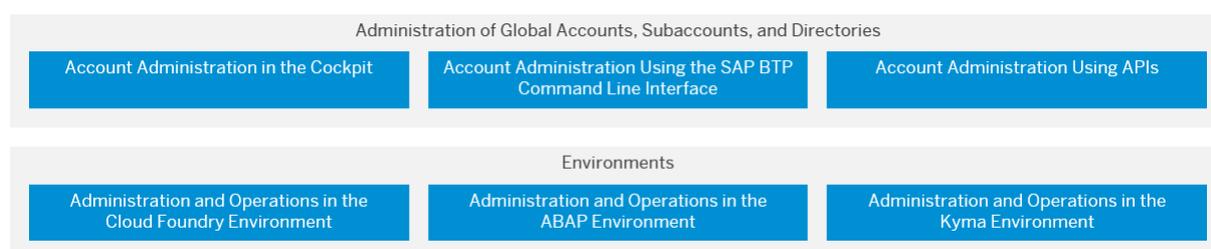

3. Select the *Use default JDK truststore* checkbox.
4. Save your entries.

## 6.1.1.1 Access the Cockpit

Learn how to access the SAP BTP cockpit.

### Context

When accessing the SAP BTP cockpit, be aware that your global account can be using either cloud management tools feature set A or B.

When using cloud management tools feature set A: Choose <https://account.eu1.hana.ondemand.com> to access the cockpit.

When using cloud management tools feature set B: Choose <https://cockpit.btp.cloud.sap> to access the cockpit. Depending on your own geo location this URL will redirect you to the closest regional Cockpit URL.

For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

## 6.1.1.1.1 Accessibility Features in SAP BTP cockpit

To optimize your experience of the SAP Business Technology Platform (SAP BTP), SAP BTP cockpit provides features and settings that help you use the software efficiently. Learn more about these features and settings and find out how to use them.

### Note

SAP BTP cockpit is based on SAPUI5. For this reason, accessibility features for SAPUI5 also apply. See the accessibility documentation for SAPUI5 on SAP Help Portal at [Accessibility for End Users](#).

For more information on screen reader support and keyboard shortcuts, see [Screen-Reader Support for SAPUI5 Controls](#) and [Keyboard Handling for SAPUI5 Elements](#).

Additionally, SAP BTP cockpit offers a high contrast black theme. See [Use High Contrast Black Theme \[page 1937\]](#).

## Use High Contrast Black Theme

### Context

This feature is recommended for users with need for high contrast themes.

### Steps

1. In the header toolbar choose [Your Name](#) [Settings](#).
2. Select the [High Contrast Black](#) theme and click [Apply](#).
3. Once you've saved your changes, the cockpit starts with the theme of your choice.

## 6.1.1.2 Navigate in the Cockpit

Learn how to navigate to your global accounts and subaccounts in the SAP BTP cockpit.

### Prerequisites

- Sign up for an enterprise or a trial account and receive your logon data. For more information, see [Try Out SAP BTP for Free \[page 127\]](#) or [Sign up for a Customer Account \[page 128\]](#).

### Procedure

1. Find out which cloud management tools feature set your global account uses. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).
2. Become familiar with the navigation behavior in the SAP BTP cockpit.
  - [Navigate in the Cockpit to Global Accounts and Subaccounts \[Feature Set A\] \[page 1938\]](#)
  - [Navigate in the Cockpit to Global Accounts and Subaccounts \[Feature Set B\] \[page 1939\]](#)

### Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

## Navigate in the Cockpit to Global Accounts and Subaccounts [Feature Set A]

### Procedure

1. Navigate to a global account.

You can see the following path in the breadcrumbs:

 Home /  <global\_account>

2. Navigate to a subaccount.

- a. Select the global account that contains the subaccount you'd like to navigate to by following the steps described above.
- b. Select the subaccount.

You can see the following path in the breadcrumbs:

 Home /  <global\_account> /  <subaccount>

# Navigate to Global Accounts, Directories, and Subaccounts [Feature Set B]

## Procedure

1. Navigate to a global account.

- **You have only one global account:**

When you log on to the cockpit you're automatically taken into your global account, to the *Account Explorer* page.

- **You have multiple global accounts:**

When you log on to the cockpit, a dialog opens up containing the list of all global accounts that you're part of. In this dialog, select the global account you want to navigate to.

### → Tip

If you have one global account you usually navigate to, you can choose *Remember my selection* in the initial dialog. This means you'll be automatically redirected to your preferred global account after logging on, without seeing the dialog with all the options each time.

If you've chosen a default global account, you can change or remove it anytime. To do so, navigate to the *Account Explorer* page of any global account, choose *Switch Global Account*.

To change it, choose the desired new default global account from the list, select *Save new selection as default global account* and choose *Continue*. Your new default is saved and you're redirected to that global account.

To delete the default global account and go back to seeing the selection dialog after each logon, simply choose the  icon next to your default global account name in the dialog and choose *Close*.

You can see which global account you are in at any time by looking at the first item in the breadcrumbs. It looks like this:  *<global account name>*

2. Navigate to a different global account.

- Navigate to the *Account Explorer* page at global account level and choose *Switch Global Account*.
- Use the dropdown menu next to the  *<global account name>*.

3. (Optional) Navigate to directories.

- a. When you enter your global account, you are by default taken to the *Account Explorer* page of that global account. To navigate to a directory, choose the corresponding entry in one of the views in the *Directories & Subaccounts* tab.

### 📌 Note

If a directory has the **user management** capability enabled, then you can access this directory (or its subdirectories) only if you are a global account admin or you are assigned as a member of the directory. See [Manage Users in Directories \[Feature Set B\] \[page 1973\]](#).

The  (*Locked*) icon is shown next to directories that you aren't authorized to access.

4. Navigate to subaccounts.

- a. When you enter your global account, you are by default taken to the *Account Explorer* page of that global account. To navigate to a subaccount, choose the corresponding entry from one of the views.

Once you've entered a subaccount, the breadcrumbs look like this:  [<global account name>](#) /  [<subaccount name>](#)

#### Note

To access a subaccount your user must either have authorizations in the subaccount tenant or, in the case of a subaccount that has the Cloud Foundry environment enabled, have authorizations in the Cloud Foundry org or space of the subaccount. See [About User Management in the Cloud Foundry Environment \[page 2243\]](#).

The  (*Locked*) icon is shown next to subaccounts that you aren't authorized to access.

### 6.1.1.3 Managing Global Accounts Using the Cockpit

Your SAP BTP global account is the entry point for managing the resources, landscape, and entitlements for your departments and projects in a self-service manner.

#### Feature Set B: Global Account Settings

As a global account administrator, you can access the global account settings by clicking  (*Global Account Settings*) in the SAP BTP cockpit.

In the *General* tab of the global account settings, you can obtain general information about your global account, including your global account ID, global account name, account type, payment models, contract status, global account subdomain, geographic access restrictions, and when your account was created.

#### Note

In this tab, you can change any of the values. The only value that is editable by you is the global account name, and you can do this in the *Account Explorer* page (see [Change the Display Name of Your Global Account \[page 1942\]](#)).

In the *Subaccount Defaults* tab in the global account settings, you can set the supported providers, the default provider, and the default region. These default settings are used when creating a new subaccount in this global account.

#### Related Information

[Setting Up Your Account Model](#)

[Managing Directories Using the Cockpit \[Feature Set B\] \[page 1968\]](#)

[Managing Subaccounts Using the Cockpit \[page 1976\]](#)

## 6.1.1.3.1 Log On to Your Global Account

Use the SAP BTP cockpit to log on to your global account and start working in SAP BTP.

### Prerequisites

You have received a welcome e-mail from SAP for your global account.

### Context

#### Note

The content in this section is only relevant for cloud management tools feature set A. For more information, see [Cloud Management Tools - Feature Set Overview](#).

When your organization signs a contract for SAP BTP services, an e-mail is sent to the e-mail address specified in the contract. The e-mail message contains the link to log on to the system and the SAP Cloud Identity credentials (user ID) for the specified user. These credentials can also be used for sites such as the [SAP Store](#) or the [SAP Community](#).

### Procedure

1. Use the link in your Welcome e-mail.

When using cloud management tools feature set A: Choose <https://account.eu1.hana.ondemand.com> to access the cockpit.

When using cloud management tools feature set B:

Choose <https://cockpit.btp.cloud.sap> to access the cockpit. Depending on your own geo location this URL will redirect you to the closest regional Cockpit URL.

For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

#### Note

If single sign-on has not been configured for you, you will have to enter your credentials. You'll find your logon ID in your Welcome e-mail.

2. Choose a global account.

## Results

When using cloud management tools feature set A: The global account [Overview](#) page opens.

When using cloud management tools feature set B: The [Account Explorer](#) page for that global account opens.

## Next Steps

- Track and monitor usage of services in your global account:
  - Use the filters to specify which usage information to display in the tables and monthly usage charts. The *Period* filter is applied to the chart display.
  - Some rounding or shortening is applied to large values. Mouse over values in the table to view the exact values in the tooltips.
  - Choose a row in the table to view its historic information in the [Monthly Usage](#) chart. To display a larger view of a chart, choose the  (*Zoom*) button.
  - To download the information in the [Overview](#) page to a Microsoft Excel file, choose the [Export](#) button.
- Access your subaccounts and create new subaccounts.  
See [Create a Subaccount \[page 1977\]](#).

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

[Account Model \[page 75\]](#)

[Global Accounts \[page 75\]](#)

[Create a Subaccount \[page 1977\]](#)

### 6.1.1.3.2 Change the Display Name of Your Global Account

Change the display name for the global account using the SAP BTP cockpit.

## Context

### → Tip

To find out how to tell which cloud management tools feature set your global account uses, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

# Changing the global account name [Feature Set A]

## Prerequisites

You are a member of the global account that you'd like to edit.

## Context

The overview of global accounts available to you is your starting point for viewing and changing global account details in the cockpit. To view or change the display name for a global account, trigger the intended action directly from the tile for the relevant global account.

## Procedure

1. Choose the global account for which you'd like to change the display name and choose  on its tile.  
A new dialog shows up with the mandatory *Display Name* field that is to be changed.
2. Enter the new human-readable name for the global account.
3. Save your changes.

# Changing the global account name [Feature Set B]

## Prerequisites

You are an admin of the global account that you'd like to edit.

## Context

### → Tip

You can also change the account's display name using the SAP BTP command line interface (btp CLI) with the `btp update accounts/global-account` command. See [Account Administration Using the SAP BTP Command Line Interface \(btp CLI\) \[page 2136\]](#).

## Procedure

1. Open your global account in the SAP BTP cockpit.
2. Navigate to the *Account Explorer* page.
3. In the *Directories & Subaccounts* view, locate the first entry in your account structure, which is your global account, and click **••• Actions**. Then select *Edit*.
4. In the *Edit Global Account* dialog box, enter the new human-readable name for the global account.
5. Save your changes.

## Related Information

[Account Model \[page 75\]](#)

### 6.1.1.3.3 Add Members to Your Global Account

Add users as global account members using the SAP BTP cockpit.

## Prerequisites

You have the Administrator role in the global account.

## Procedure

1. Find out which cloud management tools feature set your global account uses. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).
2. Learn how to add members to your global account.
  - [Add Members to Your Global Account \[Feature Set A\] \[page 1945\]](#)
  - [Add Members to Your Global Account \[Feature Set B\] \[page 1946\]](#)

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

[User and Member Management \[page 85\]](#)

# Add Members to Your Global Account [Feature Set A]

Add users as global account members using the SAP BTP cockpit.

## Context

The users you add as members at global account level are automatically assigned the Administrator role.

All global account administrators can do the following:

- View all the subaccounts in the global account, meaning all the subaccount tiles in the global account's [Subaccounts](#) page.
- Edit general properties of the subaccounts in the global account from the [Edit](#) icon in the subaccount tile.
- Create a new subaccount in the global account.
- View, add, and remove global account members.
- Manage entitlements for the global account.

On the [Members](#) page at the global account level in the cockpit, all global account members can view the global account administrators. If you're a subaccount member, you're also a member of the global account.

## Procedure

1. Choose the global account to which you'd like to add members.
2. In the navigation area, choose [Members](#).
3. Choose [Add Members](#).
4. Enter up to 100 user IDs. To separate them, you can use commas, spaces, semicolons, or line breaks.
5. Choose [Add Members](#).

## Next Steps

To delete members at global account level, choose  ([Delete](#)) next to the user's ID.

# Add Members to Your Global Account [Feature Set B]

Add members to your global account by assigning them a role collection.

## Prerequisites

- You must be a global account administrator to add other global account members.
- The users exist in a trusted platform identity provider.  
All users of SAP BTP are stored in identity providers, either in the default or in a custom identity provider. SAP BTP needs a copy of the user, sometimes called a shadow user. You assign the shadow user authorizations to access resources in SAP BTP. When a user authenticates, SAP BTP forwards the request to the identity provider.  
For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

## Context

Assign predefined or custom role collections to users who need to manage or view the global account in SAP BTP cockpit. Examples of predefined role collections include the following:

- *Global Account Administrator*
- *Global Account Viewer*

For more information about these role collections, see [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

## Procedure

1. Navigate to your global account.
2. Add a user to your global account.

For more information, see [Create Users \[page 2083\]](#).

3. Assign a role collection to the user.

For more information, see [Assign Users to Role Collections \[page 2092\]](#).

## Results

The next time this user logs on to the SAP BTP cockpit, the user can access this global account.

## 6.1.1.3.4 Managing Resource Providers

SAP BTP allows you to connect your global account in the SAP BTP cockpit to your provider account from a non-SAP cloud vendor, and consume remote service resources that you already own and which are supported by SAP through this channel.

### Note

The use of this functionality is subject to the availability of the supported non-SAP cloud vendors in your country or region.

## Context

For example, if you are subscribed to Amazon Web Services (AWS) and have already purchased services, such as PostgreSQL, you can register the vendor as a resource provider in SAP BTP and consume this service across your subaccounts together with other services offered by SAP.

SAP BTP currently supports the following vendors and their consumable services:

Cloud Vendor	Supported Services
Amazon Web Services	Amazon Relational Database Service (RDS) - PostgreSQL
Microsoft Azure	Azure Database for PostgreSQL

More information: [PostgreSQL on SAP BTP - Product Documentation](#)

## Configure a New Resource Provider

### Context

To consume the resources provisioned by your provider account, you need to first create a resource provider instance in the cockpit.

### Procedure

1. Navigate to your global account in the cockpit.
2. Choose *Resource Providers* from the left hand-side navigation panel.
3. Choose *New Provider*.
4. Choose the provider from the list of supported vendors.
5. Enter a display name for the provider.

You can create more than one instance of a given resource provider, each with its unique configuration properties. In such cases, the display name (and technical name) should be descriptive enough so that you and developers can easily differentiate between each instance.

6. Enter a unique technical name for the provider.

The technical name can contain only letters (a-z), digits (0-9), and underscore (\_) characters.

This name can be used by developers as a parameter when creating service instances from this provider.

#### Note

After you save the settings for the resource provider, you cannot change its technical name.

7. Choose either *Manually enter provider configuration properties* or *Add provider configuration properties by JSON file*, depending on how you prefer to provide the necessary configuration properties for the given provider.

#### Tip

Each supported vendor has its own unique configuration properties. The *New Resource Provider* form provides a description of each property and indicates whether they are mandatory or optional.

If you choose to configure the properties by uploading a JSON file, which is typically provided by the vendor, make sure that the file contains the required configuration properties for connecting to the provider, and is correctly formatted.

#### Sample Code

Sample JSON for configuring Amazon Web Services (AWS) as a resource provider:

```
{
  "access_key_id": "AWSACCESSKEY",
  "secret_access_key": "SECRETKEY",
  "vpc_id": "vpc-test",
  "region": "eu-central-1"
}
```

8. Save your changes.

The new resource provider is added to the resource providers table.

## Results

After you configure a new resource provider, its supported services are added as entitlements in your global account. In the [Entitlements](#) page in the cockpit, you can then allocate the required services and quotas to the relevant directories and subaccounts in your global account.

# Manage Resource Providers and Service Entitlements

## Context

Follow these steps to manage the resource providers that you have already configured in the cockpit.

## Procedure

1. Navigate to your global account in the cockpit.
2. Open the [Resource Providers](#) page.

The page displays the resources providers that you have already configured.

3. In the [Actions](#) columns, you can perform the following for each resource provider:

Action	Description
 <b>Manage Entitlements and Quotas</b>	<p>View the subaccount entitlements and quotas of services that are consumed from a resource provider.</p> <p>This action opens the <a href="#">Entitlements</a> &gt; <a href="#">Service Assignments</a> page in the cockpit, and is prefiltered for the selected resource provider.</p> <p>→ Tip</p> <p>Whenever you need to manage assigned entitlements, you can navigate directly to the <a href="#">Service Assignments</a> or <a href="#">Subaccount Assignments</a> pages in the cockpit without going through the <a href="#">Resource Providers</a> page.</p>
 <b>Edit Resource Provider</b>	<p>Edit the display name, description, and configuration properties of a resource provider.</p> <p>ⓘ Note</p> <p>You cannot change the technical name of a resource provider.</p>
 <b>Delete</b>	<p>Delete a resource provider.</p> <p>When you delete an existing resource provider, all the services offered by this instance of the resource provider will no longer be available on SAP BTP.</p> <p>ⓘ Note</p> <p>You cannot delete a resource provider that already has service entitlements assigned to subaccounts in your global account. To delete the provider, you need to first remove its subaccount assignments in the <a href="#">Subaccount Assignments</a> page.</p>

## Related Information

[Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)

### 6.1.1.3.5 Monitoring Usage and Consumption Costs in Your Global Account

SAP BTP cockpit supports advanced usage and cost monitoring of services in your global account. You can compare the usage and costs of multiple services and subaccounts, see monthly trends, and drill into subaccounts and service plans for detailed information.

#### Note

- The use of the consumption-based commercial model is subject to its availability in your country or region.
- If your global account uses only the subscription-based commercial model, then refer only to information described here about usage data and the *Usage* view. You can ignore any information in this topic about costs, cloud credits, and the *Billing* view.
- If your global account is running in [Feature Set A], see [Monitoring Usage and Consumption Costs in Your Global Account \[Feature Set A\] \[page 1961\]](#).

The *Costs and Usage* page in the cockpit provides a central and flexible experience for the following cost control flows:

- Continuously monitor and analyze the monthly usage and costs of services consumed by subaccounts and directories in your global account.
- Help you to verify your monthly billing statement against actual resource consumption.
- Help you to verify periodic cross-charges between your various business units based on subaccount and directory allocation/distribution.

Check out also the [Enhancing Costs, Usage and Contract Transparency](#) blog for more information.

## Accessing Costs and Usage for Your Global Account

To monitor and track costs and usage in your global account, open the global account in the cockpit and choose *Costs and Usage* in the navigation area.

#### Note

The *Costs and Usage* page is available only if your global account uses the consumption-based commercial model.

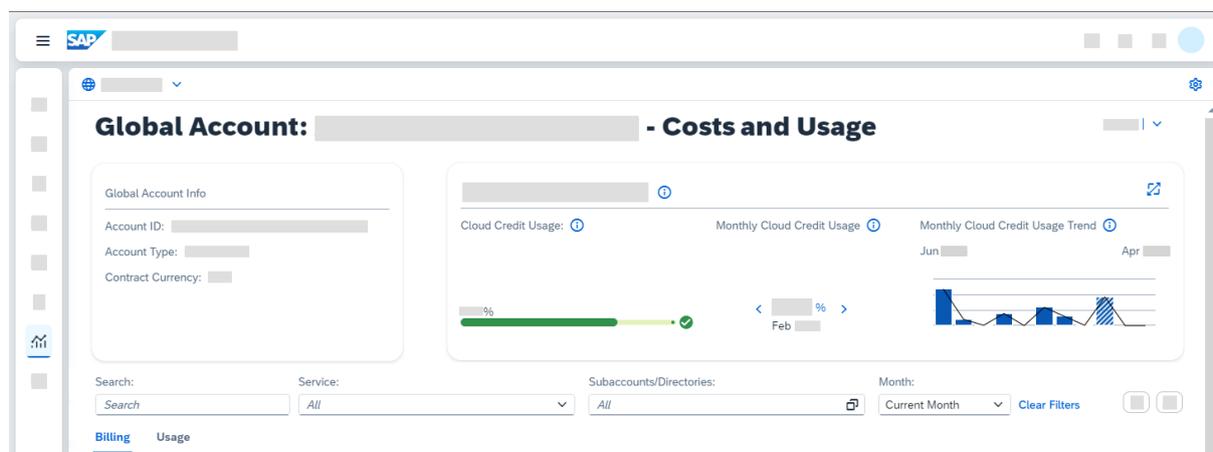

If your global account uses the subscription-based commercial model exclusively, then you must access the *Usage* page instead.

The *Usage* page is very similar to the *Costs and Usage* page, except you won't see any data relating to costs or cloud credits since your eligible services are already prepaid and you aren't charged per usage. See [Using the Usage View \[page 1958\]](#).

## Understanding the Cost and Usage Views

### Global Account and Contract Information

The upper area of the *Costs and Usage* page contains two side-by-side cards.

Simplified graphic of the upper area of the *Costs and Usage* page

The card on the left displays general info about your global account.

The card on the right displays information relating to the total consumption of your contract in relation to the consumption-based commercial model, such as SAP BTP Enterprise Agreement (SAP BTPEA), Cloud Platform Enterprise Agreement (CPEA), and Pay-As-You-Go for SAP BTP, which is used by your global account. In this

card, you'll see different information depending on the flavor of consumption-based commercial model that your global account uses:

Consumption-Based Model Flavor	What Information is Displayed
SAP BTP Enterprise Agreement (SAP BTPEA) Cloud Platform Enterprise Agreement (CPEA)	<p>Provides information relating to your cloud-credit usage per month as a percentage of your total cloud credits for the current contract phase and shows your monthly cloud credit usage trend.</p> <p>You'll see warnings if you're approaching or exceeded your cloud credit limit for the current contract phase. Any overages will be billed at list price, so make sure to contact SAP if you need more cloud credits.</p> <p>Pay attention to the following:</p> <ul style="list-style-type: none"><li>• Cloud-credit usage information is displayed for the current contract phase only. The total contract duration is split into contract phases (usually one year each) and the total cloud credits are divided between these phases.</li><li>• Your cloud credit balance is calculated each month by deducting the corresponding costs of all SAP BTP services for the previous month.</li></ul> <p>If your global account has received a cloud-credit refund at any time during the current contract phase, you may see a difference between your total usage and monthly usage in the chart.</p>
Pay-As-You-Go for SAP BTP	<p>Provides information relating to your monthly charges.</p> <p>You pay only for the SAP BTP services that you use, and you are billed monthly in arrears.</p> <p>If your global account has received a refund at any time during the current contract phase, you may see a difference between the displayed monthly costs and your billing document.</p>

If your global account uses a combination of the consumption-based commercial model and the subscription-based commercial model, this card shows billing and usage data that is charged solely according to the consumption-based commercial model. In other words, for services that are part of your subscription-based commercial agreement, the billing and usage data in this card applies only to consumption that exceeds your prepaid (subscription) quota. For this excess service usage, you are charged according to your contract for the consumption-based commercial model.

For example, if your subscription contract is entitled to consume a given service at a fixed cost for up to 100 unique site visits, and 151 unique site visits are registered, this card shows data relating only to the 51 visits that have exceeded the prepaid 100 visits.

#### → Tip

To see more details about your contract, cloud credit or cost details, and a different perspective of usage versus costs, click  (*Expand*).

#### 📘 Note

To extract all cost and usage data to a spreadsheet document for the last 12, 24, or 36 months, click the *Export* button. The default is 12 months. To choose a different period, click the button's menu. See [Exporting Usage and Cost Data Information \[page 1959\]](#).

## Filters and Search

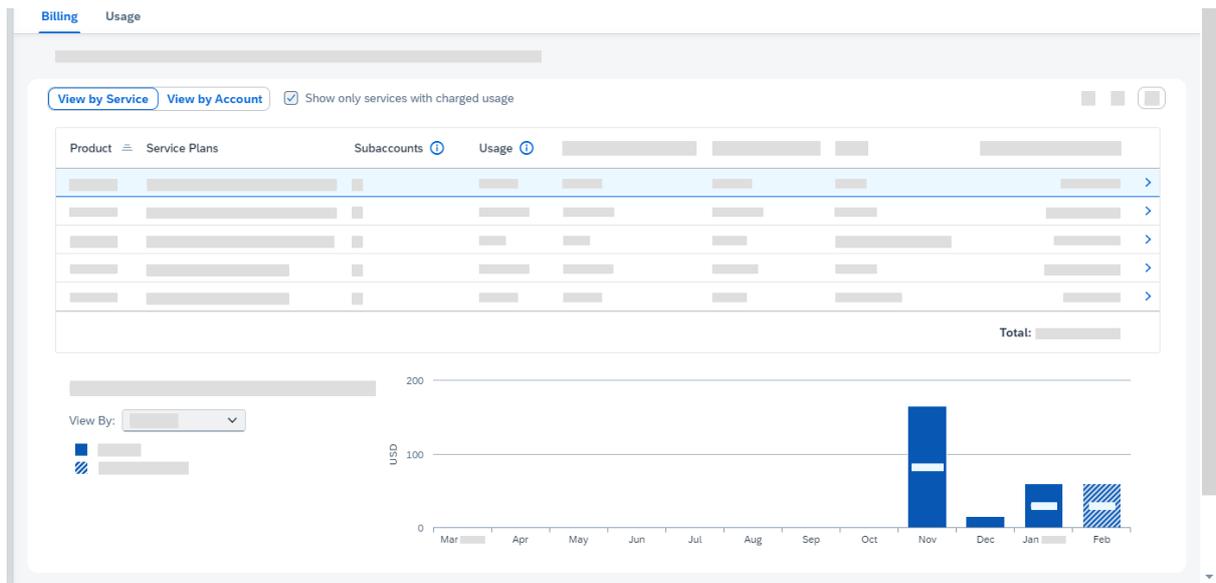

Below the two cards, is the filter and search area:

To Do This...	Do This...
Filter the data you want to view	<p>Above the <i>Billing</i> and <i>Usage</i> tabs, apply the filters to choose which services, subaccounts, directories, or billing month you want to view.</p> <p>You can also use the <i>Search</i> option. When you start typing, the search offers results that apply to service names, plan names, subaccount names, directory names, labels assigned to subaccounts and directories, product IDs (SKU), and metrics. The search offers suggestions only for items that are currently listed.</p> <div><p>→ Tip</p><p>If you've set up labels in your subaccounts and directories that reflect the distribution of these entities to your company structure or projects, you can easily track and manage cross charges by entering the labels of your subaccount and directory labels in the search.</p></div> <p>Your filter and search criteria are applied to both <i>Billing</i> and <i>Usage</i> views.</p>
Share or save the filtered view	<p>You can use the  (<i>Bookmarks</i>) option to copy the URL of the displayed view and the currently set filters.</p> <p>You can then save this URL as a bookmark in your browser, or you can share it with a colleague so they can quickly open the same view and filter settings.</p>

## Billing and Usage Views

Below the filter and search area, are the *Billing* and *Usage* views, represented by tabs:

<b>Billing</b>	<p>Shows the monthly billable service charges in your global account, based on the aggregation of your resource's actual usage.</p> <p>The aggregation of usage from all your subaccounts is calculated according to the pricing structure and legally billable metric of each service, as mentioned in the <a href="#">SAP BTP Service Description Guide</a>.</p> <div><p>ⓘ Note</p><p>This view relevant only if your global account uses a consumption-based commercial model. If your global account uses only the subscription-based commercial model, then all your eligible services and entitled quota are prepaid.</p></div> <p>For more information about this view, see <a href="#">Using the Billing View [page 1955]</a>.</p>
<b>Usage</b>	<p>Shows the data representing your actual non-aggregated monthly usage for services consumed in your subaccounts within your global account.</p> <p>This view applies to both the consumption-based and subscription-based commercial models.</p> <p>For more information about this view, see <a href="#">Using the Usage View [page 1958]</a>.</p>

Simplified graphic of the Billing view of the Costs and Usage page

The *Costs and Usage* page uses the same terminology that is used in your monthly balance statement, which facilitates better contract-to-billing traceability and verification for cost controllers. Get your latest balance statement from [SAP for Me](#).

#### → Remember

- The monthly balance statement, which is provided separately, contains legally binding information regarding your monthly costs. Details about costs on the *Costs and Usage* page in the cockpit are provided for informational purposes only. Any discrepancy between the information displayed in the cockpit and the information in your balance statement will be resolved in favor of the balance statement.
- Costs are displayed according to your contract currency.
- Global accounts are the only contractual billable entity for SAP BTP. Directories and subaccounts are used as structural entities in global accounts, and their usage and cost data should only be used for your internal cost estimations. The relative calculation per billable usage within each subaccount is an estimation only as it is based on certain measures, which in some cases can either be different from the metrics that are presented on the global account level, or that use different formulas than the ones used for billing.
- Cloud credit information and monthly costs apply to all regions used by the subaccounts in your global account. Usage and cost data is updated after your monthly balance statement has been generated.
- Usage data is updated after your monthly balance statement has been generated. For new global accounts, data is updated with the first billing cycle.
- Prices are listed as estimates if a consumable item has not yet been billed.
- In the cost and usage charts, estimated values are used for the period between the last balance statement and the current date. These are displayed as striped bars. These estimates are based on resource usage values before computation for billing and might change after the next balance statement is issued. The estimated values are not projected or forecast values.

Here are some useful tips that are common to both the *Billing* and *Usage* views:

To Do This...	Do This...
Find out what the table columns mean	Click the ⓘ ( <i>More Info</i> ) buttons in the column headings, where available.
Sort the data in ascending or descending order	Click a column heading in the table and choose the sort order you want. Sorting the tables can be very useful to determine which service plans and subaccounts have the highest and lowest costs.
Show or hide table columns	Click ⚙️ ( <i>Configure Table Columns</i> ) to configure which table columns you'd like to show and hide. The tables in each view have columns that are hidden by default. Open this setting to check if any of these columns apply to your needs.
Maximize the tables across the entire page	Click 🗉 ( <i>Expand</i> ). When you expand the view, the navigation panel is collapsed and the upper panel containing your global account and contract information is hidden. Click 🗑️ ( <i>Collapse</i> ) to go back to the standard view.
Adjust the width of table columns	Drag the column separators to the left or right.

## Using the Billing View

You can use the *Billing* view to display, monitor, and analyze your monthly charges of billable services, which have been consumed by the subaccounts in your global account over the last 12 months.

The billing data represents the aggregation of usage and its rating, which is determined by the pricing structure of each service. You can view the bill items for previous months or the estimated charge for the current month, to monitor your consumption costs.

The parameters for charged usage can include the amount of data processed, the number of users, the duration of use, or the specific functionality or modules used by each service. The specifics of these metrics are outlined in your contract.

### → Tip

This view is available only if your global account uses a consumption-based commercial model.

In the *Billing* view, you can switch between the *View by Service* and *View by Account* perspectives:

### View by Service

This perspective provides an overview of your charged usage across different services and their associated plans. It is particularly useful if you want to verify billing details.

Here are some useful tips for working in this perspective:

- To drill down and display more details about a particular service, click on an entry in the table or its > (*View Details*) button. When you drill down, a new pane opens and you can see, for example, exactly which subaccounts consume the selected service and the subtotal of charges and usage per directory and subaccount.

In this detailed view, subaccounts are displayed in the context of their account hierarchy. If you want to hide their directories and display the subaccounts as a flat list, choose the *Show subaccounts only* checkbox.

#### → Tip

In this detailed view, you can use the  (*Switch*) button for any subaccount to quickly open the *View by Account* perspective with the specific subaccount selected and displaying the plans it consumes.

You can also click  (*Configure Table Columns*) to display and hide columns.

- To filter the main table for specific services, use the *Service* dropdown list.
- If the display is cluttered by too many service plans or account entities that have no charged usage, you can choose the *Show only services with charged usage* checkbox to hide them.
- To filter the main table for specific subaccounts or directories, use the *Subaccounts/Directories* dropdown list.
- To view the monthly trend of a selected service plan over the last 12 months, scroll past the main table until you reach a graph.

#### → Tip

This graph is useful for seeing in which months a service plan has usage and costs, which service plans have increased or decreased usage/costs over time, or the months that have the highest and lowest usage/costs per service plan.

See other useful tips, such as table sorting, filtering, and searching, in the [Understanding the Cost and Usage Views \[page 1951\]](#) section.

## View by Account

This perspective provides an overview of your charged usage across different subaccounts and directories within your account hierarchy. It is particularly useful for verifying cross charges within your company or organization.

Here are some useful tips for working in this perspective:

- To drill down and display more details about a particular subaccount or directory, click on an entry in the table or its > ([View Details](#)) button. When you drill down, a new pane opens and you can see, for example, exactly which plans are consumed by the selected subaccount or directory and the subtotal of the charges and usage per plan.

### → Tip

In this detailed view, you can use the  ([Switch](#)) button to quickly open the [View by Services](#) perspective with the specific plan selected and displaying the subaccounts that consume it.

You can also click  ([Configure Table Columns](#)) to display and hide columns.

- To filter the main table for specific subaccounts or directories, use the [Subaccounts/Directories](#) dropdown list.
- If your account hierarchy includes directories, you can hide them and display your subaccounts as a flat list by choosing the [Show only subaccounts](#) checkbox.
- You can quickly expand or collapse the entire account hierarchy by clicking the  ([Expand All](#)) and  ([Collapse All](#)) buttons.
- To filter the main table for specific services, use the [Services](#) dropdown list.
- To view the monthly trend of a selected subaccount or directory over the last 12 months, scroll past the main table until you reach a graph.

### → Tip

The graph is useful for seeing in which months a subaccount or directory has usage and costs, which subaccounts or directories have increased or decreased usage/costs over time, or the months that have the highest and lowest usage/costs per subaccount or directory.

See other useful tips, such as table sorting and searching, in the [Understanding the Cost and Usage Views \[page 1951\]](#) section.

If your global account has subaccounts that have been deleted but have charges in the last 12 months while they were still active, they will still be listed. Such subaccounts are marked with ([deleted](#)) after their name. If these subaccounts were originally located under a directory, you'll see them listed directly under the root global account.

If your global accounts uses both a subscription-based and a commercial-based model, the [Usage](#) column shows the combined total usage of services, both subscription-based and consumption-based. Note that:

- The subscription-based consumption includes usage of services that falls within the prepaid quota that is specified in your subscription-based commercial model agreement. This part of the combined usage is shown in the [Prepaid Quota](#) column. There will be no additional billing for consumption of the services that falls within this prepaid quota.

- The consumption-based usage includes the usage of services that exceeds the prepaid subscription-based quota. This part of the combined usage is shown in the *Charged Usage* column. For this usage, you'll be charged based on the terms outlined in your consumption-based commercial model agreement.

## Using the Usage View

Use the *Usage* view to display, monitor, and analyze the distribution of the actual (also called raw) monthly usage metrics for services consumed by subaccounts in your global account over the last 12 months.

### Note

The *Usage* view displays data prior to aggregation for billing and can contain metrics that will not be aggregated since they are always free or belong to free services. Hence, you may notice some discrepancies when comparing the data in the *Usage* view to the overall usage data shown in the *Billing* view. Billable usage data is aggregated at the global account level and then processed according to accounting formulas to generate your monthly billing statement.

Pay attention also to the following:

- If your global account uses only a consumption-based commercial model, such as SAP BTP Enterprise Agreement (SAP BTPEA), Cloud Platform Enterprise Agreement (CPEA), and Pay-As-You-Go for SAP BTP, this view includes all usage data, including non-rated services, such as free service plans.
- If your global account uses both the consumption-based and subscription-based commercial models, this view combines all usage data, which falls under your consumption-based plans, prepaid subscription quota, and non-rated data sets, such as free service plans. You can see the distribution of charged and prepaid usage and costs in the *Billing* view.

To Do This...	Do This...
Drill down and display more details about a particular service	<p>Click on an entry in the table or its &gt; (<i>View Details</i>) button. When you drill down, a new pane opens and you can see, for example, which subaccounts are consuming the selected service and the subtotal of usage per directory and subaccount.</p> <p>In this detailed view, subaccounts are displayed in the context of their account hierarchy. If you want to hide their directories and display the subaccounts as a flat list, choose the <i>Show subaccounts only</i> checkbox.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p>→ Tip</p> <p>In this detailed view, you can click ⚙ (<i>Configure Table Columns</i>) to display and hide columns.</p> </div>
Filter by specific services	<p>Choose one or more in the <i>Service</i> dropdown list.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p>→ Tip</p> <p>If the display is cluttered by too many service plans that have no usage, choose the <i>Show only used services</i> checkbox to quickly hide them.</p> </div>

To Do This...	Do This...
Filter by specific subaccounts and directories	Choose one or more subaccounts or directories in the <a href="#">Subaccounts/Directories</a> dropdown list.
View the monthly trend of a selected service plan over the last 12 months	<p>Scroll down and view the graph below the main table.</p> <p>This graph is useful for seeing changes in usage trends over time, including the months with the highest and lowest usage per service.</p>

### → Tip

See other useful tips, such as table sorting, filtering, and searching, in the [Understanding the Cost and Usage Views \[page 1951\]](#) section.

## Exporting Usage and Cost Data Information

To export your usage and cost data to a Microsoft Excel spreadsheet document, use the [Export](#) button menu in the upper area of the page, and choose the period; either the last 12, 24, or 36 months. If you click the [Export](#) button without choosing a period in the menu, the default is 12 months.

### ⓘ Note

All of the information for the selected period is extracted to the Microsoft Excel document. It does not consider any of the filters you may have applied to the tables.

The exported document contains several sheets (tabs). The sheets that are included depend on the commercial model that is used by your global account as shown in the following table:

Sheet Name	Description	Commercial Model	
		Subscription-Based	Consumption-Based
<b>Global Account Info</b>	Provides general information about your global account. If there is a cloud-credit balance for the global account, then its cloud-credit usage, per month as a percentage of your total cloud credits for the current contract phase, is also shown.	Yes	Yes
<b>Global Account Costs</b>	<p>Allows you to view total monthly usage data and costs for all billable services and plans consumed at the level of your global account.</p> <p>The items listed are all the billed items that are created in the accounting system and deducted from the cloud-credit balance of your global account.</p>	No	Yes

Sheet Name	Description	Commercial Model	
		Subscription-Based	Consumption-Based
<b>Subaccount Costs by Service</b>	<p>Allows you to view monthly usage data and costs of all billable services consumed by plan and subaccount.</p> <p>All subaccount calculations are estimated and proportionate to the total global account usage:</p> <p>[Subaccount usage / Global account usage x Rate plan per SKU]</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>Note</b></p> <p>Global accounts are the only contractual billable entity for SAP BTP. Directories and subaccounts are used as structural entities in the global account, and their usage and cost data should only be used for your internal cost estimations. The relative calculation per billable usage within each subaccount is an estimation only as it is based on certain measures which in some cases can either be different from the metrics that are presented in the <i>Global Account Costs</i> tab, or which use different formulas than the ones used for billing.</p> </div>	No	Yes
<b>Actual Usage</b>	<p>Allows to you to view the actual monthly usage data of all consumed services by plan, subaccount, and space.</p> <p>Actual or raw usage data is different to the billed usage that is used in your billing document, and includes non-billable services.</p> <p>The aggregated usage for each service is based on a formula that is specific to each service, for example, MIN, MAX, or AVG.</p>	Yes	Yes
<b>Labels</b>	<p>Lists the user-defined labels that are assigned directly to each subaccount that has usage data. Also lists the labels that are inherited by the subaccounts from their parent directories, and the IDs of those subaccounts.</p> <p>This sheet does not display any usage data; however, you can use this information to determine usage by label by extrapolating the subaccount usage data in the other sheets to the labels assigned to the subaccounts in this sheet.</p>	Yes	Yes

### 6.1.1.3.5.1 Monitoring Usage and Consumption Costs in Your Global Account [Feature Set A]

In a global account that uses the consumption-based commercial model, you can monitor the usage of billed services and your consumption costs in the SAP BTP cockpit.

#### Note

The content in this section is only relevant for cloud management tools feature set A. For more information, see [Cloud Management Tools - Feature Set Overview](#).

#### Note

- The use of the consumption-based commercial model is subject to its availability in your country or region.
- If your global account uses the subscription-based commercial model, then information in this topic that refers to usage data also applies to you. Ignore information about costs and cloud credits.

## Accessing Usage Analytics for Your Global Account

To monitor and track usage in your global account, open the global account in the cockpit and choose [Overview](#) in the navigation area.

The global account's [Overview](#) page provides information about the usage of cloud credits (if your account has a cloud-credit balance) and costs for a global account, and the usage of services in the global account and its subaccounts.

## Using the Global Account's Usage Analytics / Overview Page

### Note

- Global accounts that use the consumption-based commercial model can include actual usage information on the Cloud Foundry space level, which is different from billed usage used in your billing document. Usage data is processed according to accounting formulas that generate a billing document that aggregates all usage, from all spaces, so that it is favorable to customers. There is no unified method to calculate costs based on actual usage.
- Costs are displayed according to your contract currency.
- If your global account uses the subscription-based commercial model exclusively, then only usage data is displayed. Cloud credits and cost information is not relevant for such accounts.
- If your global account is licensed for both the consumption-based and subscription-based commercial models, the *Global Account Costs*, *Cloud Credits Usage*, and *Global Account Overview* views in this page show billing and usage data that is charged solely according to the consumption-based commercial model. For services in your subscription-based commercial agreement, you'll see billing and usage data for usage that exceeds your subscribed quota. For any excess service usage, you are charged according to your contract for the consumption-based commercial model.  
For example, if your subscription contract is entitled to consume a given service at a fixed cost for up to 100 unique site visits, and 151 unique site visits are registered, these views will show data relating only to the 51 visits that have exceeded the 100 limit.  
When viewing usage data on the service or subaccount level for such accounts in the remaining views in this page, the displayed data is the total combined usage for both consumption-based and subscription-based commercial models.

- When there is a cloud-credit balance for the global account, the cloud-credit usage information is displayed for the current contract period. The total contract duration is split into contract periods (usually of one year each) and the total cloud credits are divided between these periods.

### Note

If your global account has received a cloud-credit refund at any time during the current contract phase, you may see a difference between your total usage and monthly usage in the chart.

- When there is no cloud-credit balance for the global account, the monthly total costs for the global account are displayed from the contract start date.

### Note

If your global account has received a refund at any time during the current contract phase, you may see a difference between the displayed monthly costs and your billing document.

- In the resource usage views, use the filters to specify which information to display. The *Period* filter applies only to the chart display.
- Some rounding or shortening is applied to large values. Mouse over values in the table to view the exact values in the tooltips.
- Choose a row in the table to view its historic information in the *Monthly Usage* chart.
- To display a larger view of a chart, choose the  (*Zoom*) button.

## Understanding the Views

View	Description	Action
<b>Global Account Info</b>	Displays general information about the global account, including the number of subaccounts it contains and the number of regions which have these subaccounts.	Click the <a href="#">Subaccounts</a> link to navigate directly to the <a href="#">Subaccounts</a> page.
<b>Cloud Credits Usage</b> (Only displayed when there is a cloud-credit balance for a global account that uses the consumption-based commercial mode.)	<p>Displays the current balance and monthly usage of cloud credits as a percentage of the cloud credits allocated per contract period.</p> <ul style="list-style-type: none"> <li>Cloud-credit information is based on the monthly balance statements for the global account.</li> <li>For the time period between the last balance statement and the current date, the chart uses estimated values, which are displayed as striped bars. These estimates are based on resource usage values before computation for billing, and might change after the next balance statement is issued. The estimated values are not projected or forecast values.</li> </ul> <p>Alerts are displayed when you have used more than 90% and when you reach 100% of your cloud credits.</p>	
<b>Global Account Costs</b> (Only displayed when there is no cloud-credit balance for a global account that uses the consumption-based commercial mode.)	<p>Displays the total cost per month for usage of services in the global account from the contract start date.</p> <p>All cost information is for all regions in the global account.</p> <p>Actual costs are updated after the monthly statement is generated.</p>	

View	Description	Action
<b>Global Account Overview</b>	<p>Displays usage and costs of all services in the global account. The information is broken down according to service plans. All the regions in which a service plan is available are displayed; however, actual usage is only in the regions of your subaccounts.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>Usage and cost information is updated every 24 hours. Data for the first of the month might not appear until the following day.</p> </div> <p>The charts display information for each month for all service plans in the table or only for the selected row. Provisional data for the current month is displayed as striped bars.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>Some service plans have differential pricing depending on the region. Usage and costs of a service plan in multiple regions with differential pricing are displayed as separate items.</p> </div>	<p>Use the <a href="#">View By</a> options to switch the view between service plan usage and costs for the global account.</p> <p>Use the filter to select the environment and service for which you want to view information.</p> <p>For the chart display, select a row, and filter by period. If no row is selected, the chart displays information for all the service plans in the table.</p>
<b>Service Usage</b>	<p>Displays resource usage according to service. Some service plans may display usage according to multiple metrics.</p>	<p>Use the filter to select the service and subaccount for which to display usage.</p> <p>For the chart display, select a row, and filter by period. If no row is selected, the chart displays information for all the service plans in the table.</p>
<b>Subaccount Usage</b>	<p>Displays resource usage according to subaccount. Some service plans may display usage according to multiple metrics.</p>	<p>Use the filter to select the subaccount for which to display usage.</p> <p>For the chart display, select a row and filter by period. If no row is selected, the chart displays information for all the service plans in the table.</p>

## Exporting Usage and Cost Data Information

You can export the displayed usage and cost data to a spreadsheet document:

- To export usage and cost data from all the views, choose [Export > All Data](#).
- To export only cloud-credit usage data, choose [Export > Cloud Credits Usage](#).

The document with the relevant data is downloaded. The document contains several sheets (tabs). The sheets that are included in the export depend on the commercial model that is used by your global account (and the export option that you selected).

Sheet Name	Description	Commercial Model	
		Subscription-Based	Consumption-Based
Global Account Info	Provides general information about your global account. If there is a cloud-credit balance for the global account, then its cloud-credit usage, per month as a percentage of your total cloud credits for the current contract period, is also shown.	Yes	Yes
Global Account Costs	Allows you to view total monthly usage data and costs for all billable services and plans consumed at the level of your global account.  The items listed are all the billed items that are created in the accounting system and deducted from the cloud-credit balance of your global account.	No	Yes
Subaccount Costs by Service	Allows you to view monthly usage data and costs of all billable services consumed by plan and subaccount.  All subaccount calculations are estimated and proportionate to the total global account usage:  [Subaccount usage / Global account usage x Rate plan per SKU]	No	Yes

**Note**

Global accounts are the only contractual billable entity for SAP BTP. Subaccounts are used as structural entities in global account, and their usage and cost data should only be used for your internal cost estimations. The relative calculation per billable usage within each subaccount is an estimation only as it is based on certain measures which in some cases can either be different from the metrics that are presented in the *Global Account Costs* tab or which use different formulas than the ones used for billing.

Sheet Name	Description	Commercial Model	
		Subscription-Based	Consumption-Based
Actual Usage	<p>Allows to you to view the actual monthly usage data of all consumed services by plan, subaccount, and space.</p> <p>Actual or raw usage data is different to the billed usage that is used in your billing document, and includes non-billable services.</p> <p>The aggregated usage for each service is based on a formula that is specific to each service, for example, MIN, MAX, or AVG.</p>	Yes	Yes

### ❖ Example

A global account, which uses the consumption-based commercial model, has the following usage data in a given month, where SAP HANA and Application Runtime are billable services, and Destination is a non-billable service:

Subaccount 1	1x SAP HANA 256 GB, 200 MB of Application Runtime, and 300 API calls of Destination
	200 MB of Application Runtime and 300 API calls of Destination
Subaccount 2	1x SAP HANA 512 GB, 600 MB of Application Runtime, and 300 API calls of Destination

Based on these usage measurements, you would see the following data in the spreadsheet. Each listed item represents one row in the spreadsheet. Cost prices shown are for illustration purposes only and do not reflect the actual rates for the mentioned services.

Sheet	Sample Usage and Cost Data Displayed in Spreadsheet
Global Account Costs	<ul style="list-style-type: none"> <li>1 instance of SAP HANA 256 = EUR 1024</li> <li>1 instance of SAP HANA 512 = EUR 2048</li> <li>1 GB of Application Runtime = EUR 100 + estimated cost distribution to subaccounts</li> </ul>
Subaccount Costs by Service	<ul style="list-style-type: none"> <li>Subaccount 1: 1 instance of SAP HANA 256 = EUR 1024</li> <li>Subaccount 2: 1 instance of SAP HANA 512 = EUR 2048</li> <li>Subaccount 1: 400 MB of Application Runtime = EUR 40 (400 MB / 1 GB x EUR 100)</li> <li>Subaccount 2: 600 MB of Application Runtime = EUR 60 (600 MB / 1 GB x EUR 100)</li> </ul>

Sheet	Sample Usage and Cost Data Displayed in Spreadsheet
Actual Usage	<ul style="list-style-type: none"> <li>• Subaccount 1   Space A: 1 instance of SAP HANA 256</li> <li>• Subaccount 2   Space C: 1 instance of SAP HANA 512</li> <li>• Subaccount 1   Space A: 200 MB of Application Runtime</li> <li>• Subaccount 1   Space B: 200 MB of Application Runtime</li> <li>• Subaccount 2   Space C: 600 MB of Application Runtime</li> <li>• Subaccount 1   Space A: 300 API calls of Destination</li> <li>• Subaccount 1   Space B: 300 API calls of Destination</li> <li>• Subaccount 2   Space C: 300 API calls of Destination</li> </ul>

### 6.1.1.3.6 Configure Legal Information

Administrators can define legal links per enterprise global account in the SAP BTP cockpit.

## Prerequisites

You have the Administrator role for the global account for which you'd like to define legal links.

## Context

You can define the privacy link relevant for a global account so the members of this global account can view this information.

## Procedure

1. Choose the global account for which you'd like to make changes.
2. In the left-hand navigation, choose ► [Legal Information](#) ► [Configure Privacy Link](#) ►.
3. Enter the relevant URL.

4. Save your changes.

The links you configured are available in the *Legal Information* menu.

## Related Information

[Navigate in the Cockpit \[page 1938\]](#)

### 6.1.1.4 Managing Directories Using the Cockpit [Feature Set B]

Learn how to organize and manage your subaccounts according to your technical and business needs by using directories in the SAP BTP cockpit.

## Context

### Note

This feature is new in Feature Set B so there is no equivalent in Feature Set A. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

## Procedure

1. Learn how to [Create a Directory \[Feature Set B\] \[page 1969\]](#).
2. Learn how to [Manage the Account Explorer Hierarchy \[Feature Set B\] \[page 1971\]](#).
3. Learn how to [Manage Users in Directories \[Feature Set B\] \[page 1973\]](#).
4. Learn how to [View Directory Usage Analytics \[Feature Set B\] \[page 1974\]](#).

## Related Information

[Directories \[Feature Set B\] \[page 77\]](#)

[Managing Subaccounts Using the Cockpit \[page 1976\]](#)

## 6.1.1.4.1 Create a Directory [Feature Set B]

Create a directory using the SAP BTP cockpit to organize and manage your subaccounts. For example, you can group subaccounts by project, team, or department.

### Context

#### 📘 Note

This feature is new in Feature Set B so there is no equivalent in Feature Set A. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

#### → Recommendation

Before creating your subaccounts, we recommend you learn more about [Setting Up Your Account Model](#).

For more information about directories, see [Directories \[Feature Set B\] \[page 77\]](#).

### Procedure

1. In your global account, navigate to the [Account Explorer](#) page.
2. In the [Create](#) dropdown, choose [Directory](#).

#### → Tip

You can also create a directory by selecting [Create Directory](#) from the **⋮ Actions** menu button of the global account or an existing directory.

3. In the [Create Directory](#) dialog box, enter a display name for your new directory and choose a parent. The parent can be the global account or another directory.
4. **Optional:** Under [Advanced](#), choose the [Enable entitlement management](#) option if you want to manage the entitlements that are used by the subaccounts under this directory. This allows you to reserve quota for service plans so that they cannot be assigned to other subaccounts or directories. For more information, see [Entitlements and Quotas \[page 81\]](#) and [Configure Entitlements and Quotas for Directories \[Feature Set B\] \[page 1998\]](#).

You can enable this feature later from the [▶ Entitlements > Entity Entitlements ▶](#) page or by editing the directory in the [Account Explorer](#) page.

If you don't enable this feature, then subaccounts in this directory use the entitlements and quota from the global account level.

#### 📘 Note

Only a single directory in any given directory path can have the user management (see next option) and/or entitlement management features enabled.

For example, if you have 3 stacked directories in your account hierarchy and the middle directory has both the user and entitlement management features enabled, then neither of these features can be enabled for its parent or child directory since these two directories are in the same direct path as the middle directory.

5. **Optional:** Under *Advanced*, choose the *Enable user management* option if you want to assign specific users as administrators or viewers of this directory. For more information, see [Manage Users in Directories \[Feature Set B\] \[page 1973\]](#).

You can enable this feature later from the directory's *Users* page or by editing the directory in the *Account Explorer* page.

If you don't enable this feature, then any user that has access to the directory in the account hierarchy can view and work in it.

#### Note

- The user management feature can be enabled only in combination with the entitlement management feature on the same directory in given path.
- Only a single directory in any given directory path can have the user management and/or entitlement management features enabled.  
For example, if you have 3 stacked directories in your account hierarchy and the middle directory has both the user and entitlement management features enabled, then neither of these features can be enabled for its parent or child directory since these two directories are in the same direct path as the middle directory.

6. **Optional:** Under **Advanced > Labels**, assign labels to the directory to make organizing and filtering your directories and their subaccounts easier. For more information, see [Labels \[Feature Set B\] \[page 79\]](#).

#### Tip

- When adding multiple values to a label, press  after each value.
- When you start typing, any matching label names and values that are already assigned to other directories in your global account are offered as suggestions.

#### Note

All subaccounts in the path of this directory also inherit all labels that are assigned to this directory.

7. Review the details of your directory and choose *Create* to finalize the process.

## Results

Your directory is created.

## Next Steps

Once you've created a directory, you can perform the following actions:

- Edit the directory - you can edit the name, description, entitlements, and labels of the directory.
- Add subaccounts to the directory - [Manage the Account Explorer Hierarchy \[Feature Set B\] \[page 1971\]](#).
- Assign users and entitlements to the directory (if you've enabled the user and entitlement management features, respectively).
- Delete the directory - you can only delete a directory that does not contain any subaccounts or subdirectories.

### 6.1.1.4.2 Manage the Account Explorer Hierarchy [Feature Set B]

Create an account structure by creating a hierarchy of directories and subaccounts using the SAP BTP cockpit. Add, move, and delete subaccounts and directories in your structure.

## Context

Here, you'll learn how to:

- Add directories and subaccounts to a directory
- Move directories and subaccounts in the account structure
- Delete directories and subaccounts from the account structure
- Export the account structure to Microsoft Excel format.

A subaccount moves with its assigned service plans and quota. The entitlements of the source and target directories are adjusted accordingly.

If any entitlement for a plan in the target directory is configured with the auto-assign option, it is then automatically applied to the moved subaccount. Automatic quota assignments are subject to available quota in the target directory.

You can create a hierarchical structure that is up to 7 levels deep. The highest level of a given path is always the global account and the lowest is a subaccount, which means that you can have up to 5 levels of directories between the global account and the lowest level subaccount.

## Procedure

- Add directories and subaccounts to a directory.
  - In the *Create* dropdown, choose *Directory*.  
When creating the new directory, you choose its location in the account structure by selecting its parent directory or the global account directly in the creation dialog box.
  - You can also create a directory by selecting *Create Directory* from the *...* *Actions* menu button for the global account or a specific parent directory.
- Move subaccounts in the account structure.
  - Click *...* *Actions* and select *Edit*. Then select a new parent.
  - Click *...* *Actions* and select *Move*. Then select a new parent.
  - Click  *Move* to move subaccounts by drag and dropping.
- Delete directories and subaccounts from the account structure.
  - Click *...* *Actions* and select *Delete*.
  - To delete a subaccount, you can also navigate into the subaccount and click *Delete Subaccount*.
- Export the account structure to Microsoft Excel format.
  - Click  *Export*.  
The exported Microsoft Excel file contains a sheet (tab) called *Account Structure*, which lists all the subaccounts and directories in the account structure, and includes information about each entity. Each subaccount and directory displays its name, ID, description, path, creation/change dates, and the user that created it.  
Subaccounts also display information about their environment, provider, region, used for production setting, and whether the beta feature option is enabled. Directories also display whether they are configured to manage users and entitlements.

## 6.1.1.4.3 Manage Users in Directories [Feature Set B]

Manage members in your directory using the SAP BTP cockpit.

### Prerequisites

- You're a directory administrator.
- User management is enabled for this directory.  
If the feature isn't enabled already, you can do so using one of the following methods:
  - Go to the [Account Explorer](#) page, edit the directory, and then under *Advanced*, choose the [Enable User Management](#) option.
  - Navigate into the directory from the [Account Explorer](#) page, and then in the *Users* page, choose the [Enable Entitlement and User Management](#) option (if entitlement management is already enabled for the directory, then choose the [Enable User Management](#) option instead).

#### Note

- The user management feature can be enabled only in combination with the entitlement management feature on the same directory in given path.
- Only a single directory in any given directory path can have the user management and/or entitlement management features enabled. See [Configure Entitlements and Quotas for Directories \[Feature Set B\] \[page 1998\]](#).  
For example, if you have 3 stacked directories in your account hierarchy and the middle directory has both the user and entitlement management features enabled, then neither of these features can be enabled for its parent or child directory since these two directories are in the same direct path as the middle directory.

- Your platform user exists in a trusted identity provider.  
All users of SAP BTP are stored in identity providers, either in the default or in a custom identity provider. SAP BTP needs a copy of the user, sometimes called a shadow user. You assign the shadow user authorizations to access resources in SAP BTP. When a user authenticates, SAP BTP forwards the request to the identity provider.  
For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

### Context

Assign predefined or custom role collections to users who need to manage or view the directory in SAP BTP cockpit. Examples of predefined role collections include the following:

- [Directory Administrator](#)
- [Directory Viewer](#)

For more information about these role collections, see [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

## Procedure

1. Navigate to your directory.
2. Add a user to your directory.

For more information, see [Create Users \[page 2083\]](#).

3. Assign a role collection to the user.

For more information, see [Assign Users to Role Collections \[page 2092\]](#).

## Results

The next time this user logs on to the SAP BTP cockpit, the user can access this directory.

## Related Information

[Working with Users \[page 2078\]](#)

[Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#)

### 6.1.1.4.4 View Directory Usage Analytics [Feature Set B]

You can explore, compare, and analyze all your actual usage data for the services and applications that are available in your directory.

To monitor and track usage in a directory, open your directory from the *Account Explorer* in the SAP BTP cockpit, and then go to the *Usage Analytics* page in the navigation area.

#### Note

This cockpit page is available only for directories that have user management enabled.

You must also be assigned as an admin of the directory. For the more information, see [Create a Directory \[Feature Set B\] \[page 1969\]](#) and [Manage Users in Directories \[Feature Set B\] \[page 1973\]](#).

## Views in the Directory 'Usage Analytics' Page

The directory *Usage Analytics* page contains two views that display the same usage information; however, your entry point is different – either from a service/subscription or a directory/subaccount:

View	Description
<b>Service Usage</b>	Displays high-level usage information for a selected service or business application subscriptions according to the directory from which you accessed the <a href="#">Usage Analytics</a> page. You can also drill down and view usage data for specific subdirectories and subaccounts that are located in this directory.
<b>Directory/Subaccount Usage</b>	Displays high-level usage information for all services and business application subscriptions according to the directory from which you accessed the <a href="#">Usage Analytics</a> page. You can also drill down and view usage data for specific subdirectories and subaccounts that are located in this directory.

Information is shown only for those services and subscriptions whose metered consumption in the directory is greater than zero.

Usage values are updated every 24 hours. Usage data displayed in this cockpit page refers to actual usage, not billed usage.

The [Space](#) filter is available only when you've selected a subaccount and the subaccount has the Cloud Foundry environment enabled.

#### → Tip

- If your directory is in a global account that uses the consumption-based commercial model, you can view information about your billed usage for billable services in your global account's [Usage Analytics](#) page. The global account's [Usage Analytics](#) page also provides information about cloud-credit usage. For more information, see [Monitoring Usage and Consumption Costs in Your Global Account \[page 1950\]](#).
- You can also view usage information by subaccount directly in a subaccount's [Usage Analytics](#) page. For more information, see [View Subaccount Usage Analytics \[page 1991\]](#).

## Working with the Tables and Charts

Both the [Service Usage](#) and [Directory/Subaccount Usage](#) views display the usage information in tabular and chart formats.

- The tables present accumulated usage values based on the aggregation logic of each service plan and its metric over the selected time period. The usage values are broken down by resource.
- The charts present usage values for one or more service plans that you select in the adjacent tables.

Select a table row to display the usage information in the chart. You can also compare usage between service plans in the same service by selecting multiple rows. To compare usage, the rows items must also share the same metric.

In the charts, you can view the data as a column chart or as a line chart.

To display a larger view of a chart, choose the  ([Zoom](#)) button.

Some rounding or shortening is applied to large values. You can mouse over values in the table to view the exact values as tooltips.

### 6.1.1.5 Managing Subaccounts Using the Cockpit

Learn how to structure a global account according to your organization's and project's requirements with regard to members, authorizations, and entitlements by managing subaccounts.

#### Context

To learn more about the concept of subaccounts, see [Subaccounts \[page 75\]](#).

#### Procedure

1. Learn how to create subaccounts.
  - [Create a Subaccount \[page 1977\]](#)
2. Learn how to manage users.
  - [Managing Security Administrators in Your Subaccount \[Feature Set A\] \[page 1980\]](#)
  - [Add Members to Your Subaccount \[Feature Set B\] \[page 1984\]](#)
3. Learn how to administer your subaccount.
  - [Change Subaccount Details \[page 1987\]](#)
  - [View Subaccount Usage Analytics \[page 1991\]](#)
  - [Delete a Subaccount \[page 1993\]](#)

## 6.1.1.5.1 Create a Subaccount

Create subaccounts in your global account using the SAP BTP cockpit.

### Create a Subaccount [Feature Set A]

#### Prerequisites

You are a global account administrator.

##### → Recommendation

Before creating your subaccounts, we recommend you learn more about [Setting Up Your Account Model](#).

#### Context

You create subaccounts in your global account. Once you create a new subaccount, you see a tile for it in the global account view, and you are automatically assigned to it as an administrator.

#### Procedure

1. From your global account, choose [New Subaccount](#).
2. Specify a display name.
3. **Optional:** Enter a description.
4. Leave the [Neo Environment](#) checkbox deselected. This ensures that a multi-environment subaccount is created.
5. Choose the desired infrastructure provider and region for your subaccount.
6. Enter a subdomain for your subaccount. This will become part of the URL for accessing applications that you subscribe to from this subaccount.

##### ⓘ Note

The subdomain can contain only letters, digits and hyphens (not allowed in the beginning or at the end), and must be unique across all subaccounts in the same region. Uppercase and lowercase letters can be used, however that alone does not qualify as a means to differentiate subdomains (e.g. **SUBDOMAIN** and **subdomain** are considered to be the same).

The subdomain can't be changed once you have created the subaccount.

7. **Optional:** If your subaccount is to be used for production purposes, select the [Used for production](#) option.

#### ⓘ Note

This does not change the configuration of your subaccount. Use this flag for your internal use to operate your production subaccounts in your global account and systems more efficiently. Your cloud operator may also use this flag to take appropriate action when handling incidents related to mission-critical accounts in production systems.

You can change your selection at any time by editing the subaccount properties. Do not select this option if your account is used for non-production purposes, such as development, testing, and demos.

8. **Optional:** To use beta services and applications in the current subaccount, select [Enable beta features](#).

#### ⚠ Caution

You shouldn't use SAP BTP beta features in subaccounts that belong to productive enterprise accounts. For more information, see [Important Disclaimers and Legal Information](#).

#### ⓘ Note

Once you have enabled this setting in a subaccount you cannot disable it.

9. Save your changes.

## Results

A new tile appears in the global account page with the subaccount details.

## Next Steps

Once you've created your subaccount, navigate to it to enable the environment that you wish to use.

# Create a Subaccount [Feature Set B]

## Prerequisites

You are a global account administrator.

#### → Recommendation

Before creating your subaccounts, we recommend you learn more about [Setting Up Your Account Model](#).

## Context

You create subaccounts in your global account. Once you create a new subaccount, you see a tile for it in the global account view, and you are automatically assigned to it as an administrator.

## Procedure

1. From your global account, navigate to the [Account Explorer](#) page.
2. Select **► Create ► Subaccount ▾**.

### → Tip

You can also create a subaccount by selecting [Create Subaccount](#) from the **⋮ Actions** menu button of the global account or a directory.

3. Specify a display name.
4. **Optional:** Enter a description.
5. Enter a subdomain for your subaccount. This will become part of the URL for accessing applications that you subscribe to from this subaccount.

### ⓘ Note

The subdomain can contain up to 63 characters such as letters, digits and hyphens (not allowed in the beginning or at the end), and must be unique across all subaccounts in the same region. Uppercase and lowercase letters can be used, however that alone does not qualify as a means to differentiate subdomains (e.g. **SUBDOMAIN** and **subdomain** are considered to be the same).

6. Choose the desired region for your subaccount.
7. Select a parent for your subaccount. The parent can either be the global account or a directory.
8. If your subaccount is to be used for production purposes, select the [Used for production](#) option.

### ⓘ Note

This does not change the configuration of your subaccount. Use this flag for your internal use to operate your production subaccounts in your global account and systems more efficiently. Your cloud operator may also use this flag to take appropriate action when handling incidents related to mission-critical accounts in production systems.

You can change your selection at any time by editing the subaccount properties. Do not select this option if your account is used for non-production purposes, such as development, testing, and demos.

9. **Optional:** To use beta services and applications in the current subaccount, under [Advanced](#), select [Enable beta features](#).

### ⚠ Caution

You shouldn't use SAP BTP beta features in subaccounts that belong to productive enterprise accounts. For more information, see [Important Disclaimers and Legal Information](#).

### Note

Once you have enabled this setting in a subaccount you cannot disable it.

10. **Optional:** Under **Advanced > Labels**, assign labels to the subaccount to make organizing and filtering your subaccounts easier. For more information, see [Labels \[Feature Set B\] \[page 79\]](#).

### Tip

- When adding multiple values to a label, press `Enter` after each value.
- When you start typing, any matching label names and values that are already assigned to other subaccounts in your global account are offered as suggestions.

11. Save your changes.

## Results

A new tile appears in the global account page with the subaccount details.

## Next Steps

Once you've created your subaccount, navigate to it to enable the environment that you wish to use.

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

[Global Accounts \[page 75\]](#)

[Navigate in the Cockpit \[page 1938\]](#)

[Account Model \[page 75\]](#)

### 6.1.1.5.2 Managing Security Administrators in Your Subaccount [Feature Set A]

Running on the cloud management tools feature set A: When you create a subaccount, SAP BTP automatically grants your user the role for the administration of business users and their authorizations in the subaccount. Having this role, you can also add or remove other users who will then also be user and role administrators of this subaccount.

After having created a subaccount in SAP BTP, your user automatically has the administration role. This means that your user also has the *Security* tab, where you can perform security administration tasks. As a security

administrator, you can manage authentication and authorization in this subaccount, such as configuring trust to identity providers, and assigning role collections to business users.

You can delegate the security administration to other users. Simply add the users as security administrators to your subaccount. SAP BTP grants the `User & Role Administrator` role to these users.

To see the `User & Role Administrator` role and all users with this role, go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)). Choose **► Security ► Administrators ▾**.

You can also remove the users who are not supposed to have this role.

#### Note

All users with the `User & Role Administrator` role can manage this subaccount, including the security administration tasks.

## Related Information

[User and Member Management \[page 85\]](#)

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

### 6.1.1.5.2.1 Add Security Administrators to Your Subaccount [Feature Set A]

Running on the cloud management tools feature set A: Security administrators manage the user and role assignments in their subaccounts. They also determine which identity providers their subaccounts trust.

#### Note

The content in this section is only relevant for cloud management tools feature set A. For more information, see [Cloud Management Tools - Feature Set Overview](#).

## Prerequisites

Your user is already a security administrator:

- Your user inherited the role as the global account administrator, who created this subaccount.
- Another security administrator assigned the `User & Role Administrator` role to your user using this procedure.

## Context

The users can come from different identity providers. The origin uniquely identifies the identity provider that stores the users. If the platform users are stored in SAP ID service, the origin of the users is [sap.ids](#). If your platform users are stored in a custom identity provider, the users have a different origin.

## Procedure

1. In the SAP BTP cockpit, go to your subaccount.

Your user is a security administrator in your subaccount, so you see [Security](#) in the navigation area.

2. Choose [Security](#) > [Administrators](#).
3. Choose [Add Administrators](#).

A popup appears, where you can enter the user ID and the origin and assign roles.

4. Enter the required data.

If the origin of the platform users is the default identity provider (SAP ID service), choose [sap.ids](#).

If the origin of the platform users is a custom identity provider, choose the name of the origin or [Other](#) and enter the name of the origin. The origin of a custom identity provider is provided during the configuration of the platform identity provider. For more information, see the related link.

5. Save your entries.

## Next Steps

To see [Security](#) in the navigation area, the users must also have one of the following member roles:

- The users are members of the Cloud Foundry organization in the subaccount.  
To add members to the Cloud Foundry organization, you must enable Cloud Foundry for your subaccount, even if you don't otherwise use the Cloud Foundry environment.

### Note

Once you add organization membership to such users, the system can take up to 30 minutes to replicate the required data so these users can view the subaccount in the SAP BTP cockpit.

- The users are members of the global account that contains your subaccount.

### Tip

Making users administrators of the global account adds wide ranging authorizations, such as the ability to create new subaccounts. Ask yourself if users really need these authorizations before adding members to the global account.

## Related Information

[Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#)

### 6.1.1.5.2 Remove Security Administrators from Your Subaccount Feature Set A

Running on the cloud management tools feature set A: You can remove security administrators from your subaccount by deleting them.

#### Prerequisites

- You can remove users as security administrators: You either created this subaccount, or an authorized user has assigned the `User & Role Administrator` role to your user for it.
- Your user and these users must have at least one of the following member roles (see the related link):
  - They are members of the Cloud Foundry organization (if available) in the subaccount.
  - They are members of the Cloud Foundry spaces that belong to the organization.
  - They are members of the global account that contains your subaccount.

#### Context

To remove security administrators from your subaccount, take the following steps.

#### Procedure

1. Open the SAP BTP cockpit.
2. Go to your subaccount (see [Navigate to Orgs and Spaces \[page 2246\]](#)). Since your user is the security administrator of your subaccount, you see *Security* in the navigation area.
3. Choose **► Security ► Administrators ▾**.  
You see a list of the security administrators with their respective roles.
4. To remove a security administrator from your subaccount, choose  (*Delete*).

## Related Information

[Add Org Members Using the Cockpit \[page 2248\]](#)  
[User and Member Management \[page 85\]](#)

### 6.1.1.5.3 Add Members to Your Subaccount [Feature Set B]

Add members to your subaccount to enable users to access resources available there. Platform users manage subaccounts with cloud management tools, while business users consume applications and services.

#### Prerequisites

- You're managing a multi-environment subaccount.  
For more information about adding members to Neo subaccounts, see [Add Members to Your Neo Subaccount](#).
- You must be a subaccount administrator to add other subaccount members.
- The users exist in a trusted identity provider.  
All users of SAP BTP are stored in identity providers, either in the default or in a custom identity provider. SAP BTP needs a copy of the user, sometimes called a shadow user. You assign the shadow user authorizations to access resources in SAP BTP. When a user authenticates, SAP BTP forwards the request to the identity provider.  
For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

#### Context

##### 📘 Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

There are two types of users in subaccounts:

- Platform users  
These users are members of your team. Platform users manage the subaccount with the cloud management tools.  
Assign predefined or custom role collections to users who need to manage or view the subaccount in SAP BTP cockpit. Examples of predefined role collections include the following:
  - *Subaccount Administrator*
  - *Subaccount Viewer*For more information about the available role collections, see [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

To work in the Cloud Foundry, ABAP, Kyma, and Neo environments, your team members need additional authorizations.

For more information, see [Giving Access Rights to Platform Users](#) in the *SAP BTP Best Practices Guide*.

- Business users  
These users consume applications and services. Business users don't access cloud management tools like the SAP BTP cockpit. Assign role collections required by the applications and services the business users consume.

## Procedure

### → Tip

If you're a global account administrator, you can quickly assign yourself as an administrator of a subaccount by going to the [Account Explorer](#) page and then choosing the [Add Me as Admin](#) option in the [Actions](#) (•••) context menu of the subaccount. To assign other users, follow the instructions below.

This feature may not be available if it has been disabled for your global account.

To disable this feature, send an opt-out request using the component BC-NEO-CIS-OPS. See [Getting Support \[page 2863\]](#) for information about opening a case and getting technical assistance.

1. Navigate to your subaccount.
2. Add a user to your subaccount.

For more information, see [Create Users \[page 2083\]](#).

3. Assign role collections to the user.

For more information, see [Assign Users to Role Collections \[page 2092\]](#).

## Results

The user can log on to SAP BTP and access resources according to the role collections you've assigned to the user.

## Related Information

[User and Member Management \[page 85\]](#)

[Navigate in the Cockpit \[page 1938\]](#)

## 6.1.1.5.4 Enable Environment or Create Environment Instance

Enable an environment or create an environment instance using the SAP BTP cockpit.

### Prerequisites

- You're managing a multi-environment subaccount.
- You're a subaccount administrator.
- You have free quota assigned to your subaccount.

### Context

On a subaccount level, environments constitute the actual platform-as-a-service (PaaS) offering of SAP BTP that allows for the development and administration of business applications.

Each environment comes equipped with specific tools, technologies, and runtimes that you need to build applications. The availability of different environments allows for greater flexibility in your development process.

For more information, see [Environments \[page 42\]](#).

### Procedure

1. Navigate into the subaccount.
2. Choose your method: **Enable Environment** or **Create an Environment Instance**.
  - **Enable Environment:** On the *Subaccount - Overview* page, click *Enable <Environment>*.
  - **Create an Environment Instance:** See [Environment Instances](#).

### Results

You can use the environment or environment instance in your subaccount.

## 6.1.1.5.5 Change Subaccount Details

Edit subaccounts using the SAP BTP cockpit.

### Context

You edit a subaccount by choosing the relevant action on its tile. It's available in the global account view, which shows all its subaccounts.

The subaccount technical name is a unique identifier of the subaccount on SAP BTP that is generated when the subaccount is created.

You can change to the following subaccount details:

Editable Subaccount Details [Feature Set A]

Field	Details
Display Name	Specify a human-readable name for your subaccount and change it later on, if necessary. This way you can distinguish between multiple subaccounts.
Description	(Optional) Specify a short descriptive text about the subaccount.
Used for production	<p>Select this option if your subaccount is being used for production purposes.</p> <p>This does not change the configuration of your subaccount. Use this flag for your internal use to operate your production subaccounts in your global account and systems more efficiently. Your cloud operator may also use this flag to take appropriate action when handling incidents related to mission-critical accounts in production systems.</p> <p>Do not select this option if your account is used for non-production purposes, such as development, testing, and demos.</p>

Field	Details
Enable beta features	<p>(Optional) Enable the subaccount to use services and applications which are occasionally made available by SAP for beta usage on SAP BTP. This option is available to administrators only and is, by default, unselected.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-bottom: 5px;"> <p><b>⚠ Caution</b></p> <p>You shouldn't use SAP BTP beta features in subaccounts that belong to productive enterprise accounts. For more information, see <a href="#">Important Disclaimers and Legal Information</a>.</p> </div> <div style="border: 1px solid #ccc; padding: 5px; margin-bottom: 5px;"> <p><b>📌 Note</b></p> <p>Once you have enabled this setting in a subaccount you cannot disable it.</p> </div> <div style="border: 1px solid #ccc; padding: 5px;"> <p><b>📌 Note</b></p> <p>If you enable this setting in a subaccount that is already consuming services and subscriptions, these consumed resources will not be automatically updated to beta versions if they exist.</p> </div>

#### Editable Subaccount Details [Feature Set B]

Field	Details
Display Name	Specify a human-readable name for your subaccount and change it later on, if necessary. This way you can distinguish between multiple subaccounts.
Description	(Optional) Specify a short descriptive text about the subaccount.
Parent	<p>Change the parent of your subaccount.</p> <p>When you create a subaccount, this is added as a direct child of the global account you created it in. You can change your subaccount's parent and add it to a directory, move it from one directory to another, or remove from a directory by making the global account its parent once again.</p>

Field	Details
Used for production	<p>(Optional) Select this option if your subaccount is being used for production purposes.</p> <p>This does not change the configuration of your subaccount. Use this flag for your internal use to operate your production subaccounts in your global account and systems more efficiently. Your cloud operator may also use this flag to take appropriate action when handling incidents related to mission-critical accounts in production systems.</p> <p>Do not select this option if your account is used for non-production purposes, such as development, testing, and demos.</p>
Labels	<p>(Optional) Assign, change, or remove labels from your subaccount. Labels help to make organizing and filtering your subaccounts easier. For more information, see <a href="#">Labels [Feature Set B] [page 79]</a>.</p> <div data-bbox="804 902 1396 1202" style="background-color: #f0f0f0; padding: 10px;"> <p>→ Tip</p> <ul style="list-style-type: none"> <li>• When adding multiple values to a label, press <code>Enter</code> after each value.</li> <li>• When you start typing, any matching label names and values that are already assigned to other subaccounts in your global account are offered as suggestions.</li> </ul> </div>

Field	Details
Enable beta features	<p>(Optional) Enable the subaccount to use services and applications which are occasionally made available by SAP for beta usage on SAP BTP. This option is available to administrators only and is, by default, unselected.</p> <div data-bbox="826 533 967 562" style="border: 1px solid orange; padding: 5px;"> <p><b>⚠ Caution</b></p> <p>You shouldn't use SAP BTP beta features in subaccounts that belong to productive enterprise accounts. For more information, see <a href="#">Important Disclaimers and Legal Information</a>.</p> </div> <div data-bbox="826 770 927 799" style="border: 1px solid blue; padding: 5px;"> <p><b>📌 Note</b></p> <p>Once you have enabled this setting in a subaccount you cannot disable it.</p> </div> <div data-bbox="826 925 927 954" style="border: 1px solid blue; padding: 5px;"> <p><b>📌 Note</b></p> <p>If you enable this setting in a subaccount that is already consuming services and subscriptions, these consumed resources will not be automatically updated to beta versions if they exist.</p> </div>

## Procedure

1. Choose the subaccount for which you'd like to make changes and choose  on its tile.  
You can view more details about the subaccount such as its description and additional attributes by choosing [Show More](#).
2. Make your changes and save them.

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)  
[Change the Default Database System](#)

## 6.1.1.5.6 View Subaccount Usage Analytics

You can explore, compare, and analyze all your actual usage data for the services and applications that are available in your subaccount.

To monitor and track usage in a subaccount, open the subaccount in the SAP BTP cockpit and choose [Usage Analytics](#) in the navigation area.

### Views in the Subaccount 'Usage Analytics' Page

The subaccount [Usage Analytics](#) page contains views that display usage at different levels of detail:

View	Description
<b>Subaccount</b>	Displays high-level usage information for your subaccount relating to services, business application subscriptions, and Cloud Foundry org spaces.  Some information in this view is displayed only for global account admins.
<b>Services</b>	Displays usage per service plan for the region of the subaccount, and the selected metric and period. Information is shown for all services whose metered consumption in the subaccount is greater than zero.
<b>Spaces</b>	(Cloud Foundry environment only) Displays service plan usage per space for the services shown in the <a href="#">Services</a> view.

#### 📘 Note

The information displayed in this page depends on the environments that are enabled for your subaccount. For example, information about spaces is displayed only for subaccounts in the Cloud Foundry environment.

Usage values are updated every 24 hours.

Usage data displayed in this cockpit page refers to actual usage, not billed usage.

#### → Tip

- [Feature Set A] If your subaccount is in a global account that uses the consumption-based commercial model, you can view information about your billed usage for billable services in your global account's [Overview](#) and subaccount's [Overview](#) pages. The global account's [Overview](#) page also provides information about cloud-credit usage.
- [Feature Set B] If your subaccount is in a global account that uses the consumption-based commercial model, you can view information about your billed usage for billable services in your global account's [Usage Analytics](#) page. The global account's [Usage Analytics](#) page also provides information about cloud-credit usage. A directory's [Usage Analytics](#) page also allows you to view usage information for each subaccount that is located in the directory.

- [Feature Set B] If you use directories to group your subaccounts, you can view usage information by directory in your global account's *Usage Analytics* page or directly in the directory's *Usage Analytics* page.

For more information, see [Monitoring Usage and Consumption Costs in Your Global Account \[page 1950\]](#) and [View Directory Usage Analytics \[Feature Set B\] \[page 1974\]](#).

## Working with the Tables and Charts

In the *Services* and *Spaces* views, the usage information is displayed in both tabular and chart formats.

- The tables present accumulated usage values based on the aggregation logic of each service plan and its metric over the selected time period. The usage values are broken down by resource.
- The charts present usage values for one or more service plans or spaces that you select in the adjacent tables. The resolution of the charts is automatically set to days, weeks, or months, depending on the range of the selected time period.

You can perform various actions within the tables and charts:

- In the *Services* and *Spaces* views, select a table row to display the usage information in the chart. You can also select multiple rows to compare usage in the following ways:
  - In the *Services* view, you can compare usage between service plans in the same service. Multi-row selection in the table is possible only when you have selected a single service in the *Service* filter and the row items share the same metric.
  - In the *Spaces* view, you can compare usage between spaces for the same service and service plan. Multi-row selection in the table is possible only when you have selected a single service plan in the *Service Plan* filter.
- In the charts, you can view the data as a column chart or as a line chart.
- To display a larger view of a chart, choose the  (*Zoom*) button.
- Some rounding or shortening is applied to large values. You can mouse over values in the table to view the exact values as tooltips.

## Using the Filters

Use the filters in the *Services* and *Spaces* views to choose which usage information to display.

The *Spaces* view inherits the filter settings, except for the *Period*, from the *Services* view above it. In other words, when you modify filters in the *Services* view, it affects the information that is displayed in the *Spaces* view. You can apply the *Period* filter independently to each view.

In the *Services* view, you can apply the *Metric* filter only when you have selected a service with more than one metric.

Click the  (*Reset*) icon in each view to reset the filters to their default settings. If you reset the filters in the *Services* view, the filters in the *Spaces* are also reset.

### 6.1.1.5.7 Delete a Subaccount

Delete subaccounts using the SAP BTP cockpit to clean up your account hierarchy, free up quota used by services in your subaccounts, and to reduce overall costs.

## Delete a Subaccount [Feature Set B]

### Prerequisites

- You're a global account administrator.

### Procedure

- In the cockpit, go to the *Account Explorer* page of your global account.
- In the account hierarchy, locate the subaccount that you want to delete.
- In the *Actions* (•••) context menu of the subaccount, choose *Delete*.

The cockpit first checks if the subaccount contains data, such as active subscriptions, service instances, brokers, or platforms.

- If the subaccount is empty, then confirm the operation, after which the subaccount is deleted.

If you are a subaccount administrator and the subaccount contains data, such as applications, service instances, spaces, active subscriptions, brokers, and members, then we strongly recommended that you visit the *Instances and Subscriptions* page to review the content in the subaccount and to manually remove the content from there. Then you can come back and safely delete the subaccount.

#### Note

If you are not a subaccount administrator, then you won't be able to access the *Instances and Subscriptions*. Instead, you'll have to ask a subaccount administrator in your organization to review the content in this subaccount and to manually remove the content from there.

### ⚠ Caution

If the subaccount contains data, then you're also given the option to use the **force-delete** option, which deletes the subaccount and all its data for you.

You must use this option with extreme caution because any data in the subaccount is deleted permanently, including productive data, without any recovery option.

It is your responsibility to confirm that the subaccount is safe to delete before using the force-delete option. If you cannot check the content of the subaccount, you can get the subaccount reviewed by other qualified members of your organization.

### ℹ Note

The deletion may take up to 12 hours to complete depending on the amount of content in your subaccount. If your subaccount contains service instances, subscriptions, and runtime environments, these need to be deprovisioned as part of the purge operation, which is a timely process. After the subaccount is deleted, it could take a few more days for some related services to be deleted. Note that you won't be charged for any continued usage of these services in the subaccount during the deletion cleanup.

[Relationship Between Global Accounts, Subaccounts, and Directories \[Feature Set B\] \[page 79\]](#)

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

## Delete a Subaccount [Feature Set A]

### Prerequisites

- You're a global account administrator.
- The subaccount doesn't contain any active subscriptions, service instances, brokers, or platforms. Active subscriptions, service instances, brokers, or platforms can be removed by roles that are environment-specific, for example an org manager in a Cloud Foundry environment.

### Context

To prevent accidental deletion of subaccounts and creation of orphaned data, any active subscriptions, service instances, brokers, or platforms must be removed from the subaccount before it can be deleted. Only subaccount administrators can remove such content from a subaccount.

## Procedure

1. In the cockpit, navigate into the subaccount that you want to delete.
2. Choose *Delete Subaccount* and confirm the operation.

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

### 6.1.1.6 Managing Entitlements and Quotas Using the Cockpit

When you purchase an enterprise account, you are entitled to use a specific set of resources, such as the amount of memory that can be allocated to your applications.

An entitlement equals your right to provision and consume a resource. A quota represents the numeric quantity that defines the maximum allowed consumption of that resource.

Entitlements are managed at the global account level, where services plans and their allowed quota are distributed to subaccounts, and then consumed by the subaccounts. When quota is freed at the subaccount level, it becomes available again at the global account level.

#### Note

Only global account administrators can configure entitlements and quotas for subaccounts.

There are two places in the SAP BTP cockpit where you can view entitlements and assign service plans and quotas for subaccounts - at the global account level and at the subaccount level. Depending on your permissions, you may only have access to one of these pages. You can find more details below:

Entitlements Pages [Feature Set A]

Page in cockpit	Navigation Level	Visible to	Permissions
<a href="#">▶ Entitlements</a> <a href="#">▶ Subaccount Assignments</a> ▶	Global account level	Global account administrators only	<ul style="list-style-type: none"><li>• View &amp; Edit - Global account administrators</li></ul>
<a href="#">▶ Entitlements</a> ▶ <a href="#">Service Assignments</a> ▶	Global account level	Global account administrators only	<ul style="list-style-type: none"><li>• View - Global account administrators (you cannot make changes to entitlements or quota assignments from this page)</li></ul>

Page in cockpit	Navigation Level	Visible to	Permissions
<a href="#">Entitlements</a>	Subaccount level	Subaccount members (regardless of whether they are also global account administrators or not)	<ul style="list-style-type: none"> <li>View - Subaccount members who are not global account administrators</li> <li>View &amp; Edit - Global account administrators who are also subaccount members</li> </ul>

#### Entitlements Pages [Feature Set B]

Page in cockpit	Navigation Level	Visible to	Permissions
<a href="#">▶ Entitlements ▶ Entity Assignments ▶</a>	Global account level	Global account administrators only	<ul style="list-style-type: none"> <li>View &amp; Edit - Global account administrators</li> </ul>
<a href="#">▶ Entitlements ▶ Service Assignments ▶</a>	Global account level	Global account administrators only	<ul style="list-style-type: none"> <li>View - Global account administrators (you cannot make changes to entitlements or quota assignments from this page)</li> </ul>
<a href="#">Entitlements</a>	Subaccount level	Subaccount members (regardless of whether they are also global account administrators or not)	<ul style="list-style-type: none"> <li>View - Subaccount members who are not global account administrators</li> <li>View &amp; Edit - Global account administrators who are also subaccount members</li> </ul>

#### Note

You can also assign service plans to directories. These directories must be configured to manage entitlements. See [Configure Entitlements and Quotas for Directories \[Feature Set B\] \[page 1998\]](#).

To assign plans to managed directories you must a global account administrator.

Similarly, if you're assigning plans to a subaccount that is under a directory that has the user management feature enabled, then you must be the directory administrator or a global account administrator.

The [▶ Entitlements ▶ Entity Assignments ▶](#) is where you view and edit assignments and quota from the perspective of subaccounts and directories. This page contains these views (tabs):

View	Description
<a href="#">Manage Assignments</a>	Allows global account admins to distribute the entitled service plans of their global account to subaccounts and directories.
<a href="#">View Commercial Information</a>	Allows global account admins and viewers to view the commercial source of their service entitlements. This feature is not available for trial accounts.

For information about setting assignments and quota, see:

- [Configure Entitlements and Quotas for Directories \[Feature Set B\] \[page 1998\]](#)
- [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)

The **Entitlements > Service Assignments** is where you view assignments and quota from the perspective of services. This page contains these views (tabs):

View	Description
<a href="#">All Services</a>	<p>Provides an overview of all available service entitlements of your global account.</p> <div><p>→ Tip</p><p>The <i>Assigned To</i> column in this view shows you the total number of directories and subaccounts to which each service plan is assigned in your global account. You can click on the links in this column to quickly navigate to the selected service in the <i>Assignments by Service</i> view and display more details about these assignments.</p><p>Turn on the <i>Show commercial info</i> option to display additional columns in the main table. These columns can help you to gain a better understanding of the relationship between contractual service entitlements and the technical assets (services and plans) in your global account.</p></div>
<a href="#">Assignments by Service</a>	<p>Allows you to choose specific services and see how their service plans are assigned to subaccounts and directories within your global account.</p> <div><p>→ Tip</p><p>Turn on the <i>Show commercial info</i> option to display additional columns in the main table. These columns can help you to gain a better understanding of the relationship between contractual service entitlements and the technical assets (services and plans) in your global account.</p></div>

#### Note

- [Feature Set B] To subscribe to a multitenant application, you must first assign its plan to the specific subaccount (in one of the *Entitlements* pages). If you remove a subaccount's entitlement to a multitenant application, any subscriptions to it from that subaccount will stop working.
- [Feature Set B] Before a subaccount admin can enable a quota-based environment, such as Kyma, the subaccount admin must first assign the environment's plan to the subaccount (in one of the *Entitlements* pages). Other non-quota-based environments, such as Cloud Foundry, are available by default to all subaccounts, and therefore are not available as entitlements.

In the Cloud Foundry environment, you can further distribute the quotas that are allocated to a subaccount. This is done by creating space quota plans and assigning them to the spaces. For more information on space quota plans in the Cloud Foundry environment, see:

- [Managing Space Quotas \[page 2254\]](#)
- <https://docs.cloudfoundry.org/aringuide/quota-plans.html> 🖱️

### → Tip

Optionally, you can configure assignments and quotas for supported services that you own or subscribe to from supported non-SAP cloud vendors. These services can be consumed in SAP BTP in your subaccounts alongside your self-developed services and those provided by SAP. This functionality requires first setting up a resource provider instance for your provider account in the cockpit. For more information, see [Managing Resource Providers \[page 1947\]](#).

### ⓘ Note

- In global accounts that use the consumption-based commercial model, SAP BTP, Cloud Foundry Runtime is not listed in the *Entitlements* pages in the SAP BTP cockpit. A technical limit of 200 GB of Cloud Foundry Runtime memory is assigned by default to every subaccount. The limit defines the maximum amount of runtime memory that can be used in the subaccount. Note that the “Standard” plan in the consumption-based commercial model is a paid plan and that you are billed based on the amount of Cloud Foundry Runtime you consume. For more information on consumption monitoring, see [Consumption Monitoring](#).
- If you need to increase this limit, report an incident to [SAP support](#) on the BC-NEO-CIS component. This also applies to other services that have a technical quota limit.

**Tutorial:** [Manage Entitlements on SAP BTP Trial](#)

**Troubleshooting:** [Entitlement and Quota Problems](#)

### 6.1.1.6.1 Configure Entitlements and Quotas for Directories [Feature Set B]

### ⓘ Note

Directories are available only in [Feature Set B], and there is no equivalent in [Feature Set A]. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

Distribute entitlements that are available in your global account to directories by adding service plans and their allowed quotas by using SAP BTP cockpit.

## Enable Entitlement Management for a Directory

Before you can assign plans and quotas to a directory so that they can be further distributed to the subaccounts in the directory, you must first enable the **entitlement management** feature for the directory. This configuration only needs to be done once for each directory. In this documentation, we'll refer to these types of directories as "managed directories".

### Note

- In the account hierarchy, each directory path can have only one directory enabled with the entitlement management feature (or the user management feature). Consequently, if a directory in the path already has one of these features enabled, it is not possible to enable either of them for other parent or child directories within the same path as this directory.
- Enabling entitlement management for a directory that already contains subaccounts will result in the automatic assignment of any existing assignments and quotas (for the subaccounts) to the directory.

## Prerequisites

- You are a global account administrator.

## Procedure

- There are several ways you can enable the entitlement management feature for a directory:
- In the *Account Explorer*, click the **...** *Actions* button for a specific directory and select *Edit*. In the *Edit Directory* dialog box, under *Advanced*, choose the *Enable entitlement management* option.
- Navigate to the directory's *Entitlements* page and select *Enable Entitlement Management*.
- Navigate to your global account and open the **Entitlements > Entity Assignments** from the navigation panel. Select the  icon in the *Select Entity* dropdown menu.

Then, in the *Select Entities* dialog box, choose the directory for which you want to manage assignments. Click *Select* and then *Enable Entitlement Management*.

### → Tip

To disable entitlement management for a directory, redo these steps from the global account's **Entitlements > Entity Assignments** page, but choose *Disable Entitlement Management* at the end. When you disable entitlement management, any assignments and quota that are currently assigned to the directory are "returned" to the global account and are then available for distribution to other directories and subaccounts.

## Next Steps

Once you've enabled entitlement management for a directory, you can now configure its service plan and quota assignments as described below.

## Configure Assignments and Quotas for Managed Directories

Use this procedure to configure the service plan assignments and quotas for one or more managed directories.

### Note

To get an overview of all the services and plans available in your global account, navigate to the [▶ Entitlements > Service Assignments ▶](#) page. There you can see the global usage of each service plan in the *All Services* view, as well as the detailed assignments of each service across subaccounts and directories in the *Assignments by Service* view.

- In the *All Services* view of this page, the *Assigned To* column shows you the total number of directories and subaccounts to which each service plan is assigned in your global account. You can click on the links in this column to quickly navigate to the selected service in the *Assignments by Service* view and display more details about these assignments.
- You can turn on the *Show commercial info* toggle option in the *Service Assignments* page to display additional table columns that can help you to gain a better understanding of the relationship between contractual service entitlements and the technical assets (services and plans) in your global account; in other words, how each entitled plan was added to your global account.
- The *Service Assignments* page is for viewing purposes only; you cannot make any assignment changes from it.

You can also access the [▶ Entitlements > Service Assignments ▶](#) page from the directory level (only for directories that are configured to manage entitlements) to display the directory's assignments.

## Prerequisites

- You are a global account administrator.  
Note that if the directory also has the user management feature enabled, then you must be either the directory administrator or a global administrator. See [Manage Users in Directories \[Feature Set B\] \[page 1973\]](#).
- The service and applications that you intend to assign to your directories must be entitled to your global account.
  - For enterprise accounts that use the subscription-based commercial model, your account receives only the services that you've already purchased and subscribed to according to your SAP BTP contract. To access additional services, at an extra cost, you can modify your contract via your sales representative or account executive.
  - For enterprise accounts that use the consumption-based commercial model, your global account receives all pay-for-use and free services that are eligible for this commercial model.

- If you have a trial account, you'll receive a restricted set of free platform resources and services for a limited time period. To access additional services, you'll have to switch to an enterprise account.

## Procedure

1. Navigate to your global account.
2. Choose ► [Entitlements](#) ► [Entity Assignments](#) ▾ from the left hand-side navigation.

Alternatively, you can navigate to a directory from the [Account Explorer](#), and then access the ► [Entitlements](#) ► [Entity Assignments](#) ▾ page for that specific directory.

3. Open the [Manage Assignments](#) view (tab).

Skip this step if you have a trial account.

### → Tip

You can use the [View Commercial Information](#) view in this page to display comprehensive commercial information about the entitlements in your global account (you cannot make assignments in this view). Note that this view is not available for trial accounts.

4. Select the  icon in the [Directories / Subaccounts](#) dropdown menu.
5. In the [Select Subaccounts and Directories](#) dialog box, choose the directories for which you want to manage assignments.
6. Click [Select](#).

### ⓘ Note

If you select a directory for which entitlement management is not enabled, you can click [Enable Entitlement Management](#) to enable the feature. Remember that you can enable this feature only for a single directory in a path.

You get a table for each of the directories you selected, displaying the current assignments and quotas. You can choose [Show subaccount assignments](#) next to the table title to see the assignments and quotas for the subaccounts in a specific directory.

### → Tip

Under the [Service Technical Name](#) column, click on the ⓘ ([Service Details](#)) icon of any service to access its service-related links to documentation, support information, and SAP Discovery Center.

7. Choose [Edit](#) to start editing assignments for a particular directory.

### ⓘ Note

You can only edit assignments for one directory at a time.

8. You can now edit the assignments table:

Action	Steps
<p><b>Add new service plans to the directory</b></p>	<p>Choose <a href="#">Add Service Plans</a> and from the dialog box select the services and the plans from each service that you would like to add to the directory. Choose <a href="#">Add &lt;x&gt; Service Plans</a> in the dialog box to confirm.</p> <p>Remember, the services that you see depend on the type of global account you have and your contract details (see the prerequisites above for more information).</p> <p>Once you've added new service plans, you can also change the quota for those plans as described in the following row and enable the option to auto-assign quota to new subaccounts that are added to the directory. For service plans where quota can be increased or decreased, you can also specify what amount should be auto-assigned to each subaccount that is created or added to the directory.</p> <div data-bbox="598 698 1396 884" style="background-color: #f0f0f0; padding: 5px;"> <p><b>Note</b></p> <p>To subscribe a subaccount to a multitenant application, you must first assign the application to the specific subaccount using the process described in <a href="#">Configure Entitlements and Quotas for Subaccounts [page 2003]</a>.</p> </div> <div data-bbox="598 898 1396 1160" style="background-color: #f0f0f0; padding: 5px;"> <p><b>→ Tip</b></p> <p>If your global account is configured to consume remote services from a non-SAP cloud vendor (resource provider), an additional dropdown list is displayed in the <a href="#">Service Details</a> pane, where you can choose a configured resource provider. You can then choose the required service plans that are available for the selected resource provider to add them to the subaccount.</p> <p>For more information, see <a href="#">Managing Resource Providers [page 1947]</a>.</p> </div>
<p><b>Edit the quota for one or more service plans</b></p>	<p>Use <b>+</b> (<i>Plus</i>) and <b>-</b> (<i>Minus</i>) in the <a href="#">Quota Assignment</a> column to increase or decrease the quota for each service plan.</p> <p>Note some service plans do not have a numeric quota assignment. In other words, you do not assign a specific quantity but grant access to the plan by simply assigning it to the subaccount. See <a href="#">Quotas</a> in <a href="#">Managing Entitlements and Quotas Using the Cockpit [page 1995]</a>.</p> <div data-bbox="598 1413 1396 1796" style="background-color: #f0f0f0; padding: 5px;"> <p><b>→ Tip</b></p> <p>If you would like to have quota automatically assigned to subaccounts that are created or moved to the directory, select the <a href="#">Auto-Assign to Subaccounts</a> checkbox and follow the same process to set the amount that should be auto-assigned to each subaccount.</p> <ul style="list-style-type: none"> <li>• The auto-assign feature doesn't apply to subaccounts that are already in the directory when the feature is enabled.</li> <li>• You cannot use the auto-assign feature with beta services and applications.</li> </ul> </div>
<p><b>Set a quota limit to unlimited service plans that use the consumption-based commercial model</b></p>	<p>The usage of most service plans is unlimited by default in global accounts that use the consumption-based commercial model. To control costs of such plans, you can set a quota limit on the service plans for this directory by first selecting the checkbox in the <a href="#">Set Quota Limit</a> column.</p>

Action	Steps
	<p>Now, you can increase or decrease the quota for this service plan in the <a href="#">Quota Assignment</a> column by using <b>+</b> (<i>Plus</i>) and <b>-</b> (<i>Minus</i>).</p> <p>Note some service plans do not have a numeric quota assignment. In other words, you do not assign a specific quantity but grant access to the plan by simply assigning it to the directory (and then subsequently to the subaccount). See <a href="#">Quotas</a> in <a href="#">Managing Entitlements and Quotas Using the Cockpit [page 1995]</a>.</p>
<b>Delete a service plan and its quota from the directory</b>	Choose  ( <i>Remove Service Plan</i> ) from the <i>Actions</i> column.

9. Once you're done, choose [Save](#) to save the changes and exit edit mode for that directory.
10. **Optional:** Repeat steps 7 to 9 to configure assignments for the other selected directories.

### 6.1.1.6.2 Configure Entitlements and Quotas for Subaccounts

Distribute the entitlements that are available in your global account by adding service plans and their allowed quotas to your subaccounts using SAP BTP cockpit.

#### Prerequisites

- You must be a global account administrator to configure subaccount assignments. Note that if the subaccount is under a directory that is configured to manage users, then you must be either the directory administrator or a global account administrator to configure the subaccount's assignments.
- The service and applications that you intend to assign to your subaccounts must be entitled with the required quota to your global account. If you're assigning a service plan to a subaccount, which is

under a directory that is configured to manage entitlements, then the managed directory must have the relevant service plans and needed quota assigned to it so that you can distribute them to the directory's subaccounts, as required.

- For enterprise accounts that use the subscription-based commercial model, your account receives only the services that you've already purchased and subscribed to according to your SAP BTP contract. To access additional services, at an extra cost, you can modify your contract via your sales representative or account executive.
- For enterprise accounts that use the consumption-based commercial model, your global account receives all pay-for-use and free services that are eligible for this commercial model.
- If you have a trial account, you'll receive a restricted set of free platform resources and services for a limited time period. To access additional services, you'll have to switch to an enterprise account.
- To assign beta service plans, your subaccount must have the [Enable beta features](#) option selected. See [Change Subaccount Details \[page 1987\]](#). Only applies to non-production subaccounts.

## Context

You can distribute assignments and quotas across subaccounts within a global account from these places in the cockpit:

- The [Entitlements > Entity Assignments](#) page at the global account level (visible only to global account administrators).  
If your account is part of cloud management tools feature set A, this page is called [Subaccount Assignments](#).
- The [Entitlements > Entity Assignments](#) page at the directory level by first navigating into the directory from the [Account Explorer](#). This applies only subaccounts that resides in the path of a directory that is configured to manage entitlements.
- The [Entitlements](#) page at the subaccount level (visible to all subaccount members, but editable only by global account administrators) by first navigating into the subaccount from the [Account Explorer](#).

For more information, see [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#).

### → Tip

To get an overview of all the services and plans available in your global account, navigate to the [Entitlements > Service Assignments](#) page. There you can see the global usage of each service plan in the [All Services](#) view, as well as the detailed assignments of each service across subaccounts and directories in the [Assignments by Service](#) view.

- The [Service Assignments](#) page is for viewing purposes only; you cannot make any assignment changes from it.
- In the [All Services](#) view of this page, the [Assigned To](#) column shows you the total number of directories and subaccounts to which each service plan is assigned in your global account. You can click on the links in this column to quickly navigate to the selected service in the [Assignments by Service](#) view and display more details about these assignments.
- You can turn on the [Show commercial info](#) toggle option in this page to displays additional table columns that can help you to gain a better understanding of the relationship between contractual service entitlements and the technical assets (services and plans) in your global account; in other words, how each entitled plan was added to your global account.

If you navigate to a subaccount from the [Account Explorer](#), you view its assignments in its [Overview](#) page view.

### Note

- [Feature Set B] To subscribe to a multitenant application, you must first assign it to the specific subaccount using the same process explained below. If you remove a subaccount's assignments to a multitenant application, any subscriptions to it from that subaccount stop working.
- [Feature Set B] Before a subaccount admin can enable a quota-based environment, such as Kyma, the subaccount admin must first assign the environment's plan and quota to the subaccount. Other non-quota-based environments, such as Cloud Foundry, are available by default to all subaccounts, and therefore aren't available as entitlements.

## Configure Assignments and Quotas from Your Global Account

### Procedure

1. Navigate to your global account.
2. [Feature Set B] Choose ► [Entitlements](#) ► [Entity Assignments](#) ► from the left hand-side navigation.  
[Feature Set A] Choose ► [Entitlements](#) ► [Subaccount Assignments](#) ► from the left hand-side navigation.

#### → Remember

There are other ways you can access the subaccount to manage its assignments, such as navigating to the subaccount or its managed directory from the [Account Explorer](#). See above for more information.

3. Open the [Manage Assignments](#) view (tab).

Skip this step if you have a trial account.

#### → Tip

You can use the [View Commercial Information](#) view in this page to display comprehensive commercial information about the entitlements in your global account (you cannot make assignments in this view). Note that this view is not available for trial accounts.

4. Select the  icon in the [Directories / Subaccounts](#) dropdown menu.
5. In the [Select Subaccounts and Directories](#) dialog box, select all the subaccounts that you want to manage assignments.

#### → Tip

[Feature Set A] If your global account contains more than 20 subaccounts, choose  to open up the value help dialog. There you can filter subaccounts by role, environment, and region to make your selection easier and faster. You can only select a maximum of 50 subaccounts at once.

6. Choose [Select](#) to apply the filter.

You get a table for each of the subaccounts you selected, displaying the current assignments and quota.

→ Tip

Under the *Service Technical Name* column, click on the ⓘ (*Service Details*) icon of any service to access its service-related links to documentation, support information, and SAP Discovery Center.

7. Choose *Edit* to start editing assignments for a particular subaccount.

ⓘ Note

You can only edit assignments for one subaccount at a time.

8. You can now edit the assignments table:

Action	Steps
<b>Add new service plans to the subaccount</b>	<p>Choose <i>Add Service Plans</i> and from the dialog box, select the services and the service plans from each service that you would like to add to the subaccount. Choose <i>Add &lt;x&gt; Service Plans</i> in the dialog box to confirm.</p> <p>Remember, the services that you see depend on the type of global account you have and your contract details (see the prerequisites above for more information).</p> <p>→ Tip</p> <p>If your global account is configured to consume remote services from a non-SAP cloud vendor (resource provider), an additional dropdown list is displayed in the <i>Service Details</i> pane, where you can choose a configured resource provider. You can then choose the required service plans that are available for the selected resource provider to add them to the subaccount.</p> <p>For more information, see <a href="#">Managing Resource Providers [page 1947]</a>.</p>
<b>Edit the quota for one or more assigned service plans</b>	<p>Use + (<i>Plus</i>) and - (<i>Minus</i>) in the <i>Quota Assignment</i> column to increase or decrease the quota for each service plan.</p> <p>Note some service plans do not have a numeric quota assignment. In other words, you do not assign a specific quantity but grant access to the plan by simply assigning it to the subaccount. See <i>Quotas</i> in <a href="#">Managing Entitlements and Quotas Using the Cockpit [page 1995]</a>.</p>
<b>Set a quota limit to unlimited service plans that use the consumption-based commercial model</b>	<p>The usage of most service plans is unlimited by default in global accounts that use the consumption-based commercial model. To control costs of such plans, you can set a quota limit on the service plans for this subaccount by first selecting the checkbox in the <i>Set Quota Limit</i> column.</p> <p>Now, you can increase or decrease the quota for this service plan in the <i>Quota Assignment</i> column by using + (<i>Plus</i>) and - (<i>Minus</i>).</p>

Action	Steps
Delete a service plan and its quota from the subaccount	Choose  ( <i>Remove Service Plan</i> ) from the <i>Actions</i> column.

9. Once you're done, choose *Save* to save the changes and exit edit mode for that subaccount.
10. **Optional:** Repeat steps 7 to 9 to configure assignments for the other selected subaccounts.

## Related Information

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

## Configure Assignments and Quotas from a Subaccount

If you're working in a subaccount and realize you're missing assignments or quota, you can edit the assignments directly from that subaccount.

### Prerequisites

In addition to being a global account administrator, you must also be a member of the subaccount to be able to access that subaccount.

### Procedure

1. Navigate into the subaccount where you would like to configure the assignments.
2. Choose *Entitlements* from the left hand-side navigation to see the assignments for your subaccount.
3. Choose *Edit*.
4. You can now edit the assignments table as described in the procedure above.
5. Once you're satisfied with the changes, choose *Save* to save and exit edit mode.

## 6.1.1.7 Subscribe to Multitenant Applications Using the Cockpit

Subscribe to multitenant applications from the [Service Marketplace](#) page in the SAP BTP cockpit.

### Prerequisites

- If you're subscribing to an application provided by SAP:
  - If your global account uses the subscription-based commercial model, then you must have purchased SaaS licenses for the applications you want to consume. See <https://cloudplatform.sap.com/pricing.html>. You can also contact us on [SAP BTP](#) or via an SAP sales representative.

#### Note

If your global account is licensed with the consumption-based commercial model, then you are eligible to subscribe to any multitenant application that is available to this model.

- You have created a multi-environment subaccount. See [Create a Subaccount \[page 1977\]](#).
- If you are an application owner who is subscribing consumer tenants to your own multitenant application that you created in the Cloud Foundry environment:
  - The application must be deployed to your provider subaccount, configured, and registered as described in [Developing Multitenant Applications in the Cloud Foundry Environment \[page 327\]](#).
  - You have created a multi-environment subaccount for each application consumer in the region in which the application is deployed. See [Providing Multitenant Applications to Consumers in the Cloud Foundry Environment \[page 344\]](#).
- [Feature Set A] You are an administrator of the global account.
- [Feature Set B] You are an administrator of the subaccount.
- [Feature Set B] Your subaccount is entitled to the multitenant application. See [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#).

### Context

The instructions provided here apply whether you are an SAP customer subscribing to an application provided by SAP or you are an application owner who is sharing your multitenant application with your consumers.

## Procedure

1. Open your global account in the cockpit.
2. Do one of the following:
  - If you are subscribing to an SAP application, open your subaccount.
  - If you are sharing your multitenant application with other consumers in your global account, open the subaccount of each consumer.

See [Navigate in the Cockpit \[page 1938\]](#).

3. In the navigation area of each subaccount, choose ► [Services](#) ► [Service Marketplace](#) ►.

All resources you are entitled to consume in the subaccount appear as tiles.

### Note

To create a subscription, you need to open the [Create](#) wizard. There are 2 ways to reach this wizard, either from the [Service Marketplace](#) or from the [Instances and Subscriptions](#) page.

In steps 3, 4, 5, and 6, we describe how to reach the wizard from the [Service Marketplace](#) page.

This way is useful if you want to get an overview of all the applications your subaccount is entitled to use and if you want to get more details about the available plans before you create a subscription.

If you already know these details, select ► [Services](#) ► [Instances and Subscriptions](#) ►, click on [Create](#) in the top-right corner, and skip to step 7 to learn about the wizard.

4. In the filters area, select the [All Types](#) filter, and from the dropdown menu, select [Application](#).

You can use other filters to narrow down your search by the environments for which the application is available, capabilities, and its status.

[Active](#) status means you are currently subscribed to that application.

5. Click the application name to open its [Overview](#) page.

There, you can find more information about the application including all the available plans.

### → Tip

You can also create a new subscription without opening its overview by selecting the three dots in the top-right corner of the tile.

6. Choose [Create](#).
7. In the wizard that opens, select one of the plans of type subscription and choose [Create](#).

### Note

The wizard contains more than one step if additional subscription configuration input parameters are provided by the app provider.

A confirmation popup appears with the link to the [Instances and Subscriptions](#) page, where you can follow the status of your new subscription under the [Subscriptions](#) table.

The [Go to Application](#) link becomes available once the subscription is activated. Choose the link to launch the application and obtain its URL.

To find the link, either click on the application's name or click on the  (*Go to Application*) icon in the *Application* column.

#### → Tip

To update an existing subscription plan, select the three dots at the end of the subscription row, and from the menu, select *Update*.

#### ⓘ Note

You can update a subscription plan only if additional plans for the subscription are entitled to the subaccount you're using and if your subscription is eligible for a plan update.

#### → Tip

To remove an existing subscription, select the three dots at the end of the subscription row, and from the menu, select *Delete*. All data related to the multitenant application will be deleted in the respective subaccount.

8. **Optional:** Assign labels to the subscription to make it searchable and organized within the subaccount according to various criteria.
  - a. In the navigation area, choose  *Services*  *Instances and Subscriptions* .
  - b. Find the subscription to which you want to assign labels under the *Subscriptions* section of the page.
  - c. Select the actions (•••) menu and from the dropdown list, choose *Add Labels*.

#### ⓘ Note

If there are already labels assigned to the subscription, the action becomes *Change Labels*.

You can see the existing labels under the *Labels* column.

If you do not see the column, unhide it by clicking on  (*Configure Table Columns*).

For more information, see [Labels \[Feature Set B\] \[page 79\]](#).

## Next Steps

1. Configure user access to the application.  
See [Working with Role Collections \[page 2087\]](#).
2. If the application consumer isn't the subaccount owner or administrator, provide the consumer-specific URL of the application to the consumer or the users of the application.

## Related Information

## 6.1.1.7.1 Configure Application Roles and Assign Roles to Users

View, create, and modify application roles and then assign users to these roles using the SAP BTP cockpit.

### Prerequisites

Your subaccount is subscribed to a multitenant application in the Cloud Foundry environment. See [Subscribe to Multitenant Applications Using the Cockpit \[page 2008\]](#).

### Context

You can use any SAML 2.0 standard compliant identity provider. See [Trust and Federation with Identity Providers \[page 2014\]](#).

## View, Create, and Modify Application Roles

### Procedure

1. Navigate to your subaccount. For more information, see [Navigate in the Cockpit \[page 1938\]](#).
2. In the navigation area, choose ► [Services](#) ► [Instances and Subscriptions](#) ▾.
3. Under the [Subscriptions](#) table, click on the row with the application for which you want to manage app roles to open its [Overview](#) page.
4. Open the tab [Roles](#) to view, create, and modify the application roles.

#### → Tip

You can also manage roles without opening the application overview page, by selecting the three dots at the end of the application row. Choose [Manage Roles](#) from the drop-down menu.

## Assign Users to Application Roles

### Procedure

1. Navigate to your subaccount. For more information, see [Navigate in the Cockpit \[page 1938\]](#).
2. Choose ► [Security](#) ► [Roles Collections](#) ▾ in the navigation area and include the roles into the roles collection.

3. Choose **Security > Trust Configuration** and assign role collections to users.

## Related Information

[User and Member Management \[page 85\]](#)

### 6.1.1.8 Security Administration: Managing Authentication and Authorization

This section describes the tasks of administrators in the Cloud Foundry environment of SAP BTP. Administrators ensure user authentication and assign authorization information to users and user groups.

Since identity providers provide the users or user groups, you make then sure that there is a trust relationship between your subaccount and the identity provider. This is a prerequisite for authentication. Now you can manage the authorizations of the business users.

#### Note

Running on the cloud management tools feature set A: Only the administrator who created the current subaccount can use the SAP BTP cockpit to add other administrators as members. The added administrators can use all the security administration functions. This enables the administrators to manage authentication and authorization in this subaccount.

## Authentication

Identity providers provide the business users. The default platform identity provider for SAP BTP is SAP ID service. If you use external identity providers, you must configure the trust relationship using the SAP BTP cockpit. The respective subaccount must have a trust relationship with the identity provider. Using the SAP BTP cockpit, you, as an administrator of the Cloud Foundry environment, establish this trust relationship.

## Authorization

In the Cloud Foundry environment, application developers create and deploy application-based authorization artifacts for business users. Administrators use this information to assign roles, build role collections, and assign these collections to business users or user groups. In this way, they control the users' permissions.

## Setting Up Authorization Artifacts (Administrators)

Task	User Role	Tool
Use an existing role or create a new one using role templates <a href="#">Add Roles to Role Collections on the Application Level [page 2107]</a>	Administrator of the Cloud Foundry environment	SAP BTP cockpit  Command line interface for SAP BTP
Create a role collection and assign roles to it <a href="#">Define a Role Collection [page 2089]</a>	Administrator of the Cloud Foundry environment	SAP BTP cockpit  Command line interface for SAP BTP
Assign the role collections to users and user groups, manage attribute mappings <a href="#">Managing Users and Their Authorizations Using the btp CLI [page 2177]</a> or <a href="#">Mapping Role Collections in the Subaccount [page 2094]</a>	Administrator of the Cloud Foundry environment	SAP BTP cockpit  Command line interface for SAP BTP
(If you do not use <code>SAP ID Service</code> ) Assign the role collections to user groups (cloud management tools feature set A regions) <a href="#">Map Role Collections to User Groups [page 2095]</a>	Administrator of the Cloud Foundry environment	SAP BTP cockpit
Assign the role collection to the business users provided by an identity provider <a href="#">Working with Role Collections [page 2087]</a>	Administrator of the Cloud Foundry environment	SAP BTP cockpit  Command line interface for SAP BTP

### Note

When users log on, their authorizations are stored in each user's current browser session. These authorizations are not dynamically updated and are removed from there only if the session is terminated or invalidated. This means that if you assign a role collection to a user, only the authorizations that are in their current token, apply. The user must log out and log on again to get a new token.

## Related Information

[Trust and Federation with Identity Providers \[page 2014\]](#)

[Monitoring and Troubleshooting \[page 2793\]](#)

[SAP Authorization and Trust Management Service \[page 2778\]](#)

[Default Identity Provider \[page 2072\]](#)

## 6.1.1.8.1 Trust and Federation with Identity Providers

When setting up accounts you need to assign users. While we provide you with your first users to get you started, your organization has identity providers that you want to integrate.

SAP BTP supports identity federation, a concept of linking and reusing digital identities of a user base across loosely coupled systems. Identity federation frees applications on SAP BTP as well as the platform itself from the need to obtain and store the credentials of users and to authenticate them. Instead, the user base is reused from identity providers, which support the administration of digital user identities, authentication, and authorizations in a centralized and decoupled manner. To enable communication between SAP BTP and identity providers, you must cross-configure the communication endpoints of the involved systems, establishing a trust relationship between them.

### → Recommendation

We recommend that you always use SAP Cloud Identity Services - Identity Authentication as single identity provider for SAP BTP. If you use corporate identity providers, connect them to your Identity Authentication tenant, which then acts as a hub. We especially recommend this if you are using multiple corporate identity providers. For platform users, the use of SAP Cloud Identity Services - Identity Authentication is mandatory.

For more information, see [Corporate Identity Providers](#) and [Configure Conditional Authentication for an Application](#) in [What Is Identity Authentication](#) and [SAP Cloud Identity Services - Identity Authentication](#)

### Identity Provider and XSUAA in SAP BTP Architecture

Identity Authentication is a multitenancy-enabled identity provider and authentication service for all applications powered by SAP BTP and optionally on-premise applications. The service provides capabilities for authentication, single sign-on, and on-premise integration as well as self-services like self-registration or password reset — for both the employees and the partners and customers of your organization. For administrators, the service offers features for user management and reporting capabilities in the administration console.

SAP has its own Identity Authentication tenant, SAP ID service. SAP ID service is the default identity provider of SAP BTP and where you register to get initial access to SAP BTP. Trust to SAP ID service is preconfigured by default.

We recommend that you request your own Identity Authentication tenant (see [Getting a Tenant](#)), but you can also use any other identity provider. To establish trust with your identity provider, perform one of the following procedures.

For business users: [Business Users \[page 2015\]](#)

For platform users: [Platform Users \[page 2049\]](#)

## Related Information

[Settings for Default SAML Federation Attributes of Identity Providers for Business Users \[page 2042\]](#)

## 6.1.1.8.1.1 Business Users

**User accounts** enable users to log on to SAP BTP and access subaccounts and use services according to the permissions given to them. In this context, it's important to understand the difference between the two types of users that we refer to: business users and platform users.

**Business users** use the applications that are deployed to SAP BTP. For example, the end users of SaaS apps or services, such as SAP Workflow service or SAP Cloud Integration, or end users of your custom applications are business users.

In the Cloud Foundry environment, application developers ([platform users \[page 2049\]](#)) create and deploy application-based security artifacts for business users. Administrators use these artifacts to assign roles, build role collections, and then assign those role collections to business users or user groups. The assignment of role collections enables administrators to control the permissions that the users have in the deployed applications.

For business users, there's a [default identity provider \[page 2072\]](#). We expect that you have your own user base. We recommend that you configure the Identity Authentication service as the identity provider and connect Identity Authentication to your own corporate identity provider.

[Platform Users \[page 2049\]](#)

[Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#)

[Manually Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2035\]](#)

[Establish Trust and Federation with UAA Using Any SAML Identity Provider \[page 2039\]](#)

[Using Multiple Identity Providers from the Same Subaccount \[page 2044\]](#)

### 6.1.1.8.1.1.1 Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication

Use your SAP Cloud Identity Services - Identity Authentication tenant as an identity provider or a proxy to your own identity provider hosting your business users. This method avoids the upload and download of SAML meta data by using Open ID Connect (OIDC) to establish trust.

### Prerequisites

- You've subaccount administrator permissions or you are a security administrator (cloud management tools feature set A) of this account. For more information, see the related link.

- You've a tenant of SAP Cloud Identity Services - Identity Authentication.  
For more information, see [Tenant Model and Licensing](#) in the documentation for Identity Authentication.
- The Identity Authentication tenant is associated with the customer IDs of the relevant global account of SAP BTP.  
For more information, see [Reuse SAP Cloud Identity Services Tenants for Different Customer IDs](#) in the documentation for Identity Authentication.

## Context

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Consider the following restrictions and tips before you start.

### Restriction

- You can only establish trust with a single tenant of Identity Authentication per subaccount using this method.
- Your Identity Authentication tenant can be changed only when no Identity Authentication-based subscriptions (for example, SAP Build or SAP Integration Suite, advanced event mesh) exist.
- You've already created a trust configuration with a custom identity provider for applications. In this case, you can't add a trust configuration with the same Identity Authentication tenant using another protocol.  
Consider the upper limits for trust configurations in the subaccount. See [Limits for the Subaccount \[page 2818\]](#).

### Tip

- We recommend that you always use SAP Cloud Identity Services - Identity Authentication as single identity provider for SAP BTP. If you use corporate identity providers, connect them to your Identity Authentication tenant, which then acts as a hub. We especially recommend this if you are using multiple corporate identity providers. For platform users, the use of SAP Cloud Identity Services - Identity Authentication is mandatory.  
For more information, see [Corporate Identity Providers](#) and [Configure Conditional Authentication for an Application](#) in [What Is Identity Authentication](#) and [SAP Cloud Identity Services - Identity Authentication](#)
- We provide APIs so you can perform this procedure programmatically. For more information, see the [Identity Provider Management API](#) on [SAP Business Accelerator Hub](#).

## Procedure

1. In the SAP BTP cockpit, go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **Security > Trust Configuration**.

2. Choose *Establish Trust*.  
The *Configure Tenant* wizard opens.
3. Choose the Identity Authentication tenant. The identity providers listed are the Identity Authentication tenants associated with your customer ID. Continue with *Next*.
4. Choose the domain configured with the Identity Authentication tenant and continue with *Next*.
5. You can change the name and the description of the tenant, display and change the origin key, and provide a link text for user logon (see [Using Multiple Identity Providers from the Same Subaccount \[page 2044\]](#)). Continue with *Next*.
6. Review your configuration and confirm using *Finish*.

## Results

You've configured trust in your tenant of the Identity Authentication service, which is your identity provider. Identity Authentication creates an application with the prefix *SAP BTP subaccount* and the display name of your subaccount in the administration console for Identity Authentication.

### ❖ Example

If your subaccount was named *My Subaccount*, the resulting application in Identity Authentication would be *SAP BTP subaccount My Subaccount*.

Older applications start with *XSUAA\_*.

### → Tip

To troubleshoot problems with tokens from Identity Authentication, see [Logging OpenID Connect Tokens](#) in the documentation for Identity Authentication.

### ⚠ Restriction

If the OIDC issuer is changed in the trust configuration, the trust breaks. To adapt the trust configuration on SAP BTP side, use the `btpt update security/trust` command of the SAP BTP command line interface together with the `--refresh` parameter. This parameter refreshes the trust configuration to reflect changes in the Identity Authentication tenant, for example the issuer value. For more information, see [Managing Trust from SAP BTP to an Identity Authentication Tenant \[page 2175\]](#).

## Next Steps

If you don't need the default identity provider anymore, set it to inactive or hide the logon link.

## Related Information

## 6.1.1.8.1.1.1.1.1 Map User Attributes from a Corporate Identity Provider for Business Users

When you enable trust with a tenant of SAP Cloud Identity Services - Identity Authentication, you get an OpenID Connect (OIDC) application in Identity Authentication to represent your subaccount, in the context of business users. When Identity Authentication authenticates users using a corporate identity provider, map the user attributes provided by the corporate identity provider to the attributes required by your applications.

### Finding the Application for Your Subaccount

The name of the application in the administration console of Identity Authentication that represents your subaccount has the prefix `SAP_BTP_subaccount` or `XSUAA_` and the display name of your subaccount.

If your subaccount is named `My_Subaccount`, the resulting application in Identity Authentication is `SAP_BTP_subaccount_My_Subaccount` or `XSUAA_My_Subaccount`.

### Customizing Attribute Mappings

There are several options to customize attribute mappings in Identity Authentication, depending on whether identity federation is enabled or disabled.

For more information about identity federation, see [Configure Identity Federation](#).

- When identity federation is disabled, Identity Authentication always propagates all the attributes received from the corporate identity provider to all the applications, on a 1:1 basis. You have the following options:
  - Configure the corporate identity provider to directly send the attributes.
  - If needed, use **enriched token claims** or **enriched assertion attributes** (depending on whether the corporate identity provider is connected with SAML or OIDC) to map the attributes sent by the corporate identity provider, to the attribute names needed by SAP BTP.  
**Enriched token claims** or **enriched assertion attributes** add additional attributes, either based on the corporate identity provider attributes (for example, by renaming them) or on static values.
- When identity federation is enabled, Identity Authentication doesn't automatically propagate any attributes from the corporate identity provider to the application. This option requires mappings in the Identity Authentication application, for each attribute that is needed by the application.  
Use the [Attributes](#) in the Identity Authentication application representing your subaccount.  
SAP BTP expects the following attributes. The default configuration of the trust configuration sets up the values in the following table in the Identity Authentication tenant.

Self-Defined Attributes	Identity Directory
email	Email
email_verified	Email Verified
family_name	Last Name
given_name	First Name
groups	Groups
user_uuid	Global user ID

If the corporate identity provider sends user attributes with other names, set the source to the corporate identity provider and the value to the correct attribute name.

### Example

If your corporate identity provider sends users' last names as the **sn** attribute, add the corporate identity provider as source to the *last\_name* attribute with the value **sn**.

### Self-defined Attributes

Name	Source	Value	
email			+
	Identity Directory	Email	🗑️
email_verified			+
	Identity Directory	Email Verified	🗑️
family_name			+
	Identity Directory	Last Name	🗑️
given_name			+
	Identity Directory	First Name	🗑️
groups			+
	Identity Directory	Groups	🗑️
last_name			+
	Corporate Identity Provider	sn	🗑️
user_uuid			+
	Identity Directory	Global User ID	🗑️

#### Customized Last Name Attribute Configuration in Identity Authentication

For more information, see [User Attributes](#) in the documentation of Identity Authentication.

The subject name identifier attribute is used by SAP BTP to uniquely identify the application user.

For more information, see [Configure the Subject Name Identifier Sent to the Application](#) in the documentation of Identity Authentication.

## Default Configuration of ID Tokens

In the default configuration, the attributes provided in the ID token issued by Identity Authentication are described in the following table.

Default Attributes of Identity Authentication Tokens

Identity Authentication User Attribute	Assertion Attribute	Description
mail	email	E-mail address of the subject. By default, this value is used for the subject name identifier.  See the table <i>Default Configurations of the Subaccount in Identity Authentication</i> following this table.
mailVerified	email_verified	Indicates whether the subject has confirmed their e-mail address. Your identity provider might require users to verify their e-mail address.
lastName	family_name	Last name of the subject.
firstName	given_name	First name of the subject.
companyGroups	groups	Any groups the subject is assigned to in the identity provider.

Identity Authentication User Attribute	Assertion Attribute	Description
userUuid	user_uuid	<p>An identifier for a user that's unique across technology layers such as user interface, APIs, and security tokens, as well as across products and lines of businesses contributing to a business process in the Intelligent Enterprise.</p> <p>Business applications can use this identifier to correlate information about the user. While not necessary for platform users, the attribute doesn't hinder such users either.</p> <div data-bbox="1007 763 1396 1279" style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>Note</b></p> <p>SAP Authorization and Trust Management service supports global user identifiers. When Identity Authentication sends a global user identifier, it's included in the SAP Authorization and Trust Management service tokens, which means that you can use it in scenarios where you need to use global user identifiers.</p> <p>For more information, see <a href="#">Global User ID in Integration Scenarios</a>.</p> </div>

## Default Configuration the Identity Authentication Application

In the application of Identity Authentication that represents the subaccount, the configuration sets defaults as shown in the following table.

Default Configurations of the Subaccount in Identity Authentication

Configuration	Description
Subject name identifier	<p>This attribute is used to by the SAP Authorization and Trust Management service to identify the user for authentication.</p> <p>Default value: E-Mail.</p> <p>For more information, see <a href="#">Configure the Subject Name Identifier Sent to the Application</a> in the documentation of Identity Authentication.</p>

Configuration	Description
List of allowed redirect URIs	<p>The list of URIs to which Identity Authentication is allowed to redirect from the application that represents your subaccount.</p> <p>Default value: <code>https://&lt;subdomain&gt;.authentication.&lt;landscape&gt;/login/callback/&lt;origin&gt;</code>.</p> <p>For example: <code>https://mysubdomain.authentication.us10.hana.ondemand.com/login.callback/sap.custom</code></p> <p>For more information, see <a href="#">OpenID Connect Application Configurations</a> in the documentation of Identity Authentication.</p>
Post logout redirect URIs	<p>The list of URIs to which Identity Authentication is allowed to direct users when logging out.</p> <p>Default value: <code>https://&lt;subdomain&gt;.authentication.&lt;landscape&gt;/*</code>.</p> <p>For example: <code>https://mysubdomain.authentication.us10.hana.ondemand.com/*</code></p> <p>For more information, see <a href="#">OpenID Connect Application Configurations</a> in the documentation of Identity Authentication.</p>

## Related Information

[Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#)

[Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#)

### 6.1.1.8.1.1.2 Migration from SAML Trust to OpenID Connect Trust with Identity Authentication

To use or get the most out of some applications, such as SAP Build Work Zone and SAP Build Apps, your subaccount must use Identity Authentication with OpenID Connect (OIDC) as the custom identity provider. This process helps you change an SAML trust configuration to an OIDC configuration with as little impact to your application users as possible, especially in productive subaccounts.

The goal of this process is as follows:

- Preserve user records, including their authorizations, and also all user-related data in applications and services. User IDs don't change. We update the existing trust configuration instead of creating a new one.
- Preserve role collection mappings to groups or other attributes.
- Ensure that applications receive exactly the same information about users as they did before. We provide guidance and verification steps for when you reconfigure authentication along the chain of subaccount, Identity Authentication tenant, and potentially corporate identity provider.

### ⚠ Caution

You could achieve a similar result by deleting your current SAML trust configuration and setting up a new trust with OIDC. However, this method can cause an interruption in the service to your business users. Deleting the trust deletes any local shadow users in the subaccount and their role collection assignments. You would need to re-create those users and their role collection assignments. You would also permanently lose any connection to application data for those users. The internal IDs of the re-created users will never be the same as with the original trust configuration.

## Restrictions

In the SAP BTP cockpit under *Custom Identity Provider for Applications*, there are no trust configurations with protocol OpenID Connect and no more than one with SAML.

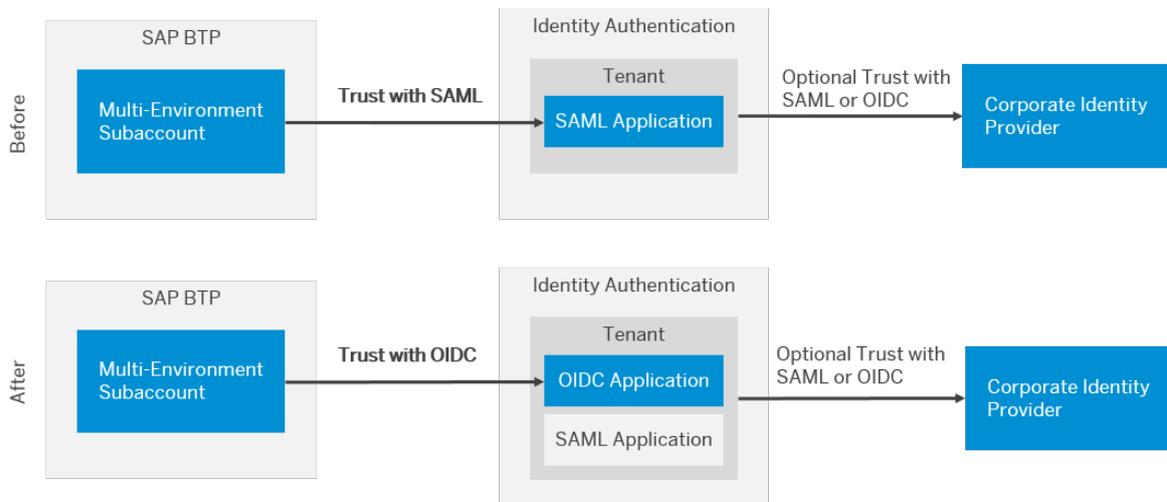

### 📌 Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

## Architecture

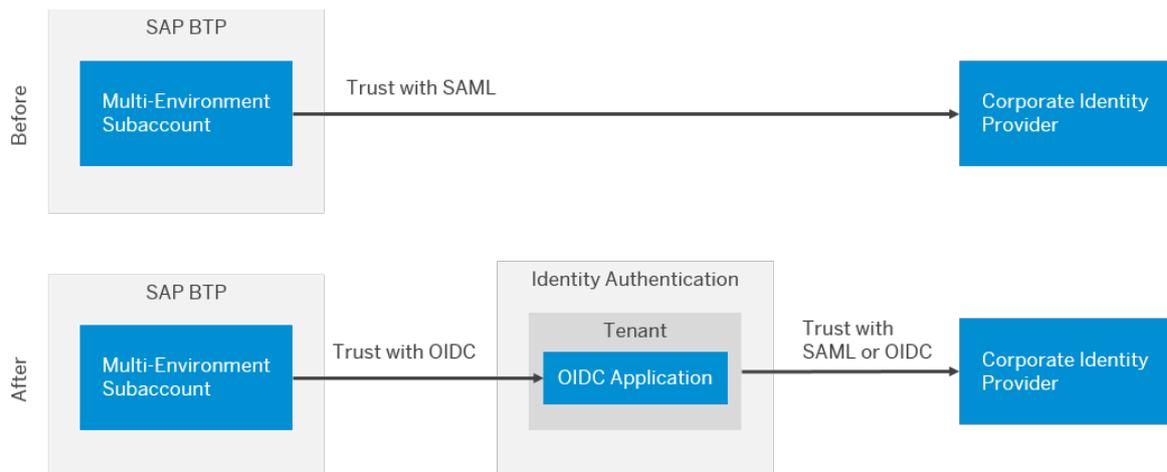

You have one of the following configurations:

- You've already configured Identity Authentication as a trusted identity provider, but with SAML. Optionally the Identity Authentication tenant trusts a corporate identity provider. For this case, you don't change the architecture, only the protocol between the subaccount and the Identity Authentication tenant. If you use a corporate identity provider, configure the new Identity Authentication application to authenticate with it.

### Update of Existing Trust Configuration for Identity Authentication

- You've connected your corporate identity provider directly with your subaccount as the trusted identity provider with SAML. For this case, you insert trust to Identity Authentication in between and configure Identity Authentication as a proxy for your corporate identity provider.

### Insertion of Identity Authentication in Trust Chain of Identity Providers

## Risks and Downtime

Expect a downtime between the time when you start the migration and when you've re-established and configured the chain of trust with your identity providers, including the new Identity Authentication application representing your subaccount.

### → Recommendation

Practice this procedure in your dev or test subaccounts before carrying it out in your productive subaccounts. Practice helps you to learn how the migration works, enabling you to minimize the risk of misconfiguration and downtime in your productive environments.

If you use the same Identity Authentication tenant for nonproductive and productive subaccounts, the integration between Identity Authentication and your corporate identity provider is already complete as

part of the preparation for the nonproductive subaccounts. This setup reduces the risk and downtime for productive subaccounts.

We provide a rollback function if you encounter any problems.

For more information, see [Restore SAML Trust Configuration \[page 2034\]](#).

## Process Overview

1. Prepare for the migration to minimize the downtime starting in step 2.
  1. Collect and save the user data with the existing SAML trust. After the migration, use this information to verify that everything works correctly.
  2. If you use a corporate identity provider and it isn't yet trusted by your Identity Authentication tenant, establish trust now.  
For more information, see [Prepare for Migration from SAML Trust to OpenID Connect \[page 2025\]](#).
2. Migrate the subaccount's trust configuration, updating the existing SAML trust to an OIDC trust with Identity Authentication.  
For more information, see [Migrate from SAML Trust Configuration to OpenID Connect Trust with Identity Authentication \[page 2027\]](#).
3. Configure your new OIDC application for your subaccount.  
Adjust the user subject and any attributes used by your new application in Identity Authentication to match your old trust configuration.  
If you use a corporate identity provider, configure the application in Identity Authentication to use the corporate identity provider for user authentication.  
For more information, see [Configuration of Identity Authentication After Migration from SAML to OIDC \[page 2029\]](#).
4. Verify that user authentication works as before the migration.  
For more information, see [Test the Trust Configuration After the Migration \[page 2032\]](#).

### 6.1.1.8.1.1.2.1 Prepare for Migration from SAML Trust to OpenID Connect

Before migrating your trust configuration, check which user data are sent today, so you can validate the new configuration after the migration. If you use a corporate identity provider, prepare the trust between your Identity Authentication tenant and your corporate identity provider ahead of time.

## Procedure

1. Check what attributes your users have.

To see what attributes your user has, open the following page of your subaccount:

```
https://<subaccount_subdomain>.authentication.<region>.hana.ondemand.com/config?action=who&details=true&trustMigrationOnly=true
```

For example

```
https://my-subdomain.authentication.eu10.hana.ondemand.com/config?
action=who&details=true&trustMigrationOnly=true
```

If at logon you see multiple identity providers, choose the one you want to migrate from for your applications.

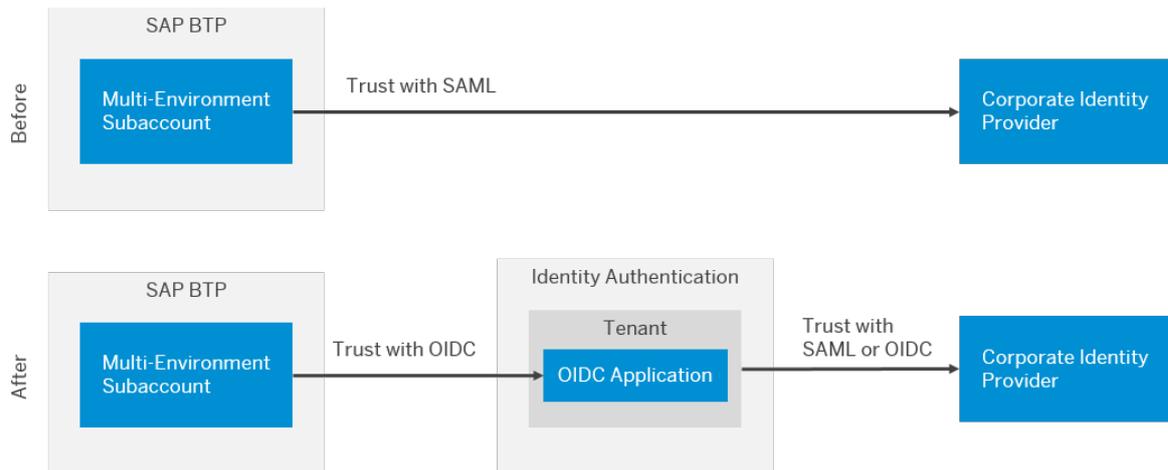

→ Remember

Save the results. You'll need to compare the attributes with the attributes you get after migrating the trust configuration.

For an example, see [Test the Trust Configuration After the Migration \[page 2032\]](#).

2. Determine if you need to establish trust between your corporate identity provider and your Identity Authentication tenant.

If you previously had configured your subaccount trust to your corporate identity provider directly, configure your Identity Authentication tenant to trust your corporate identity provider.

Insertion of Identity Authentication in Trust Chain of Identity Providers

In the preceding figure, we're configuring the SAML or OIDC trust between the Identity Authentication tenant and the corporate identity provider. Configure the corporate identity provider to send the same value for subject name identifier and the attributes. Keep the attribute names the same, too, except for the attribute names listed in the following table.

From User Attribute	To Assertion Attribute
first_name	given_name
last_name	family_name
mail	email

For more information, see [Corporate Identity Providers](#) in the documentation of Identity Authentication.

## 6.1.1.8.1.1.2.2 Migrate from SAML Trust Configuration to OpenID Connect Trust with Identity Authentication

If your subaccount uses the SAML protocol to connect to your custom identity provider, you can't consume applications or application features that require direct authentication with Identity Authentication, such as SAP Build Work Zone and SAP Build Apps. To consume such applications or features, switch to using OpenID Connect (OIDC) with Identity Authentication.

### Prerequisites

- The prerequisites for working with the SAP BTP command line interface (CLI) are fulfilled (see [Log in \[page 2149\]](#)).
- In the SAP BTP cockpit under *Custom Identity Provider for Applications*, there are no trust configurations with the OpenID Connect protocol and no more than one with SAML; namely the configuration that you want to migrate.  
For more information, see [Migration from SAML Trust to OpenID Connect Trust with Identity Authentication \[page 2022\]](#).

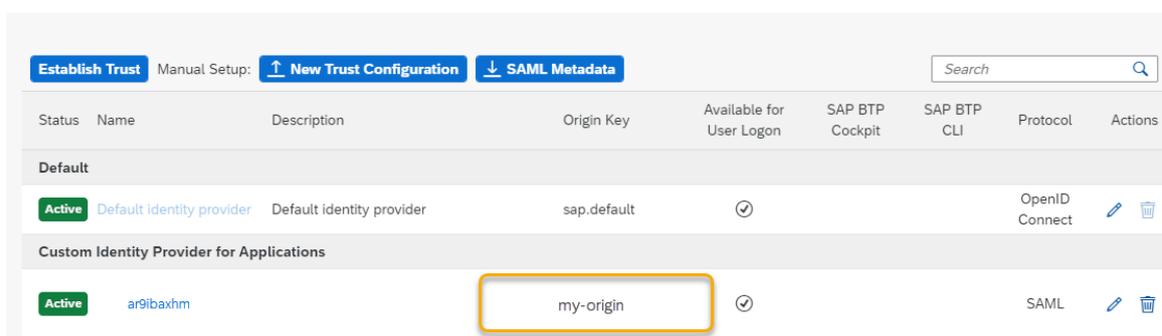

### Procedure

1. Find the origin key of the identity provider that you want to switch.

You can look up the origin key in the trust configuration in the SAP BTP cockpit using the btp CLI, or the Identity Provider Management API.

Subaccount: testme - Trust Configuration

All: 2

Status	Name	Description	Origin Key	Available for User Logon	SAP BTP Cockpit	SAP BTP CLI	Protocol	Actions
<b>Default</b>								
Active	Default identity provider	Default identity provider	sap.default	☑			OpenID Connect	 
<b>Custom Identity Provider for Applications</b>								
Active	ar9ibaxhm		my-origin	☑			SAML	 

#### Finding the Origin Key in the Cockpit

2. To migrate the trust configuration from SAML to OIDC, use the SAP BTP command line interface (CLI).  
For more information, see [Managing Trust from SAP BTP to an Identity Authentication Tenant \[page 2175\]](#).
3. Log on to the btp CLI (see [Log in \[page 2149\]](#)).

4. Make sure that you set the target to the relevant SAP BTP subaccount.
5. Find the name of the Identity Authentication tenant you want to migrate to OpenID Connect. Use the following command:

```
btpt list security/available-idp
```

You receive a list of all Identity Authentication tenants that are available in this subaccount. It's a good idea to copy the name of the Identity Authentication tenant that you want to migrate.

6. Migrate your trust configuration using the following command:

```
btpt migrate security/trust ORIGIN --idp TENANT
```

#### Example

```
btpt migrate security/trust my-origin-key --idp myidp.accounts.ondemand.com
```

The btpt CLI returns that the trust configuration is active and that the protocol is OIDC.

7. Check that your SAML trust configuration was migrated to a trust configuration with the OpenID Connect protocol. Go to your subaccount in the SAP BTP cockpit and choose [Security](#) > [Trust Configuration](#) .

## Results

In the cockpit, there's a new OIDC trust configuration for your Identity Authentication tenant. The original SAML trust configuration has been set to inactive and has received a new `oidc-migration-backup` origin key. If you need to roll back the change, the service uses this configuration to restore your original configuration.

In your Identity Authentication tenant, there's a new application that represents the trust configuration. The name is `SAP BTP subaccount <subaccount_display_name>`.

## Next Steps

Configure your new Identity Authentication application to match your old configuration. Check that your users can log on with all the required attributes. If necessary, configure your new application to consume your corporate identity provider.

#### Note

If everything works, you can delete the original SAML trust configuration. If you do so, you can't restore it.

## Related Information

[Configuration of Identity Authentication After Migration from SAML to OIDC \[page 2029\]](#)

[Restore SAML Trust Configuration \[page 2034\]](#)

## 6.1.1.8.1.1.2.3 Configuration of Identity Authentication After Migration from SAML to OIDC

You replaced an SAML trust configuration to your custom identity provider with an OIDC trust configuration to Identity Authentication. Now, you need to make sure that the subaccount gets the same user attributes (names and values) as before.

How you proceed depends on which architecture you're trying to achieve. We provide guidance for the configuration according to your target architecture.

- Business users authenticate directly with Identity Authentication  
See [Identity Authentication Without Corporate Identity Provider \[page 2029\]](#).
- Business users authenticate with a corporate identity provider. Identity Authentication is a proxy:
  - Identity federation is disabled (default flow)
  - Identity federation is enabled (advanced)See [Identity Authentication with Corporate Identity Provider \[page 2030\]](#).

### Related Information

[Migration from SAML Trust to OpenID Connect Trust with Identity Authentication \[page 2022\]](#)

[Restore SAML Trust Configuration \[page 2034\]](#)

[Map User Attributes from a Corporate Identity Provider for Business Users \[page 2018\]](#)

### 6.1.1.8.1.1.2.3.1 Identity Authentication Without Corporate Identity Provider

You've only changed the protocol of the trust configuration between your SAP Business Technology Platform subaccount and Identity Authentication.

Copy the following configurations from the old SAML-based Identity Authentication application to your new OIDC-based Identity Authentication application:

- Subject name identifier  
See [Configure the Subject Name Identifier Sent to the Application](#) in the documentation of Identity Authentication.
- Attributes  
Change the names of the following attributes as listed in the following table.

From User Attribute	To User Attribute
first_name	given_name
last_name	family_name
mail	email

See [Configuring User Attributes from the Identity Directory](#).

## Related Information

[Configuration of Identity Authentication After Migration from SAML to OIDC \[page 2029\]](#)

[Test the Trust Configuration After the Migration \[page 2032\]](#)

### 6.1.1.8.1.1.2.3.2 Identity Authentication with Corporate Identity Provider

You want to insert your Identity Authentication tenant in the user authentication flow between your SAP BTP subaccount and your corporate identity provider. So far, you've migrated the trust configuration from your subaccount to use Identity Authentication. Now, you configure Identity Authentication to delegate user authentication to the corporate identity provider.

We already asked you to configure trust between your Identity Authentication tenant and your corporate identity provider in this step: [Prepare for Migration from SAML Trust to OpenID Connect \[page 2025\]](#).

How you configure the connection depends on whether you're using identity federation or not. Identity federation is a configuration of Identity Authentication. If you haven't connected Identity Authentication to the corporate identity provider yet, use the disabled approach. If your Identity Authentication tenant already trusts your corporate provider, then choose the approach that fits to the existing trust configuration.

For more information about identity federation, see [Configure Identity Federation](#) in the documentation of Identity Authentication.

- Identity federation is disabled (default option)  
See [Choose Default Identity Provider for an Application](#) in the documentation of Identity Authentication.
- Identity federation is enabled (advanced)  
See [Configure Conditional Authentication for an Application](#) in the documentation of Identity Authentication.

### Identity Federation Is Disabled

As you were preparing for this migration, you saw what subject and attributes you need for your users.

For more information, see [Prepare for Migration from SAML Trust to OpenID Connect \[page 2025\]](#).

Attributes are passed to SAP BTP just as they're received from the corporate identity provider. Subject and attribute configurations on the Identity Authentication application are ignored. The subject **must** be provided by the corporate identity provider as required. Attributes **ideally** come from the corporate identity provider with the attribute names used by the subaccount so far.

Compare the attributes you got before the migration to the attributes you get now.

For more information, see [Test the Trust Configuration After the Migration \[page 2032\]](#).

If the assertion attributes don't come from the corporate identity provider as you expected, change the names of the following assertion attributes as listed in the following table.

From User Attribute	To User Attribute
first_name	given_name
last_name	family_name
mail	email

Map the attribute names between what the corporate identity provider provides and what the subaccount expects, according to the protocol of the trust configuration:

- For OIDC: See [Enrich Token Claims Coming from Corporate IdP](#) in the documentation of Identity Authentication.
- For SAML: [Enrich Assertion Attributes Coming from Corporate IdP](#) in the documentation of Identity Authentication.

## Identity Federation Is Enabled

As you were preparing for this migration, you saw what subject and attributes you need for your users.

For more information, see [Prepare for Migration from SAML Trust to OpenID Connect \[page 2025\]](#).

Configure your new OIDC-based Identity Authentication application to send the same information to your SAP BTP subaccount as before.

- Subject name identifier  
See [Configure the Subject Name Identifier Sent to the Application](#) in the documentation of Identity Authentication.
- Assertion attributes

### → Recommendation

Change the names of the following assertion attributes as listed in the following table.

From User Attribute	To User Attribute
first_name	given_name
last_name	family_name
mail	email

See [Configuring User Attributes from a Corporate Identity Provider](#) in the documentation of Identity Authentication.

Compare the attributes you got before the migration to the attributes you get now.

For more information, see [Test the Trust Configuration After the Migration \[page 2032\]](#).

## 6.1.1.8.1.1.2.4 Test the Trust Configuration After the Migration

Check that your users can still access their applications and have all the attributes they require. Use these steps to validate your new configuration.

### Prerequisites

You saved the list of attributes you get before the migration.

For more information, see [Prepare for Migration from SAML Trust to OpenID Connect \[page 2025\]](#).

### Procedure

1. Check what attributes your user has now.

```
https://<subaccount_subdomain>.authentication.<region>.hana.ondemand.com/config?
action=who&details=true&trustMigrationOnly=true
```

For example

```
https://my-subdomain.authentication.eu10.hana.ondemand.com/config?
action=who&details=true&trustMigrationOnly=true
```

2. Compare with the results you had before the migration.

In the following example, the user has a few special attributes in addition to the standard ones:

- Custom attribute `cost_center`
- Group assignment `my-group`
- Authorization assignment over the group to the role collection for reading audit logs

## Before (SAML)

```
userName P000011
origin my-origin-key
zoneId 9fcd13d0-77d7-4cfa-86b0-
a41b02e662a6
User Attributes {
  user_uuid=[7ebf5c32-cacd-4ad2-
a208-6bcb3e764f6f],
  email=[maria.fontes@example.com],
  cost_center=[my-cost-center],
  Groups=[my-group],
  family_name=[Fontes],
  given_name=[Maria]
}
email maria.fontes@example.com
userId 128af760-ad57-4213-
b063-2dd381a4d92e
externalId P000011
given_name Maria
family_name Fontes
verified true
authorities [
  openid,
  user_attributes,
  auditlog-management!
b8.ReadAuditLogs,
  uaa.user
]
```

## After (OIDC)

```
userName P000011
origin my-origin-key
zoneId 9fcd13d0-77d7-4cfa-86b0-
a41b02e662a6
User Attributes {
  given_name=[Maria],
  user_uuid=[7ebf5c32-cacd-4ad2-
a208-6bcb3e764f6f],
  cost_center=[my-cost-center],
  groups=[my-group],
  family_name=[Fontes],
  email=[maria.fontes@example.com]
}
email maria.fontes@example.com
userId 128af760-ad57-4213-
b063-2dd381a4d92e
externalId P000011
given_name Maria
family_name Fontes
verified true
authorities [
  openid,
  user_attributes,
  auditlog-management!
b8.ReadAuditLogs,
  uaa.user
]
```

### Note

In the new OIDC application, uppercase or lower case G in the `groups` attribute name doesn't matter.

3. If there are any remaining differences, adjust the configuration of the Identity Authentication tenant or applications or of the corporate identity provider until you get the same attributes.

For more information, see [Configuration of Identity Authentication After Migration from SAML to OIDC \[page 2029\]](#).

Use the OIDC token logging in Identity Authentication to help troubleshoot any problems.

For more information, see [Logging OpenID Connect Tokens](#) in the documentation of Identity Authentication.

If you can't get the configuration to work, restore the SAML trust configuration.

For more information, see [Restore SAML Trust Configuration \[page 2034\]](#).

## Next Steps

Once everything is working as you expected and are certain you don't need it anymore, delete your old SAML trust configuration with the origin `oidc-migration-backup`.

### Caution

If you delete the old SAML trust configuration too early, you can't use the restore feature anymore.

## Related Information

[Restore SAML Trust Configuration \[page 2034\]](#)

### 6.1.1.8.1.1.2.5 Restore SAML Trust Configuration

You replaced a SAML trust configuration to your custom identity provider with an OpenID Connect (OIDC) trust configuration to Identity Authentication, and the authentication of application users in the subaccount isn't working as you expected. Restore your SAML configuration to get your applications working again.

## Prerequisites

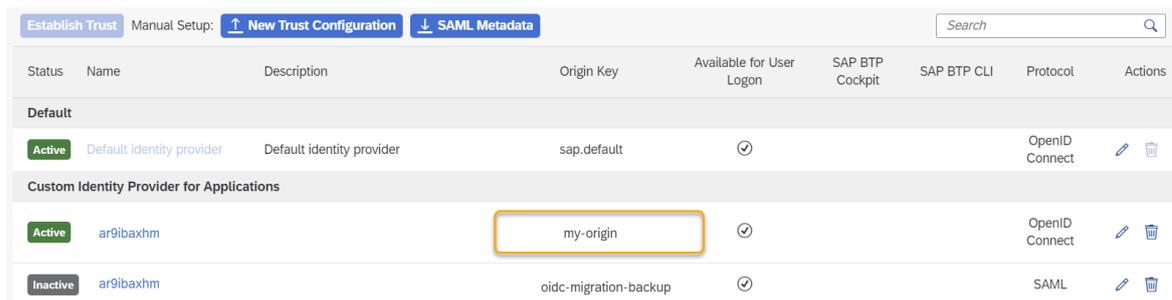

You previously migrated your trust configuration from SAML to OIDC.

For more information, see [Migrate from SAML Trust Configuration to OpenID Connect Trust with Identity Authentication \[page 2027\]](#).

## Procedure

1. Find the inactive OIDC trust configuration with the `oidc-migration-backup` origin key. There is an active trust configuration with the same name and a different origin key. This is the one you can restore to a SAML trust configuration.

You can look up the origin key in the trust configuration in the SAP BTP cockpit, using the SAP BTP command-line interface (CLI), or the Identity Provider Management API.

Status	Name	Description	Origin Key	Available for User Logon	SAP BTP Cockpit	SAP BTP CLI	Protocol	Actions
<b>Default</b>								
Active	Default identity provider	Default identity provider	sap.default	☑			OpenID Connect	<a href="#">✎</a> <a href="#">🗑️</a>
<b>Custom Identity Provider for Applications</b>								
Active	ar9ibaxhm		my-origin	☑			OpenID Connect	<a href="#">✎</a> <a href="#">🗑️</a>
Inactive	ar9ibaxhm		oidc-migration-backup	☑			SAML	<a href="#">✎</a> <a href="#">🗑️</a>

#### Finding the Origin Key in the Cockpit

2. To restore the trust configuration from OIDC to SAML, use the SAP BTP command line interface (CLI).  
For more information, see [Managing Trust from SAP BTP to an Identity Authentication Tenant \[page 2175\]](#).
3. Log on to the btp CLI (see [Log in \[page 2149\]](#)).
4. Make sure that you set the target to the relevant SAP BTP subaccount.
5. Find the name of the (currently active) OIDC trust configuration that you want to restore to the SAML protocol.

### Note

There is also an inactive trust configuration with the same name, but it has the `oidc-migration-backup` origin key and the SAML protocol. It still has the data and assignments of the original SAML trust configuration.

6. Restore your trust configuration. Use the original key of the active OIDC trust configuration using the following command:

```
btp restore security/trust my-origin-key
```

The `btp` CLI returns that the restored trust configuration is active and that the protocol is SAML.

7. Check whether your trust configuration with the OpenID Connect protocol has been restored to SAML. Go to your subaccount in the SAP BTP cockpit and choose **Security > Trust Configuration**. You see only one SAML trust configuration - the restored one. The OIDC trust configuration has disappeared.

## Results

The original SAML trust configuration has been restored, with its original role collection assignments and origin key. The respective OIDC trust configuration no longer exists. In your Identity Authentication tenant, the application for the OIDC trust configuration, SAP BTP subaccount `<subaccount_display_name>` has been deleted.

### 6.1.1.8.1.1.3 Manually Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication

Use your SAP Cloud Identity Services - Identity Authentication tenant as an identity provider or a proxy to your own identity provider hosting your business users. Exchange SAML metadata to establish trust with the Identity Authentication tenant and then register your subaccount with the tenant. To complete federation, maintain the federation attributes of the user groups.

## Context

### Note

Instead of manually exchanging SAML metadata, we recommend that you use the automatic method based on the OpenID Connect (OIDC) protocol.

For more information, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).

## 6.1.1.8.1.1.3.1 Establish Trust with an SAML 2.0 Identity Provider in a Subaccount

You want to use an SAML 2.0 identity provider, for example, SAP Cloud Identity Services - Identity Authentication. The identity provider authenticates business users for SAP BTP.

### Prerequisites

- You have subaccount administrator permissions or you are a security administrator (cloud management tools feature set A) of this account. For more information, see the related link.
- You have downloaded the SAML 2.0 metadata file from the Identity Authentication tenant using the URL `https://<Identity_Authentication_tenant>.accounts.ondemand.com/saml2/metadata`.

#### ❖ Example

```
https://my-ias-tenant.accounts.ondemand.com/saml2/metadata
```

For more information, see [Tenant SAML 2.0 Configuration in the SAP Cloud Identity Services - Identity Authentication](#).

### Context

The following procedure describes how to establish trust with an SAP Cloud Identity Services - Identity Authentication tenant.

#### ⚠ Restriction

You've already created a trust configuration with a custom identity provider for applications. In this case, you can't add a trust configuration with the same Identity Authentication tenant using another protocol.

#### ❖ Example

If there's already a trust configuration with Open ID Connect, you can't create one using the SAML protocol.

#### ⚠ Restriction

Consider the upper limits for trust configurations in the subaccount. See [Limits for the Subaccount \[page 2818\]](#).

## Procedure

1. In the SAP BTP cockpit, go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **Security > Trust Configuration**.
2. Choose **New SAML Trust Configuration**.
3. Enter a name and a description that make it clear to which identity provider that the trust configuration refers.

### Note

Make sure that the users who are supposed to log on to this identity provider understand the name of the trust configuration.

4. Download the relevant metadata (see prerequisites) and save it in an XML file.
5. Choose the **Upload** button to insert the SAML 2.0 metadata.
6. To validate the metadata, choose **Parse**. The system fills the **Subject** and **Issuer** fields with the relevant data from the Identity Authentication - your SAML 2.0 identity provider. You see the fields when you choose **Show Details**.

The name of the new trust configuration now shows the value `<Identity_Authentication_tenant>.accounts.ondemand.com`. It represents the custom identity provider Identity Authentication.

This action also fills the fields for the single sign-on URLs and the single logout URLs.

7. Save your changes.
8. To get the SAML metadata of your subaccount, choose **Download SAML Metadata**. You download an XML file with the SAML metadata of your subaccount. Its name is `saml-<subdomain>-sp.xml`. Use this file to import the SAML metadata into your identity provider.

## Next Steps

Register your SAP BTP subaccount in the SAML 2.0 Identity Provider

(Optional, cloud management tools feature set A) If you don't need the SAP ID service, set it to inactive.

## Related Information

[Managing Security Administrators in Your Subaccount \[Feature Set A\] \[page 1980\]](#)

### 6.1.1.8.1.1.3.2 Register SAP BTP Subaccount in the SAML 2.0 Identity Provider

An SAML service provider interacts with an SAML 2.0 identity provider to authenticate users signing in by means of a single sign-on (SSO) mechanism. In this scenario, the SAP Authorization and Trust Management

service (XSUAA) acts as a service provider representing a single subaccount. To establish trust between an identity provider and a subaccount, you must register your subaccount by providing the SAML metadata to the identity provider. The identity provider is SAP Cloud Identity Services - Identity Authentication.

## Context

Administrators must configure trust on both sides, in the service provider and in the identity provider. This description covers the side of the identity provider (Identity Authentication). The trust configuration on the side of the Identity Authentication must contain the following items:

- Metadata for web-based authentication or the relevant configuration information  
The metadata contains the configuration information, including the signing certificate and the required URLs. Create the metadata file of your subaccount using the [Download SAML Metadata](#) button in [▶ Security ▶ Trust Configuration ▶](#) of your subaccount.
- Use e-mail as the unique name ID attribute, and map the user attribute `Groups` to the assertion attribute `Groups` (case-sensitive). This assertion attribute is required for the assignment of roles.

We illustrate the process of configuring trust in the service provider by describing how administrators use the administration console of Identity Authentication to register the subaccount.

To establish trust from a tenant of Identity Authentication to a subaccount, assign a metadata file and define attribute details. The SAML 2.0 assertion includes these attributes. With the SAP Authorization and Trust Management service as SAML 2.0 service provider, they're used for automatic assignment of SAP Authorization and Trust Management service authorizations based on information maintained in the identity provider.

## Procedure

1. Open the administration console of Identity Authentication.  
`https://<Identity_Authentication_tenant>.accounts.ondemand.com/admin`
2. Choose [▶ Applications & Resources ▶ Applications ▶](#) in the menu or the [Applications](#) tile.
3. To add a new SAML service provider, choose [Create](#).
4. Enter the required data and choose [+ Create](#).
  - Enter a name for the application that clearly identifies it as your new service provider. Users see this name in the logon screen when the authentication is requested by the SAP Authorization and Trust Management service. Seeing the name, they know which application they currently access after authentication.
  - Choose [SAML 2.0](#) as the protocol type.
5. Choose [▶ Trust ▶ SAML 2.0 Configuration ▶](#).
6. Under [Define from Metadata](#), upload the relevant metadata XML file and choose [Save](#).

### Note

Use the `saml-<subdomain>-sp.xml` metadata file of your subaccount. You can create the file using the [Download SAML Metadata](#) button in [▶ Security ▶ Trust Configuration ▶](#) of your subaccount.

If the contents of the metadata XML file are valid, the parsing process extracts the information required to populate the remaining fields of the SAML configuration. It provides the name, the URLs of the assertion consumer service and single logout endpoints, and the signing certificate.

7. Choose *Default Name ID Format* and select *E-Mail* as a unique attribute. Save your changes.
8. Choose *Attributes*, use *Add* to add an attribute named **Groups** with a source **Identity Provider** and the value **Groups** (case-sensitive). Save your changes.

#### Note

Be aware that the X.509 certificates exposed in the SAML 2.0 metadata have specific validities. This applies to both SAML service providers and SAML identity providers. Authentication may fail with an error once the X.509 certificates expire.

Ensure that the SAML 2.0 metadata is updated before the X.509 certificate expiry dates.

Sign the certificate with a new signing key. For more information, see [Rotate Signing Keys of SAML Token \[page 2126\]](#).

## 6.1.1.8.1.1.4 Establish Trust and Federation with UAA Using Any SAML Identity Provider

To establish trust, configure the trust configuration of the SAML 2.0 identity provider in your subaccount using the SAP BTP cockpit. Next, register your subaccount in User Account and Authentication service using the administration console of your SAML 2.0 identity provider. To complete federation, maintain the federation attributes of the SAML 2.0 user groups. This makes sure that you can assign authorizations to user groups.

### 6.1.1.8.1.1.4.1 Establish Trust with Any SAML 2.0 Identity Provider in a Subaccount

You want to use an SAML 2.0 identity provider. This is where the business users for SAP BTP are stored.

#### Prerequisites

- You have subaccount administrator permissions or you are a security administrator (cloud management tools feature set A) of this account. For more information, see the related link.
- You have downloaded the SAML 2.0 metadata file from your SAML 2.0 identity provider using the relevant URL. For more information, see the documentation of your identity provider.

## Context

You must establish a trust relationship with an SAML 2.0 identity provider in your subaccount in SAP BTP. The following procedure tries to guide you through the trust configuration in your SAML 2.0 identity provider.

## Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose ► **Security** ► **Trust Configuration** ► in the SAP BTP cockpit.
2. Choose **New Trust Configuration**.
3. Enter a name and a description that make it clear that the trust configuration refers to your identity provider.

### Note

Make sure that the users who are supposed to log on to this identity provider understand the name of the trust configuration.

4. To get the relevant metadata, get to the metadata of your identity provider.
5. Copy the SAML 2.0 metadata and paste it into the **Metadata** field.
6. To validate the metadata, choose **Parse**. Take care that the **Subject** and **Issuer** fields are filled with the relevant data from your SAML 2.0 identity provider.

The name of the new trust configuration now shows the value of your identity provider. It represents your custom identity provider.

Check whether the fields for the single sign-on URLs and the single logout URLs are filled.

7. Save your changes.
8. (Optional, cloud management tools feature set A) If you do not need SAP ID service, set it to inactive.

You have successfully configured trust in your SAML 2.0 identity provider.

9. To get the SAML metadata of your subaccount, choose the **SAML Metadata** button. You create an XML file with the SAML metadata of your subaccount. Its name is `saml-<subdomain>-sp.xml`. Use this file to import the SAML metadata into your identity provider.

## Related Information

[Managing Security Administrators in Your Subaccount \[Feature Set A\] \[page 1980\]](#)

## 6.1.1.8.1.1.4.2 Register SAP BTP Subaccount in Any SAML 2.0 Identity Provider

An SAML service provider interacts with an SAML 2.0 identity provider to authenticate users signing in by means of a single sign-on (SSO) mechanism. In this scenario, the User Account and Authentication (UAA) service acts as a service provider representing a single subaccount. To establish trust between an identity provider and a subaccount, you must register your subaccount by providing the SAML details for web-based authentication in the identity provider itself.

### Context

Administrators must configure trust on both sides, in the service provider and in the SAML identity provider. This description tries to guide you through the configuration of your identity provider. The trust configuration on the side of the SAM 2.0 identity provider must contain the following items:

- Metadata for web-based authentication or the relevant configuration information  
If available, the metadata contains the configuration information, including the signing certificate and the required URLs. You can create the metadata file of your subaccount using the [SAML Metadata](#) button in [▶ Security ▶ Trust Configuration ▶](#) of your subaccount.
- Use e-mail as the unique name ID attribute, and map the user attribute `Groups` to the assertion attribute `Groups` (capitalized). This attribute is required for the assignment of roles.  
This makes sure that there is a trust relationship between your SAM 2.0 identity provider and the subaccount.

Your administrators use the administration console of your SAML 2.0 identity provider to register the subaccount.

To establish trust from a tenant of your identity provider to a subaccount, assign a metadata file and define attribute details. The SAML 2.0 assertion includes these attributes. With the UAA as SAML 2.0 service provider, they are used for automatic assignment of UAA authorizations based on information maintained in the identity provider.

### Procedure

1. Open the administration console of your SAML 2.0 identity provider.
2. Go to the configuration of your SAML 2.0 identity provider.
3. Add a new SAML service provider as described in the documentation of your identity provider.
4. (If applicable) Choose a name for your identity provider that clearly identifies it as your new service provider. Save your changes.

Users see this name in the logon screen when the authentication is requested by the UAA service. Seeing the name, they know which application they currently access after authentication.

5. Choose the SAML 2.0 configuration and import the relevant metadata XML file. Save your changes.

### Note

Use the `saml-<subdomain>-sp.xml` metadata file of your subaccount. You can create the file using the *SAML Metadata* button in **Security > Trust Configuration** of your subaccount.

Take care that the fields of the SAML configuration are filled. The metadata provides information, such as the name, the URLs of the assertion consumer service and single logout endpoints, and the signing certificate.

6. Choose or create the name ID attribute and select E-mail as a unique attribute. Save your changes.
7. Choose or create a user attribute, and enter **Groups** (capitalized) as attribute name for the *Groups* user attribute. Save your changes.

## Related Information

[Settings for Default SAML Federation Attributes of Identity Providers for Business Users \[page 2042\]](#)

### 6.1.1.8.1.1.4.3 Settings for Default SAML Federation Attributes of Identity Providers for Business Users

This table shows the attribute settings of the identity provider and the values administrators use to establish trust between the SAML 2.0 identity provider and a subaccount.

Since there are multiple identity providers you can use, we display the parameters and values of SAP Cloud Identity Services - Identity Authentication. Use the information in this table as a reference for the configuration of your identity provider.

Settings of Identity Authentication for SAML 2.0 Trust

Section in the User Interface	Description	Recommended Value
<a href="#">SAML 2.0 Configuration</a>	Configures the trust with a service provider using an uploaded metadata file.	Upload the metadata file from the SAP Authorization and Trust Management service.

Section in the User Interface	Description	Recommended Value
<a href="#">Default Name ID Format</a>	<p>Configures the attribute that the identity provider uses to identify the users. The attribute is sent as the name ID for the authenticated user in SAML assertions.</p> <p>Possible settings:</p> <ul style="list-style-type: none"> <li>• <a href="#">User ID</a></li> <li>• <a href="#">E-Mail</a></li> <li>• <a href="#">Display Name</a></li> <li>• <a href="#">Login Name</a></li> <li>• <a href="#">Employee Number</a></li> </ul>	<p><a href="#">E-Mail</a></p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>Note</b></p> <p>We recommend that you use exactly this name ID format.</p> </div>
<a href="#">Attributes</a>	<p>To assign authorizations indirectly, provide the user groups in the assertion attribute <b>Groups</b> (capitalized).</p> <p>You can change the default names of the assertion attributes that the application uses to recognize the user attributes. You can use multiple assertion attributes for the same user attribute.</p> <p>Some possible settings:</p> <ul style="list-style-type: none"> <li>• <a href="#">Groups</a></li> <li>• <a href="#">first_name</a></li> <li>• <a href="#">last_name</a></li> <li>• <a href="#">email</a></li> </ul> <p>You can choose from a number of user attributes and add them.</p>	<p>Select the <a href="#">Groups</a> user attribute and enter <b>Groups</b> as assertion attribute. You must set this attribute to enable that the assignment of role collection to user groups. For more information, see the related link.</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>Caution</b></p> <p>Use exactly this spelling:</p> <p><b>Groups</b></p> </div>

## ❖ Example

In the following, you see what John Doe's SAML 2.0 assertion looks like if [Default Name ID Format](#) was set to [E-Mail](#) and [Assertion Attribute](#) to [Groups](#).

## 🔗 Sample Code

```
<Assertion xmlns="urn:oasis:names:tc:SAML:2.0:assertion"

### 6.1.1.8.1.1.5 Using Multiple Identity Providers from the Same Subaccount

You need to use multiple identity providers for different groups of business users. You want to guide business users to the right identity provider for logon.

Usually there's a single identity provider, which is needed for most users.

Additional identity providers are only needed in exceptional cases.

## Basic Considerations Before You Provide a Logon Link for Business Users

Recommendation	Description
(Preferred) Try to avoid multiple trust configurations at all.	<p>Hide the default identity provider and connect a single Identity Authentication tenant.</p> <p>Connect further identity providers as corporate identity providers in the Identity Authentication tenant and use conditional authentication rules in Identity Authentication.</p>
(Feasible) If multiple trusts are really needed in the subaccount, avoid that business users must pick a specific trust by giving them dedicated application URLs, which choose the right identity provider (only supported by some applications).	<p>Some applications can be accessed using a URL that includes a query parameter to define the trust configuration for user login, instead of asking the user to choose one.</p> <div data-bbox="823 719 1394 913"><h3>❖ Example</h3><pre>https:// application.cfapps.eu10.hana.ondemand .com/sap_idp=some-origin-key</pre></div> <p>Options</p> <ol style="list-style-type: none"><li>1. Make sure all users access applications with such URLs.</li><li>2. Choose one standard trust configuration as the one to be used when applications are accessed without such a query parameter. Only use the parameter when any other trust configuration should be used. To achieve this, disable <i>Available for User Logon</i> for all trust configurations other than the one you want to use as standard trust configuration. For more information, see <a href="#">Provide Logon Link to Identity Provider for Business Users [page 2046]</a>.</li></ol> <p>If your custom applications use application router, you can enable support for the parameter by following the application router documentation. See <a href="#">Dynamic Identity Provider Configuration</a> or <a href="#">routes [page 392]</a>.</p> <div data-bbox="805 1503 1394 1697"><h3>ⓘ Note</h3><p>For SaaS applications, check the application documentation to find out whether or not they support the parameter.</p></div>
(Exceptional) If business users must really choose the identity provider. Make sure the respective link texts on the login page makes sense to them, so that they can easily choose the right one.	<p>Review the link texts of all trust configurations, where <i>Available for User Logon</i> is enabled, so that business users understand which one to choose.</p> <p>For more information, see <a href="#">Rename the Logon Link Text for Custom Identity Providers [page 2048]</a>.</p>

## 6.1.1.8.1.1.5.1 Provide Logon Link to Identity Provider for Business Users

You want to provide an understandable link on the logon page and guide business to the right identity provider.

You want to make life easy for business users and provide a logon link that they can easily recognize as such. This link provides an identity provider logon that enables them to log on to the application that they want to work with. To make it even easier, you can hide the logon of the default trust configuration (`SAP ID service`) for platform users, although it remains active. That way, your business users know at once which link to use for their logon.

We strongly recommend to use the following procedure:

1. Hide the default identity provider (`SAP ID service`) from the logon page.  
[Hide Logon Link for Default Identity Provider \[page 2046\]](#)
2. Display the custom identity provider at logon time.  
[Display Logon Link for Custom Identity Provider for Business Users \[page 2047\]](#)
3. (Optional) Give the logon link of the custom identity provider a name the business users understand.  
[Rename the Logon Link Text for Custom Identity Providers \[page 2048\]](#)

## 6.1.1.8.1.1.5.2 Hide Logon Link for Default Identity Provider

You use one or multiple custom identity providers for business users as well as the default identity provider primarily for platform users. To provide a good logon experience for your business users, you want to hide the default identity provider, which remains active.

### Prerequisites

- You have configured a custom trust configuration for a custom identity provider, for example Identity Authentication, and set it to active.
- You've checked the [Available for User Logon](#) checkbox in your custom trust configuration.
- The default trust configuration (`SAP ID service`) is active.

## Context

To hide the default identity provider at logon time, proceed as follows:

## Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose ► *Security* ► *Trust Configuration* ▾ in the SAP BTP cockpit.

You see the list of trust configurations: the default trust configuration and the custom trust configuration(s).

2. Choose  (Edit) for the default trust configuration. It has the status *Default*.
3. To hide the default trust configuration (*SAP ID service*) for logon, uncheck the *Available for User Logon* checkbox.
4. Save your changes.

The default trust configuration is now hidden but remains active.

## 6.1.1.8.1.1.5.3 Display Logon Link for Custom Identity Provider for Business Users

You want to display a logon link of the custom identity provider that business users should use to log on to an application.

## Context

## Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose ► *Security* ► *Trust Configuration* ▾ in the SAP BTP cockpit.

You see the list of trust configurations: the default trust configuration and the custom trust configuration(s).

2. Go to the desired trust configuration with the status *Custom*.
3. Choose  (Edit) for the custom trust configuration.
4. Make sure that the status of your custom trust configuration is *Active*.

5. Check the *Available for User Logon* checkbox.
6. Save your changes.

## Results

Whenever business users want to log on to their application, they see a logon link for the custom identity provider that they should use.

### 6.1.1.8.1.1.5.4 Rename the Logon Link Text for Custom Identity Providers

You can provide a logon link and give the link a name the business users understand. That way, they know which link they should use to log on.

## Prerequisites

- You have already made your custom identity provider available for user logon (see the related link).

## Context

You want to define an understandable name for the logon link of the custom identity provider that the business users should use.

## Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **Security** **Trust Configuration** in the SAP BTP cockpit.  
You see the list of trust configurations: the default trust configuration and the custom trust configuration(s).
2. Choose the link of your custom identity provider. It has the *Custom* status.
3. Choose *Edit*.
4. Go to *Link Text for User Logon* and give the logon link an understandable name.
5. Save your changes.

## Results

Whenever business users want to log on to their application, they see the logon link of the custom identity provider that they should use. It has the caption you entered in *Link Text for User Logon*.

## Related Information

### 6.1.1.8.1.2 Platform Users

**User accounts** enable users to log on to SAP BTP and access subaccounts and use services according to the permissions given to them. In this context, it's important to understand the difference between the two types of users that we refer to: Platform users and business users.

**Platform users** are usually developers, administrators or operators who deploy, administer, and troubleshoot applications and services on SAP BTP.

Platform users who were added as members and have administrative permissions can view or manage the list of global accounts, directories (Feature Set B), subaccounts, and Cloud Foundry orgs and spaces that are available to them. Members access them using the SAP BTP Cockpit, the SAP BTP command-line interface (btp CLI) (available only for Feature Set B), or the Cloud Foundry command-line interface (CF CLI).

#### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

For platform users, there's a [default identity provider \[page 2072\]](#). We expect that you have your own user base. We recommend that you configure the Identity Authentication service as the custom identity provider and connect Identity Authentication to your own corporate identity provider.

## Related Information

[Business Users \[page 2015\]](#)

[Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#)

[Supported Tools and Services When Using Custom Identity Providers for Platform Users \[page 2062\]](#)

[Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#)

[Log on with a Browser to the Cloud Foundry CLI and Service Dashboards \[page 2070\]](#)

## 6.1.1.8.1.2.1 Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts [Feature Set A]

### Note

The content in this section is only relevant for cloud management tools feature set A. For more information, see [Cloud Management Tools - Feature Set Overview](#).

### Note

The content in this section is only relevant for **platform users** and **not** business users.

For more information about establishing trust for subaccounts for business users, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).

By default, platform users in multi-environment subaccounts are users in SAP ID service. The use of your own identity provider requires integration between the user bases of multi-environment and Neo subaccounts.

## Prerequisites

- You have an Identity Authentication tenant.  
For more information, see the [documentation](#) for SAP Cloud Identity Services - Identity Authentication.
- You've a subaccount with the Neo environment in addition to your multienvironment subaccount.  
You need this subaccount in the Neo environment to access the SAP BTP cockpit. We're using the subaccount in the Neo environment with a configured trust to an Identity Authentication tenant, and then establish trust between the Identity Authentication tenant and multi-environment subaccounts.  
For more information setting up a Neo subaccount, see [Managing Global Accounts Using the Cockpit and Platform Identity Provider](#).  
If you run your own identity provider, connect it to the Identity Authentication service, which has a custom trust configuration with SAP BTP.  
For more information, see [Configure Trust with Corporate Identity Provider](#) in the documentation for the Identity Authentication service.
- Make sure that the e-mail addresses of all users in your identity provider are correct since the e-mail address is the unique identifier of users in the Cloud Foundry environment.

## Context

Platform users perform technical development, deployment, and administration tasks. They perform subaccount administration in the SAP BTP cockpit or access the Cloud Foundry command-line interface (CF CLI). By hosting these users in your own identity provider, you gain a number of advantages over hosting them in SAP ID service.

- Integrate the management of these users with your broader identity management strategy, hosted on your own identity providers. You control your own user lifecycle and single sign-on strategies throughout the entire landscape.
- Enforce your own password and authentication policies, such as stronger passwords or multifactor authentication.

For more information, see [Supported Tools and Services When Using Custom Identity Providers for Platform Users \[page 2062\]](#).

## Procedure

1. Connect your Identity Authentication tenant to your subaccount in the Neo environment.

For more information, see *Create Trust with the Identity Authentication Tenant* under [Platform Identity Provider](#) in the documentation for SAP BTP, Neo Environment.

2. In your Identity Authentication tenant, create an application of type *OpenID Connect*, and configure it. For configuring the Identity Authentication tenant, see [Configure OpenID Connect Application for Resource Owner Password Credentials Flow](#) in the documentation for Identity Authentication service.

### Note

Use the complete URL of the Identity Authentication tenant starting with `https` as name of the identity provider settings. The OIDC protocol uses the name as the issuer of the Identity Authentication tenant.

Skip creating redirect URIs for now. SAP Support provides the redirect URIs later.

3. In your Identity Authentication application, add a client ID and client secret for the application.

For more information, see [Configure Secrets for API Authentication](#) in the documentation for the Identity Authentication service.

4. Open a ticket with SAP Support (for the component, see [Monitoring and Troubleshooting \[page 2793\]](#)) and provide the following information:

- Component (BC-CP-CF-SEC-IAM)
- Multi-environment regions that you want to access using the SAP BTP cockpit.
- URL of your Identity Authentication tenant.  
For example: `https://caev6ngwk.accounts.ondemand.com`
- Client ID and client secret of the Identity Authentication application connected to the Cloud Foundry landscape for the OIDC token of your Identity Authentication account.

### Caution

Enter the client secret in the secure area of the ticket.

- Origin that identifies the identity provider during logon using Cloud Foundry command-line interface and during the assignment of platform authorizations to users.

### Restriction

The origin has a 1-to-1 relationship with the user base of the Identity Authentication tenant. This origin must be unique for all customers of SAP BTP. The origin is used in the list of members. It

shows in which identity provider the user is stored. Provide an origin name with a maximum of 36 7-bit ASCII characters. SAP support will get back to you if necessary.

We recommend using the tenant ID as the origin. For example:

- caev6ngwk from `https://caev6ngwk.accounts.ondemand.com`
- acme-test from `https://acme-test.accounts.ondemand.com`

Or choose a name that's easier for you to remember. Whatever you choose, choose your origin carefully. We don't support changing the origin after configuration.

### Note

Our operations team needs to make manual adjustments in the SAP BTP regions to establish trust between the Identity Authentication tenant and Neo regions.

For more information about opening a ticket, see [Getting Support \[page 2863\]](#).

SAP answers with redirect URIs and test instructions to confirm that everything has been set up correctly.

5. In your Identity Authentication application, update your *OpenID Connect Configuration* with the redirect URIs provided by SAP Support.

### → Remember

If the OIDC issuer was changed in the trust configuration, the trust breaks, but the global account automatically repairs the trust after 24 hours.

To adapt the trust configuration on SAP BTP side, use the `btpt update security/trust` command of the SAP BTP command line interface together with the `--refresh` parameter. This parameter immediately refreshes the trust configuration to reflect changes in the Identity Authentication tenant, for example the issuer value. For more information, see [Managing Trust from SAP BTP to an Identity Authentication Tenant \[page 2175\]](#).

For more information, see [Configure OpenID Connect Application for Resource Owner Password Credentials Flow](#) in the documentation for the Identity Authentication service.

6. Test the login redirect URI.

With the instructions provided by the support ticket, log on with a user in your custom identity provider.

For more information about the Identity Authentication tenant, see [Configuring Tenant Settings](#) in the documentation for the Identity Authentication service.

7. To find the SAP BTP cockpit logon URL of the custom platform identity provider, go to the *Platform Identity Provider* tab of the Neo subaccount in `>> <trusted__subaccount> > Security > Trust >`.
8. To start the logon page of the custom platform identity provider, choose the *Cockpit* button.

You can now log on with your user of the custom identity provider.

### ⚠ Restriction

This location does not support use of a custom domain.

## Next Steps

- Add platform users to your orgs and spaces.  
For more information about adding members with the SAP BTP cockpit, see [Add Org Members Using the Cockpit \[page 2248\]](#) and [Add Space Members Using the Cockpit \[page 2252\]](#).  
For more information about adding members with the command-line interface, see [Add Organization Members Using the Cloud Foundry Command Line Interface \[page 2288\]](#) and [Add Space Members Using the Cloud Foundry Command Line Interface \[page 2291\]](#).
- Work in the Cloud Foundry command-line interface.  
For more information, see [Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#).
- If you want to impose, for example, two-factor authentication to protect your subaccounts, you must configure two-factor authentication in all Identity Authentication applications involved.  
For more information, see [Configure Risk-Based Authentication](#) in the documentation for the Identity Authentication service.
  - In the application of the Identity Authentication tenant for your Neo subaccount (required for SAP BTP cockpit access)
  - In the application of the Identity Authentication tenant for the Cloud Foundry environment

## Related Information

[User and Member Management \[page 85\]](#)

[Bringing Your Corporate Identity Provider for Platform Users \[Feature Set A\] \[page 96\]](#)

[SAP Note 2964274 - Establish Trust and Federation for Cloud Foundry Platform Users for Custom Identity Providers \[Feature Set A\]](#) 

### 6.1.1.8.1.2.2 Establish Trust and Federation of Custom Identity Providers for Platform Users [Feature Set B]

You want to use a custom identity provider for the platform users of SAP BTP in different environments and at the different account levels: global account, directory, and subaccount. By default, platform users in multi-environment subaccounts are users in the default identity provider.

## Prerequisites

- You've a tenant of SAP Cloud Identity Services - Identity Authentication.  
For more information, see [Tenant Model and Licensing](#) in the documentation for Identity Authentication.
- The Identity Authentication tenant is associated with the customer IDs of the relevant global account of SAP BTP.

For more information, see [Reuse SAP Cloud Identity Services Tenants for Different Customer IDs](#) in the documentation for Identity Authentication.

- Make sure that the email addresses of all users in your identity provider are unique and correct.

## Context

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Platform users perform technical development, deployment, and administration tasks. For example, they perform subaccount administration in the SAP BTP cockpit or access the Cloud Foundry command line interface (CF CLI). By hosting these users in your own identity provider, you gain a number of advantages over hosting them in the default identity provider.

- Integrate the management of these users with your corporate identity management strategy, hosted on your own identity providers. You control your own user lifecycle and single sign-on strategies throughout the entire landscape.
- Enforce your own password and authentication policies, such as stronger passwords or multifactor authentication.

### Note

The content in this topic is relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

### Note

The content in this section is only relevant for **platform users** and **not** business users.

For more information about establishing trust for business users, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).

You must establish a trust relationship with a custom identity provider in your global account in SAP BTP. The following procedure guides you through the trust configuration in your custom identity provider.

## Procedure

1. Go to your global account (see [Navigate in the Cockpit \[page 1938\]](#)) and choose ► **Security** ► **Trust Configuration** ▾ in the SAP BTP cockpit.
2. Choose [Establish Trust](#).

The identity providers listed are the Identity Authentication tenants associated with your customer ID.

3. Select an identity provider from the list of available tenants and choose [Next](#).
4. Choose your desired domain of the tenant and continue with [Next](#). For a good single sign-on experience, choose the same domain for all SAP BTP accounts and non SAP BTP applications that use this tenant.

5. Enter a name and a description of the new trust configuration. If possible, set the origin key. The origin key always ends with `-platform`. Continue with *Next*.

#### Note

The origin key is a technical identifier of an identity provider for platform users. Administrators need it when managing users. Platform users from the identity provider need the origin key when signing in with certain tools, such as the Cloud Foundry command line interface or service dashboards.

You can only set the origin key once for the whole landscape. You can't change the origin key later.

6. The wizard shows you a preview of your configuration. To complete your new trust configuration, choose *Finish*.

#### Remember

If the OIDC issuer was changed in the trust configuration, the trust breaks, but the global account automatically repairs the trust after 24 hours.

To adapt the trust configuration on SAP BTP side, use the `btpt update security/trust` command of the SAP BTP command line interface together with the `--refresh` parameter. This parameter immediately refreshes the trust configuration to reflect changes in the Identity Authentication tenant, for example the issuer value. For more information, see [Managing Trust from SAP BTP to an Identity Authentication Tenant \[page 2175\]](#).

## Results

You've configured trust in your tenant of the Identity Authentication service, which is your identity provider. Identity Authentication creates an application with the name *SAP Business Technology Platform*.

#### Tip

To troubleshoot problems with tokens from Identity Authentication, see [Logging OpenID Connect Tokens](#) in the documentation for Identity Authentication.

## Next Steps

- Add platform users to your orgs and spaces.  
For more information about adding members with the SAP BTP cockpit, see [Add Org Members Using the Cockpit \[page 2248\]](#) and [Add Space Members Using the Cockpit \[page 2252\]](#).  
For more information about adding members with the command-line interface, see [Add Organization Members Using the Cloud Foundry Command Line Interface \[page 2288\]](#) and [Add Space Members Using the Cloud Foundry Command Line Interface \[page 2291\]](#).
- Add platform users at different levels (global account, directory, subaccount) from the custom identity provider.  
For more information, see [Working with Users \[page 2078\]](#).

### 📘 Note

- For subaccounts in the Neo environment, the identity provider will be offered in the value help only if a user in that identity provider has created at least one Neo subaccount in the corresponding global account and Neo region.
- For global accounts upgraded from feature set A, in addition to at least one Neo subaccount being in the corresponding global account, you also need to ensure that the Neo region has a platform identity provider trust to the Identity Authentication tenant in feature set A.

#### → Tip

If the identity provider isn't available in the value help for Neo subaccount members, log on to the global account with a user from that identity provider and create a new Neo subaccount. If it's not needed otherwise, you can delete it.

### → Recommendation

We recommend that you keep at least one global account administrator from the default identity provider. You can then use this administrator to log on in the rare instance that access to the custom identity provider fails.

- Log on to the SAP BTP cockpit as a user from the custom identity provider. In the [Trust Configuration](#) page, the [Open](#) link in the *SAP BTP Cockpit* column contains the URL (for example, <https://emea.cockpit.btp.cloud.sap/cockpit/?idp=cidppuxhm.accounts.ondemand.com>) for the user to log on with the custom identity provider. Copy the link and send it to your platform user colleagues. Remember if you have the cockpit open and if you want to work in parallel, your current session may be shared by your browser. Open the link in a private or incognito browsing mode. For more information, see [Log On with a Custom Identity Provider to the SAP BTP Cockpit \[page 2069\]](#).
- If you want to impose, for example, two-factor authentication for platform users, you must configure [two-factor authentication](#) in **all** the Identity Authentication applications involved. Multifactor authentication is just used as an example. For more information, see [Multi-Factor Authentication](#) in the documentation for the Identity Authentication service. Keep all settings for Identity Authentication applications the same.

#### → Tip

Instead of configuring two-factor authentication in all the Identity Authentication applications, you could also configure it once in your corporate identity provider.

### 📘 Note

For all the Neo datacenters where you have subaccounts, you might have to configure a separate SAML application (for example, [SAP Cloud Platform hhw9g3jrx](#)) in the Identity Authentication service.

- Integrate your Identity Authentication tenant with your identity authentication management solution. For more information, see [Corporate Identity Provider](#) in the documentation for the Identity Authentication service.
- Work in the SAP BTP command line interface (btp CLI). To log on to a global account, you need to provide the hostname of the tenant (for example, [ar9ibaxhm](#)) with the `--idp` parameter. See [Log in with a Custom Identity Provider \[page 2154\]](#). To work with users and role collections on global account, directory, or subaccount level, you need to provide the origin key with the `--of-idp` parameter in the following commands: `btp list security/`

```
user,btp get security/user,btp delete security/user,btp assign security/role-  
collection,btp unassign security/role-collection.
```

Both values can be found in the cockpit under [Security → Trust Configuration → Custom Platform Identity Providers](#).

As an administrator, you want to determine which of the Identity Authentication tenants' domains SAP BTP should use for platform user logon. For this reason, you specify a custom domain for an Identity Authentication tenant. You can use the `btp update security/trust` command and specify the domain in the `--domain` parameter.

- Work in the Cloud Foundry command line interface (CF CLI).  
For more information, see [Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#).
- The Kyma environment has a separate configuration for the identity provider. We recommend that you also configure your Kyma environment to use Identity Authentication as your custom identity provider.  
For more information, see [Configure a Custom Identity Provider for Kyma](#).

### 6.1.1.8.1.2.2.1 Restrictions When Using Custom Identity Providers for Platform Users [Feature Set B]

The following is a list of restrictions that apply to the use of custom identity providers with platform users in Feature Set B.

#### Supported with Restrictions When Using Custom Identity Providers for Platform Users [Feature Set B]

Supported with Restrictions	Description
Maximum number of parallel sessions per user per identity provider	Each user is allowed a maximum of 10 parallel sessions, per identity provider. This number considers all tools, including the cockpit and CLIs. <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p><b>Note</b></p><p>When accessing the cockpit, a user is allowed one session in each region. For example, if you access <a href="https://emea.cockpit.btp.cloud.sap">https://emea.cockpit.btp.cloud.sap</a>, it counts as the first session and <a href="https://amer.cockpit.btp.cloud.sap">https://amer.cockpit.btp.cloud.sap</a> as the second one.</p></div>

**Supported with Restrictions**

**Description**

---

Single logout (SLO)	For platform users of custom identity providers, logging out from the SAP BTP cockpit (including Neo cockpit) terminates the session in the used Identity Authentication tenant and sessions of other applications that connect to the same tenant. What is required is that the sessions support this kind of logout. This requirement doesn't apply for other instances of the SAP BTP cockpit except for instances where the user initially logged out from. In this case, sessions remain active.
---------------------	---

---

## Supported with Restrictions for Neo Subaccounts Before the Changes in the Trust Configuration

The following is a list of restrictions that only apply for Neo subaccounts when using custom identity providers for platform users.

- All individual Neo subaccounts that have been created before July 2023.
- Neo subaccounts in global accounts that have custom identity providers for platform users. For these subaccounts, [SAP Note 3330671](#) hasn't been applied yet.

**Supported with Restrictions**

**Description**

---

Working with custom domains for an Identity Authentication tenant	<p>SAP BTP always uses the default domain of the Identity Authentication tenant, regardless of a potentially configured custom domain. Therefore, when you use this tenant as a platform identity provider:</p> <ul style="list-style-type: none"><li>• Single sign-on (SSO) doesn't work between applications that use this custom domain and cloud management tools. Exception: if you use the same Identity Authentication tenant for both platform and business users, as custom domain is a tenant setting.</li><li>• The OpenID Connect (OIDC) issuer in the <i>Name</i> field of the Identity Authentication tenant must be the default domain (&lt;origin&gt;.accounts.ondemand.com). For more information, see <a href="#">Tenant OpenID Connect Configurations</a>.</li></ul>
---	---

---

OpenID Connect (OIDC) issuer in the *Name* field of the Identity Authentication tenant

**Caution**

Don't change the *Name* field after configuring trust. Changing the issuer breaks the trust between the systems.

---

Neo CLI	<p>No restriction for new Neo subaccounts if this <a href="#">prerequisite</a> is fulfilled.</p> <p>For basic authentication, the Neo CLI has limited support for existing Neo subaccounts when using custom identity providers for platform users.</p>
Neo Git service	Logging on with a password to the Neo Git service doesn't work with custom identity providers for platform users.

---

Supported with Restrictions	Description
Cloud connector	Logging on with a password to the Cloud connector doesn't work with custom identity providers for platform users.
SAP HANA studio	No restriction for new Neo subaccounts if this <a href="#">prerequisite</a> is fulfilled.

## 6.1.1.8.1.2.2 Map User Attributes from a Corporate Identity Provider for Platform Users

When you enable trust with a tenant of SAP Cloud Identity Services - Identity Authentication, you get an OpenID Connect (OIDC) application in Identity Authentication to represent SAP BTP, in the context of platform users. When you authenticate users using a corporate identity provider, map the user attributes provided by the corporate identity provider to the attributes required by SAP BTP. The following information explains which attributes SAP BTP needs for which purpose, and how you can map those attributes.

### Finding the Application for Your Platform Users

The name of the application in the administration console of Identity Authentication that represents SAP BTP in the context of platform users has the name, *SAP Business Technology Platform*.

For more information, see [OpenID Connect](#) in the documentation of Identity Authentication.

### Customizing Attribute Mappings

There are several options to customize attribute mappings in Identity Authentication, depending on whether identity federation is enabled or disabled. For more information about identity federation, see [Configure Identity Federation](#).

- When identity federation is disabled, Identity Authentication always propagates all the attributes received from the corporate identity provider to all the applications, on a 1:1 basis. You have the following options:
  - Configure the corporate identity provider to directly send the attributes.
  - If needed, use **enriched token claims** or **enriched assertion attributes** (depending on whether the corporate identity provider is connected with SAML or OIDC) to map the attributes sent by the corporate identity provider, to the attribute names needed by BTP. **Enriched token claims** or **enriched assertion attributes** add additional attributes, either based on the corporate identity provider attributes (for example, by renaming them) or on static values.
- When identity federation is enabled, Identity Authentication doesn't automatically propagate any attributes from the corporate identity provider to the application. This option requires mappings in the Identity Authentication application, for each attribute that is needed by the application. Use the attributes in the Identity Authentication application representing SAP BTP.

## Note

You can add attribute sources or disable the default application attributes. You can also add self-defined attributes for mapping to role collections.

For example, you have so many groups being added to your token and you're running into size limits. You can disable the standard groups configuration and add a regular expression to include only those groups, which begin with BTP. So, to the *groups* attribute, you add a source of type **Expression** with the value `${companyGroups:regex[BTP.*]}`.

To check which groups Identity Authentication actually sends, use the troubleshooting logs for OpenID Connect. For more information, see [Logging OpenID Connect Tokens](#) in the documentation for Identity Authentication.

## Application Attributes

Name	Source	Value	
▼ first_name			+
	Identity Directory	First Name	⊗
	Corporate Identity Provider	given_name	⊗
▼ groups			+
	Identity Directory	Groups	⊗
▼ last_name			+
	Identity Directory	Last Name	⊗
	Corporate Identity Provider	family_name	⊗
▼ mail			+
	Identity Directory	Email	⊗
	Corporate Identity Provider	email	⊗
▼ uid			+
	Identity Directory	User ID	⊗

Default Configuration of Application Attributes for the Platform Identity Provider

If the corporate identity provider sends user attributes for email address, first and last name with other names than *mail*, *first\_name*, or *last\_name*, set the right attribute name by replacing those values.

## Example

If your corporate identity provider sends users' last names as the *sn* attribute, add the corporate identity provider as source to the *last\_name* attribute with the value **sn**.

For more information, see [User Attributes](#) in the documentation of Identity Authentication.

The following table provides the information needed for mapping the attributes.

The subject name identifier attribute is used by SAP BTP to uniquely identify the user in Neo subaccounts. The e-mail address is used as the user identifier in the Cloud Foundry environment (global account, directory, multi-environment subaccount).

For more information, see [Configure the Subject Name Identifier Sent to the Application](#) in the documentation of Identity Authentication.

Attribute Mapping in Identity Authentication Tokens

User Attribute Expected by SAP BTP	Purpose
Subject name identifier	User identifier for Neo subaccounts. Default value: User ID
mail	E-mail address of the user.
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>User identifier for all the account levels (global account, directory, multi-environment subaccount), and for the Cloud Foundry environment.</p> </div> <p>The e-mail addresses of all the users in the Identity Authentication tenant must be unique.</p> <p>For more information, see the <a href="#">prerequisites [page 2053]</a> for establishing trust and federation of custom identity providers for platform users [feature set B].</p>
first_name	First name of the user.
last_name	Last name of the user.
groups	Any groups the subject is assigned to in the identity provider.

## 6.1.1.8.1.2.3 Supported Tools and Services When Using Custom Identity Providers for Platform Users

Not all tools and services of SAP BTP support the use of custom identity providers with platform users. We provide a list of tools and services, which support this feature and any restrictions that apply.

Supported When Using Identity Providers for Platform Users

Supported	Description
Cloud Connector	<p>You can connect a Cloud Connector with a multi-environment subaccount of SAP BTP.</p> <p>For more information, see <a href="#">Use a Custom IDP for Subaccount Configuration</a>.</p> <div><p><b>⚠ Restriction</b></p><p>Currently in Feature Set B, Cloud Connector can be connected to an SAP BTP subaccount only with users from the default identity provider.</p></div> <div><p><b>ℹ Note</b></p><p>In addition to the the initial connection from Cloud Connector to SAP BTP, the regular rotation of the client certificate that is used for the ongoing connection, is also affected.</p></div>
SAP BTP Command Line Interface (btp CLI)	<p>Once trust has been configured on the global account level in the cockpit, platform users can log on using the custom identity provider and use the full range of the btp CLI.</p> <div><p><b>ℹ Note</b></p><p>The btp CLI is available only for Feature Set B.</p></div> <p>To log on to a global account, you need to provide the hostname of the tenant (for example, <i>ar9ibaxhm</i>) with the <code>--idp</code> parameter. See <a href="#">Log in with a Custom Identity Provider [page 2154]</a>.</p> <p>To work with users and role collections on global account, directory, or subaccount level, you need to provide the origin key with the <code>--of-idp</code> parameter in the following commands: <code>btp list security/user</code>, <code>btp get security/user</code>, <code>btp delete security/user</code>, <code>btp assign security/role-collection</code>, <code>btp unassign security/role-collection</code>.</p> <p>Both values can be found in the cockpit under <a href="#">Security</a> → <a href="#">Trust Configuration</a> → <a href="#">Custom Platform Identity Providers</a>.</p>

Supported	Description
Cloud Foundry command-line interface (CF CLI)	<p>Make sure you use the Cloud Foundry command-line interface (CF CLI v7). For more information, see <a href="https://docs.cloudfoundry.org/cf-cli/v7.html">https://docs.cloudfoundry.org/cf-cli/v7.html</a> .</p> <div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>⚠ Restriction</b></p> <p>With v6 of the CF CLI, you can't use the <code>--origin</code> option in <code>cf set-org-role</code> and <code>cf set-space-role</code>. Use the <code>Members</code> tab in the SAP BTP cockpit. Go to the SAP BTP cockpit under <code>&lt;my_global_account&gt;</code> <code>&gt;</code> <code>&lt;my_subaccount&gt;</code> <code>&gt;</code> <code>Security</code> <code>&gt;</code> <code>Members</code> <code>&gt;</code> to set the user's permissions.</p> </div> <p>For more information, see <a href="#">Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface [page 2065]</a>.</p> <p>See also <a href="#">Using the Cloud Foundry CLI with SAP HANA Cloud</a></p>
SAP Application Logging service and Kibana	<p>Users logged on using custom identity providers can analyze logs written using the SAP Application Logging service.</p> <p>For more information, see the <a href="#">SAP Application Logging service</a> documentation.</p>
SAP BTP cockpit	<p>Platform users logged on using custom identity providers can use the full range of the SAP BTP cockpit.</p>
SAP Cloud Transport Management	<p>Platform users logged on to SAP Cloud Transport Management service using custom identity providers can use all functions of the service as described in the SAP Cloud Transport Management documentation.</p> <p>For more information, see <a href="#">SAP Cloud Transport Management</a>.</p>
SAP HANA Cloud Cockpit	<p>Platform users logged on using custom identity providers can use the full range of SAP HANA Cloud Cockpit.</p> <p>For more information, see <a href="#">SAP HANA Cockpit</a>.</p>
SAP Job Scheduling service	<p>Platform users logged on using custom identity providers can use the SAP Job Scheduling service dashboard.</p>
SAP Mobile Services	<p>SAP Mobile Services uses platform users to log on to the admin cockpit and manage apps and configurations.</p> <p>Based on their space member roles, platform users can log on using a custom identity provider and access the SAP Mobile Services admin cockpit.</p> <p>For more information, see <a href="#">Set Up Customer Accounts</a> in the SAP Mobile Services documentation.</p>

Supported with Restrictions When Using Platform Identity Providers

Supported with Restrictions	Description
SAP Business Application Studio	<p>SAP Business Application Studio supports custom identity providers with the following restrictions.</p> <ul style="list-style-type: none"><li>• When you log on with the SAP Business Application Studio web-based user interface, you authenticate with the identity provider for business users.</li><li>• When you log on to the Cloud Foundry environment from the terminal mode of SAP Business Application Studio with the Cloud Foundry environment command-line interface (CF CLI), you can authenticate with the identity provider for platform users.</li></ul> <p>For more information, see <a href="#">Terminal</a> in the SAP Business Application Studio documentation.</p>
SAP HANA Service Dashboard	<p>This tool doesn't support log on with a platform user from a custom identity provider. You can only log on with a user from the default identity provider.</p> <ul style="list-style-type: none"><li>• <a href="#">Open the SAP HANA Service Dashboard</a> in AWS and Google Cloud regions</li><li>• <a href="#">Open the SAP HANA Service Dashboard</a> in the China (Shanghai) region</li></ul>
SAP Rapid Application Development by Mendix	<p>You can't perform operations on multi-environment subaccounts, like deployments with SAP Rapid Application Development by Mendix when using a custom identity provider for platform users.</p> <p>For more information, see <a href="#">SAP Rapid Application Development by Mendix</a> .</p>
Service dashboards of services that aren't listed as supported.	<p>If you use services with dashboards, you can't access these dashboards with a platform user from a custom identity provider. Using service dashboards is only possible with the default identity provider (SAP ID service).</p>
SAP Web IDE	<p>SAP Web IDE running in a multi-environment subaccount of SAP BTP only supports users from SAP ID service.</p> <p>For more information, see <a href="#">User Authentication and Authorization</a>.</p> <div style="background-color: #f0f0f0; padding: 10px;"><p>→ Recommendation</p><p>Use SAP Business Application Studio.</p></div>

## Related Information

[Administration and Operations in the Cloud Foundry Environment \[page 2237\]](#)

## 6.1.1.8.1.2.4 Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface

Learn how to use different methods to log on to Cloud Foundry using a custom identity provider (IdP).

### Prerequisites

- You've created at least one subaccount and enabled the Cloud Foundry environment in this subaccount. For more information, see [Create a Subaccount \[page 1977\]](#).
- You've downloaded and installed the Cloud Foundry command-line interface (cf CLI). For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- Your administrator has configured your Cloud Foundry environment to use a custom identity provider. For more information, see [Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#) and [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#).
- You've configured the login screen to display your custom identity provider, see [Log on with a Browser to the Cloud Foundry CLI and Service Dashboards \[page 2070\]](#) (relevant for the manual login process).

### Context

The cf CLI provides different options to log on using a custom IdP. One scenario is recommended for an interactive logon because you must switch from the CLI to the browser to log on. This scenario supports multifactor authentication and other passwordless authentication methods, as well as single sign-on. The other scenario focuses on automation scenarios where switching between the CLI and a browser isn't possible.

### Procedure

Decide which scenario applies to you according to this table.

Scenario	See
You can open a browser during the logon process.	<a href="#">Log On Manually With a Custom Identity Provider [page 2066]</a> .
The logon process is automated, for example with a script or there's no possibility to open a browser during logon.	<a href="#">Log On as a Technical User With a Custom Identity Provider [page 2068]</a>

**⚠ Restriction**

This scenario is only supported if the users exist directly in your tenant of the SAP Cloud Identity Services - Identity Authentication and not in a corporate identity provider.

## Related Information

[Log on with a Browser to the Cloud Foundry CLI and Service Dashboards \[page 2070\]](#)

### 6.1.1.8.1.2.4.1 Log On Manually With a Custom Identity Provider

To log on to Cloud Foundry, using a custom identity provider identity provider, use the single sign-on option of the CF CLI.

## Prerequisites

- You've configured the login screen to display your custom identity provider.  
For more information, see [Log on with a Browser to the Cloud Foundry CLI and Service Dashboards \[page 2070\]](#).
- You know the origin key of the identity provider.  
For more information, see [Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#) and [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#).

## Context

During logon, the system provides you with a URL to your custom identity provider for you to enter in a web browser. If you're already logged on to your custom identity provider, the system provides a temporary authentication code to complete your logon. If you don't have an active session with your custom IdP, you need to log on to receive the temporary authentication code.

## Procedure

1. Open a command line.
2. Set the target API endpoint to endpoint of your subaccount.

```
cf api https://api.cf.<region>.hana.ondemand.com
```

### Sample Code

```
cf api https://api.cf.eu10.hana.ondemand.com
```

3. Log on to the Cloud Foundry environment with single sign-on:

```
cf login --sso
```

The command-line interface displays a login URL and prompts you to enter a temporary authentication code.

4. Open the URL that is provided on the screen to go to the logon screen.

If this is the first time you're logging on or your browser cache has been cleaned of cookies, you're prompted to provide the origin key of your custom identity provider or choose the default identity provider.

Otherwise the sign in page lists your accounts on custom identity providers with which you previously logged on.

5. Choose the account of your identity provider.

If you don't have an active session yet, you're prompted to log on to your IdP.

After you've successfully logged on, you receive a temporary authentication code.

6. Enter the passcode.

You've logged on successfully. You can now choose your org.

## Related Information

[Log on with a Browser to the Cloud Foundry CLI and Service Dashboards \[page 2070\]](#)

## 6.1.1.8.1.2.4.2 Log On as a Technical User With a Custom Identity Provider

To log on to Cloud Foundry, using a custom identity provider, use the `--origin` option of the Cloud Foundry command-line interface (cf CLI).

### Prerequisites

The users exist:

- Directly in your tenant of the SAP Cloud Identity Services - Identity Authentication.
- In a corporate identity provider with Identity Authentication working as a proxy.
  - Trust to your Identity Authentication tenant must be configured with OIDC and not SAML.
  - Your corporate identity provider must support the password grant flow.

For more information, see [Configure Trust with OpenID Connect Corporate Identity Provider](#) in the documentation for Identity Authentication.

### Context

We recommend this method of logging on if you want to use an automated script and can't open a browser during the logon process.

### Procedure

Set up a script with the following code:

```
cf api https://api.cf.<region>.hana.ondemand.com
cf login --origin <origin> -u <user> -p <password>
```

#### Sample Code

```
cf api https://api.cf.eu10.hana.ondemand.com
cf login --origin sap.ids -u julie.armstrong@sap.com -p mysecurepassword
```

- Find the `<region>` value, that applies to you in the section [Regions \[page 17\]](#).
- Find the `<origin>` value for the user that you want to use in the cockpit.
  1. Navigate to the subaccount of your user.
  2. Choose **Cloud Foundry** **Org Members**.
  3. Find the `<origin>` value of your user in the table.

## 6.1.1.8.1.2.5 Log On with a Custom Identity Provider to the SAP BTP Cockpit

All users can log on to the SAP BTP cockpit with a custom identity provider.

### Prerequisites

- Your user has administration or viewer rights in this subaccount or global account. For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).
- You have established trust with a custom identity provider for platform users. For more information, see [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#).

### Context

Use the [Open](#) link in the *SAP BTP Cockpit* column. It contains a URL for the user to log on with the custom identity provider.

#### ❁ Example

<https://emea.cockpit.btp.cloud.sap/cockpit/?idp=cidppuxhm.accounts.ondemand.com>

### Procedure

1. Go to your global account or subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose ► *Security* ► *Trust Configuration* ► in the SAP BTP cockpit.
2. Use the [Open](#) link in the SAP BTP *Cockpit* column.
  - To enable other platform users to log on with a custom identity provider, send the link to these users.
  - To work with your user accounts from multiple identity providers at the same time, open the link in a private or incognito browser window or tab.

#### 📄 Note

A browser that isn't in private or incognito mode has one single session with the cockpit. If you have an existing cockpit session with one identity provider and log on with another one, the existing session closes and creates a new session. For this reason, you can't have parallel sessions with different identity providers.

3. Log on using the custom identity provider.

## 6.1.1.8.1.2.6 Log on with a Browser to the Cloud Foundry CLI and Service Dashboards

Platform users of the Cloud Foundry environment have the option to log on with a custom identity provider or the default identity provider.

### Prerequisites

- You know the origin key of the identity provider.  
For more information, see [Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#) and [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#).
- You don't already have a session with the Cloud Foundry environment.  
If you're already authenticated, you skip the logon process and go straight to your application.

### Context

When accessing a web application, like a service dashboard (for example `logs.cf.eu10.hana.ondemand.com`) or you log into your Cloud Foundry account using the CLI with `cf login -sso`, you're prompted by a login screen. This method enables you to log on to a custom identity provider or makes it easier to log on when multifactor authentication is required.

### Procedure

1. Navigate to the URL for your service dashboard or provided by the CF CLI.

The login screen appears.

If this is the first time you're logging on or your browser cache has been cleaned of cookies, you're prompted to provide the origin key of your custom identity provider or choose the default identity provider.

# SAP Business Technology Platform

Choose your identity provider

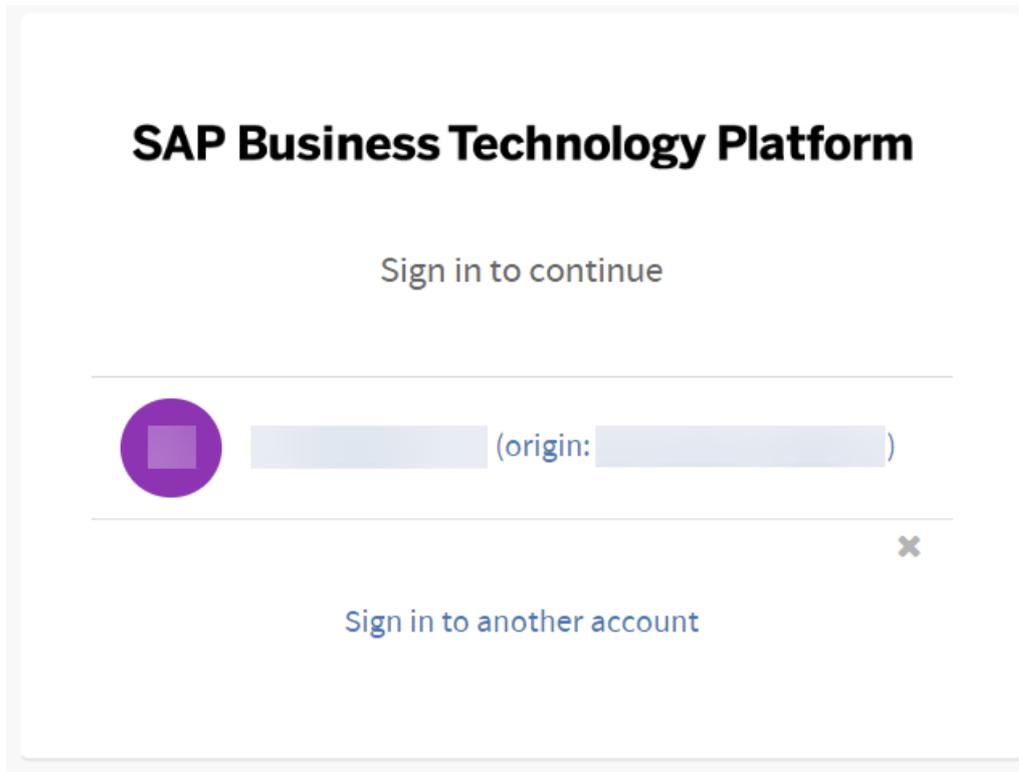

**Sign in with default identity provider**

Enter the origin key of your identity provider

**Sign in with alternative identity provider**

Logon Page Without Cookies

Otherwise the sign in page lists your accounts on custom identity providers with which you previously logged on.

Logon Page With Previous Logon

2. Choose your identity provider and log on.

## Related Information

[Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#)

### 6.1.1.8.1.3 Default Identity Provider

SAP ID service is the default identity provider for both platform users and business users (in applications) at SAP BTP. You can start using it without further configuration.

#### Note

For China (Shanghai) region, a different default identity provider is used.

For more information, see this [blog article](#) on *SAP Community*.

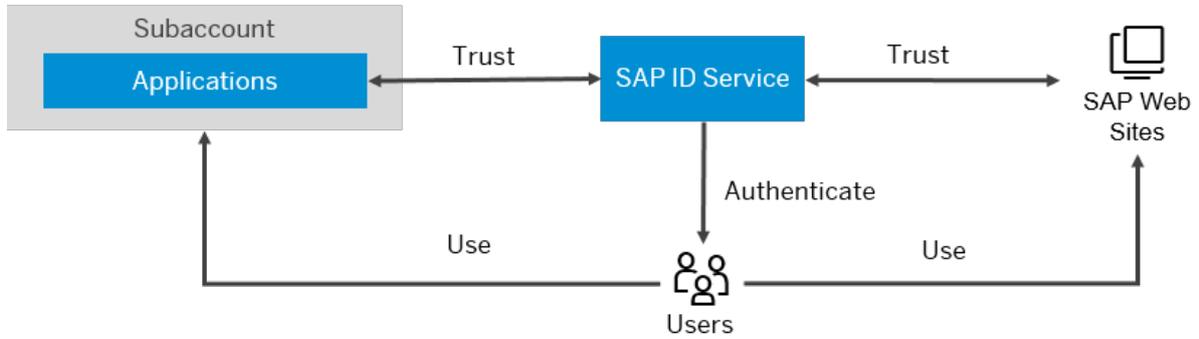

For Government Cloud (US) region, a different default identity provider is used.

SAP ID service provides:

- A central user store

- A Single Sign-On (SSO) service. It enables users to log on once and get access to all your applications.

Use SAP ID service as a preconfigured user store in your starter scenarios or for testing. You can also use the default identity provider as a backup identity provider if access to your custom identity provider fails. SAP ID service is the place where you register to get initial access to SAP BTP.

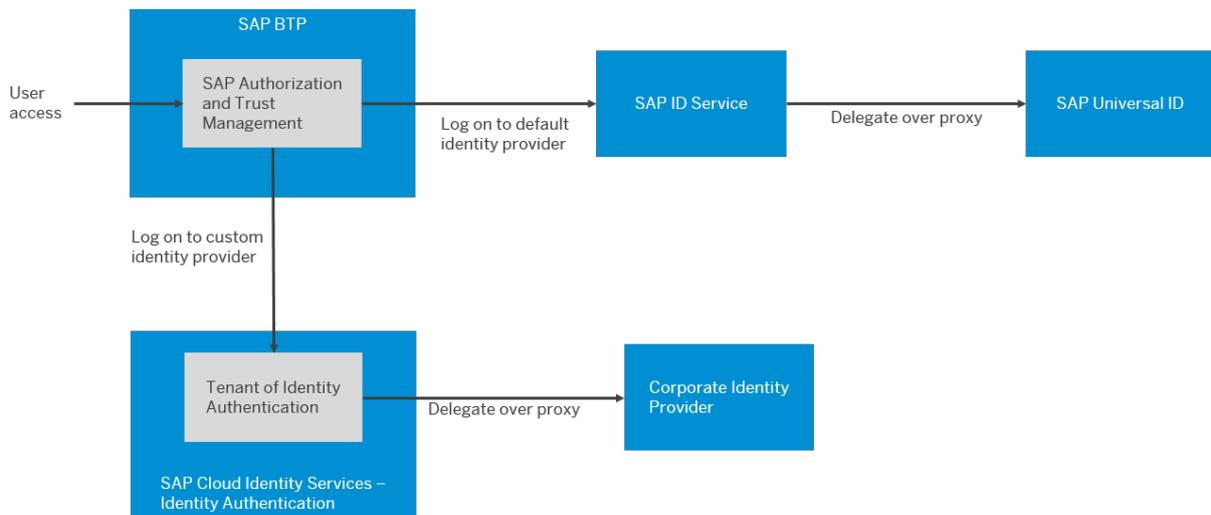

SAP ID Service Authenticates Users

If you're a new user, you can use the self-service registration option at the [SAP Web site](#). The SAP website registers you with SAP Universal ID, which also registers you with SAP ID service.

## SAP Universal ID

SAP Universal ID manages the users of official SAP sites, including the SAP developer and partner community. If you already have such a user, then you're already registered with SAP ID service as well. SAP ID service acts as a proxy for SAP Universal ID, when users log on with their e-mail addresses. Users can log on with and manage all their user accounts with SAP Universal ID.

The following figure illustrates how default and custom identity providers can federate other identity providers.

Identity Providers and Federation

## Managing Users

To add users to a subaccount, the users must exist in an identity provider.

For more information about adding users to our default identity providers, see [Create SAP User Accounts \[page 2075\]](#).

To add new users to a subscribed app or service, such as Web IDE, add those users to your subaccount.

For more information, see [Add Users from SAP ID Service for Multi-Environment Subaccounts \[page 2076\]](#).

## Multifactor Authentication

For SAP ID service, you can ask users hosted by this identity provider to enable multifactor authentication as a self-service. There's **no** mechanism to enforce users in SAP ID service to use this function.

### → Recommendation

To enforce multifactor authentication, we recommend that you trust SAP Cloud Identity Services - Identity Authentication and configure enforcement. Optionally, integrate Identity Authentication with your corporate identity provider and enforce the policy there.

For more information, see:

- [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#)
- [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#)

For more information about your users of SAP ID service can enable multifactor authentication themselves, see [How to Enable Multi-Factor Authentication \(MFA\)](#)  on the *SAP Support Portal*.

### ⓘ Note

Some user interfaces don't offer an interactive way to support multifactor authentication, such as time-based one time passwords (TOTP). Instead, such tools offer fixed logon ID and password fields. For such tools, enter your password directly followed, without any spaces or dividers, by the TOTP offered by your multifactor device.

User ID: **MylogoniD**

Password: **MystrongpasswordMytotppasscode**

For some tools, this behavior affects log on to the tool itself:

- Cloud Foundry command-line interface (cf CLI)  
Alternatively, you can log on through a browser instead.  
For more information, see [Log On Manually With a Custom Identity Provider \[page 2066\]](#).
- SAP Business Technology Platform command-line interface (btp CLI)  
Alternatively, you can log on through a browser instead.  
For more information, see [Log in with Single Sign-On \[page 2153\]](#).

For other tools, this behavior doesn't affect log on to the tool itself, but log on to the platform when establishing connections or deploying software and such. For example:

- Cloud Connector
- SAP Business Application Studio
- SAP Web IDE

## Trust and Identity Providers

Trust between your subaccount and SAP ID service is preconfigured by default, so you can start using it without further configuration.

In cloud management tools feature set A, you can set the default trust to inactive, for example if you prefer to use another identity provider.

In cloud management tools feature set B, you can hide the default trust.

For more information, see [Hide Logon Link for Default Identity Provider \[page 2046\]](#).

To use a custom identity provider, establish trust to your custom identity provider. We describe a custom trust configuration using the example of Identity Authentication.

For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

## Related Information

[Security \[page 2776\]](#)

[Platform Identity Provider](#)

[Working with Users \[page 2078\]](#)

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

### 6.1.1.8.1.3.1 Create SAP User Accounts

To grant authorizations to people from the default identity provider in your subaccount, ensure that they have a user account.

## Context

If the person in question already has a user account on `sap.com` Web sites, then that person already has a user in the default identity provider. Add this user to your accounts, if you know this person's e-mail address.

Consider using a custom identity provider to integrate your own identity and access management solution.

### Note

For technical users, create the user in your custom identity provider. In your custom identity provider, you control the access policies of these users independently from the policies we set for the default identity provider. Our default identity provider is meant for **human** users, who interact with SAP and our solutions.

## Procedure

Send your colleagues the self-registration URL.

```
https://account.sap.com/core/create/register?
redirectURL=https%3A%2F%2Fmea.cockpit.btp.cloud.sap%2Fcockpit%2F
```

The Web site registers you with SAP Universal ID, which also registers you with the SAP ID service. If you already have a user in the SAP ID service, associate this user with your new SAP Universal ID account. SAP Universal ID manages the users of official SAP sites, including the SAP developer and partner community.

### → Tip

After your colleagues sign up, add them to a subaccount. Assign role collections to them. Then your colleagues can log on to the SAP BTP cockpit.

## Related Information

[Add Users from SAP ID Service for Multi-Environment Subaccounts \[page 2076\]](#)

[Default Identity Provider \[page 2072\]](#)

[Trust and Federation with Identity Providers \[page 2014\]](#)

## 6.1.1.8.1.3.2 Add Users from SAP ID Service for Multi-Environment Subaccounts

Before you can assign role collection to a user from SAP ID service, ensure that this user exists in your subaccount.

## Prerequisites

The user you want to add to your subaccount must have an SAP user account (for example, an S-user or P-user).

For more information, see [Create SAP User Accounts \[page 2075\]](#).

## Context

When you create your own trial account, your SAP user is automatically created and assigned to SAP ID service. When you onboard new members to your subscribed app, add them to your subaccount. Then you can assign a role collection to the user.

## Procedure

Create users and assign role collections to users in [Security > Users](#).

It's possible to create users in custom identity providers and in the SAP ID service.

For more information, see [Working with Users \[page 2078\]](#).

## Related Information

[Platform Identity Provider](#)

[Mapping Role Collections in the Subaccount \[page 2094\]](#)

### 6.1.1.8.1.4 Switch Off Automatic Creation of Shadow Users

To switch off the creation of shadow users in the trust configuration of custom identity providers, administrators must explicitly allow users to log on. Administrators then have full control over who is allowed to log on.

## Context

Whenever a user authenticates at an application in your subaccount using any identity provider, the User Account and Authentication service always stores user-related data provided by the identity provider in the form of shadow users. The UAA uses details of the shadow users to issue tokens that refer to a certain user.

By default, the UAA allows any user of any connected identity provider to authenticate to applications in the subaccount. When there's no corresponding shadow user, it automatically creates one based on the information received from the identity provider.

#### Note

With new subaccounts created after 24 September 2020, automatic creation of shadow users is switched off by default for the default identity provider, SAP ID service.

Usually, you want your administrators to be fully aware of which users they allow to log on. If you've switched off automatic creation of shadow users for a certain identity provider, you enforce that only those users can

log on where shadow users have been created explicitly. You can create them in the SAP BTP cockpit, typically when you assign the first role collection to them. For more information, see [Create Users \[page 2083\]](#).

To switch off creation of shadow users during logon, proceed as follows:

## Procedure

1. In the SAP BTP cockpit, go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **▮ Security ▸ Trust Configuration ▾**.
2. Choose your custom trust configuration.
3. Choose *Edit*.
4. Go to *Create Shadow Users on User Logon* and remove the checkmark.
5. Save your changes.

From now on, the User Account and Authentication service doesn't automatically create shadow users for a certain identity provider during logon.

[Deletion \[page 2843\]](#)

[Delete Users \[page 2086\]](#)

[Delete Shadow Users for Data Protection and Privacy Using APIs \[page 2847\]](#)

### 6.1.1.8.2 Working with Users

In the SAP BTP cockpit, you can see the users of your global account or subaccount, user-related identity provider information, and their authorizations. In a user's overview, you can create and delete users, and assign role collections. You can also display an overview of the role collections, where you can drill down all the way to the role, and see the application that the role is belongs to.

## Overview

All users in the global account, subaccount, directories, and environments are stored in identity providers. Users in the subaccounts of SAP BTP are either stored in the default identity provider or in a custom identity provider.

SAP BTP creates a copy of the user in the global account or in the subaccount when a user-related action happens. This copy of the user is called a shadow user. Global account or subaccount administrators of SAP BTP assign role collections to shadow users. To comply with data protection and privacy regulations, administrators can be obliged to delete shadow users who belonged to employees who left the company.

## Note

For access tokens of subaccounts created after September 23, 2020, user IDs preserve the case that they are created in. This means that both uppercase and lowercase letters can be used. However, this does not qualify as a means to differentiate between them; for example, denise.smith@example.com and Denise.Smith@example.com are considered to be the same.

Subaccounts before this date convert the user IDs to lowercase.

## Prerequisites

- You have administration rights in this global account, subaccount, or directory. For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).
- The users are stored in identity providers that are connected to SAP BTP.
  - Default identity provider. For more information, see [Default Identity Provider \[page 2072\]](#).
  - Custom identity provider. For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

Use Case	Description
Enable a new hire to log on to the subaccount and have access to necessary resources.	<p>If automatic creation of shadow users was switched off for this identity provider, shadow users aren't created automatically in the subaccount (see the related link). This means that the new user can't log on to the subaccount. As an administrator, create a shadow user that corresponds to the user in the identity provider and assign the necessary role collections to this user.</p> <p>See <a href="#">Create Users [page 2083]</a>.</p>
	<p>If automatic creation of shadow users was switched off for this identity provider, shadow users aren't created automatically in the subaccount (see the related link). Add the user group to the role collections that are necessary for this user if the user belongs to a user group in the identity provider.</p> <p>See <a href="#">Assign User Groups to Role Collections [page 2093]</a>.</p>
Enable a new hire to have access to necessary resources.	<p>A shadow user is automatically created in the subaccount. This means that the new user can log on to the subaccount, but the user doesn't have any authorizations. As an administrator, you have created new role collections or you want to use existing ones for the new hire. You grant authorizations by assigning the role collections to this user.</p> <p>See <a href="#">Assign Users to Role Collections [page 2092]</a>.</p>

Use Case	Description
Enable a new hire to log on.	<p>If automatic creation of shadow users was switched off for this identity provider, shadow users aren't created automatically in the subaccount (see the related link). As an administrator, create a new shadow user in the subaccount.</p> <p>See <a href="#">Create Users [page 2083]</a>.</p>
Review authorizations of individual users.	<p>If your subaccount uses the default trust configuration, you can also create a shadow user there.</p> <p>See <a href="#">Add Users from SAP ID Service for Multi-Environment Subaccounts [page 2076]</a>.</p> <p>You want to find out which authorizations have been granted to users. To do so, access the list of all users, find the users you want to review, and check the role collection assignments. From the user's role collection, you can drill down to the roles of the role collection. You can also assign and remove role collections.</p> <p>See <a href="#">Find Users and Their Role Collection Assignments [page 2081]</a>.</p>
Delete users of employees who have left the company.	<p>You want to find and delete users of employees who have left the company, but their users still exist in the system.</p> <p>How to find users, see <a href="#">Find Inactive Users [page 2082]</a>.</p> <p>How to delete users, see <a href="#">Delete Users [page 2086]</a>.</p>
Automate the provisioning of users.	<p>You want to provision users to SAP cloud solutions, such as SAP BTP so that you can manage your identities centrally.</p> <p>How to provision users to SAP BTP, see <a href="#">Provision Users to SAP BTP [page 2085]</a>.</p>
Find users who have never logged on.	<p>You want to find users who never logged on. For example, they could be manually created shadow users with a typo in their user ID, so they don't match the user ID provided by the identity provider. They were never used, and it might make sense to delete them.</p> <p>See <a href="#">Delete Users [page 2086]</a>.</p>
Delete shadows user to comply with data protection and privacy regulations.	<p>For data protection and privacy reasons, administrators might be legally obliged to delete shadow users who belonged to employees who left the company. You can find and delete the shadow users in the SAP BTP cockpit.</p> <p>See <a href="#">Delete Users [page 2086]</a>.</p>

Use Case	Description
	<p>You can also delete the users using APIs.</p> <p>See <a href="#">Delete Shadow Users for Data Protection and Privacy Using APIs [page 2847]</a>.</p>

## Related Information

[Switch Off Automatic Creation of Shadow Users \[page 2077\]](#)

[Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#)

### 6.1.1.8.2.1 Find Users and Their Role Collection Assignments

You want to find the authorizations granted to specific users in your global account and subaccount. You can search or sort the list of users, and view their role collection assignments.

## Context

You want to find out which authorizations have been granted to single or multiple users. To do so, access the list of all users, find the users you want to review, and check the role collection assignment. From the user's role collection, you can drill down to the roles of the role collection.

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and/or subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose ► [Security](#) ► [Users](#) ▾.

You see all the users of your subaccount.

### → Tip

If you want to see users that were updated before a certain point of time, use the *Last Updated* field. You can filter the list according to the point of time of the last update.

4. To search for users, choose  (Search).
5. Enter a string occurring in the user name, last name, first name, or e-mail address. The SAP BTP cockpit returns a list of all the users containing this string.

6. Select a user and open the overview section.

You can see all of the role collection assignments of this user. You can also drill down into the roles.

## 6.1.1.8.2.2 Find Inactive Users

As an administrator, you want to have an overview of the users in your subaccount, no matter which identity provider stores them. You want to clean them up if necessary.

### Context

- You want to find users that haven't been used for some time. The reason could be that employees left the company, but the users still exist in the system.
- You want to find users who never logged on. For example, they could be manually created shadow users with a typo in their e-mail address, so they didn't match the user ID provided by the identity provider. They were never used, and it might make sense to delete them.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and/or subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose ► [Security](#) ► [Users](#) ►.

You see all the users in your subaccount.

4. If you want to see users that were updated at a certain point in time, use the [Last Updated](#) field. You can filter the list according to the following filter criteria:
  - All
  - Today
  - This week
  - This month
  - This year

If you want to see the users who haven't logged on at a certain point in time, use the [Hasn't Logged On](#) field. You can filter the list according to the following filter criteria:

- All
- Last 7 Days
- Last 30 Days
- Last 180 Days
- Last 365 Days
- Choose a Date

The SAP BTP cockpit displays the filtered list of users. The *Last Updated* column shows you the point in time when the user was updated last. The *Last Logon* column shows you the point of time of the user's last logon.

5. (Optional) To see whether a user has never logged on, choose the user to display the user's overview section.

The SAP BTP cockpit displays the user's overview section. If the user has never logged on, the *Last Logon* field shows the message *User has never logged on*.

6. (Optional) To delete the user, close the overview section and choose  (Delete).

→ Remember

You can't undo the deletion of a user.

## 6.1.1.8.2.3 Create Users

As an administrator, you can create shadow users in your subaccount. When you create a shadow user, you must know and specify which identity provider stores the user.

### Prerequisites

You've administration rights in this subaccount. For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

### Context

All users in the subaccounts of SAP BTP are stored in identity providers, either in the default or in a custom identity provider. SAP BTP creates a copy of the user in the subaccount when a user-related action happens. The copy of the user in the subaccount is called shadow user. It's also possible to switch off the creation of shadow users (see the related link).

A new hire starts to work in your company next month. As an administrator, you want to provide a user, enable logon to the SAP BTP subaccount, and provide the necessary authorizations for this new hire. You create the actual user in the identity provider. However, you can't assign subaccount authorizations to an individual user in an identity provider. You need a shadow user in the SAP BTP subaccount to assign authorizations. After having created a shadow user, you can assign role collections. Thus, you make sure that the new hire can log on to the subaccount and that the necessary authorizations are in place when the new hire starts.

If you switched off the creation of shadow users in the trust configuration of your custom identity providers, new users created in the identity provider don't have a user copy (shadow user) in the respective SAP BTP subaccount. You, as a subaccount administrator, have full control of who can log on to this subaccount. The new user can log on to the subaccount if you've created a shadow user with the same e-mail address in the SAP BTP subaccount. Now, you can grant authorizations by assigning role collections.

You can alternatively grant authorizations in the subaccount by mapping role collections to the user group if the user belongs to a user group in the identity provider.

As an administrator, you can create shadow users in your subaccount and you must determine which identity provider stores the user. You can then give the user authorizations by assigning role collections to the user.

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and/or subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose ► **Security** ► **Users** ►.
4. Choose **Create**.

The SAP BTP cockpit displays a new row where you can enter the user data.

5. Enter the user ID and e-mail address.

### Note

To specify the last name and first name of the user, maintain the names in the identity provider that stores the user. This information is automatically added to the shadow users when the user logs on with their identity provider using a URL such as:

```
https://<myapplication>.cfapps.<region>.hana.ondemand.com/
```

For example: `https://my-application.cfapps.eu10.hana.ondemand.com/`

Logging on with the SAP BTP cockpit or the command-line interface isn't enough.

6. Choose the identity provider where the user is stored. The dropdown list displays the identity providers configured in the trust configuration of your subaccount.
7. Save your changes.

You can now proceed to assign role collections to the new user.

## Related Information

[Switch Off Automatic Creation of Shadow Users \[page 2077\]](#)

## 6.1.1.8.2.4 Provision Users to SAP BTP

As people join, change roles, and eventually leave your organization, you care for the onboarding, maintenance, and offboarding of their users in your systems. If you're a small organization, you can use manual processes; otherwise, you may need to automate.

### Prerequisites

You have the required authorizations.

For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

### Context

We recommend creating users within the SAP Cloud Identity Services. The persistency layer of SAP Cloud Identity Services is the Identity Directory. Use SAP Cloud Identity Services - Identity Provisioning to provision users to SAP cloud solutions, such as SAP BTP. Identity Provisioning has connectors to distribute user artifacts needed at different levels of your SAP BTP accounts. By managing your identities centrally, you also ensure that when you offboard users, they're removed from target systems.

#### Note

Currently, you can't provision platform users (org/space members) to the Cloud Foundry environment.

### Procedure

1. Get API credentials. See [Accessing Administration Using APIs of the SAP Authorization and Trust Management Service \[page 2229\]](#) for more information.
2. Integrate with your identity and access management solution.
  - To integrate with SAP Cloud Identity Services, see [SAP BTP Integration Scenario](#) for more information.
  - To integrate with another solution, use the User Management SCIM API. See [User Management \(System for Cross-domain Identity Management \(SCIM\)\)](#)  for more information.

### Next Steps

[Configure your IAM solution to provision users to SAP BTP. \[page 2078\]](#)

## 6.1.1.8.2.5 Delete Users

As an administrator, you can delete users from your subaccount. When you delete a user, you also delete the user's role collection assignments.

### Prerequisites

You have the required authorizations.

For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).

### Context

All users in the subaccounts of SAP BTP are shadow users. As an administrator, you might want to clean up users from your subaccount. Or for data protection and privacy reasons, it might be a legal obligation that administrators delete shadow users who belonged to employees who left the company. For more information, see [Working with Users \[page 2078\]](#).

It's also possible to delete users using APIs. For more information, see the related links.

Keep in mind that you also delete the user's role collection assignments.

#### → Remember

When you delete a user at the Cloud Foundry level, SAP BTP doesn't delete the corresponding shadow user at the subaccount level.

When you delete a user at the subaccount level, ensure that you delete the user at the Cloud Foundry level too. Otherwise, if the Cloud Foundry user logs on again, the system automatically creates the corresponding user at the subaccount level.

So ensure that you delete the shadow users on all levels.

#### ⚠ Caution

You cannot undo the deletion of a user.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account, directory, or subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security > Users >**

### Note

For directories, choose *Users*. There is no *Security* menu item.

4. Choose from the following options:

Options	Procedure
Delete a single user	<ol style="list-style-type: none"><li>1. Select the row of a user.</li><li>2. Choose  <i>Delete</i>.</li></ol>
Delete multiple users	<ol style="list-style-type: none"><li>1. Choose  <i>Select multiple users</i> and select users (see the related link).</li><li>2. Choose <i>Delete</i>.</li></ol>

## Related Information

[Working with Users \[page 2078\]](#)

[Deletion \[page 2843\]](#)

[Delete Shadow Users for Data Protection and Privacy Using APIs \[page 2847\]](#)

### 6.1.1.8.3 Working with Role Collections

As an administrator, you group application roles in role collections. You then assign role collections to application users.

Application developers have defined application-specific role templates in the security descriptor file. The role templates contain the role definitions. You can assign the role to a role collection.

#### → Tip

Application developers can even directly define role collections with default roles. For more information, see [Create Role Collections with Predefined Roles \[page 503\]](#).

Typically, these role collections provide authorizations for certain types of users, for example, sales representatives.

Once you have created a role collection, you can pick the roles that apply to the typical job of a sales representative. Since the roles are application-based, you must reference the application to see which roles come with the role template of this application. You are free to add roles from multiple applications to your role collection.

Finally, you assign the role collection directly to users or indirectly to attributes such as groups. For more information, see the related link.

## Prerequisites

- Your user has administration rights in this subaccount and or global account. For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).
- The roles defined by your application developers in the application security descriptor are available in the SAP BTP cockpit. For more information, see [Adding Authentication and Authorization \[page 465\]](#).
- The users are stored in identity providers that are connected to SAP BTP.
  - Default identity provider (SAP ID service). For more information, see [Default Identity Provider \[page 2072\]](#).
  - Custom identity provider. For more information, see [User Management](#) in SAP Cloud Identity Services - Identity Authentication.

### Note

SAP BTP provides default role collections. You can use the default role collections, but you can't change or delete them. For this reason, the *Delete* icon of a default role collection is grayed out.

You can perform the following tasks:

- [Define a Role Collection \[page 2089\]](#)
  - [Add Roles to a Role Collection \[page 2089\]](#)
  - [Delete Roles from a Role Collection \[page 2090\]](#)
- [Assigning Role Collections to Users or User Groups \[page 2091\]](#)
  - [Assign Users to Role Collections \[page 2092\]](#)
  - [Delete Users from Role Collections \[page 2092\]](#)
  - [Assign User Groups to Role Collections \[page 2093\]](#)
  - [Delete User Groups from Role Collections \[page 2094\]](#)

## Related Information

[Security Administration: Managing Authentication and Authorization \[page 2012\]](#)

[Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#)

[Limits for Technical Artifacts of the SAP Authorization and Trust Management Service \[page 2817\]](#)

## 6.1.1.8.3.1 Define a Role Collection

To define a role collection, you can create a new role collection or copy an existing one. Add the roles, users, and user groups as needed.

### Context

One way to define a role collection is to create a new role collection. After you've entered a name and description, you find the new role collection in the list of role collections. You can then add the roles you need and assign users and user groups.

If you have an existing role collection that you want to use as a template, it's a good idea to copy it. The copied role collection includes all of the roles of the origin. However, it doesn't include the users or user groups. You can give it a new name and description. You can find the copy in the list of role collections and assign users and user groups.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. To create a new role collection, choose **+** (Create New Role Collection). To copy an existing role collection, choose *Copy* at the end of the row.
5. Enter a new name and description. If you copied an existing role collection, you can see the included roles.
6. Save your changes.

You can now add or remove roles and assign users or user groups.

### 6.1.1.8.3.1.1 Add Roles to a Role Collection

You can add roles to a role collection.

### Context

The roles are derived from role templates that are provided by applications. For more information, see the related links.

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. To add roles, choose the role collection name.
5. Go to the *Roles* section and choose *Edit*.
6. To add a role to the role collection, choose the input field. The role selection screen opens.

If you accidentally deleted the input field for the new roles, choose **+** (Add a role) to display a new input field.

7. Use the dropdown list or the F4 function key under *Role Name* to display the roles that are available. The roles are sorted alphabetically. Choose the role you want to add. You can also select multiple roles from the list below.
8. Choose *Add*.
9. Save your changes.

## Related Information

[Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#)  
[Protecting Your Application \[page 467\]](#)

### 6.1.1.8.3.1.2 Delete Roles from a Role Collection

You can delete roles from a role collection.

## Context

The roles are derived from role templates that are provided by applications. For more information, see the related links.

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.

4. To delete roles, choose the role collection name.  
To drill down into the role details, choose the chevron on the right side of the row.
5. Choose [Edit](#).
6. To delete a role from the role collection, choose  (Delete) in the row of the role that you want to delete.  
The roles are sorted alphabetically.
7. Confirm the popup.
8. Save your changes.
9. Repeat to delete more roles.

## 6.1.1.8.3.2 Assigning Role Collections to Users or User Groups

You can assign role collections to users and user groups.

### Prerequisites

- You have administration rights in this subaccount or global account. For more information, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#) or [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).
- The roles defined by your application developers in the application security descriptor are available in the SAP BTP cockpit. For more information, see [Adding Authentication and Authorization \[page 465\]](#).
- The users are stored in identity providers that are connected to SAP BTP.
  - Default identity provider (SAP ID service). For more information, see [Default Identity Provider \[page 2072\]](#).
  - Custom identity provider. For more information, see [User Management](#) in SAP Cloud Identity Services - Identity Authentication.

You perform the following tasks to assign role collections to users and user groups stored by identity providers. The identity providers are connected to SAP BTP using trust configurations.

#### Note

Custom identity providers can provide user groups and users whereas default identity providers can only provide individual users.

- [Assign Users to Role Collections \[page 2092\]](#)
- [Delete Users from Role Collections \[page 2092\]](#)
- [Assign User Groups to Role Collections \[page 2093\]](#)
- [Delete User Groups from Role Collections \[page 2094\]](#)

## 6.1.1.8.3.2.1 Assign Users to Role Collections

You can assign users to a role collection by adding them to the role collection.

### Context

You can assign users from default identity providers, and from custom identity providers, to a role collection. After having entered the user's user ID, choose the origin key of the identity provider and the e-mail address.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. Choose the role collection to which you want to assign users.
5. Go to the *Users* section and choose *Edit*.
6. Enter the user ID of the user that you want to assign to the role collection. If the user only exists in a connected identity provider, you must choose the identity provider and type in the e-mail address.
7. (Optional) To add more users, choose **+** (Add a user).
8. Save your changes.

You've now assigned this user to the role collection. The user has all of the authorizations of the role collection.

## 6.1.1.8.3.2.2 Delete Users from Role Collections

You can unassign users from a role collection by deleting them from the role collection.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. Choose the role collection from which you want to unassign users.
5. Choose *Edit*.
6. Choose **🗑** (Delete) in the row of the user you want to unassign.

7. Save your changes.

You've now unassigned this user by deleting the user from the role collection.

### 6.1.1.8.3.2.3 Assign User Groups to Role Collections

You can assign users groups to a role collection by adding them to the role collection.

#### Prerequisites

- You're using a custom identity provider. For more information, see [Trust and Federation with Identity Providers \[page 2014\]](#).

#### Context

You can assign user groups from custom identity providers to a role collection. After having chosen the identity provider, enter the user group name.

#### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. Choose the role collection to which you want to assign user groups.
5. Go to the *User Groups* section and choose *Edit*.
6. Select the identity provider where the user group is stored.
7. Enter the name of the user group.

#### Note

If you're using SAP Cloud Identity Services - Identity Authentication, you can find the name of the user group in the administration console under **► Users & Authorizations ► User Groups ►**. For more information, see the related link.

8. (Optional) To add other user groups, choose **+** (Add a user group).
9. Save your changes.

## Related Information

[User groups in the SAP Cloud Identity Services - Identity Authentication](#)

### 6.1.1.8.3.2.4 Delete User Groups from Role Collections

You can unassign users groups from a role collection by deleting them from the role collection.

#### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **► Security ► Role Collections ►**.
4. Choose the role collection from which you want to unassign a user group.
5. Go to the **User Groups** section and choose **🗑️** (Delete).
6. Confirm the popup and save your changes.

### 6.1.1.8.3.3 Mapping Role Collections in the Subaccount

You've arranged roles in role collections, and now want to assign or map these role collections to business users.

How you assign users to their authorizations depends on the type of trust configuration and on whether or not you prefer to maintain the authorizations of individual users rather in the identity provider or in SAP BTP. The following options are available:

- Directly assign role collections to users.
- Map role collections to user groups or other user attributes defined in the identity provider. You initially maintain the mapping between user groups or other user attributes and role collections once in SAP BTP, and maintain group memberships or other attributes of users in the identity provider.

#### 📘 Note

If you're using the default trust configuration with the default identity provider, you directly assign users to role collections. For more information, see [Default Identity Provider \[page 2072\]](#).

However, if you're using a custom trust configuration, for example, with SAP Cloud Identity Services - Identity Authentication, you can use both options. For more information about configuring the trust between your subaccount and a custom identity provider, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).

Trust Configuration	Assignment Options
Default trust configuration (SAP ID service)	<a href="#">Assign Users to Role Collections [page 2092]</a>
Custom trust configuration (for example: a tenant of the Identity Authentication service)	<ul style="list-style-type: none"> <li>• <a href="#">Assigning Role Collections to Users or User Groups [page 2091]</a></li> <li>• <a href="#">Map Role Collections to User Groups [page 2095]</a></li> <li>• <a href="#">Map Role Collections to User Attributes [page 2096]</a></li> </ul>

## Related Information

[Working with Role Collections \[page 2087\]](#)

[Trust and Federation with Identity Providers \[page 2014\]](#)

### 6.1.1.8.3.3.1 Map Role Collections to User Groups

You want to assign a role collection to a user group provided by an identity provider that has a custom trust configuration in SAP BTP. In this case, the assignment is a mapping of a user group to a role collection. Your identity provider provides the user groups using the attribute called `groups`. Each value of the attribute is mapped to a role collection as described in this procedure.

## Prerequisites

- You've configured your custom identity provider and established trust with your subaccount.

### → Remember

The name of the trust configuration is different from SAP ID service. The name of a custom trust configuration to SAP Cloud Identity Services - Identity Authentication could be as follows:

```
https://<tenant_id>.accounts.ondemand.com
```

- You've configured the identity provider so that it conveys the user's group memberships in the `groups` attribute.
  - For business users, see [Map User Attributes from a Corporate Identity Provider for Business Users \[page 2018\]](#).
  - For platform users, see [Map User Attributes from a Corporate Identity Provider for Platform Users \[page 2059\]](#).
- You've created role collections.

## Context

The identity provider provides the users, who can belong to user groups. It's efficient to map user groups to role collections. The role collection as a reusable element contains the authorizations that are necessary for this user group. Mappings save time when you want to add a new user. Simply add the user to the respective user group or groups, and the user automatically gets all the authorizations that are included in the role collections.

## Procedure

To map a user group to a role collection, see [Assign User Groups to Role Collections \[page 2093\]](#).

You can also map role collections to attributes other than groups. For more information, see the related links.

## Related Information

[Trust and Federation with Identity Providers \[page 2014\]](#)

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

[Map Role Collections to User Attributes \[page 2096\]](#)

### 6.1.1.8.3.3.2 Map Role Collections to User Attributes

Map role collections to users dynamically through the use of user attributes. When user agents present the attributes of their users, the SAP Authorization and Trust Management service can assign role collections based on the values of those attributes.

## Prerequisites

- You've configured your custom identity provider and established trust with your subaccount.
- You've configured the identity provider so that it conveys the user attributes in the assertion attributes.
  - For business users, see [Map User Attributes from a Corporate Identity Provider for Business Users \[page 2018\]](#).
  - For platform users, see [Map User Attributes from a Corporate Identity Provider for Platform Users \[page 2059\]](#).
- You've created role collections.

## Context

The identity provider hosts the users and their attributes. When a user is authenticated by the SAP Authorization and Trust Management service, a user agent presents a number of attributes of the user, such as an e-mail address. The SAP Authorization and Trust Management service uses this attribute to identify the user. You can use such attributes to assign role collections. For example, you can use the `company_region` attribute to assign role collections specific to the provinces or states your users are located. More use cases are to have different role collections for different cost centers or job functions. Mapping role collections to the attribute `Groups` is so common that we have a separate use case for it. For more information, see *Map Role Collections to User Groups* in the related links.

### → Tip

Mappings save time when you add new users. Simply set the relevant attributes in the identity provider for the users, and the users automatically gets all the authorizations that are included in the role collections.

## Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **Security** > **Role Collections**.
2. Search for and choose a role collection.
3. In the overview page for the role collection, choose the *Edit* button.
4. Under *Attribute Mapping*, select an identity provider.
5. Enter the name of the attribute and the value for the SAP Authorization and Trust Management service to use to map the role collection to users. The attributes are combined with logical OR operations. If you assign multiple attributes to the role collection, and one of them is true, the users with this attribute are assigned to this role collection.

### → Tip

Provide the **exact** name of the attribute and its value as provided by the identity provider. These values are case-sensitive.

For more information, see [Settings for Default SAML Federation Attributes of Identity Providers for Business Users \[page 2042\]](#) and [Configure the User Attributes Sent to the Application](#) in the documentation of the Identity Authentication service.

6. Save your entries.

## Related Information

## 6.1.1.8.4 Building Roles and Role Collections for Applications

As an administrator, you can maintain application roles and role collections which can be used in user management.

The user roles are derived from role templates that are defined in the security description (`xs-security.json`) of applications that have been registered as OAuth 2.0 clients at the User Account and Authentication service during application deployment. The application security-descriptor file also contains details of the authorization scopes that are used for application access and defines any attributes that need to be applied. The roles you create can be added to role collections.

You can perform the following tasks:

- Create and delete user roles  
User roles define authorization scopes and are based on the role templates and scopes defined in the application's security descriptor file
- Add user roles to one or more "role collections"
- Configure and manage role collections

### → Tip

Using the SAP BTP cockpit, you can assign the role collections to users directly or indirectly over attributes, such as groups.

## Related Information

[Adding Authentication and Authorization \[page 465\]](#)

## 6.1.1.8.4.1 Roles and Role Collections

Usually a role collection consists of one or multiple roles. You can use the SAP BTP cockpit to add or remove roles.

### Role

A role is an instance of a role template; you can build a role based on a role template and assign the role to a role collection. The SAP BTP cockpit helps you to display information about the selected application and any related roles in the following windows, tabs, and panes:

- Roles
- Scopes
- Attributes
- Role templates

### Role Collection

Roles are assigned to role collections which are assigned in turn to users or user groups if an SAML 2.0 identity provider stores the users. Using the SAP BTP cockpit, you can display information about the role collections that have been maintained as well as the roles available in a role collection. Additional information includes: which templates the roles are based on, and which applications the roles apply to. Role collections enable you to group together the roles you create. The role collections you define can be assigned as follows:

- To users logged on to the `SAP ID service`.
- To user groups containing users logging on with SAML 2.0 assertions.

### Related Information

## 6.1.1.8.4.2 Create Roles for Applications Using Existing Role Templates

Use the SAP BTP cockpit to create a role using an existing role template. You can refine the role by assigning attributes and add the role to role collections.

### Context

You can use existing role templates to create new roles. An SAP BTP cockpit wizard helps you to configure new roles.

#### Note

You can only create roles from roles templates that come with attributes.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose *Security* in the navigation pane.
4. Choose *Roles*.

Here you see a complete list of all existing roles sorted by application name. It also contains the role template, role names, and role description. On the right side, you find the action buttons.

5. Choose *Create Role* in the row of the role template that you want to use.

The *Create Role* wizard opens.

6. Enter a role name and a description, and choose *Next*.
7. Configure the attributes and choose *Next*. The attributes further refine the role. For more information, see the related link.
8. Select the available role collections for your new role and choose *Next*.
9. You can review your role configuration in the next window and complete the creation of the role by choosing *Finish*.

### Related Information

[Attributes \[page 2102\]](#)

## 6.1.1.8.4.3 Create Roles for Subscribed Applications Using Existing Role Templates

Use the SAP BTP cockpit to create a role for a subscribed application using an existing role template. You can refine the role by assigning attributes and add the role to role collections.

### Context

You can use existing role templates to create new roles. An SAP BTP cockpit wizard helps you to configure new roles.

#### Note

You can only create roles from roles templates that come with attributes.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose **Services** > **Instances and Subscriptions** in the navigation pane.
4. To see your subscribed application, choose the **Subscriptions** tab.
5. To get to the place where you can manage roles, choose the chevron next to your subscribed application.  
Here you see a complete list of all existing roles sorted by the role template. It also contains the role names and the role description. On the right side, you find the action buttons.
6. (Optional) To add more roles, choose **+** (Add a role).  
The **Create Role** wizard opens.
7. Enter a role name and a description, and choose **Next**.
8. Configure the attributes and choose **Next**. The attributes further refine the role. For more information, see the related link.
9. Select the available role collections for your new role and choose **Next**.
10. You can review your role configuration in the next window and complete the creation of the role by choosing **Finish**.

### Related Information

[Configure Application Roles and Assign Roles to Users \[page 2011\]](#)  
[Attributes \[page 2102\]](#)

## 6.1.1.8.4.4 Delete Roles

Use the SAP BTP cockpit to delete a role. If this role has been added to a role collection, it's also deleted from the role collection.

### Context

You can use existing role templates to create new roles. An SAP BTP cockpit wizard helps you to configure new roles.

#### Note

You cannot delete roles that belong to default role collections delivered by SAP BTP.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. If your role comes with a subscribed application, continue as described in [Configure Application Roles and Assign Roles to Users \[page 2011\]](#).
4. Choose *Security* in the navigation pane.
5. Choose *Roles*.

Here you see a complete list of all existing roles sorted by application name. It also contains the role template, role names, and role description. On the right side, you find the action buttons.

6. Choose the  (Delete) action button in the row of the role that you want to delete. If the role has been added to a role collection, it's also deleted from the role collection.
7. Confirm that you want to delete the role.

## 6.1.1.8.4.5 Attributes

Attributes use information that is specific to the user, for example the user's country. If the application developer in the Cloud Foundry environment of SAP BTP has created a country attribute to a role, this restricts the data a business user can see based on this attribute.

A lot of applications provide purely functional role templates which grant access for all data of a certain type within your subaccount. Roles for such role templates are generated automatically. Some other applications also provide the possibility for administrators to restrict access not only by functional authorizations, but also by instance-based authorizations. That means that users can only work with a certain subset of the data in your subaccount.

The restriction can be either based on information within the respective role, or on user-specific information provided by the identity provider. This makes instance-based authorizations specific for each customer

because the respective roles cannot be generated automatically. Instead, administrators must create them. Typical restrictions depend on information like the user's country or cost center.

Each restriction is represented by a dedicated attribute which belongs to a role template of the application.

#### Note

Application developers can define attribute references in the application security descriptor file (`xs-security.json`): For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

For each attribute, administrators have multiple options to specify the value which restricts data access:

- **Static attributes**  
They are stored in the role. The user is given the attribute value when the administrator assigns the role collection with this role to the user.
- **Attributes from a custom identity provider**  
Since an identity provider provides the business users, you can dynamically reference all attributes that come with the SAML 2.0 assertion. You define the attributes and the attribute values in the identity provider. In the Cloud Foundry environment of SAP BTP, administrators can use the attributes to refine the roles.

#### Note

If you want to reference attributes from your identity provider, you must know the exact identifier of the attribute. Go to the SAML 2.0 or OpenID Connect configuration of your identity provider and use the attributes as they are defined there.

- **Unrestricted attributes**  
In this case, you want to express that it is not necessary to set a specific value for this attribute. The behavior is the same as if the attribute would not exist for this role.

## Related Information

[Specify Attributes in a Role \[page 2104\]](#)

## 6.1.1.8.4.5.1 Specify Attributes in a Role

As an administrator of the Cloud Foundry environment, you can specify attributes in roles to refine authorizations of the business users. Depending on these attributes, business users with this role have restricted access to data.

### Prerequisites

You have maintained the attributes of the users in your identity provider.

#### 📘 Note

In Identity Authentication or any identity provider, you find the attributes in the configuration.

### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account (cloud management tools feature set B ) or subaccount (cloud management tools feature set A). For more information, see [Navigate in the Cockpit \[page 1938\]](#).
3. Choose your space in **Cloud Foundry > Spaces** or, in the case of subscriptions, see [Configure Application Roles and Assign Roles to Users \[page 2011\]](#).
4. Choose the application.
5. Choose **Security > Roles**.
6. Select a role.

The role overview pane displays the attribute name and fields where you can select the source and enter a value.

7. Choose *Edit*.
8. To specify an attribute, choose the source of the attribute. The following sources are available:

Attribute Sources

Source	Value/Attribute
<i>Static</i>	Enter a static value, for example <b>USA</b> to refine the role depending on the country.

#### → Remember

Follow entries with the  key. Otherwise you can't save the role.

Source	Value/Attribute
<i>Identity Provider</i>	<p>Enter an attribute as defined in your identity provider. Check in your identity provider for the exact syntax of the attribute identifier.</p> <p>For Identity Authentication, you find the attribute identifier in the settings of the attributes of your identity provider under ► <i>Applications &amp; Resources</i> ► <i>Applications</i> ► <i>&lt;Application_Name&gt;</i> ► <i>Trust</i> ► <i>Attributes</i> ►.</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>❖ Example</b></p> <p>To use the attribute for cost center, you must enter the value <b>cost_center</b>.</p> </div>
<i>Unrestricted</i>	<p>In this case, you want to express that it is not necessary to set a specific value for this attribute. The behavior is the same as if the attribute would not exist for this role.</p>

9. Save your changes.

## 6.1.1.8.4.5.2 Specify Attributes in a New Role

As an administrator, you can specify attributes in a new role to refine authorizations of business users. Depending on these attributes, business users with this role have restricted access to data.

## Prerequisites

You have maintained the attributes of the users in your identity provider.

### ❗ Note

In Identity Authentication or any identity provider, you find the attributes in the configuration.

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account (China (Shanghai) region) or subaccount. For more information, see [Navigate in the Cockpit \[page 1938\]](#).
3. Choose your space in [Cloud Foundry > Spaces](#) or, for subscriptions, see [Configure Application Roles and Assign Roles to Users \[page 2011\]](#).
4. Choose the application.
5. Choose [Security > Roles](#).
6. To create a new role, choose *Create*.

A wizard guides you through the role creation process.

7. Enter a name and a description of the new role.
8. Select the role template that you want to use.
9. Choose *Next*.
10. To specify an attribute, choose the source of the attribute. The following sources are available:

Attribute Sources

Source	Value/Attribute
<i>Static</i>	Enter a static value, for example <b>USA</b> to refine the role depending on the country/region.
<i>Identity Provider</i>	<p>Enter an attribute as defined in your identity provider. Check in your identity provider for the exact syntax of the attribute identifier.</p> <p>For SAP Cloud Identity Services - Identity Authentication, you find the attribute identifier in the settings of the attributes under <a href="#">Applications &amp; Resources &gt; Applications &gt; &lt;Application Name&gt; &gt; Trust &gt; Attributes</a>.</p> <div data-bbox="826 1451 1401 1608"><p><b>❖ Example</b></p><p>To use the attribute for cost center, you must enter the value <b>cost_center</b>.</p></div>
<i>Unrestricted</i>	In this case, you want to express that it isn't necessary to set a specific value for this attribute. The behavior is the same as if the attribute wouldn't exist for this role.

11. Choose *Next*.
12. Select the role collections for your new role. For more information, see the related link.
13. Choose *Next* and *Finish*.

You have now created a new role with attributes.

## Related Information

[Subscribe to Multitenant Applications Using the Cockpit \[page 2008\]](#)

[Attributes \[page 2102\]](#)

[Specify Attributes in a New Role \[page 2105\]](#)

### 6.1.1.8.4.6 Add Roles to Role Collections on the Application Level

Roles are used to define the type of access granted to an application.

#### Context

A role is an instance of a role template; you can build a role based on a role template and assign the role to a role collection. Role collections are then assigned to SAML 2.0 groups or users. The role template defines the type of access permitted for an application, for example: the authorization scope, and any attributes that need to be applied. Attributes define information that comes with the respective user, for example 'cost center' or 'country' (see the related link). This information can only be resolved at run time.

#### Note

The User Account and Authentication service automatically creates default roles for all role templates that do not include attribute references. They have the same name as the role template. You can't delete them. You can recognize them because their description contains *Default Instance*.

#### Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose *Security* in the navigation pane or go to ► *Cloud Foundry* ► *Spaces* ► *<your\_space>* ► *<your\_application>* ►.
4. Choose *Roles* in the navigation pane.

Here you see a complete list of all roles sorted by role templates. It also contains information about attributes used in this role and about the role collections the role has been added to. On the right side, you find the action buttons.

#### Note

You cannot edit or delete predefined roles for default role collections. For this reason, the action buttons are grayed out. For more information, see the related link.

5. To directly assign a role to role collections, choose the action button **+** (Add) in the same row.

A new window shows all role collections that are available in your global account (cloud management tools feature set B ) or subaccount (cloud management tools feature set A).

6. Select the role collections to which you want to add your role.
7. Choose *Add*.

The number in the role collections column counts up. You have now assigned this role to the role collections you selected earlier.

## Related Information

[Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#)

[Cloud Management Tools — Feature Set Overview \[page 111\]](#)

### 6.1.1.8.5 Managing Secrets of the SAP Authorization and Trust Management Service

The SAP Authorization and Trust Management service maintains a number of secrets to ensure secure operation of the service. Your organization can have policies that require you change secrets or you may need to respond to the loss of a secret.

The SAP Authorization and Trust Management service uses the following secrets in its operation:

- [Service Instance Secrets \[page 2108\]](#)
- [Rotate Binding Secrets \[page 2111\]](#)
- [Migrate from Instance Secrets to Binding Secrets \[page 2113\]](#)
- [Rotating Instance Secrets \[page 2114\]](#)
- [Binding Parameters of SAP Authorization and Trust Management Service \[page 2115\]](#)
- [Rotate Signing Keys of Access Tokens \[page 2122\]](#)
- [Rotate Signing Keys of SAML Token \[page 2126\]](#)

#### 6.1.1.8.5.1 Service Instance Secrets

When an application consumes a service instance of the SAP Authorization and Trust Management service (XSUAA), the application identifies itself to the service instance with a client ID and a secret. The client ID and secret are the credentials with which an application authenticates itself to the service instance.

The system creates these credentials either when you bind the application to the service instance or when you create a service key for the service instance.

The service instance can use multiple secrets in the application plan.

- The instance secret is the default secret type. The secret is the same for all bindings of the service instance. The secret remains valid as long as the instance exists.

#### Note

Instance secrets are supported only in the Cloud Foundry environments with just one organization. For multiple organizations or other environments, binding secrets are the default secret type. For more information, see [Rotating Secrets](#).

- Binding secrets must be enabled in the application security descriptor (`xs-security.json`) when you create the service instance. When you bind an application to a service instance or create a service key, you can pass a `parameters.json` to use a binding secret. The secret remains valid as long as the binding or the service key exists.

#### Note

The `apiaccess` plan only uses binding secrets. However, some old instances of the `apiaccess` plan still use the instance secret.

- X.509 secrets must be enabled in the application security descriptor (`xs-security.json`) when you create the service instance. When you bind an application to a service instance or create a service key, you can pass a `parameters.json` to use an X.509 secret. SAP Authorization and Trust Management service can generate an X.509 certificate for you or you can provide your own. The X.509 secret remains valid as long as the certificate itself is valid.

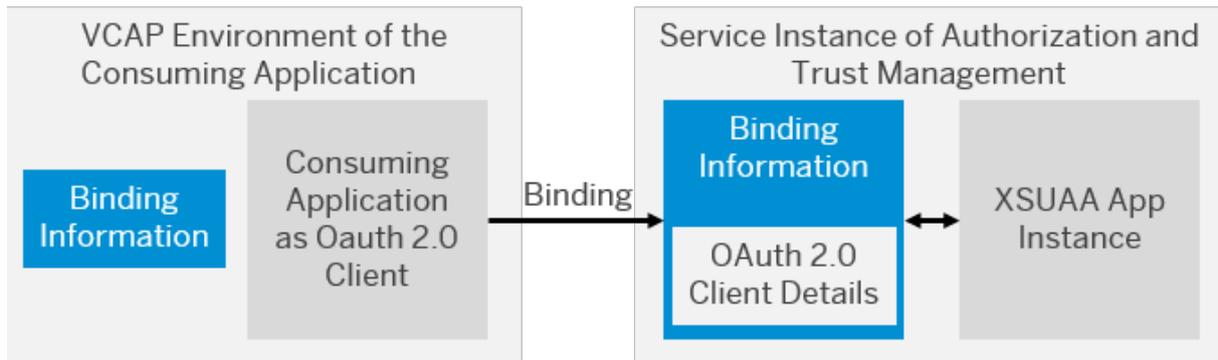

#### Note

The service doesn't check for certificate revocation. To stop the service from accepting a certificate that is still valid, delete the relevant bindings or service keys. As soon as the binding is deleted, the service stops accepting the certificate.

For bindings with self-managed certificates and the `certificate-pinning` parameter set to `false`, you can rotate the secrets without deleting bindings. Just use a new certificate with the same subject and issuer distinguished name (DN). The service saves the new validity date of the new certificate.

For more information, see [Parameters for Self-Managed X.509 Certificates \[page 2118\]](#).

The following figure illustrates the XSUAA app and the binding information about the OAuth 2.0 client as part of a service instance of the SAP Authorization and Trust Management service. A consuming application, functioning as an OAuth 2.0 client is bound to the SAP Authorization and Trust Management service instance. The secret is part of the environment of the consuming application and the information about the OAuth 2.0 client saved with the XSUAA app. Alternatively, this information is saved as part of a service key.

Binding Between an SAP Authorization and Trust Management Service Instance and a Consuming Application

The `credential-types` parameter of the OAuth client configuration in the application security descriptor (`xs-security.json`) determines which types of secrets that bindings support.

In the following example, the service instance creates a binding secret for all new bindings. It allows the creation of X.509 secrets and still accepts instance secrets.

#### Example

##### Sample Code

```
"oauth2-configuration": {
  "credential-types": [ "binding-secret", "x509", "instance-secret" ]
}
```

In the following example, the service instance creates a binding secret for all new bindings, but doesn't accept the instance secret or the use of X.509 secrets.

#### Example

##### Sample Code

```
"oauth2-configuration": {
  "credential-types": [ "binding-secret" ]
}
```

## Related Information

[Limits for Technical Artifacts of the SAP Authorization and Trust Management Service \[page 2817\]](#)

## 6.1.1.8.5.2 Rotate Binding Secrets

Service instances of the SAP Authorization and Trust Management service use different binding secrets for each binding. To rotate binding secrets, unbind and rebind any consuming applications.

### Prerequisites

- You've enabled support for binding secrets.  
For more information, see [Migrate from Instance Secrets to Binding Secrets \[page 2113\]](#).
- If you have to replace any service keys, create the new service keys before proceeding.  
For more information, see [Creating Service Keys \[page 236\]](#).

### Procedure

1. Unbind the application that consumes your service instance.

Use the following syntax:

```
cf unbind-service <APP_NAME> <SERVICE_INSTANCE>
```

```
cf unbind-service my-app my-xsuaa-service
```

2. Rebind the application that consumes your service instance.

Use the following syntax:

```
cf bind-service <APP_NAME> <SERVICE_INSTANCE> [-c <PARAMETERS_AS_JSON>]
```

```
cf bind-service my-app my-xsuaa-service
```

### Results

When you rebind the application, the system creates a new binding secret.

### Next Steps

Delete any old service keys that you don't need anymore.

## Related Information

[Service Instance Secrets \[page 2108\]](#)

### 6.1.1.8.5.3 Rotate X.509 Secrets

When your private key is exposed or your certificates are about to expire, it's time to rotate secrets. Rotating secrets can be as easy as unbinding and rebinding your application or service key.

#### Prerequisites

- If you provide your own certificates, you've prepared new certificates.
- If you need to replace any service keys, create the new service keys before proceeding. For more information, see [Creating Service Keys \[page 236\]](#).

#### Context

##### Note

The service doesn't check for certificate revocation. To stop the service from accepting a certificate that is still valid, delete the relevant bindings or service keys. As soon as the binding is deleted, the service stops accepting the certificate.

For bindings with self-managed certificates and the `certificate-pinning` parameter set to `false`, you can rotate the secrets without deleting bindings. Just use a new certificate with the same subject and issuer distinguished name (DN). The service saves the new validity date of the new certificate.

For more information, see [Parameters for Self-Managed X.509 Certificates \[page 2118\]](#).

#### Procedure

1. Unbind the application that consumes your service instance.

Use the following syntax:

```
cf unbind-service <APP_NAME> <SERVICE_INSTANCE>
```

```
cf unbind-service my-app my-xsuaa-service
```

2. Rebind the application that consumes your service instance.

Use the following syntax:

```
cf bind-service <APP_NAME> <SERVICE_INSTANCE> [-c <PARAMETERS_AS_JSON>]
```

```
cf bind-service my-app my-xsuaa-service -c parameters.json
```

If you provide your own certificates, include them in a `parameters.json` file.

## Related Information

[Binding Parameters of SAP Authorization and Trust Management Service \[page 2115\]](#)

[Binding Service Instances to Applications \[page 234\]](#)

[Service Instance Secrets \[page 2108\]](#)

### 6.1.1.8.5.4 Migrate from Instance Secrets to Binding Secrets

To simplify the management of secrets for service instances of the SAP Authorization and Trust Management service, we recommend that you configure service instances to use binding secrets.

## Context

By default, service instances of the SAP Authorization and Trust Management service use the instance secret for all bindings of the service instance. In the application security descriptor (`xs-security.json`), enable binding secrets for service instances. All bindings have their own secret. You can enable both at once for the following plans:

- Application plan

The API access plan only uses binding secrets.

## Procedure

1. Modify the application security descriptor (`xs-security.json` service use the instance) to support both instance secrets and binding secrets.

Edit the OAuth client configuration of the `xs-security.json` as follows:

### Sample Code

```
"oauth2-configuration": {  
  "credential-types": ["binding-secret", "instance-secret"]  
}
```

2. Update the service instance with the new application security descriptor.
3. Unbind and rebind any consuming applications.

With each new binding, the system creates a new binding secret.

4. Replace any service keys with new service keys.

At this point, none of the applications consuming your service instance need the instance secret anymore.

5. Modify the application security descriptor (`xs-security.json`) to disable support for instance secrets.

Edit the OAuth client configuration of the `xs-security.json` as follows:

#### Sample Code

```
"oauth2-configuration": {  
  "credential-types": [ "binding-secret" ]  
}
```

6. Update the service instance with the new application security descriptor.

## Related Information

[Update a Service Instance \[page 496\]](#)

[Creating Service Keys \[page 236\]](#)

[Service Instance Secrets \[page 2108\]](#)

## 6.1.1.8.5.5 Rotating Instance Secrets

When configured for instance secrets, a service instance of the SAP Authorization and Trust Management service uses the same instance secret for all bindings. You can't really rotate instance secrets, but must rotate the applications and service instance together.

### → Recommendation

Migrate to using binding secrets instead of instance secrets.

Using instance secrets forces you to redeploy the entire application under a new `xsappname` and repeat the assignment of any role collections.

For more information, see [Migrate from Instance Secrets to Binding Secrets \[page 2113\]](#).

## Related Information

[Service Instance Secrets \[page 2108\]](#)

## 6.1.1.8.5.6 Binding Parameters of SAP Authorization and Trust Management Service

When binding applications or creating service keys for services instances of the SAP Authorization and Trust Management service (XSUAA), provide configuration parameters in JSON format.

Set parameters according to the following use cases:

- For instance or binding secrets, you want to suppress the creation of client secrets.
- For X.509 secrets, set parameters according to the following scenarios:
  - The SAP Authorization and Trust Management service generates certificates for you.
  - You already have your own public key infrastructure (PKI), with certificates issued from one of the supported certificate authorities (CA). See the links in the related information.

### → Remember

The types of secrets that a service instance can accept in a binding or service key is configured in the application security descriptor (`xs-security.json`).

For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

## Related Information

[Parameters for Suppressing Client Secrets \[page 2115\]](#)

[Parameters for X.509 Certificates Managed by SAP Authorization and Trust Management Service \[page 2117\]](#)

[Parameters for Self-Managed X.509 Certificates \[page 2118\]](#)

[Trusted Authorities for X.509 Certificates \[page 2121\]](#)

[Limits for Technical Artifacts of the SAP Authorization and Trust Management Service \[page 2817\]](#)

### 6.1.1.8.5.6.1 Parameters for Suppressing Client Secrets

When binding or creating a service key for an `xsuaa` service instance, you can pass some parameters in JSON format or in a JSON file (see `cf bind-service` and `cf create-service-key` in the related links). The `"hide-secret"` element enables you to suppress the client secret when binding or creating a service key. It's useful if some applications only want to bind the `xsuaa` service for authorization purposes.

## Prerequisites

- In the application security descriptor file (`xs-security.json`), you've included the "credential-type" key with `"instance-secret"` and/or `"binding-secret"` when you created or updated the service instance. The `"hide-secret"` element is only taken into account if the credential type is `"instance-secret"` or `"binding-secret"`.

### Note

If the "credential-type" element isn't defined in the binding descriptor, it defaults to the first value of the array passed as "credential-types" in `xs-security.json` for the service instance or for the first value of the default list.

For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

## Parameters for Suppressing Client Secrets

The `cf create-binding` or `cf create-service-key` commands expect a valid `parameters.json` file containing the service-specific configuration parameters in the following format.

### Sample Code

```
{
  "credential-type": "instance-secret",
  "hide-secret": "true"
}
```

### Sample Code

```
{
  "credential-type": "binding-secret",
  "hide-secret": "true"
}
```

The `hide-secret` element defines whether the client secret is omitted.

Element for Suppressing Client Secrets

Element	Value	Description
hide-secret	true	The client secret is omitted in the binding information.
	false (default)	The client secret is included in the binding information.

## Related Information

[Cloud Foundry CLI Reference](#)

## 6.1.1.8.5.6.2 Parameters for X.509 Certificates Managed by SAP Authorization and Trust Management Service

Use the parameters to have the service generate X.509 certificates for you.

### Prerequisites

You've enabled the service instance to use X.509 secrets.

For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

### Parameters for Certificates Managed by the Service

The `create-binding` or `create-service-key` commands expect a `parameters.json` in the following format.

```
{
  "credential-type": "x509",
  "x509": {
    "key-length": 2048,
    "validity": 8,
    "validity-type": "DAYS"
  }
}
```

The following table describes the supported parameters.

Parameters for Service-Managed Certificates

Parameter	Description
<code>credential-type</code>	Only required to use X.509 when X.509 isn't specified as default in the application security descriptor ( <code>xs-security.json</code> ).  For more information, see <a href="#">Application Security Descriptor Configuration Syntax [page 511]</a> .
<code>x509</code>	In this parameter, you define the certificate options of key length, validity period, and unit of length. This parameter is optional.
<code>key-length</code>	Specifies the byte length of the generated private key. The default length is 2048 bytes. You can also choose 4096 bytes or 8192 bytes.

Parameter	Description
validity	Specifies the number of time units for <code>validity-type</code> . The default value is 7.  Together with the <code>validity-type</code> the range of validity runs from 1 <code>DAYS</code> to 30 <code>DAYS</code> .
validity-type	Specifies the time unit for validity. Supported value is <code>DAYS</code> . The default value is <code>DAYS</code> .

## Related Information

[Service Instance Secrets \[page 2108\]](#)

### 6.1.1.8.5.6.3 Parameters for Self-Managed X.509 Certificates

Use these parameters to provide your own certificates for a binding or service key to service instances of the SAP Authorization and Trust Management service (XSUAA).

## Prerequisites

- You've enabled the service instance to use X.509 secrets.  
For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).
- To use your own public key infrastructure (PKI), the certificates must be issued from one of the following certificate authorities (CA).  
For more information, see [Trusted Authorities for X.509 Certificates \[page 2121\]](#).

## Parameters for Self-Managed Certificates

The `create binding` or `create service key` command expects a `parameters.json` in the following format.

```
{
  "credential-type": "x509",
  "x509": {
    "certificate": "-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----",
    "ensure-uniqueness": false,
    "certificate-pinning": true,
    "hide-certificate": true
  }
}
```

## Parameters for Self-Managed Certificates

Parameter	Description
<code>credential-type</code>	<p>Only required to use X.509 when X.509 isn't specified as default in the application security descriptor (<code>xs-security.json</code>).</p> <p>For more information, see <a href="#">Application Security Descriptor Configuration Syntax [page 511]</a>.</p>
<code>x509</code>	<p>In this parameter, you include the certificate and the options of uniqueness and pinning. This parameter is required.</p>
<code>certificate</code>	<p>Provide the certificate string in privacy-enhanced mail (PEM) format. This parameter is required.</p> <div data-bbox="821 772 1396 1187"><p><b>⚠ Restriction</b></p><p>You can only use each certificate once per service instance. The uniqueness of the certificate among all bindings and keys of a service instance is dependent on the value of <code>certificate-pinning</code>:</p><ul style="list-style-type: none"><li>• <code>true</code> The certificate hash must be unique.</li><li>• <code>false</code> The combination of subject and issuer DN must be unique.</li></ul></div>
<code>ensure-uniqueness</code>	<p>Ensures that the certificate is unique among all following clone instances. The default value is <code>false</code>.</p> <div data-bbox="821 1310 1396 1456"><p><b>📌 Note</b></p><p>This parameter only applies to the broker plan of the service.</p></div>

Parameter	Description
<code>certificate-pinning</code>	<p>Set to <code>false</code> for applications that are rarely updated or deployed. The incoming certificate's subject and issuer DN is compared to the subject and issuer of the stored certificate. If the values match and the certificate was issued on or after the stored issuer date, the authentication is accepted. Afterwards the incoming certificate's issuer date is stored for future authentication attempts.</p> <p><b>Exception:</b> Matching certificates with a <code>valid-from</code> parameter that is less than 10 minutes old are always accepted.</p> <p>Set to <code>true</code> for blue and green deployments, where you deploy a new application or version of an application regularly and rotate the certificate in parallel. For this use case, you need a new certificate to use in the binding of the new application.</p> <p>The default value is <code>true</code>.</p>
<code>hide-certificate</code>	<p>If this parameter is set to <code>true</code> (default is <code>false</code>), the X.509 certificate is not returned in the binding or service key. This is useful to reduce the size of the environments when the Cloud Foundry environment limit of 130k has been reached. This parameter is optional.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>This parameter works only with self-managed certificates as otherwise, the public key would not be known to the user.</p> </div>

## 6.1.1.8.5.7 Rotate Signing Keys of Access Tokens

Components of the Cloud Foundry environment use the digital signature of the access tokens to verify the validity of access tokens. Periodically rotate the signing keys of access tokens.

### Related Information

[Rotate Signing Keys of Access Tokens with the SAP BTP CLI \[page 2122\]](#)

[Rotate Signing Keys of Access Tokens with the Security Setting API \[page 2124\]](#)

### 6.1.1.8.5.7.1 Rotate Signing Keys of Access Tokens with the SAP BTP CLI

The SAP BTP CLI enables you to rotate the signing keys of access tokens.

#### Prerequisites

Plan for waiting time in hours between the steps of this procedure.

After activating a new key, wait for access tokens signed by the old key to expire before deleting the old key. The default lifetime of access tokens is 12 hours.

To support this delay in rotation, the service enforces a minimum 1-hour delay between rotation and the activation.

#### Note

In emergency cases or in automated test setups, you can bypass the delay in activation and deletion by using the `--force` option. Forcing changes can also cause service interruption for access tokens that haven't expired yet.

#### Context

To rotate the signing key of access tokens, use the SAP BTP command-line interface (btp CLI). You can rotate signing keys for the global account, directory, or subaccount.

For more information, see [Managing Signing Keys for Access Tokens \[page 2180\]](#).

## Procedure

1. Log on to the SAP BTP CLI.  
For more information, see [Log in \[page 2149\]](#).
2. Check that there's space for a new signing key.  
You can store two signing keys per subaccount.

Use the following command:

```
btpt list security/token-key
```

The service lists any keys.

Key ID	Enabled	Created	Fips
Compliant			
default-jwt-key-491aae9c42		Fri Feb 02 14:48:51 UTC 2024	yes
default-jwt-key-ca81ebbb43	yes	Mon Feb 05 14:42:26 UTC 2024	yes

2 entries  
OK

Delete the inactive key if you already have two. In the previous example, delete `default-jwt-key-491aae9c42`. For more information on how to delete keys, see step 6.

### ⚠ Caution

If the `keyID` is `key-id-0` or `key-id-1`, these keys are legacy signing keys. When you enable the first signing key after a legacy signing key, the legacy signing key is immediately invalid. Clients with access tokens issued within the lifetime of an access token can't use their access tokens anymore. Affected clients must reauthenticate to get a new token.

Plan for possible service interruption when you add your first signing key.

3. Add a new signing key for the access token.

Use the following command:

```
btpt create security/token-key  
Created default signing key
```

A new signing key is generated.

4. Enable the new signing key.

Use the following command:

```
btpt enable security/token-key --key <Key_ID>
```

For example:

```
btpt enable security/token-key --key default-jwt-key-ca81ebbb43  
Enabled signing key 'default-jwt-key-ca81ebbb43'
```

New access tokens are now signed with the new signing key.

5. Wait for access tokens signed by the old key to expire.

As long as the old signing key exists, the system still accepts digital signatures signed by that key. Once you've waited out the lifetime of any access tokens signed by the old key, you can delete the old key.

6. Delete the old signing key for the access token.

Use the following command:

```
btpt delete security/token-key --key <Key_ID>
```

For example:

```
btpt delete security/token-key --key default-jwt-key-491aae9c42
Do you really want to delete signing key 'default-jwt-key-491aae9c42'? [no]>
Yes
Deleted signing key 'default-jwt-key-491aae9c42'
```

## 6.1.1.8.5.7.2 Rotate Signing Keys of Access Tokens with the Security Setting API

You can use the Security Setting API of the SAP Authorization and Trust Management service to rotate the signing keys of access tokens .

### Prerequisites

- You've enabled API access to the service.  
For more information, see [Get Access to the APIs Using the apiaccess Service Plan \[page 2233\]](#)
- Plan for waiting time in hours between the steps of this procedure.  
After activating a new key, wait for access tokens signed by the old key to expire before deleting the old key.  
The default lifetime of access tokens is 12 hours.  
To support this delay in rotation, the service enforces a minimum 1-hour delay between rotation and the activation (UPDATE) or deletion (DELETE) of signing keys.

#### Note

In emergency cases or in automated test setups, you can bypass the delay in activation and deletion by using the `FORCE_UPDATE` and `FORCE_DELETE` change modes. Forcing changes can also cause service interruption for access tokens that haven't expired yet.

### Context

### Procedure

1. Check that there's space for a new signing key.

You can store two signing keys per subaccount. Get the settings of your subaccount to see how many keys are stored there.

Call the **GET** method of the Security Settings API at the following endpoint:

```
https://api.authentication.<region>.hana.ondemand.com/sap/rest/authorization/v2/securitySettings
```

For more information, check the security settings API on the [SAP Business Accelerator Hub](#).

The API returns a JSON with the security settings. Examine the key IDs in the token policy settings.

```
{
  ...
  "tokenPolicySettings": {
    ...
    "activeKeyId": "jwt-sig-2022-12-01",
    "keyIds": [
      "jwt-sig-2022-09-10",
      "jwt-sig-2022-12-01"
    ]
  },
  ...
}
```

Delete the inactive key if you already have two. In the previous example, delete `jwt-sig-2022-09-10`. For more information on how to delete keys, see step 5.

#### ⚠ Caution

If the `keyID` is `key-id-0` or `key-id-1`, these keys are legacy signing keys. When you enable the first signing key after a legacy signing key, the legacy signing key is immediately invalid. Clients with access tokens issued within the lifetime of an access token, can't use their access tokens anymore. Affected clients must reauthenticate to get a new token.

Plan for possible service interruption when you add your first signing key.

2. Add a new signing key for the access token.

Call the **PATCH** method of the same endpoint.

In the body, include a key ID and set `changeMode` to **ADD** in the token policy settings.

#### ↗ Sample Code

```
{
  "tokenPolicySettings": {
    "keyId": "jwt-sig-2023-01-30",
    "changeMode": "ADD"
  }
}
```

A new signing key is generated.

3. Enable the new signing key.

Call the **PATCH** method of the same endpoint, but set `changeMode` to **UPDATE**.

```
{
  "tokenPolicySettings": {
    "keyId": "jwt-sig-2023-01-30",
```

```
    "changeMode" : "UPDATE"
  }
}
```

New access tokens are now signed with the new signing key.

4. Wait for access tokens signed by the old key to expire.

As long as the old signing key exists, the system still accepts digital signatures signed by that key. Once you've waited out the lifetime of any access tokens signed by the old key, you can delete the old key.

5. Delete the old signing key for the access token.

Call the *PATCH* method of the same endpoint, but set `keyID` to the old key ID and `changeMode` to **DELETE**.

#### Sample Code

```
{
  "tokenPolicySettings": {
    "keyId": "jwt-sig-2022-12-01",
    "changeMode": "DELETE"
  }
}
```

## Related Information

[Managing Secrets of the SAP Authorization and Trust Management Service \[page 2108\]](#)

### 6.1.1.8.5.8 Rotate Signing Keys of SAML Token

The SAP Authorization and Trust Management service uses an X.509 certificate to sign SAML 2.0 protocol messages between itself, a SAML service provider, and an SAML identity provider. To rotate the signing keys for SAML tokens, use the Security Settings API of the SAP Authorization and Trust Management service and then establish trust by exchanging metadata between the service provider and identity provider.

## Prerequisites

- You've enabled API access to the SAP Authorization and Trust Management service.  
For more information, see [Get Access to the APIs Using the apiaccess Service Plan \[page 2233\]](#)
- Optionally, to use your own signing key for SAML tokens, you've obtained an X.509 certificate for the SAP Authorization and Trust Management service.
- You've checked that you've space for an additional signing key.  
You can store two signing keys per subaccount. Get the settings of your subaccount to see how many signing keys you've stored there. Delete an inactive signing key if you already have two.

## Context

The signed SAML tokens are used to validate and authenticate the protocol messages between the SAP Authorization and Trust Management service instance and the identity provider.

## Procedure

1. Add a new signing key for SAML tokens.

Call the **PATCH** method of the Security Settings API at the following endpoint:

```
https://api.authentication.<region>.hana.ondemand.com/sap/rest/authorization/v2/securitySettings
```

In the body, include a key ID and set `changeMode` to **ADD** in the SAML configuration settings.

### Sample Code

```
{
  "samlConfigSettings": {
    "keyId": "my-new-key",
    "changeMode": "ADD"
  }
}
```

A new signing key is generated.

Optionally, provide your own signing key with the `key` parameter. The signing key is your private key of the certificate key pair. Provide the certificate.

### → Recommendation

We recommend providing an empty passphrase. We believe that there's no reason to view the private key.

```
{
  "samlConfigSettings": {
    "keyId": "my-new-key",
    "changeMode": "ADD",
    "key": {
      "key": "<key_data>",
      "passphrase": "",
      "certificate": "<certificate_data>"
    }
  }
}
```

2. Enable the new signing key.

Call the **PATCH** method of the same endpoint, but set `changeMode` to **UPDATE**.

```
{
  "samlConfigSettings": {
    "keyId": "my-new-key",
    "changeMode": "UPDATE"
  }
}
```

```
}  
}
```

New SAML tokens are now signed with the new signing key.

3. Establish trust with the identity providers you consume.

Upload the new metadata information to your identity providers.

For more information, see the related documentation:

- [Manually Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2035\]](#)
- [Establish Trust and Federation with UAA Using Any SAML Identity Provider \[page 2039\]](#)

### ⚠ Caution

Until you upload the metadata to your identity provider, the identity provider rejects the signed SAML tokens.

4. Delete the old signing key for SAML tokens.

Call the *PATCH* method of the same endpoint, but set `keyID` to the old key ID and `changeMode` to **DELETE**.

### 🔗 Sample Code

```
{  
  "samlConfigSettings": {  
    "keyId": "my-old-key",  
    "changeMode": "DELETE"  
  }  
}
```

## 6.1.1.8.6 Configure Trusted Domains for SAP Authorization and Trust Management Service [Feature Set B]

By default, login pages of the SAP Authorization and Trust Management service (XSUAA) can't be framed by other applications in different domains for security reasons.

### Prerequisites

#### → Recommendation

Review the security implications of using inline frames (IFrames) with SAP Authorization and Trust Management service.

For more information, see [Implications of Using IFrames \[page 2804\]](#).

### Context

To prevent clickjacking or overlay attacks, web browsers follow a same origin policy. The same origin policy means you can only embedded content in your web page if the content shares the same protocol, host, and port as your web page. If the origins don't match, you must maintain a list of origins that allows for exceptions to the same origin policy. The same origin policy also applies to cookies. Cookies enable single sign-on scenarios. If the cookies have a different origin, the browser rejects them like any other content.

#### → Recommendation

Instead of configuring lists of trusted domains, ensure that your application runs under the same domain as the framing application.

For more information about SAP Custom Domain service, see the documentation of the [SAP Custom Domain Service](#).

If your custom identity provider runs under a different domain as the framing application, you must configure the identity provider to trust the domain of the framing application, too.

### Procedure

1. Go to your subaccount (see [Navigate in the Cockpit \[page 1938\]](#)) and choose **► Security ► Settings ▾**.
2. Choose **+** (*Add*).
3. Enter the host name for the trusted domain.

For example: `https://store.example.com`

#### Note

All the trusted domains together, including their space separators, can't exceed 2048 characters.

4. Save your entries.

## Next Steps

Ensure that other component framed by the host application also trust the framing domain. Typical components include the application router and the identity provider.

## Related Information

[Application Router \[page 377\]](#)

[Configure Trust Domains \(in SAP Cloud Identity Services - Identity Authentication Documentation\)](#)

## 6.1.1.8.7 Configure Token Policy for SAP Authorization and Trust Management Service

Set the token policy in the SAP BTP cockpit for SAP Authorization and Trust Management service by configuring the validity of the OpenID Connect (OIDC) tokens the service issues.

## Prerequisites

### → Recommendation

Review the security implications of token policies for SAP Authorization and Trust Management service.

For more information, see [Setting Token Policy \[page 2806\]](#).

## Context

On request, SAP Authorization and Trust Management service issues access and refresh tokens.

With a valid access token, you can access a protected resource. Once an access token expires, you can get new access tokens with a refresh token. Once the refresh token expires, you must reauthenticate and request new access and refresh tokens.

## → Recommendation

Relaxing the token policy means that users reauthenticate less. However, increasing the token validity also means that if a malicious user manages to steal a token, that malicious user has access until the token expires. Keep token validity as short as possible, but not less than 30 minutes.

To change the token validity, access the security settings. The change applies to all service instances in the subaccount that haven't set a specific value in the application security descriptor (`xs-security.json`).

## Procedure

1. Open the SAP BTP cockpit.
2. Go to your global account and subaccount (see [Navigate in the Cockpit \[page 1938\]](#)).
3. Choose ► *Security* ► *Settings* ▾.
4. Choose the *Token Validity* tab.

You see the setting of the current access token validity and of the current refresh token validity.

5. Use the slider to set the validity for each token. The tooltip shows the selected value in seconds.

### ❖ Example

- Set the access token validity to 1800 seconds
- Set the refresh token validity to 43200 seconds.

6. To save the value, choose *Set Token Validity*.

### 📘 Note

It is also possible to change the token validity in the Security Settings API.

For more information, see [Security Settings API](#) on [SAP Business Accelerator Hub](#).

## Related Information

[Application Security Descriptor Configuration Syntax \[page 511\]](#)

## 6.1.2 Account Administration Using Joule (Beta)

Learn about the administrative tasks that SAP's generative AI assistant, Joule, can perform for you in the SAP BTP cockpit.

### Note

This offering is a beta feature. Beta features aren't part of the officially delivered scope that SAP guarantees for future releases. For more information, see [Important Disclaimers and Legal Information](#).

Joule makes it easier than ever to create subaccounts and manage account users in the cockpit. With Joule integrated into the cockpit, you can accomplish your goals faster.

- Ask Joule to perform an administrative action for you from a set of pre-defined administrative workflows.
- Ask Joule a question about SAP BTP services or the cockpit. Joule references SAP BTP cockpit documentation and provides a summary of what it finds, as well as links to relevant help content.

#### [Get Started with Joule \(Beta\) \[page 2132\]](#)

Find out how to request access to the beta and start using Joule.

#### [Access Joule \(Beta\) \[page 2133\]](#)

Launch Joule directly from SAP BTP cockpit.

#### [Supported Administrative Tasks \(Beta\) \[page 2134\]](#)

Learn about the administrative tasks that Joule can perform for you in the SAP BTP cockpit.

#### [Conversations with Joule \(Beta\) \[page 2135\]](#)

Let Joule help you find answers to questions about managing your accounts in SAP BTP cockpit.

## Related Information

[What is Joule?](#)

[Using Joule](#)

### 6.1.2.1 Get Started with Joule (Beta)

Find out how to request access to the beta and start using Joule.

### Note

This offering is a beta feature. Beta features aren't part of the officially delivered scope that SAP guarantees for future releases. For more information, see [Important Disclaimers and Legal Information](#).

If the use cases covered in this beta release seem intriguing to you and align with your needs, you can register with our beta program. Participating in this program lets you:

- Give feedback to directly influence how Joule simplifies administrator tasks in the SAP BTP cockpit.
- Get a first glimpse of SAP's generative AI assistant in the SAP BTP cockpit and try it out.

## Beta Program Access

To apply to the beta program, you can:

- Visit our [SAP Influence page](#) and register with our beta program.

After you apply to the beta program, we'll contact you and discuss the technical requirements that need to be in place to support Joule in SAP BTP cockpit.

## Related Information

[Supported Administrative Tasks \(Beta\) \[page 2134\]](#)

### 6.1.2.2 Access Joule (Beta)

Launch Joule directly from SAP BTP cockpit.

#### Note

This offering is a beta feature. Beta features aren't part of the officially delivered scope that SAP guarantees for future releases. For more information, see [Important Disclaimers and Legal Information](#).

Joule is accessed directly from the cockpit when you click the diamond icon  in the cockpit tool header. When the chat window opens, you can ask Joule to perform one of the supported administrative tasks or you can ask Joule a question about SAP BTP.

## Authentication

Joule only supports SAP-managed IAS tenants for authentication at this time.

## Authorization

Because you're already logged into the SAP BTP cockpit, Joule recognizes you and can perform administrative actions on your behalf. It's important to know that Joule is bound to your cockpit authorization. In other words, Joule can only accomplish tasks for you that you're authorized to perform.

## Related Information

[Supported Browsers](#)

[Supported Administrative Tasks \(Beta\) \[page 2134\]](#)

[Conversations with Joule \(Beta\) \[page 2135\]](#)

[Using Joule](#)

### 6.1.2.3 Supported Administrative Tasks (Beta)

Learn about the administrative tasks that Joule can perform for you in the SAP BTP cockpit.

#### Note

This offering is a beta feature. Beta features aren't part of the officially delivered scope that SAP guarantees for future releases. For more information, see [Important Disclaimers and Legal Information](#).

You can ask Joule to perform certain administrative tasks for you in the cockpit. If Joule recognizes the task as a supported workflow, then it walks you through the steps to complete the task.

You can ask Joule to do these things in the cockpit:

- Create a subaccount.

#### Note

Subaccounts are created with a beta label to identify that they're part of the beta program. These subaccounts aren't available in global accounts that are part of a production landscape.

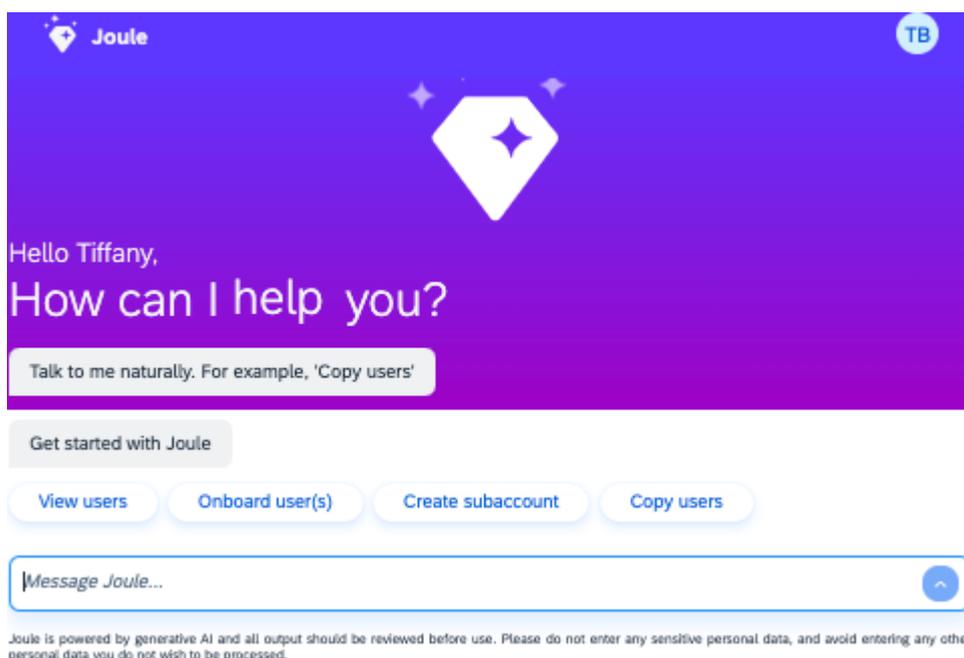

- Add a new user to a subaccount and assign a role collection.
- Copy users from a global account to a subaccount. By default, users are assigned the **Subaccount Viewer** role.
- Copy users from one subaccount to another subaccount. Users are copied over with the same role permissions that they were assigned in the source subaccount.

There are times when it's helpful to see a summary of your global account and subaccount user details. You can also ask Joule to show you these things in the cockpit:

- View global account users and filter by role.
- View subaccount users and filter by role.

### Best Practices

- When working with Joule, you're presented with options in the chat. Make your choices from the options provided for you. Don't type text directly in the chat. Joule works best if you select from the suggested options in the chat.
- You can't mix an administrative action with a separate conversation about SAP BTP. Let Joule complete a task before you ask questions about SAP BTP.

## 6.1.2.4 Conversations with Joule (Beta)

Let Joule help you find answers to questions about managing your accounts in SAP BTP cockpit.

### Note

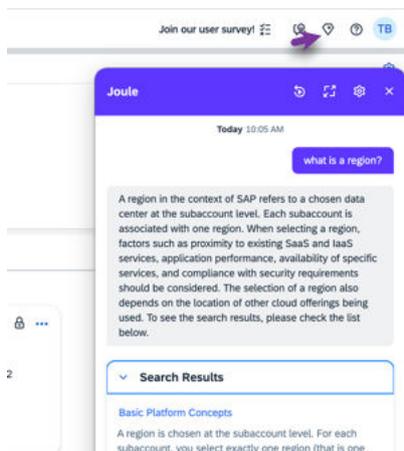

This offering is a beta feature. Beta features aren't part of the officially delivered scope that SAP guarantees for future releases. For more information, see [Important Disclaimers and Legal Information](#).

Take your SAP BTP cockpit administration questions to Joule. Just type a question in the Joule chat using natural language and let Joule scan the product documentation on the SAP Help Portal for answers.

Joule summarizes the relevant SAP Help Portal information. This summary is then displayed along with the top three search results. If you select a link result, you're taken directly to the topic on the SAP Help Portal.

### Note

Joule is an addition to in-app help content, guided tours, embedded learning content, and customer-specific enablement content in SAP Companion.

## Related Information

[Features of Joule](#)

[Supported Administrative Tasks \(Beta\) \[page 2134\]](#)

### 6.1.3 Account Administration Using the SAP BTP Command Line Interface (btp CLI)

Use the SAP BTP command line interface (btp CLI) for all account administration tasks, such as creating or updating subaccounts, authorization management, and working with service brokers and platforms. It is an alternative to the SAP BTP cockpit for users who like to work in a terminal or want to automate operations using scripts.

The btp CLI offers convenient features for interactive use as well as for scripting: For the interactive user, there's login via SSO, command autocompletion, as well as several interactive commands with prompts. But all commands can also be run with parameters, and the command output can be set to json format, so the btp CLI is perfect for scripting.

If you want to use the btp CLI for scripting, we recommend to use the `--format json` option or to persistently set the output format to json with `btp set config --format json`. See [Change the Output Format to JSON \[page 2163\]](#) and [Change Configuration Settings \[page 2162\]](#).

#### Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

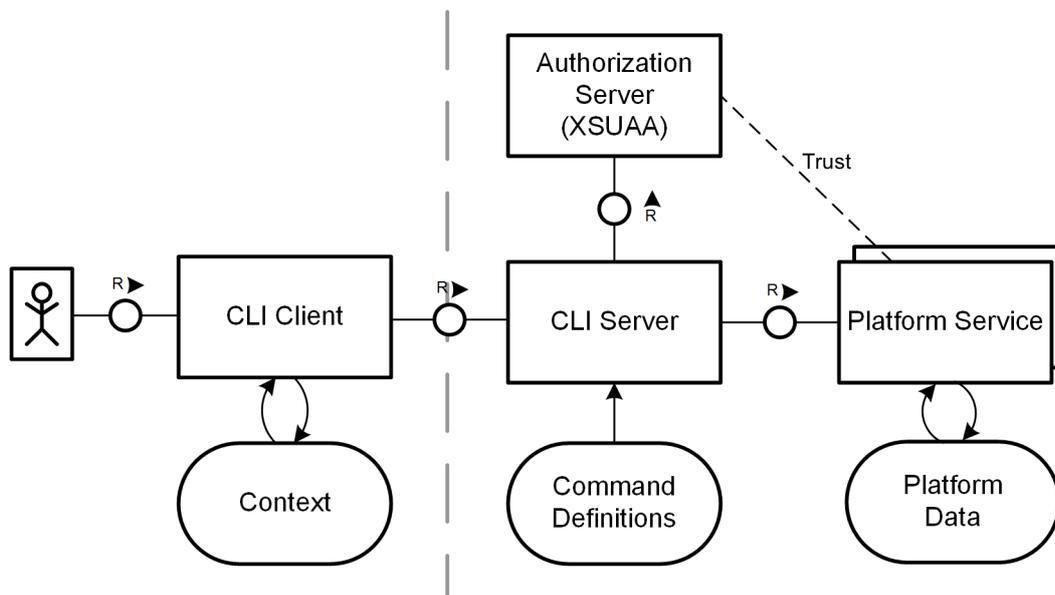

## Documentation

In this documentation, you learn how to download, install, update, and use the `btp CLI`. Additionally, see the following:

- [btp CLI Command Reference](#): The command reference contains descriptions of all commands with their parameters, as well as examples, tips, and links to further conceptual documentation.
- [Get Started with the SAP BTP Command Line Interface \(btp CLI\)](#): This tutorial walks you through downloading and installing the `btp CLI` client, understanding the syntax, and running your first commands.
- [Automate Account Operations with the Command Line Interface](#): This tutorial uses a bash shell script to automate the setup of a global account.
- [Setting Up a Global Account via the Command Line \[page 145\]](#): This chapter lists the commands of the `btp CLI` and the `cf CLI` that you need to create a subaccount and enable Cloud Foundry.
- [What's New for SAP BTP Command Line Interface](#): Release notes for the `btp CLI`.

When working with the `btp CLI` in your terminal, you can access the help by executing `btp help` or by appending `--help` to a command.

## How the btp CLI Works

You download the `btp CLI` client to your local desktop and access it through the shell of your operating system. The client then accesses all required platform services through its backend, the `CLI` server, where the command definitions are stored. The `CLI` server delegates authentication and authorization to the authorization server, and forwards trust to the platform services, which then take care of authorization at the execution of each command.

## Related Information

[btp CLI Command Reference](#)

### 6.1.3.1 Download and Start Using the btp CLI Client

To use the SAP BTP command line interface (btp CLI), you need to download the client first.

#### Context

The client is available for 64-bit versions of the following operating systems:

- Microsoft Windows (amd64)
- Apple macOS (amd64 and arm64)
- Linux (amd64 and arm64)

Each client version is supported for at least a year and most of the updates to the btp CLI don't require a new client installation, but are made available through the btp CLI server, so that you can use them in your installed version of the client. However, to make sure you don't miss any new features or security updates, we recommend to regularly update the client anyways.

In the [What's New for SAP Business Technology Platform](#) page on SAP Help Portal (filtered for *SAP BTP Command Line Interface*) we inform about new features, client releases, as well about client deprecations and discontinuations.

#### Procedure

1. Download the appropriate client for your operating system from [SAP Development Tools](#) with the links in the table below. If you prefer using the the command line or a script, you can use the curl command from the table below, which downloads and saves the latest client version to your computer and accepts the SAP Developer Agreement (EULA).

Operating System	Link to Latest Version	curl Command to Download Latest version
Microsoft Windows	<a href="#">amd64</a>	<pre>curl -LJO https://tools.hana.ondemand.com/additional/btp-cli-windows-amd64-latest.tar.gz --cookie "eula_3_2_agreed=tools.hana.ondemand.com/"</pre>

Operating System	Link to Latest Version	curl Command to Download Latest version
		<pre>developer- license-3_2.txt"</pre>
Apple macOS	<a href="#">amd64</a>   <a href="#">arm64</a>	<pre>curl -LJO https:// tools.hana.ondemand.com /additional/btp-cli- darwin-amd64- latest.tar.gz --cookie "eula_3_2_agreed=tools. hana.ondemand.com/ developer- license-3_2.txt"</pre> <pre>curl -LJO https:// tools.hana.ondemand.com /additional/btp-cli- darwin-arm64- latest.tar.gz --cookie "eula_3_2_agreed=tools. hana.ondemand.com/ developer- license-3_2.txt"</pre>
Linux	<a href="#">amd64</a>   <a href="#">arm64</a>	<pre>curl -LJO https:// tools.hana.ondemand.com /additional/btp-cli- linux-amd64- latest.tar.gz --cookie "eula_3_2_agreed=tools. hana.ondemand.com/ developer- license-3_2.txt"</pre> <pre>curl -LJO https:// tools.hana.ondemand.com /additional/btp-cli- linux-arm64- latest.tar.gz --cookie "eula_3_2_agreed=tools. hana.ondemand.com/ developer- license-3_2.txt"</pre>

2. Extract the client file from the tar.gz archive.

Linux: Use the terminal to open the tar.gz file with `tar -xzf btp-cli-linux-amd64-latest.tar.gz`.

macOS: Open the tar.gz file by double-clicking in.

Windows: Use powershell or an external program, such as WinRar, to extract the tar.gz file. Tip: Once you've unpacked the executable, you can enter `cmd` or `powershell` in the address bar of the folder. This opens the command prompt or PowerShell in this folder. Or proceed with the next step in order to enable calling `btp` from any location on your system.

3. Copy the client executable from the unpacked folder to a directory of your choice. We recommend the following, because it ensures that you can call `btp` system wide, i.e. that it is in your PATH:

Linux: /usr/local/bin

macOS: /usr/local/bin

Windows: C:\Users\

In the Windows search, enter **Environment Variable** and open the *System Properties*. On the **Advanced** tab, open **Environment Variables**. Under **User Variables**, open the **Path** entry and add the file location of the `bt.exe` (C:\Users\

4. (Optional) If you have a proxy server configured in your environment, you need to specify its address and port as environment variable `HTTPS_PROXY` or `https_proxy` to access SAP BTP. For example, `HTTPS_PROXY=https://my-https-proxy:1234`.

The specified proxy server is then used for HTTPS requests, unless overridden by the `NO_PROXY` or `no_proxy`, environment variables, which define a comma-separated list of hosts to be excluded from proxying.

5. Run `bt` in your terminal. Note that you need read and write permissions in the target folder to run this executable.
6. Log in to your global account with `bt login` or `bt login --sso`. The login flow is interactive and will prompt for all required information. Note that you need to confirm the `bt` CLI server url (`https://cli.bt.cloud.sap/`) and, if you have more than one, select your global account. For details, see [Log in \[page 2149\]](#).
7. Once you're logged in, familiarize yourself with the `bt` CLI, for example with [How to Work with the bt CLI \[page 2146\]](#), [Command Syntax of the bt CLI \[page 2141\]](#), or simply by trying out a few commands, such as the following:

```
bt list accounts/subaccount
```

```
bt list security/user
```

```
bt get security/user "name@example.com"
```

```
bt get accounts/global-account "
```

#### → Tip

You can use the command autocompletion feature in the `bt` CLI to save keystrokes when entering command actions, group-object combinations, and their parameters in the command line. For more information, see [Enable Command Autocompletion \[page 2156\]](#).

8. If you're going to work in a subaccount of this global account, consider setting the target to this subaccount using `bt target` and select the subaccount. See [Set a Target for Subsequent Commands with bt target \[page 2159\]](#).
9. To find out the current context, target, and version, use `bt`.

## Related Information

[btpt CLI Command Reference](#)

### 6.1.3.1.1 Get Updates

Updating the btpt CLI client is essentially replacing the old executable file with a newer version.

#### Context

Each btpt CLI client version is supported for at least a year after its release, but we recommend to regularly update the client. This way, you ensure not to miss any new features or security updates. The [What's New for SAP Business Technology Platform](#) page on SAP Help Portal announces new features and informs you if you need a client update to use them. If your client version is deprecated, an update hint is displayed in the client as well.

To find out the version of the CLI client you are using, run `btpt --info` or simply `btpt`.

#### Procedure

1. Get the latest version using the download links in the table in [Download and Start Using the btpt CLI Client \[page 2138\]](#).
2. Extract the client file (for example: `btpt.exe`) and replace the old file with this new one.
3. Work with the btpt CLI as usual and enjoy the new features.

#### Related Information

[Log in \[page 2149\]](#)

[Commands in the btpt CLI \[page 2167\]](#)

### 6.1.3.2 Command Syntax of the btpt CLI

Each command consists of the base call `btpt` followed by a verb (the action), a combination of group and object, and parameters.

The btpt CLI uses the following syntax:

```
btpt [OPTIONS] ACTION GROUP/OBJECT [PARAMS]
```

The commands are ordered in groups and you need to specify the object on which you want to carry out an action by the group/object combination. Words in caps are placeholders, and brackets [ ] denote optionality. Optionally, you can pass options with a command call. Here's is one example with the verbose option and no parameters before we outline the entire syntax:

### Sample Code

```
btP --verbose list accounts/subaccount
```

- `btP` is the base call to start each command
- `OPTIONS` can be added to each command, for example `--format json` to change the output format to json, or `--verbose` to execute a command in verbose mode. For details, see [How to Work with the btP CLI \[page 2146\]](#).
- `ACTION` is the verb. Depending on the `GROUP/OBJECT` combination, different verbs are available, such as `get`, `list`, `create`, `delete`, `assign`, `unassign`, `add`, `remove`. For a complete list, use `btP help`. To find out which commands are available for a specific action, use `btP help ACTION`, for example, `btP help list`.
- Special `ACTION`: the `help ACTION`. You can always place `help` at the beginning of a command and still add further parts of the command, such as the `ACTION` or `GROUP` or `GROUP/OBJECT` combination for which you want to call help. See [Get Help \[page 2148\]](#).
- The `GROUP/OBJECT` combination specifies the entity that the action is carried out on. For example, all commands related to users and their authorizations belong to the **security** group, in which **objects** such as `role`, `role-collection`, and `user` are available. There are currently three groups:
  - `accounts`: Objects related to the account model, subscriptions, and environments
  - `security`: Authorization objects and users
  - `services`: Objects related to SAP Service ManagerTo get help on a particular group, use `btP help GROUP`, for example `btP help accounts`. This will display all objects and related actions available in that group.
- `PARAMETERS` are passed with most commands. With `btP login`, for example, you don't have to pass parameters up front, but you'll be prompted to enter them. The same applies to the `btP target` command. And `btP logout` does not need parameters as it will log out the current user from the global account. Some commands have one positional parameter, which is entered directly after the command. All further parameters have a key and can be optional. The command help specifies the optional parameters as such. For example, in `btP assign security/role-collection "Global Account Administrator" --to-user example@mail.com --of-idp my-idp, "Global Account Administrator"` is the positional parameter, and the other two parameters have keys.

### Note

The commands that you type into the command line are interpreted and executed by the shell. Make sure you're familiar with your shell to avoid unexpected interferences. For examples of correct escaping, see [Passing JSON Parameters on the Command Line \[page 2144\]](#).

### Tip

You can use the command autocompletion feature in the `btP` CLI to save keystrokes when entering commands actions, group-object combinations, and their parameters in the command line. For more information, see [Enable Command Autocompletion \[page 2156\]](#).

## A Few Commands to Get Started

Here are a few commands for you to try out once you're logged in ([Log in \[page 2149\]](#)):

```
btpt list accounts/subaccount
```

```
btpt list security/user
```

```
btpt get security/user "name@example.com"
```

```
btpt list accounts/subscription
```

## Example

In this example, we assign the **Global Account Administrator** role collection to user **name@example.com** and try out some options.

Use `help` or `--help` to display command-specific help to learn how to use the command:

```
btpt help assign security/role-collection
```

```
btpt assign security/role-collection --help
```

```
btpt --help assign security/role-collection
```

Command with positional parameter and one mandatory parameter:

```
btpt assign security/role-collection "Global Account Administrator" --to-user "name@example.com"
```

Command with positional parameter, mandatory parameter, and optional parameter:

```
btpt assign security/role-collection "Global Account Administrator" --to-user "name@example.com" --of-idp "my-idp"
```

The same command in verbose mode:

```
btpt --verbose assign security/role-collection "Global Account Administrator" --to-user "name@example.com" --of-idp "my-idp"
```

## Related Information

[btpt CLI Command Reference](#)

## 6.1.3.2.1 Passing JSON Parameters on the Command Line

Depending on the shell you use, the escaping rules are different. Here you'll find examples of correct escaping and quotes when passing JSON objects on the command line using different shells.

The table below gives an overview of the escaping rules in these commonly used shells. VALUE refers to one single line in json.

Shell	Correct Escaping and Quotes
Bash	Use <code>--parameter "VALUE"</code> and escape quotes with <code>\</code> within VALUE  or  Use <code>--parameter 'VALUE'</code> and do not escape quotes within VALUE
Windows Command Prompt	Use <code>--param "VALUE"</code> and escape quotes with <code>\</code> within VALUE
Windows PowerShell	Use <code>--param "VALUE"</code> and escape quotes with <code>\</code> within VALUE

### → Tip

The CLI client provides examples in the command help for all commands. The examples that include JSON parameters use formatting that is compliant with Bash (Unix/Linux operating system, macOS) and Windows Command Prompt.

The command-line examples in this chapter are based on the following JSON:

```
{
  "Key1": ["Value1"],
  "Key2": ["Value1", "Value2"]
}
```

## Bash (Linux, macOS)

Option 1

```
--parameter "{ \"Key1\": [\"Value1\"], \"Key2\": [\"Value1\", \"Value2\"] }"
```

For example, when creating a subaccount (`btpt create accounts/subaccount`) with labels `Department = Sales` and `Contacts = name1@example.com` and `name2@example.com`, use the following syntax:

### 🔗 Sample Code

```
btpt create account/subaccount --display-name "my-subaccount" --region us10
--subdomain "my-subdomain" --labels "{ \"Department\": [\"Sales\"], \"Contacts\": [\"name1@example.com\", \"name2@example.com\"] }"
```

## Option 2

```
--parameter '{"Key1": ["Value1"], "Key2": ["Value1", "Value2"]}'
```

For example, when creating a subaccount (`btp create accounts/subaccount`) with labels `Department = Sales` and `Contacts = name1@example.com` and `name2@example.com`, use the following syntax:

### Sample Code

```
btp create account/subaccount --display-name "my-subaccount" --region us10
--subdomain my-subdomain --labels '{"Department": ["Sales"], "Contacts":
["name1@example.com", "name2@example.com"]}'
```

## Windows Command Prompt

```
--parameter "{\"Key1\":[\"Value1\"],\"Key2\":[\"Value1\", \"Value2\"]}"
```

For example, when creating a subaccount (`btp create accounts/subaccount`) with labels `Department = Sales` and `Contacts = name1@example.com` and `name2@example.com`, use the following syntax:

### Sample Code

```
btp create account/subaccount --display-name "my-subaccount" --region us10
--subdomain "my-subdomain" --labels "{\"Department\":[\"Sales\"],\"Contacts\":
[\"name1@example.com\", \"name2@example.com\"]}"
```

## Windows PowerShell

```
--parameter '{"Key1\":[\"Value1\"],[\"Key2\":[\"Value1\", \"Value2\"]}'
```

For example, when creating a subaccount (`btp create accounts/subaccount`) with labels `Department = Sales` and `Contacts = name1@example.com` and `name2@example.com`, use the following syntax:

### Sample Code

```
./btp create account/subaccount --display-name "my-subaccount" --region us10
--subdomain my-subdomain --labels '{"Department\":[\"Sales\"],\"Contacts\":
[\"name1@example.com\", \"name2@example.com\"]}'
```

## Passing JSON Parameters as Files

You can also transfer JSON parameters by providing the full path to a JSON file. For example:

```
btpt create services/binding --name my-binding-name --instance-name my-service-  
instance-name --parameters "<your-user-directory>/Documents/parameters.json"
```

## Related Information

[Working with Global Accounts, Directories, and Subaccounts Using the btpt CLI \[page 2168\]](#)

[Working with External Resource Providers Using the btpt CLI \[page 2174\]](#)

[Working with Environments Using the btpt CLI \[page 2172\]](#)

## 6.1.3.3 How to Work with the btpt CLI

Learn how to work with the SAP BTP command line interface (btpt CLI). For example, how to log in, get help, and set a default context for commands.

### General Commands

```
btpt help
```

```
btpt feedback
```

```
btpt login
```

```
btpt logout
```

```
btpt target
```

```
btpt enable autocomplete
```

```
btpt disable autocomplete
```

```
btpt list config
```

```
btpt set config
```

```
btpt reset config
```

## Options for Each Command

The following options are available for each command. They need to be typed right after the base call `btP`, and they can be combined (for example, `btP --verbose --help list accounts/subaccount`). The `--help` option also works at the end of a command call.

```
btP [OPTIONS] ACTION GROUP/OBJECT [PARAMS]
```

### Options

<code>--config</code>	Specifies the location of the configuration file. See <a href="#">Specify the Location of the Configuration File [page 2165]</a> .
<code>--info</code>	Displays client and server versions, target, and context. Note that this option only works on its own ( <code>btP --info</code> ) and cannot be added to other command calls. You can also just use <code>btP</code> to display this info. See <a href="#">View Version and Current Context [page 2149]</a> .
<code>--help</code>	Displays help. See <a href="#">Get Help [page 2148]</a> .
<code>--verbose</code>	Prints tracing information for support or for your own troubleshooting. See <a href="#">Troubleshooting and Support [page 2187]</a> .  To set the command output to verbose persistently, you can change the configuration settings with <code>btP set config --verbose true</code> . See <a href="#">Change Configuration Settings [page 2162]</a> .

#### ⚠ Caution

The `--verbose` option prints input data that you pass as parameters through files. For example, if you pass a `.json` file as a parameter without the `--verbose` option, its content is sent directly to the backend service to be processed. If you use the `--verbose` option, the `btP` CLI prints the content of the file to the terminal. If there is sensitive information in such a file, the `btP` CLI cannot filter it out, as it doesn't understand its semantics.

Use the verbose output only if you can control the output of your terminal, i.e. only locally. It should not be used in production or shared environments, where logs may be persisted or even transported out of the system.

## Options

---

<code>--format</code>	Changes the output format of a command to JSON. See <a href="#">Change the Output Format to JSON [page 2163]</a> .  To set the command output to json persistently, you can change the configuration settings with <code>btP set config --format json</code> . See <a href="#">Change Configuration Settings [page 2162]</a> .
<code>--version</code>	Prints the version of the client.

---

## Related Information

[btP CLI Command Reference](#)

### 6.1.3.3.1 Get Help

There is extensive help in the btP CLI about every command. You can get help with the `help` action or the `--help` option.

There are several ways to call help in the btP CLI, and there is help on all levels, from a basic entry page that explains the syntax to very detailed command-specific help that explains the usage of a command and its parameters in detail.

The easiest way to get help is probably the `help` action (for basic help, use `btP help`, as shown in the examples below. But you can also place `--help` at the end or beginning of a command call, for example, `btP list help`, `btP --help list`, and `btP list --help` are interchangeable.

Here's the help syntax:

- `btP help`
- `btP help <ACTION>`
- `btP help <GROUP>`
- `btP help <GROUP>/<OBJECT>`

Example Help Calls (progressing in level of detail)	What to Expect
<code>btP help</code>	Explains the syntax and shows plenty of examples.
<code>btP help all</code>	Displays an overview of all available commands, ordered according to their group/object combinations.
<code>btP help list</code>	Displays <i>list</i> commands with short summaries.
<code>btP help accounts</code>	Displays all objects in <i>accounts</i> group, and all available actions per group/object combination.

---

Example Help Calls (progressing in level of detail)	What to Expect
<code>btP help accounts/subaccount</code>	Displays all available commands for this group/object combination.
<code>btP help list accounts/subaccount</code>	Displays command-specific help, such as usage, a list of all parameters with descriptions, helpful tips, examples, and links to further documentation.

## Related Information

[Command Syntax of the btP CLI \[page 2141\]](#)

### 6.1.3.3.2 View Version and Current Context

To find out the current context you're working in, run the command `btP --info` or simply `btP`.

#### Procedure

Use `btP --info` or just `btP`.

The client displays its own version, usage information, the CLI server URL and version, the current user, the location of the configuration file, as well as the global account, directory, or subaccount you're targeting in their account hierarchy.

## Related Information

[Set a Target for Subsequent Commands with `btP target` \[page 2159\]](#)

### 6.1.3.3.3 Log in

Log in with the btP CLI is on global account level.

#### Prerequisites

- Your global account must be on feature set B. See [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

- You need to pass the CLI server URL. Usually, it is proposed during login and you can confirm with `ENTER`:  
`https://cli.btp.cloud.sap/` .  
 Note that in clients up until version 2.49.0, the old server URL `https://cpcli.cf.eu10.hana.ondemand.com` is proposed. For the time being, you can use either one, but we recommend to switch to `https://cli.btp.cloud.sap/` . If you are in a private cloud and your operator has provided you with a different server URL, you'll have to enter that one.
- Your user is assigned to the `Global Account Viewer` or the `Global Account Administrator` role collection. See [Role Collections and Roles in Global Accounts, Directories, and Subaccounts \[Feature Set B\] \[page 89\]](#).
- To log on with SAP Universal ID, you need to log on with the single sign-on parameter (`btp login --sso`). If you don't want to use single sign-on, log on with the password associated with your account (S-user or P-user) in the default identity provider, SAP ID service. If you've forgotten this password and this user is associated with your SAP Universal ID user, reset your password.  
 For more information, see SAP Note [3085908](#) and [Log in with Single Sign-On \[page 2153\]](#).

## Context

When you log in to your global account with the `btp` CLI, a token is created and stored on your computer that allows to close and reopen the command line without losing your login. With each command call, this token is renewed and valid for 12 hours. So, if you take a longer break from working with the `btp` CLI, you'll have to log in again. If you want to end your login earlier, you can use `btp logout`.

### Login with single sign-on

We recommend using single sign-on and authenticating directly at your identity provider through a web browser:

```
btp login --sso
```

See [Log in with Single Sign-On \[page 2153\]](#).

### Login with a custom identity provider

To login with a custom identity provider, use:

```
btp login --sso --idp <TENANT>
```

See [Log in with a Custom Identity Provider \[page 2154\]](#).

## Procedure

To log in manually, use `btp login`. The `btp` CLI prompts for all login information, but optionally, you can provide the required information as parameters.

Usage: `btp [OPTIONS] login [PARAMS]`

## Parameters

<code>--sso</code>	<p>Opens a browser for single sign-on at the identity provider. The <code>btcli</code> CLI doesn't prompt for this parameter. If you use SAP Universal ID, you need to use this parameter.</p> <p>To suppress automatic browser opening, use <code>--sso manual</code>.</p>
<code>--idp &lt;TENANT&gt;</code>	<p>This parameter is only needed if you want to log in through a custom identity provider. The CLI doesn't prompt for it.</p> <p>If trust is configured between your global account and a custom identity provider, use this parameter to log in through this identity provider by providing its tenant ID. To retrieve the required value, you can run <code>btcli list security/trust</code> and use the value from the <i>Tenant</i> column. Or you can use the Global Account view in the cockpit, under <i>Security</i> → <i>Trust Configuration</i> → <i>Custom Platform Identity Providers</i>. The value is displayed in the <i>BTP CLI</i> column.</p> <div data-bbox="821 920 1394 1332" style="border: 1px solid #ccc; padding: 10px;"><p><b>Note</b></p><p>To work with users from a custom identity provider, you need to specify the <code>--of-idp</code> parameter by providing the origin key of the custom identity provider. This is applicable to the following commands: <code>btcli list security/user</code>, <code>btcli get security/user</code>, <code>btcli delete security/user</code>, <code>btcli assign security/role-collection</code>, <code>btcli unassign security/role-collection</code>, and you find this origin key in the cockpit under <i>Security</i>.</p></div> <p>For more information about using a custom identity provider, see <a href="#">Establish Trust and Federation of Custom Identity Providers for Platform Users [Feature Set B] [page 2053]</a>.</p>
<code>--url &lt;URL&gt;</code>	<p>The client proposes this CLI server URL: <code>https://cli.btp.cloud.sap/</code>, which you can confirm by pressing <code>ENTER</code>. If your operator has provided you with a different server URL, you can specify it here. Note that when you enter a new server URL for the first time, you're asked to confirm that you trust it.</p>
<code>--user &lt;USER&gt;</code>	<p>Your user name, usually an email address.</p>

--password <PASSWORD>

Your password. If you have enabled Two-Factor-Authentication, append your token to your password.

#### → Tip

We don't recommend to provide the password with this parameter, as it appears in plain text and may be recorded in your shell history. Rather, enter it when you're prompted.

--subdomain <GLOBALACCOUNT>

In the interactive login, after successful authentication, the btp CLI will offer all of your global accounts so you can select the one to log in to.

You can also provide the global account as a parameter by specifying its subdomain. You should have obtained the subdomain from your operator; but you can also find it in the cockpit in the global account view.

[Trial Home](#) / [1234567xtrial](#)

Global Account: 1234567xtrial - Account Explorer

Filtered: 0 of 2 directories, 2 of 2 subaccounts | Subdomain: 1234567xtrial-ga

#### ⓘ Note

If you don't find the subdomain of the global account in your cockpit, your global account is probably not on SAP BTP feature set B, which means you cannot access it with the btp CLI. See [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

```
btp login
```

If you've logged in before, the server URL, the subdomain, and the user from the last login are suggested. You can then press Enter to confirm, or type in different values.

```
CLI server URL [https://cpcli.cf.eu10.hana.ondemand.com]>
Subdomain [my-global-account]>
User [name@example.com]>
```

## Results

Upon successful login, the btp CLI creates a folder (btp) and a configuration file (config.json) in the default location of your user data directory:

- Microsoft Windows: c:\Users\**<username>**\AppData\Roaming\SAP\btp\config.json
- Apple macOS: ~/Library/Application Support/.btp/config.json

- Linux: `~/.config/.btp/config.json`

To change this location, use the `--config` option or the environment variable. See [Specify the Location of the Configuration File \[page 2165\]](#).

#### → Tip

You've logged in to the global account and all commands are executed in this global account, unless you provide a subaccount or directory ID with the command. To change this default context for subsequent commands, you can target a subaccount or directory, or even a different global account by using `btp target`. See [Set a Target for Subsequent Commands with `btp target` \[page 2159\]](#).

### 6.1.3.3.1 Log in with Single Sign-On

Use the single sign-on parameter (`btp login --sso`) to log in to your identity provider through a browser instead of passing username and password on the command line.

## Prerequisites

Login through a browser is only available if you use the default server URL that is proposed by the CLI during login (`https://cli.btp.cloud.sap/`). This is the case unless your operator has provided you specifically with a different server URL.

## Context

If you have a custom identity provider configured in your global account, use `btp login --sso --idp <TENANT>`. See [Log in with a Custom Identity Provider \[page 2154\]](#).

#### → Tip

If you like logging in through single sign-on in a browser, you can configure this as the default behavior of `btp login` to save a few keystrokes at login. Use `btp set config --login.sso browser`. See [Change Configuration Settings \[page 2162\]](#).

## Procedure

1. Enter the following and press `ENTER` to be prompted for the server URL and the subdomain of your global account:

```
btpt login --sso
```

Alternatively, you can pass the server URL and the subdomain of your global account as parameters:

```
btpt login --sso --url https://cli.btp.cloud.sap/ --subdomain <my-subdomain>
```

To suppress the automatic browser-opening, you can run the command as follows:

```
btpt login --sso manual
```

2. Authenticate directly at your identity provider through your browser.

If you already have an active session, the identity provider immediately transfers a token to the client, which completes your login. Otherwise, you need to enter your credentials.

## Results

You've successfully logged in. You can return to the command line to work in your global account or `-` at first login `-` to select the global account for login.

## Related Information

### 6.1.3.3.2 Log in with a Custom Identity Provider

## Context

If trust is configured between your global account and a custom identity provider, you need to use the `--idp` parameter to log in through this identity provider. As value, you provide its tenant ID. To retrieve the required value, you can use `btpt list security/trust` and check the *Tenant* column. Or you can use the Global Account view of the cockpit under *Security* → *Trust Configuration* → *Custom Platform Identity Providers* and use the value from the *BTP CLI* column.

### Note

To work with users from a custom identity provider, you need to specify the `--of-idp` parameter by providing the origin key of the custom identity provider. This is applicable to the following commands: `btpt list security/user`, `btpt get security/user`, `btpt delete security/user`, `btpt assign security/role-collection`, `btpt unassign security/role-collection`, and you find this origin key in the cockpit under *Security*.

To learn how to configure trust to a custom identity provider, see [Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#) or the command help of `btpt create security/trust`.

### Restriction

Keep in mind that each user is allowed a maximum of 10 parallel sessions per identity provider. This number takes into account all tools, including the cockpit and CLIs.

For more information, see [Restrictions When Using Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2057\]](#).

## Procedure

1. To make use of single sign-on, log in with:

```
btpt login --sso --idp <TENANT>
```

2. To provide user and password on the command line, log in with:

```
btpt login --idp <TENANT>
```

You will be prompted for all required login information.

## Related Information

## 6.1.3.3.4 Log out

Logging out of the configured server removes all user-specific data from the configuration file.

### Context

Once you're finished using the `btp` CLI and you want to ensure that your locally stored credentials are immediately deleted, you can run the `logout` command. If you choose not to log out, your credentials will expire 24 hours after you last command execution, but the next time you log in, the `btp` CLI will propose your current subdomain and user so you won't have to type it in again.

### Procedure

To log out, use `btp logout`.

This terminates your active logout session and ensures that all user-specific data is removed. The next time you log in, you will have to type in the subdomain of the global account and your user.

### Related Information

[Log in \[page 2149\]](#)

## 6.1.3.3.5 Enable Command Autocompletion

Use command autocompletion to save keystrokes when entering command actions, group-object combinations, and their parameters in the SAP BTP command line interface (`btp` CLI).

### Context

Autocompletion in `btp` CLI currently supports the following shells:

- Bash
- PowerShell
- Zsh

#### Note

The respective shell must be installed on your operating system before enabling autocomplete.

Once autocomplete is enabled (it's disabled by default), you use the autocomplete feature as follows in the command line:

- Enter a partial command action, group-object combination, or parameter, and then press the `Tab` key. The command line either automatically completes your command or, when there's more than one option available, it displays a list of suggested command actions/options/parameters.
- When a suggestion list is displayed, depending on your shell, use the `Tab` or arrow keys to move through the list and press `Enter` to make a selection.

## Examples

The following examples show various ways that you can use autocomplete:

- Enter `btpr` and press `Tab` to display all available actions:

```
./btpr TAB
add          create      enable      list        logout      register
subscribe   unassign    unsubscribe
assign       delete      get         login       move        remove
target      unregister  update
```

- Partially enter `btpr cre` and press `Tab` to autocomplete the command to `btpr create`. Then, press `Tab` again to display a suggested list of group-object combinations:

```
./btpr create TAB
accounts/directory          accounts/resource-provider  security/
role                        services/binding
accounts/environment-instance  accounts/subaccount        security/role-
collection                  services/instance
```

- Partially enter a group and press `Tab` to display a suggested list of objects:

```
./btpr create accountsTAB
accounts/directory          accounts/environment-instance  accounts/
resource-provider          accounts/subaccount
```

- Partially enter a parameter and press `Tab` to display a suggested list of parameters:

```
./btpr create accounts/subaccount -TAB
--beta-enabled
--custom-properties
--description
--directory
--display-name
--global-account
--region
--subaccount-admins
--subdomain
--used-for-production
```

## Procedure

1. Use `btpr enable autocomplete <SHELL>` to enable command autocomplete for a specified shell.

The valid values for the supported shells are:

- `bash`

- powershell
- zsh

### Sample Code

```
btp enable autocomplete zsh
```

2. The client asks for confirmation to install the autocomplete plugin script at the specified location. Enter "y" or "yes" to continue.

Apart from the script being added to your file system, the RC file of your shell is modified to call this script at startup. The client looks for this RC file in your system and proposes possible files. You can choose to accept a proposal or specify a different RC file. If no RC file is found, the clients prints an error message with the full path of the missing file, so you can create it and run the enable command again.

3. Enter the option of your choice.

To specify a custom path, first choose "Custom" and then enter the full path of the RC file to use.

For example:

```
./btp enable autocomplete powershell
This will install the autocomplete plugin script for powershell to
C:\AppData\btp\autocomplete\scripts. Do you want to continue? [no]>y
Which RCFile should be used for the installation?
1: C:\Documents\WindowsPowerShell\Microsoft.PowerShell_profile.ps1
2: Custom
Enter option>2
Enter the full path of
your RCFile>C:\Documents\WindowsPowerShell\Microsoft.PowerShell_my-custom-
profile.ps1
```

4. Start a new terminal session to activate the installed autocomplete script.

## Results

When you enable command auto completion, a script containing all the autocomplete commands is downloaded and installed in your file system.

The auto completion option remains enabled in future sessions in your current client, until you disable it. To disable command auto completion and uninstall the autocomplete script, run the following command:

```
btp disable autocomplete <SHELL>
```

You can run either `btp` or `btp --info` to see if command auto completion is currently enabled and where the autocomplete script for your shell is located. If you don't see a line specifying the location of the autocomplete script, then it's disabled.

### → Tip

If you see a discrepancy between the version of the autocomplete script and the client, the update of the autocomplete script might have failed. In such a case, try to disable and enable the autocomplete feature again.

Whenever you start a new `btP` CLI terminal session, the installed autocomplete scripts are automatically updated to include the latest commands. If a script is updated, you're prompted to restart your terminal session to load the newest autocomplete information.

If disabling the command autocomplete fails or you have uninstalled the `btP` CLI client without disabling autocomplete, you can manually remove traces of the autocomplete installation in your shell initialization file (RC or profile file depending on your shell) by deleting the line that starts with `SAPCP_CLI_AUTOCOMPLETE`.

### 6.1.3.3.6 Set a Target for Subsequent Commands with `btP target`

Set the target for command calls to a subaccount, a directory, or a global account with the `btP target` command.

#### Context

During login, the `btP` CLI asks you for the global account you want to log in to and this global account is then the target. This means that commands are executed in this global account unless you specify otherwise via a parameter. There are two typical use cases for the `target` command:

- If you know that you need to work in a particular subaccount or directory, you can change the target, so that you won't have to specify that subaccount's or directory's ID as a parameter with every command call.
- If you want to switch to another global account, you can do so by setting the target to this global account without logging in again.

By setting the target to a subaccount or directory, you also target its parent entities, that is, the **target hierarchy**. If no parameter is specified in a command call, the `btP` CLI will execute the command in the innermost targeted entity where a command is applicable. If a subaccount is targeted that is inside a directory and the command is not available on subaccount level, it will be executed in the parent directory (if it's a directory command) or in the parent global account (if it's a global account command). This can be useful, for example, if you have targeted a subaccount, but want to update its parent directory. You can then execute `btP update accounts/directory` without specifying the directory ID.

To see the current target, use `btP --info` or simply `btP`.

To explicitly execute a command in a parent entity instead of in the target, you can specify this with `'-dir'` or `'-ga'` parameters without a value. The value is then taken from the target hierarchy. This can be useful, for example, if you have targeted a subaccount, but want to list the users of the parent directory. You can then execute `btP list security/user -dir`. Note, however, that this command is only available on a directory level if the directory is enabled to manage authorizations.

Usage: `btP [OPTIONS] target [PARAMS]`

## Procedure

1. Use `btpt target` to set the target for subsequent commands.
  - Run the command without parameters to see the children, siblings and parent of you current target. You can then select your target or navigate up and down.
  - Enter `--hierarchy` as parameter to see all your global accounts with their entire account hierarchies. You can then select your target from this list.

### → Tip

If you like the `--hierarchy` parameter and would like to make it the default for the `target` command, you can define it as a configuration setting with `btpt set config --target.hierarchy true`. If you then run `btpt target`, the entire hierarchy of all your global accounts is shown.

- Specify the subaccount, directory, or global account you want to target as described in the next step.
2. Enter one of the following parameters:

Parameter	Description
<code>--global-account, -ga &lt;SUBDOMAIN&gt;</code>	The subdomain of the global account to be targeted.
<code>--directory, -dir&lt;ID&gt;</code>	The ID of the directory to be targeted. You can find the directory ID by using <code>btpt get accounts/global-account --show-hierarchy</code> .
<code>--subaccount, -sa &lt;ID&gt;</code>	The ID of the subaccount to be targeted. You can find the subaccount ID by using <code>btpt list accounts/subaccount</code> .

## Results

The CLI client displays the current target as a hierarchy. To execute a command in the targeted entity, you can omit the corresponding parameter.

## Example

A global account can group together different directories and subaccounts that the global account administrator makes available to users. CLI commands can be executed on all levels of this account hierarchy, that is in the global account, a directory, or a subaccount, usually specified by the above-mentioned parameters. The table below shows some example commands, and explains in which account entity they can be executed and how the target mechanism can be used.

Let's look at a global account that contains a directory with a targeted subaccount. With `btpt`, the current target hierarchy is displayed like this:

```
Current target:
```

```

My Global Account (global account, subdomain: cee12xx112345-ga)
├─ My Directory (directory, ID: 371eXXXX-55XX-40XX-b3XX-e9947ed9XXXX)
│   └─ My Subaccount (subaccount, ID: d8aeXXXX-74XX-49XX-89XX-f058029eXXXX)

```

Now, when you run commands without specifying an account entity as parameter, they are executed in the targeted subaccount or in one of its parents.

Example Command	Command is Available for	Command is Executed in
<code>btm get accounts/available-environment</code>	<code>--subaccount</code>	The targeted subaccount
<code>btm update accounts/directory</code>	<code>[directory] ID</code> Note that the directory ID is a positional parameter in this command. You can omit it when a subaccount inside the directory is targeted: <code>btm update accounts/directory [directory ID]</code> .	The parent directory of the targeted subaccount
<code>btm list accounts/available-region</code>	<code>--global-account</code>	The parent global account of the targeted subaccount
<code>btm list security/user</code>	<code>--global-account</code> <code>--directory</code> <code>--subaccount</code>	The targeted subaccount
<code>btm list security/user --subaccount "1111XXXX-22XX-33XX-44XX-555555XXXX"</code>	<code>--global-account</code> <code>--directory</code> <code>--subaccount</code>	The specified subaccount, which overrides the target

**→ Tip**  
To execute this command in a parent entity, use the `-dir` or `-ga` parameter without a value.

## 6.1.3.3.7 Change Configuration Settings

Change the configuration settings to customize the behavior of the `btP` CLI.

### Context

There are a few configuration settings that you can set to customize how the `btP` CLI works.
