# 1 SAP Business Technology Platform

SAP Business Technology Platform (SAP BTP) is an integrated offering comprised of four technology portfolios: database and data management, application development and integration, analytics, and intelligent technologies. The platform offers users the ability to turn data into business value, compose end-to-end business processes, and build and extend SAP applications quickly.

## SAP BTP in the Intelligent Enterprise

Nowadays, companies need access to live data to make informed decisions in real time and apply advanced technologies and best practices within agile, integrated business processes. That's why a key part of SAP's strategy is integrating end-to-end processes – whether the solutions are from SAP, from partners, or from third parties.

At SAP, we drive integration across our solution portfolio, including the following business scenarios: lead to cash, source to pay, design to operate, and hire to retire.

The SAP Business Technology Platform provides integration capabilities to ensure connected end-to-end business processes across SAP and third-party applications. The following key aspects, called Suite Qualities, facilitate a consistent experience across applications:

- **Seamless User Experience:** SAP Fiori can be used to gain a common look and feel of many SAP solutions, which improves user experience and reduces interruptions.  
See: [SAP Fiori](#).
- **Consistent Security and Identity Management:** SAP Cloud Identity services on SAP BTP enable you to manage identities and use the single sign-on capability across selected end-to-end processes.  
See: [SAP Cloud Identity Services](#) on SAP BTP.
- **Aligned Domain Models, APIs and Events:** Master Data Integration is a cloud service for master data integration. It provides a consistent view on master data across a hybrid landscape. You can use APIs for process integration among SAP solutions, SAP, and third parties, or by adopting an event-based integration strategy – all based on predefined integration content available on SAP API Business Hub.  
See: [SAP One Domain Model](#), [SAP Master Data Integration service](#), [SAP Integration Suite](#) on SAP BTP
- **Embedded Analytics across Solutions:** The analytical insights in various SAP solutions helps you make informed decisions. Embedded analytics from SAP Analytics Cloud are available e.g., in SAP S/4HANA and SAP SuccessFactors.  
See: [SAP Analytics Cloud](#) on SAP BTP.
- **One Workflow Inbox:** With the unified view of pending tasks across SAP solutions in both mobile and desktop environments, you can complete tasks faster.  
See: [SAP Task Center](#) on SAP BTP, [SAP Mobile Start](#). For full workflow modeling and visibility capabilities leverage, see: [SAP Process Automation](#) on SAP BTP
- **Coordinated Lifecycle Management:** Harmonized provisioning, setup and operations, and monitoring solutions allow you to optimize implementation projects and reduce manual integration configuration effort. Automated provisioning and guided integration setup are available for selected scenarios in lead to cash, source to pay, recruit to retire, and design to operate.

See: [SAP for Me](#), [SAP CALM](#)

- End-to-End Process Blueprints: Process blueprints that follow the Industry Reference Architecture standard can help you reduce planning effort for implementation projects and also support architecture decisions.

See: [SAP API Business Hub](#)

## About This Guide

Get an overview of the basic platform concepts of SAP BTP and how they relate to each other. Learn how to manage your accounts and how to develop, extend, administer, and secure your cloud setup and applications on the platform.

### → Tip

The English version of this guide is open for contributions and feedback using GitHub. This allows you to get in contact with responsible authors of SAP Help Portal pages and the development team to discuss documentation-related issues. To contribute to this guide, or to provide feedback, choose the corresponding option on SAP Help Portal:

- [Feedback > Create issue](#): Provide feedback about a documentation page. This option opens an issue on GitHub.
- [Feedback > Edit page](#): Contribute to a documentation page. This option opens a pull request on GitHub.

You need a GitHub account to use these options.

## Services and Solutions

Get an overview on the availability of SAP BTP solutions and services according to region, infrastructure provider, and license model. Access the service details pages for information on features, service plans, related tools, APIs, and documentation: [SAP Discovery Center: Service Catalog](#).

## Neo Environment

To access the documentation for the Neo environment, see [SAP BTP, Neo environment](#).

To learn more about why and how to migrate your scenarios in the Neo environment, see [Migrating from the SAP BTP Neo Environment to the Multi-Cloud Foundation](#).

## All SAP BTP Resources

Access all of our resources on the product page: [SAP Business Technology Platform \(SAP BTP\)](#).

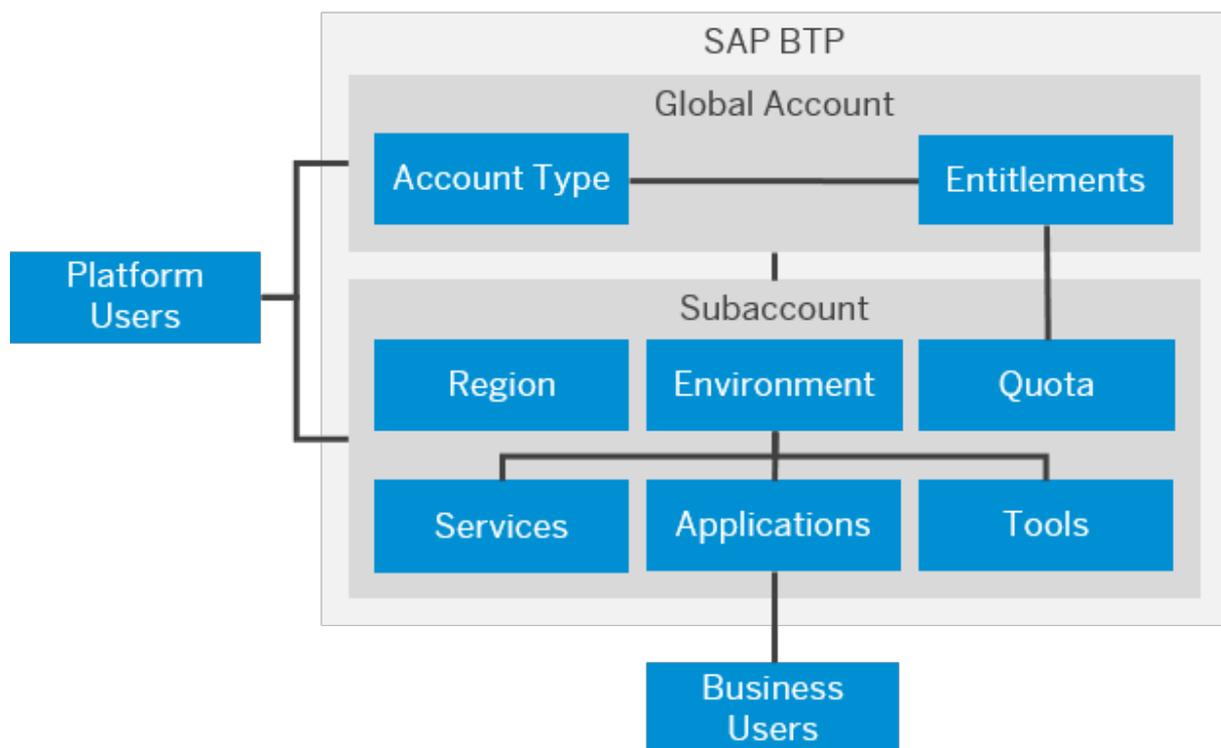

## 2 Basic Platform Concepts

SAP BTP offers users the ability to turn data into business value, compose end-to-end business processes, and build and extend SAP applications quickly.

SAP Business Technology Platform is built on a multi-cloud foundation, which lets you choose from different infrastructures and runtimes. The services and solutions of SAP BTP are available on multiple cloud infrastructure providers, and it supports different runtimes, such as Cloud Foundry, ABAP, and Kyma, as well as multiple different regions, and a broad choice of programming languages.

The counterpart of the multi-cloud foundation of SAP BTP is SAP BTP, Neo. To access the documentation for Neo, see [What Is SAP BTP, Neo Environment](#). For migration information, see [Migrating from the SAP BTP Neo Environment to the Multi-Cloud Foundation](#).

The central point of entry to the platform is the **SAP BTP cockpit**, where you can access your accounts and applications and manage all activities associated with them.

Relationship between SAP BTP Accounts and Associated Activities

### Solutions and Services

SAP BTP offers fast in-memory processing, sustainable, agile **solutions** and **services** to integrate data and extend applications, and fully embedded analytics and intelligent technologies.

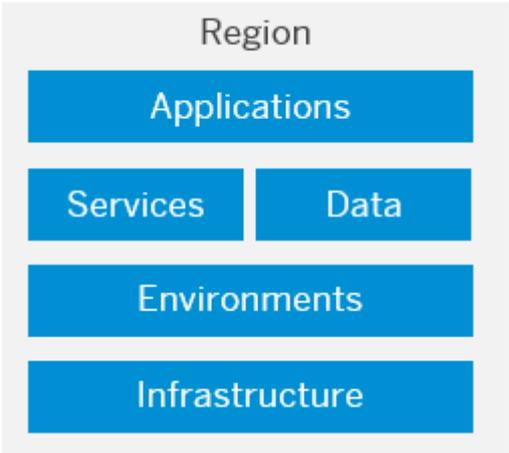

**Services** enable, facilitate, or accelerate the development of business applications and other platform services on SAP BTP.

For a complete list of services and capabilities, see [SAP Discovery Center: Services](#).

For more information, see [Solutions and Services \[page 16\]](#).

## Regions

You can deploy applications in different **regions**. Each region represents a geographical location (for example, Europe, US East) where applications, data, or services are hosted.

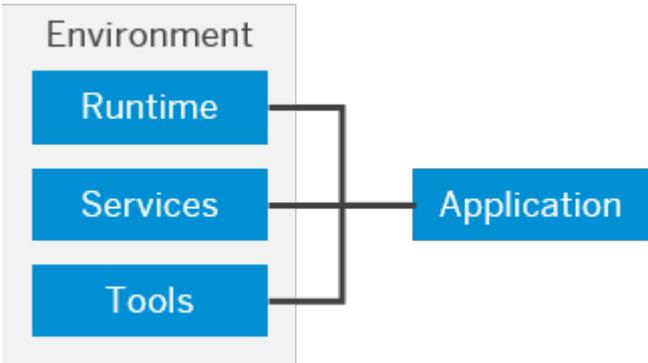

Regions are provided either by SAP or by our Infrastructure-as-a-Service (IaaS) partners Amazon Web Services (AWS), Microsoft Azure, Google Cloud, and Alibaba Cloud. The third-party region providers operate the infrastructure layer of the regions, whereas SAP operates the platform layer and Cloud Foundry.

A region is chosen at the subaccount level. For each subaccount, you select exactly one region (that is one data center).

For more information, see [Regions \[page 17\]](#).

## Environments

Environments constitute the actual platform-as-a-service offering of SAP BTP that allows for the development and administration of business applications. Environments are anchored in SAP BTP on subaccount level.

SAP BTP provides the following environments:

- [Cloud Foundry Environment \[page 44\]](#)  
The Cloud Foundry environment enables you to develop new business applications and business services, supporting multiple runtimes, programming languages, libraries, and services. You can leverage a multitude of buildpacks, including community innovations and self-developed buildpacks.
- [ABAP Environment \[page 49\]](#)  
Within the Cloud Foundry environment, you can create a new space for ABAP development. This is what we refer to as the ABAP environment. It allows you to create extensions for ABAP-based products, such as SAP S/4HANA Cloud, and develop new cloud applications. You can transform existing ABAP-based custom code or extensions to the cloud.
- [Kyma Environment \[page 54\]](#)  
The Kyma environment is a fully managed Kubernetes runtime based on the open-source project "Kyma" that allows developers to extend SAP solutions with serverless functions and combine them with containerized microservices.
- [Neo Environment \[page 62\]](#)  
The Neo environment lets you develop HTML5, Java, and SAP HANA extended application services (SAP HANA XS) applications. You can also use the UI Development Toolkit for HTML5 (SAPUI5) to develop rich user interfaces for modern web-based business applications.

## Enterprise and Trial Accounts

SAP BTP provides different types of global accounts, **enterprise** and **trial**. The type you choose determines pricing, conditions of use, resources, available services, and hosts.

- A **trial account** lets you try out the platform for free. Access is open to everyone. Trial accounts are intended for personal exploration, and not for production use or team development. They allow restricted use of the platform resources and services.  
For more information, see [Trial Accounts and Free Tier \[page 63\]](#).
- An **enterprise account** is usually associated with one SAP customer or partner and contains their purchased entitlements to platform resources and services. It groups together different subaccounts that an administrator makes available to users for deploying applications.  
For more information, see [Enterprise Accounts \[page 65\]](#).

## Commercial Models

SAP BTP offers two different commercial models:

- **Consumption-based commercial model:** Your organization receives access to all current and future services that are eligible for this model. You have complete flexibility to turn services on and off and to switch between services as your business requires throughout the duration of your contract. This commercial model is available in the following flavors: SAP BTP Enterprise Agreement (SAP BTPEA), Cloud Platform Enterprise Agreement (CPEA), and Pay-As-You-Go for SAP BTP. For more information, see [What Is the Consumption-Based Commercial Model? \[page 68\]](#)
- **Subscription-based commercial model:** Your organization subscribes only to the services that you plan to use. You can then use these services at a fixed cost, irrespective of consumption. For more information, see [What Is the Subscription-Based Commercial Model? \[page 71\]](#)

## Account Model Feature Set A

The SAP BTP cockpit is structured according to global accounts and subaccounts:

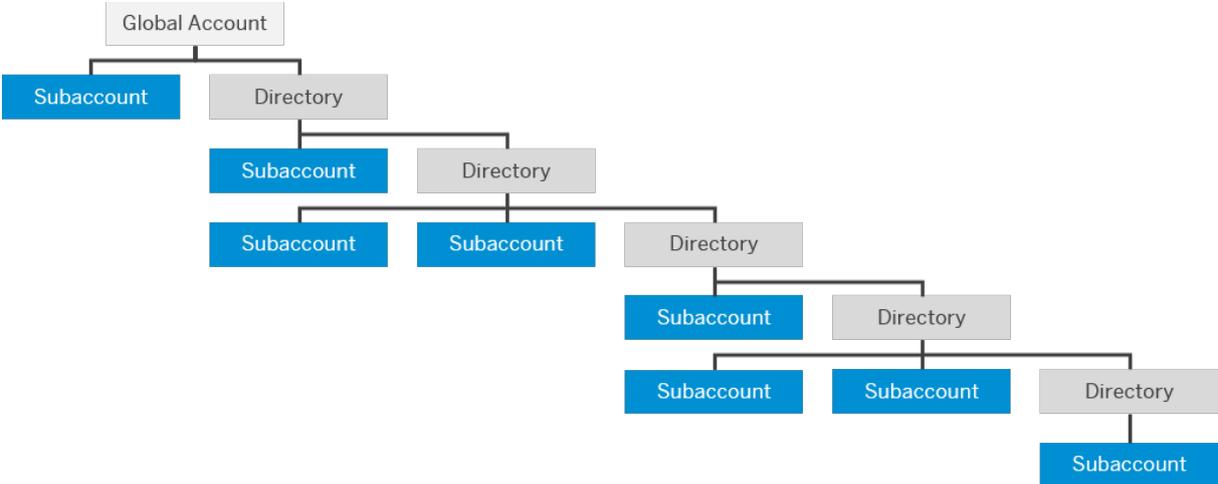

- A **global account** is the realization of a contract you or your company has made with SAP. A global account is used to manage subaccounts, members, entitlements and quotas. You receive entitlements and quotas to use platform resources per global account and then distribute the entitlements and quotas to the subaccount for actual consumption. There are two types of commercial models for global accounts: consumption-based model and subscription-based model. See [Commercial Models \[page 67\]](#)
- **Subaccounts** let you structure a global account according to your organization's and project's requirements with regard to members, authorizations, and entitlements. In the SAP BTP, Cloud Foundry environment, the subaccount is divided into one or more spaces, which is where application development, deployment, and maintenance take place.

For more information, see [Account Model \[page 75\]](#).

## Account Model Feature Set B

The SAP BTP cockpit is structured according to global accounts, directories, and subaccounts:

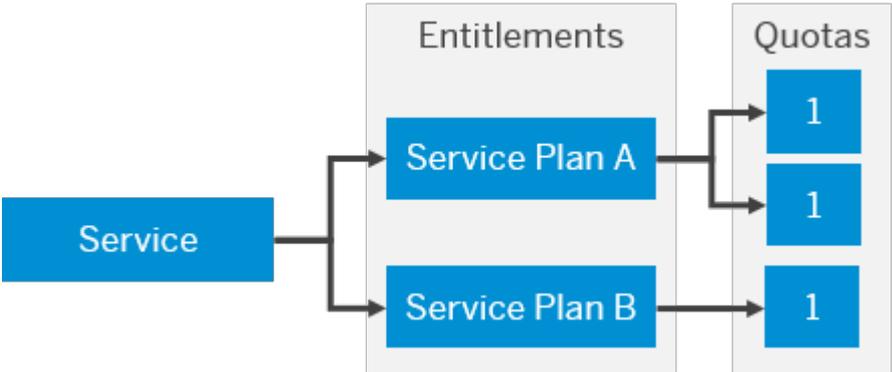

- A **global account** is the realization of a contract you or your company has made with SAP. A global account is used to manage subaccounts, members, entitlements and quotas. You receive entitlements and quotas to use platform resources per global account and then distribute the entitlements and quotas to the subaccount for actual consumption. There are two types of commercial models for global accounts: consumption-based model and subscription-based model. See [Commercial Models \[page 67\]](#)
- With **directories**, you can organize and manage your subaccounts according to your technical and business needs.
- **Subaccounts** let you structure a global account according to your organization's and project's requirements with regard to members, authorizations, and entitlements. In the SAP BTP, Cloud Foundry environment, the subaccount is divided into one or more spaces, which is where application development, deployment, and maintenance take place.

For more information, see [Account Model \[page 75\]](#).

## Entitlements and Quotas

When you purchase an enterprise account, you're entitled to use a specific set of resources, such as the amount of memory that can be allocated to your applications.

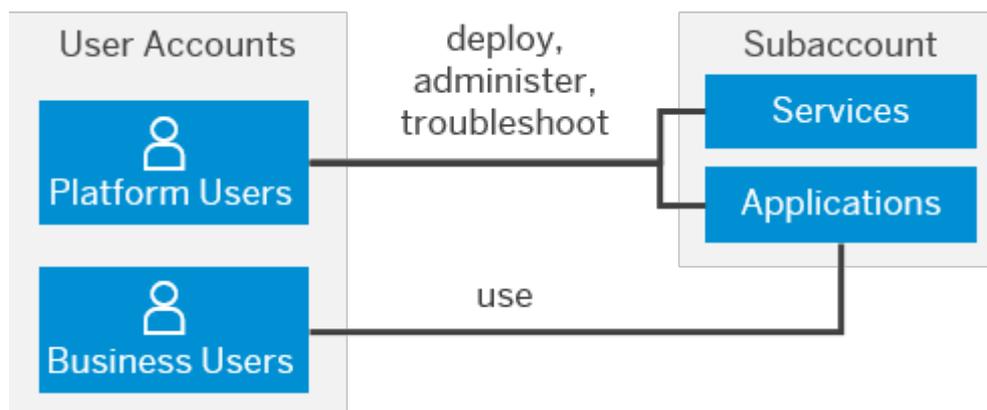

- On SAP BTP, all external dependencies such as databases, messaging systems, files systems, and so on, are **services**. In this context, multitenant applications and environments are considered services. Each service has one or more **service plans** available. A service plan is the representation of the costs and benefits for a given variant of a particular service. For instance, a database may be configured with various "T-shirt sizes", each of which is a different service plan.
- An **entitlement** is your right to provision and consume a resource. In other words, entitlements are **the service plans** that you're entitled to use.
- A **quota** represents the numeric quantity of a service plan that you're entitled to consume in your global account and its subaccounts.

For more information, see [Entitlements and Quotas \[page 81\]](#).

## User and Member Management

On SAP BTP, member management happens at all levels from global account to environment, while user management is done for business applications.

**User accounts** enable users to log on to SAP BTP and access subaccounts and use services according to the permissions given to them. We distinguish between two types of users:

- **Platform users** are usually developers, administrators or operators who deploy, administer, and troubleshoot applications and services on SAP BTP.
- **Business users** use the applications that are deployed to SAP BTP. For example, the end users of SaaS apps or services, such as SAP Workflow service or SAP Cloud Integration, or end users of your custom applications are business users.

**Member management** refers to managing permissions for platform users. A member is a user who is assigned to an SAP BTP global account or subaccount. Administrators can add users to global accounts and subaccounts and assign roles to them as needed. You can use predefined roles, for example the administrator role for managing subaccount members.

**User management** refers to managing authentication and authorization for your business users.

For more information, see [User and Member Management \[page 85\]](#).

## Tools, Programming Models, Programming Languages, and APIs

SAP BTP provides various programming languages and tools for your development project:

- SAP BTP includes many tools to help you develop and manage applications, and connect them to your on-premise systems. For more information, see [Tools \[page 105\]](#).
- SAP BTP supports many different programming languages; the availability of each depends on the development environment you're using. For more information, see [Programming Languages \[page 106\]](#).
- The SAP Cloud Application Programming Model offers a consistent end-to-end programming model that includes languages, libraries, and APIs that are tailored for full-stack development on SAP BTP. For more information, see [SAP Cloud Application Programming Model \[page 107\]](#).
- Depending on your use case, you can choose between different offerings for continuous integration and delivery. For more information, see [Continuous Integration and Delivery \(CI/CD\) \[page 107\]](#).
- Discover and consume APIs to manage, build, and extend the core capabilities of SAP BTP. For more information, see [APIs \[page 110\]](#).

## 2.1 Solutions and Services

Consume the solutions and services by SAP BTP according to your preferred development environment and use cases.

### Solutions

SAP BTP offers fast in-memory processing, sustainable, agile **solutions** and **services** to integrate data and extend applications, and fully embedded analytics and intelligent technologies.

### Services

**Services** enable, facilitate, or accelerate the development of business applications and other platform services on SAP BTP. Services are grouped into the following service types:

- **Business services:** Services that enable, facilitate, or accelerate the development of business process components or provide industry-specific functionalities or content within a business application.
- **Technical services:** Services that enable, facilitate, or accelerate the development of general or domain independent content within a business application, independent of the application's business process or task.

You find all available services, solutions, and use cases in the [SAP Discovery Center](#) .

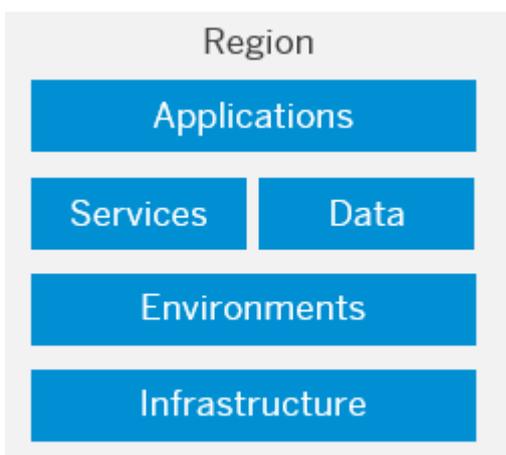

Use the service catalog to access service-specific resources:

## 2.2 Regions

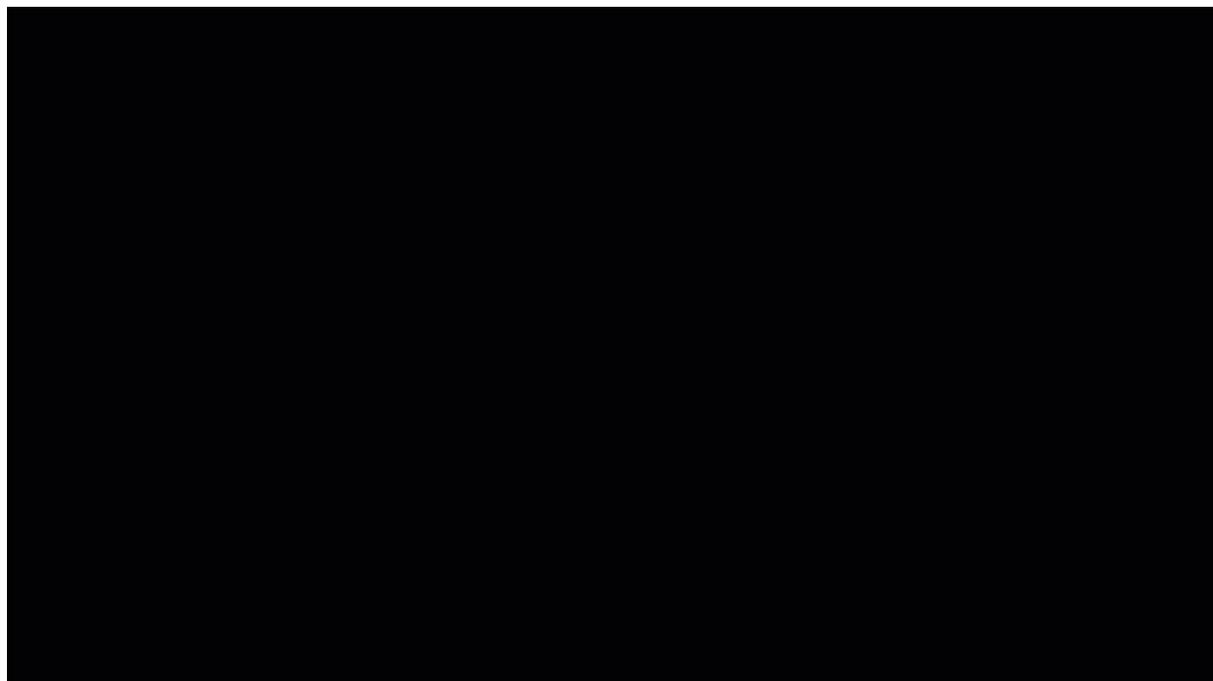

You can deploy applications in different **regions**. Each region represents a geographical location (for example, Europe, US East) where applications, data, or services are hosted.

### About SAP BTP Regions

Regions are provided either by SAP or by our Infrastructure-as-a-Service (IaaS) partners Amazon Web Services (AWS), Microsoft Azure, Google Cloud, and Alibaba Cloud. The third-party region providers operate the infrastructure layer of the regions, whereas SAP operates the platform layer and Cloud Foundry.

For an overview of all available regions, see [SAP Discovery Center](#):

## Selecting a Region

A region is chosen at the subaccount level. For each subaccount, you select exactly one region. The selection of a region is dependent on many factors: For example, application performance (response time, latency) can be optimized by selecting a region close to the user. For more information, see [Selecting a Region](#).

## Deploying Applications in Regions

When deploying applications, consider that a subaccount is associated with a particular region and that this is independent of your own location. You may be located in the United States, for example, but operate your subaccount in a region in Europe. For more information on subaccounts, see [Subaccounts \[page 75\]](#).

To deploy an application in more than one region, execute the deployment separately for each host. For more information, see [Deploy an Application \[page 2295\]](#).

Within a region, there can be multiple instances of the SAP BTP, Cloud Foundry environment. When creating a subaccount, SAP BTP automatically assigns the account to a specific instance of the environment. Several subaccounts of the same global account can be located in different datacenters in one region. This also affects the format of the API endpoint URL that is displayed in the cockpit after enabling Cloud Foundry in your

subaccount. There are two possible formats for the API endpoint URL, either displayed with or without an index. Here's an example for **eu10**:

#### ❁ Example

- <https://api.cf.eu10.hana.ondemand.com>
- <https://api.cf.eu10-<XXX>.hana.ondemand.com>

In both cases, the subaccount is located in the region eu10. The differences in the URLs are only an indicator of technical details on the side of SAP BTP and do not affect the functionality of your applications. For information on enabling Cloud Foundry, see [Create Orgs \[page 2247\]](#).

## High Availability

SAP has a number of processes in place to support resilience in SAP BTP, and provides different offerings so that you can support the high availability of your applications. For more information, see [Resilience, High Availability, and Disaster Recovery \[page 40\]](#).

## EU Access

Some customer contracts include EU Access, which restricts processing of personal data to EEA/Switzerland. If the global account is marked with EU Access, the actual EU Access compliance status of subaccounts will be displayed during creation of subaccounts.

#### 📘 Note

If you require a subaccount with EU Access, make sure to select a provider and region where EU Access is available. Regions that allow for EU Access are labeled as such in the map view filter in the SAP Discovery Center.

For some services, EU Access is generally not available, not even if the provider and region support EU Access.

## Related Information

[Regions and API Endpoints Available for the Cloud Foundry Environment \[page 20\]](#)

[Regions and API Endpoints for the ABAP Environment \[page 33\]](#)

[Regions for the Kyma Environment \[page 37\]](#)

## 2.2.1 Regions and API Endpoints Available for the Cloud Foundry Environment

Regions for Enterprise Accounts

IaaS Provider	Region	Region Name	Technical Key	Technical Key of IaaS Provider	NAT IPs (egress, IPs for requests from a Cloud Foundry app)	LB IPs (ingress, for incoming requests)	API Endpoint	Domain	Cockpit Logon

## Regions for Trial Accounts

laaS Provider	Region	Region Name	Technical Key	Technical Key of laaS Provider	Trial NAT IPs (egress, IPs for requests from a Cloud Foundry app)	LB IPs (ingress, for incoming requests)	API Endpoint	Domain	Cockpit Logon
Amazon Web Services	us10	US East (VA)	cf-us10	us-east-1	3.218.99.154, 52.72.147.227, 3.218.112.63	52.23.189.23, 52.4.101.240, 52.23.1.211	api.cf.us10.hana.on-de-mand.com	us10.hana.ondemand.com	<a href="#">Trial</a>
Microsoft Azure	ap21	Singapore	cf-ap21	Southeast Asia	52.139.216.172, 20.195.24.178, 20.195.9.69	20.184.61.122	api.cf.ap21.hana.on-de-mand.com	ap21.hana.ondemand.com	<a href="#">Trial</a>

### Note

Trial accounts and subaccounts on trial can no longer be created on eu10, Europe (Frankfurt). Existing trial accounts and subaccounts are not affected.

### Note

In the Cloud Foundry environment, IPs are controlled by the respective laaS provider (AWS, Azure, or Google Cloud). IPs may change due to network updates on the provider side. Any planned changes will be announced at least four weeks before they take effect.

### Note

In the Cloud Foundry environment, the region in which a global account was created determines the API endpoint of all subaccounts associated with it. For example, subaccounts created in a global account in region **eu10** share the API endpoint URL `api.cf.eu10.hana.ondemand.com`.

## 2.2.2 Regions and API Endpoints for the ABAP Environment

## 2.2.3 Regions for the Kyma Environment

To work with the Kyma environment, you need to specify the region for both your subaccount and the cluster.

### Note

In the Kyma environment, IP addresses for NAT Gateway that handles the egress traffic are configured dynamically. This means that you cannot identify the IP address of NAT Gateway in advance. However, once the IP address is assigned, it remains unchanged throughout the cluster's lifecycle.

## Subaccount Regions

The table lists the regions you can choose from when creating a subaccount.

Subaccount Regions for Kyma

Global Account Type	Region	IaaS Provider	Technical Key	Region Name	Plan ID
Enterprise account Partner Test, Demo, and Development account Trial account	ap21	Microsoft Azure	cf-ap21	Singapore	azure azure_lite trial
	us20	Microsoft Azure	cf-us20	US West (WA)	azure azure_lite
	jp20	Microsoft Azure	cf-jp20	Japan (Tokyo)	azure azure_lite
Enterprise account Partner Test, Demo, and Development account	us21	Microsoft Azure	cf-us21	US East (VA)	azure azure_lite
	eu20	Microsoft Azure	cf-eu20	Europe (Netherlands)	azure azure_lite

Global Account Type	Region	IaaS Provider	Technical Key	Region Name	Plan ID
Enterprise account Partner Test, Demo, and Development account	ap20	Microsoft Azure	cf-ap20	Australia (Sydney)	azure azure_lite
Enterprise account Trial account	us10	Amazon Web Services	cf-us10	US East (VA)	aws trial
Enterprise account Trial account	eu10	Amazon Web Services	cf-eu10	Europe (Frankfurt)	aws trial
Enterprise account	eu11	Amazon Web Services	cf-eu11 <sup>1</sup> <a href="#">[page 38]</a>	Europe (Frankfurt) EU Access	aws

Enterprise account	jp30	Google Cloud	cf-jp30	Japan (Osaka)	gcp
Enterprise account	sa30	Google Cloud	cf-sa30	KSA (Dammam)	gcp

### Note

1. This is an EU-Access-only region. Due to limited availability, you must open a support ticket before attempting to provision Kyma clusters in the EU-Access-only regions. To create the ticket, use the appropriate link for [internal](#) or [external](#) customers.

## Cluster Regions

When you enable a Kyma environment for a given subaccount, you must select a plan and region where the cluster is going to be created. Note that there is a number of regions available within each plan. They are all listed in the table:

Cluster Regions

Hyperscaler	Plan ID	Region	Region Name	
Microsoft Azure	azure	centralus	US Central (IA)	
		eastus	US East (VA)	
		westus2	US West (WA)	
		northeurope	North EU (Ireland)	
		uksouth	UK South (London)	
		japaneast	Japan (Tokyo)	
		southeastasia	Singapore	
		westeurope	Europe (Netherlands)	
		australiaeast	Australia (Sydney)	
	azure_lite	centralus	US Central (IA)	
		eastus	US East (VA)	
		westus2	US West (WA)	
		northeurope	North EU (Ireland)	
		uksouth	UK South (London)	
		australiaeast	Australia (Sydney)	
	trial	southeastasia	Singapore	
	Amazon Web Services	aws	eu-central-1	Europe (Frankfurt)
			eu-west-2	Europe (London)
			ca-central-1	Canada (Montreal)
sa-east-1			Brazil (São Paulo)	
us-east-1			US East (VA)	
us-west-1			US West (N. California)	
ap-northeast-1			Japan (Tokyo)	
ap-northeast-2			South Korea (Seoul)	
ap-south-1			India (Mumbai)	
ap-southeast-1			Singapore	
ap-southeast-2			Australia (Sydney)	
trial			eu-central-1	Europe (Frankfurt)

Hyperscaler	Plan ID	Region	Region Name
		us-east-1	US East (VA)
Google Cloud	gcp	europa-west3	Europe (Frankfurt)
		us-central1	US Central (IA)
		asia-south1	India (Mumbai)
		asia-northeast2	Japan (Osaka)
		me-central2	KSA (Dammam)

## Load Balancers

Depending on the IaaS Provider, the following Load Balancers are provisioned by default:

Default Load Balancers

IaaS Provider	Default Load Balancer
Microsoft Azure	Standard
Amazon Web Services	Classic Network Load Balancer
Google Cloud	External passthrough Network Load Balancer

For more details on the Load Balancers and their features, check out the official documentation of the respective IaaS provider.

## 2.2.4 Resilience, High Availability, and Disaster Recovery

SAP has a number of processes in place to support resilience in SAP BTP, and provides different offerings so that you can support the high availability of your applications.

### How SAP Provides Resilience

SAP applies resilience principles when developing, updating, and deploying our SAP BTP applications and services.

SAP BTP provides resilience through the following:

Processes and Offerings	Description	Regional Availability
<b>Availability Zones</b>	To achieve better fault-tolerance in the Cloud Foundry environment, we deploy our services across multiple AZs, which improves the availability of a service if there are issues with the infrastructure of one AZ. For more information, see <a href="#">Availability Zones in the Cloud Foundry Environment [page 47]</a> .	All regions that support the Cloud Foundry environment. See <a href="#">Regions and API Endpoints Available for the Cloud Foundry Environment [page 20]</a> .
<b>Backups in the Kyma environment</b>	The Kyma environment relies on managed Kubernetes clusters for periodic backups of Kubernetes objects. For more information, see <a href="#">Kyma Environment Backup</a> .	All regions that support the Kyma environment. See <a href="#">Regions for the Kyma Environment [page 37]</a> .
<b>Backup and Recovery for SAP HANA Cloud</b>	If you use SAP HANA Cloud, your SAP HANA Cloud instances are continually backed up to safeguard your database and ensure that it can be recovered speedily. For more information, see <a href="#">Backup and Recovery</a> .	All regions where SAP HANA Cloud is available. See <a href="#">Availability of SAP HANA Cloud</a> .
<b>Disaster Recovery</b>	The SAP BTP Disaster Recovery (DR) Plan is part of the overall SAP BTP Business Continuity Plan, which includes crisis management and process continuity activities that are triggered by a declared disaster. For more information, see <a href="#">Disaster Recovery as Part of the Business Continuity Plan [page 42]</a> .	All regions.

## Best Practices for Resilient Applications

In addition to the services offered by SAP BTP, you can follow our best practices for developing and deploying applications, which allow you to make your application running on SAP BTP stable and highly available.

- **Develop Resilient Applications**

When developing your applications, apply the principles and patterns of resilient software design that fit your use case. For more information, see [Developing Resilient Apps on SAP BTP](#). For situations where the load is highly available and where applications need to react by scaling, consider using Application Autoscaler. For more information, see [What Is Application Autoscaler?](#)

- **Working with Availability Zones**

To benefit from the high availability mechanisms in Cloud Foundry, set up your applications with multiple instances. For more information, see [Developing Resilient Applications in the Cloud Foundry Environment](#).

### 2.2.4.1 Disaster Recovery as Part of the Business Continuity Plan

The cloud platform disaster recovery (DR) plan is part of the overall cloud platform business continuity plan, which includes crisis management and process continuity activities that are triggered by a declared disaster.

## Standard Disaster Recovery

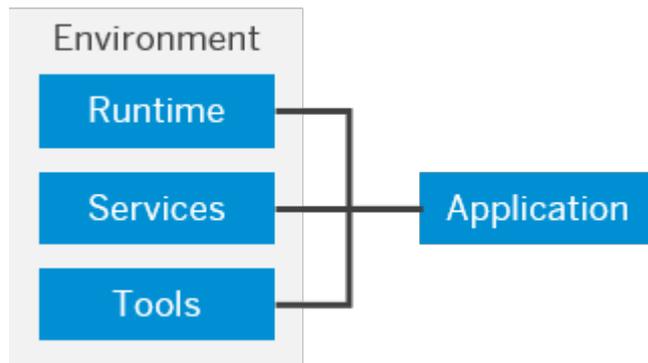

SAP can restore productive tenants from backups as soon as practicable in case of a disaster resulting in the loss of the primary production data center.

As the magnitude of a disaster is unpredictable, a region might not be restored in a reasonable time. In addition, a new infrastructure might need to be set up at a different location, which might require the purchase and setup of new hardware. Therefore, we can't guarantee any fixed recovery timelines.

## 2.3 Environments

Environments constitute the actual platform-as-a-service offering of SAP BTP that allows for the development and administration of business applications. Environments are anchored in SAP BTP on subaccount level.

Each environment comes equipped with specific tools, technologies, and runtimes that you need to build applications. So a multi-environment subaccount is your single address to host a variety of applications and offer diverse development options. One advantage of using different environments in one subaccount is that you only need to manage users, authorizations, and entitlements once per subaccount, and thus grant more flexibility to your developers.

## Environment Instances

To actually use an environment in a subaccount, you must **enable** it, which creates an instance of that environment. There are several ways to create **environment instances**:

- In the SAP BTP cockpit, on the subaccount overview, choose *Enable*.
- In the SAP BTP cockpit, under *Service Marketplace*. Here, you get more information, such as the available plans and links to further information.
- Using the btp CLI command `btp create accounts/environment-instance`

### [Cloud Foundry Environment \[page 44\]](#)

The Cloud Foundry environment allows you to create polyglot cloud applications in Cloud Foundry. It contains the SAP BTP, Cloud Foundry runtime service, which is based on the open-source application platform managed by the Cloud Foundry Foundation.

### [ABAP Environment \[page 49\]](#)

Within the Cloud Foundry environment, you can create a new space for ABAP development. This is what we refer to as the ABAP environment. It allows you to create extensions for ABAP-based products, such as SAP S/4HANA Cloud, and develop new cloud applications. You can transform existing ABAP-based custom code or extensions to the cloud.

### [Kyma Environment \[page 54\]](#)

SAP BTP, Kyma runtime provides a fully managed cloud-native Kubernetes application runtime based on the open-source project "Kyma". Based on modular building blocks, Kyma runtime includes all the necessary capabilities to simplify the development and to run enterprise-grade cloud-native applications.

### [Neo Environment \[page 62\]](#)

The Neo environment lets you develop HTML5, Java, and SAP HANA extended application services (SAP HANA XS) applications. You can also use the UI Development Toolkit for HTML5 (SAPUI5) to develop rich user interfaces for modern web-based business applications.

## Related Information

[Account Administration \[page 1935\]](#)

## 2.3.1 Cloud Foundry Environment

The Cloud Foundry environment allows you to create polyglot cloud applications in Cloud Foundry. It contains the SAP BTP, Cloud Foundry runtime service, which is based on the open-source application platform managed by the Cloud Foundry Foundation.

The Cloud Foundry environment enables you to develop new business applications and business services, supporting multiple runtimes, programming languages, libraries, and services. You can leverage a multitude of buildpacks, including community innovations and self-developed buildpacks. It also integrates with SAP HANA extended application services, advanced model.

For more information about Cloud Foundry, see the official Cloud Foundry documentation at <https://docs.cloudfoundry.org/> .

## 2.3.1.2 SAP BTP-Specific Configurations

The following technical configurations are specific to SAP BTP and differ from the default configuration:

- SAP BTP supports the Cloud Foundry command line interface (CF CLI) version 8 or newer. Older versions of the CF CLI are not supported.

- By default, a newly pushed (or started) Cloud Foundry application needs to respond to a health check within the first 60 seconds, otherwise the application is considered to have failed. For more information, see [https://docs.cloudfoundry.org/devguide/deploy-apps/healthchecks.html#health\\_check\\_timeout](https://docs.cloudfoundry.org/devguide/deploy-apps/healthchecks.html#health_check_timeout). On SAP BTP, however, you can override this timeout to up to 10 minutes. For instructions, see <https://docs.cloudfoundry.org/devguide/deploy-apps/large-app-deploy.html>.
- On SAP BTP, application SSH access is disabled by default. For more information on SSH, see <https://docs.cloudfoundry.org/devguide/deploy-apps/app-ssh-overview.html>.
- SAP BTP supports the Cloud Foundry API version 3. The Cloud Foundry API v2 has been deprecated and is no longer supported. For more information, see <https://v3-apidocs.cloudfoundry.org/>.
- On SAP BTP, the Cloud Foundry API is protected by a rate limit against misuse. The limit is in the range of a few 10k requests per hour per user on average. Starting in April 2023, the rate limit for the deprecated Cloud Foundry API v2 will be decreased and eventually reach the range of a few hundred requests per hour per user.
- In addition to the general rate limit on the Cloud Foundry API, requests for certain API endpoints related to services face a separate limit on concurrent requests. The Cloud Foundry API responds with HTTP status code 429 if a rate limit is reached and provides a Retry-After Header suggesting when the client can attempt a retry. For more information, see <https://docs.cloudfoundry.org/running/rate-limit-cloud-controller-api.html#Rate%20Limit%20Responses:%20Service%20Brokers>.
- In the SAP BTP, Cloud Foundry environment, the total HTTP Request Header and HTTP Response Header size is limited to 64 KB to protect against misuse.
- In the SAP BTP, Cloud Foundry environment, for both HTTP Request Headers and HTTP Response Headers the total amount of Headers is limited to 101.
- In the SAP BTP, Cloud Foundry environment, the HTTP `keep-alive` timeout towards the client is set to 60s to protect against misuse. 60s is the maximum time span allowed to wait for a new HTTP request to appear if `keep-alive` is enabled.
- In the SAP BTP, Cloud Foundry environment, an internal HTTP `keep-alive` is set to 90s. A higher value must be set on application-side to avoid intermittent disruptions. For more information, see step 4 of [3406978](#).
- In the Cloud Foundry environment, there's a logging rate limit to guard against malicious applications. The limit is in the range of up to a few thousand logs per second per application instance. If this limit is exceeded, additional logs from the application instance are dropped and a warning message is injected into the application instance's log stream every second. This message also contains the exact log rate limit.
- Applications requiring sent envelopes to be delivered to external Log Management Services should use the Cloud Foundry syslog drain capability. See <https://docs.cloudfoundry.org/devguide/services/log-management.html>.
- In the SAP BTP, Cloud Foundry environment, the time between signaling a container to shut down gracefully and forcefully stopping it is set to 60 seconds. The default in Cloud Foundry is 10 seconds, see <https://docs.cloudfoundry.org/devguide/deploy-apps/app-lifecycle.html#shutdown>. This time interval will not be taken into account if there are no explicit kernel signal handlers implemented in the application.
- In the SAP BTP, Cloud Foundry environment, applications get a guaranteed CPU share of  $\frac{1}{4}$  core per GB instance memory. As the maximum instance memory per application is 16 GB, this allows for vertical scaling up to 4 CPUs.  
If applications running on the same virtual machine don't use their guaranteed CPU, other applications might get more CPU. This isn't guaranteed and might be subject to change in the future. If you encounter performance problems, scale up your application or increase the application start timeout.  
The number of running threads per application instance is limited to 10,420. Reaching this limit can cause performance issues.

- When pushing or scaling your application, you can define a `disk_quota` that can be up to 10 GB. For more information, see <https://docs.cloudfoundry.org/devguide/deploy-apps/manifest-attributes.html#disk-quota> .
- When deploying applications on SAP BTP, the maximum application package size is 1.5 GB. If your application is larger than that, the deployment fails. For more information, see <https://docs.cloudfoundry.org/devguide/deploy-apps/large-app-deploy.html> .
- In the SAP BTP, Cloud Foundry environment, the hard limit for open file descriptors is 32,768 (32K) per container.
- In global accounts that support the consumption-based commercial model you might see a quota limit for certain services. This is a technical limit only, not a business limit. If you need to increase this limit, report an incident to [SAP support](#) for component BC-NEO-CIS.
- In the SAP BTP, Cloud Foundry environment, the SAP HANA database supports up to 1000 simultaneous connections per database.
- In the SAP BTP, Cloud Foundry environment, each application can be mapped to approximately 1000 routes (128 KB). The total length of the routing information must not exceed this limit.
- Cloud Foundry Audit Events have a retention period of 14 days. For more information on Audit Events, see <https://docs.cloudfoundry.org/running/managing-cf/audit-events.html> .

### 2.3.1.3 Availability Zones in the Cloud Foundry Environment

The Cloud Foundry environment follows the recommendations of our partner IaaS providers by leveraging the availability zones (AZ) concept.

#### About Availability Zones

**Availability zones (AZ)** are single failure domains within a single geographical region and are separate physical locations with independent power, network, and cooling. Multiple AZs exist in one region and are connected with each other through a low-latency network.

2-AZ and 3-AZ Deployments

To achieve better fault-tolerance, our partners recommend deploying services across multiple AZs, which improves the availability of a service if there are issues with the region infrastructure of one AZ.

## High Availability at Platform and Application Level

The SAP BTP Cloud Foundry environment follows these recommendations to support high availability at the platform and application level:

- **High availability of the platform components:**
  - The building blocks of Cloud Foundry and the virtual machines on which the Cloud Foundry application instances are scheduled run in a high availability setup. Their instances are distributed across different AZs.
  - The technology that manages the deployment of the Cloud Foundry environment monitors the health of the platform. If there are infrastructure failures, it re-creates the faulty components.
- **High availability on the application level:**
  - We recommend running multiple application instances to increase availability. For more information, see [Run Multiple Instances to Increase Availability](#) . On SAP BTP, there are three ways to increase application instances:
    - Scaling your application using the application manifest. The `manifest.yml` allows you to make and save configurations for your application. To scale, you can configure the instance count in the manifest and push the application again with the new configuration. See [App Manifest Attribute Reference](#) . To avoid downtimes when updating your application configuration, you can also consider using rolling application deployments. See [Rolling App Deployments](#) .
    - Scaling your application using the `cf scale` command in the Cloud Foundry command line interface (CF CLI). See [Scaling an App Using cf scale](#) .
    - Scaling your application using the SAP BTP cockpit. See [Add or Remove Application Instances](#).
  - The Cloud Foundry container scheduler takes care of distributing the different instances of one application on virtual machines in different AZs. For more information, see [How Diego Balances App Processes](#) .
  - Cloud Foundry is constantly monitoring the health state of application instances and restarts instances that are considered unhealthy. See [Using App Health Checks](#) .
  - When the number of desired instances doesn't match the number of actually running instances, Cloud Foundry reschedules the missing instances, for example, when the virtual machines that an application instance was initially scheduled on become unresponsive.

For more information on high availability configuration, see [High Availability in Cloud Foundry](#) .

For more information on application stability and resilience, see [Develop Resilient Applications](#).

## 2.3.1.4 Additional Information About Cloud Foundry

Links to additional information about Cloud Foundry that is useful to know but not necessarily directly connected to the SAP BTP, Cloud Foundry environment.

## 2.3.2 ABAP Environment

Within the Cloud Foundry environment, you can create a new space for ABAP development. This is what we refer to as the ABAP environment. It allows you to create extensions for ABAP-based products, such as SAP

S/4HANA Cloud, and develop new cloud applications. You can transform existing ABAP-based custom code or extensions to the cloud.

The ABAP environment is based on the latest ABAP platform cloud release that is also used for SAP S/4HANA Cloud. It leverages the innovations provided by SAP HANA. The software stack contains standard technology components that are familiar from the standalone Application Server ABAP. The ABAP environment supports the ABAP RESTful Application Programming Model including SAP Fiori and Core Data Services (CDS). SAP services and APIs are offered according to the new approach of released objects. The ABAP environment can be integrated with other SAP BTP services, such as SAP Destination service, SAP Build Work Zone, standard edition, SAP Workflow Management, and SAP Interactive Forms by Adobe.

Each ABAP system in the ABAP environment utilizes a dedicated SAP HANA database, which is provided by the SAP HANA Cloud service and managed by the ABAP environment. The database is linked 1:1 to the ABAP system.

For information about regional availability, see [Regions and API Endpoints for the ABAP Environment \[page 33\]](#).

### 2.3.2.1 ABAP Development Tools for Eclipse

ABAP development tools for Eclipse is SAP's state-of-the-art integrated development environment (IDE) for ABAP development on the open Eclipse platform.

## Features

ABAP development tools for Eclipse enables you to perform ABAP-based development tasks, when you want to build, to extend, and to run ABAP applications based on SAP products, such as SAP S/4HANA and SAP S/4HANA Cloud, private edition for classic ABAP development as well as SAP BTP, ABAP environment and SAP S/4HANA Cloud for Cloud development.

ABAP development tools for Eclipse supports ABAP developers with the following possibilities:

- Highly flexible, customizable Eclipse UI for ABAP development tools
- High-performance, failover-safe online development in multiple ABAP systems simultaneously
- Display and edit functionality for multiple ABAP objects in parallel
- Advanced and efficient source code editing including refactoring support
- Optimum support of task-oriented and test-driven development
- Robust and reliable quality assurance and supportability tools.
- Built-in extensibility of the IDE using the established Eclipse plug-in technology

In particular, ABAP development tools for Eclipse is a modern development toolset where ABAP developers can use, for example the following features:

- Syntax check
- Code completion
- Syntax highlighting
- Pretty printing
- Navigation
- Search
- Quick fixes
- and many more

## Tools User Guides

The [ABAP Development Tools: User Guide](#) describes the functionality and usage of the possibilities. It focuses on use cases for creating, editing, testing, debugging, and profiling development objects.

The [ABAP CDS Development Tools: User Guide](#) describes the functionality and usage of tools for ABAP Core Data Services (CDS) in the ABAP environment. It focuses on use cases for creating, editing, testing, and analyzing ABAP CDS entities.

## Release Notes

ABAP development tools for Eclipse is released to customers in combination with the SAP BTP ABAP environment shipments. Documentation in the context of ABAP Platform will be shipped in accordance with the relevant SAP product shipments.

The release notes are a general overview of the most significant changes relating to features of ABAP development tools for Eclipse in the context of ABAP development and the ABAP programming models.

For more information, see [Release Notes of ABAP Development Tools for Eclipse](#)

## FAQs

If you are an SE80 expert and new to ABAP development tools for Eclipse, the frequently asked questions (FAQs) enable you to skim the features you want to perform in ADT.

For more information, see [FAQs for SE80 Experts Using ADT](#)

## Installation

To install ABAP development tools for Eclipse, follow the [Installation Guide](#). Alternatively, you may get ABAP development tools for Eclipse from the [SAP Development Tools](#) page under the terms of the [SAP DEVELOPER LICENSE AGREEMENT](#).

## Support

The use of ABAP development tools for Eclipse is subject to the terms and conditions of your license agreement with SAP which is directly related to the SAP shipment channel from which ABAP development tools for Eclipse was initially downloaded and installed.

## 2.3.2.2 Commercial Information

### Service

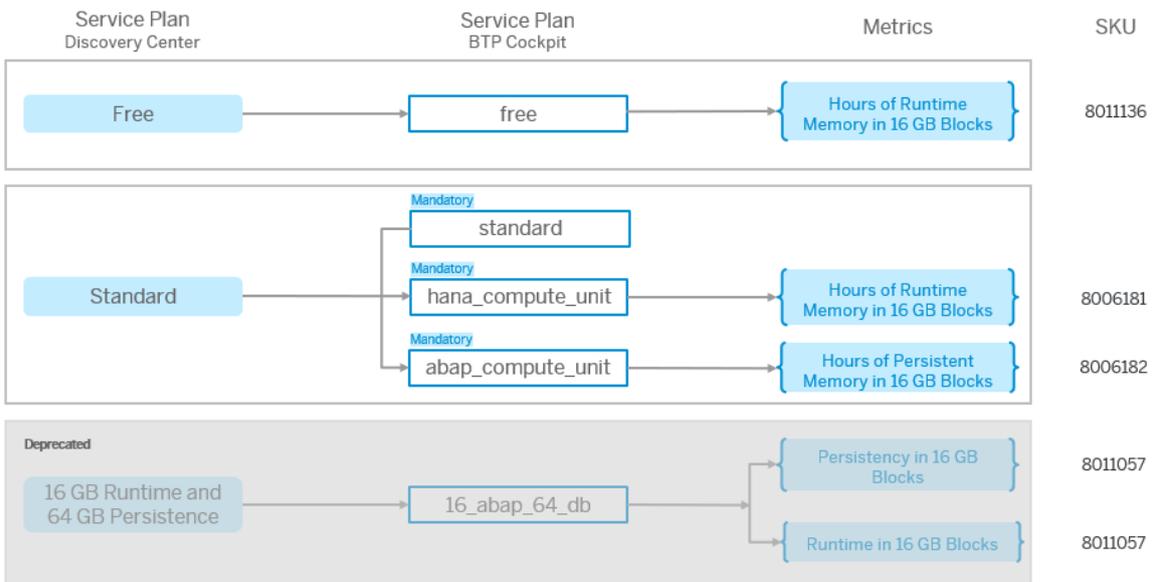

#### Description

SAP BTP ABAP environment is SAP's Platform-as-a-Service offering to create innovative ABAP applications and extensions in the cloud. It provides the modern ABAP RESTful Application Programming Model, leveraging SAP HANA, SAP Fiori, and a cloud-optimized ABAP language with a clear set of released standard APIs. Developers can utilize a development toolset that enables tight integration with Git-enabled lifecycle management.

## Overview

# SAP ABAP, environment

## Consumption-based Models

## SAP BTP Cockpit: Descriptions of the Service Plans

Name	Service Plan	Description
free	Free	For small proof-of-concept projects. Allows you to explore all development capabilities. Also includes the piloting of ABAP Test Cockpit scenarios remotely for on-premise systems via the Custom Code Migration app. The instance will be automatically stopped each night, requiring a manual restart via the Landscape Portal. Only community support available. Free tier instance is not subject to SLAs. Upgrading to paid plan seamless; non-upgraded instance and its content decommissioned after 90 days.
standard	Standard	You can size the ABAP runtime and the SAP HANA memory independently from each other. To be able to do your sizing, you must also select the quota plans abap_compute_unit and hana_compute_unit. When you create an ABAP system, you must decide on the system size in ABAP compute units. One ABAP compute unit represents 16 GB.
abap_compute_unit	Standard	Configure ABAP Runtime in blocks of 16 GB. Increase the quotas in the abap_compute_unit service plan at least by 1.

Name	Service Plan	Description
hana_compute_unit	Standard	Configure HANA Memory in blocks of 15 GB. Increase the quotas in the hana_compute_unit service plan at least by 2.
16_abap_64_db (Deprecated)	16 GB Runtime and 64 GB Persistence (Deprecated)	<p>This ABAP runtime service plan provides a 16 GB ABAP runtime with a 64 GB database. No additional sizing is possible.</p> <p>This service plan is deprecated. Please change the service plan to "standard".</p>

## Metrics

Metric	Definition
Memory	<p>Temporary memory bank where computers store data that needs to be retrieve and processed quickly.</p> <p>The memory represents the size of the data that can be processed , and CPU represents the speed at which the data can be retrieved.</p>

## Supplemental Terms and Conditions

For more information, see the [SAP Business Technology Platform Service Description Guide](#).

### 2.3.3 Kyma Environment

SAP BTP, Kyma runtime provides a fully managed cloud-native Kubernetes application runtime based on the open-source project "Kyma". Based on modular building blocks, Kyma runtime includes all the necessary capabilities to simplify the development and to run enterprise-grade cloud-native applications.

#### Kyma as a Managed Service

Kyma environment permits a native consumption of the Multi-Cloud Foundation Services ([What Is the Multi-Cloud Foundation](#)) and smooth consumption of SAP and non-SAP applications. It also supports out-of-the-box CAP, SAP Cloud SDK, application router, and HTML5 deployer.

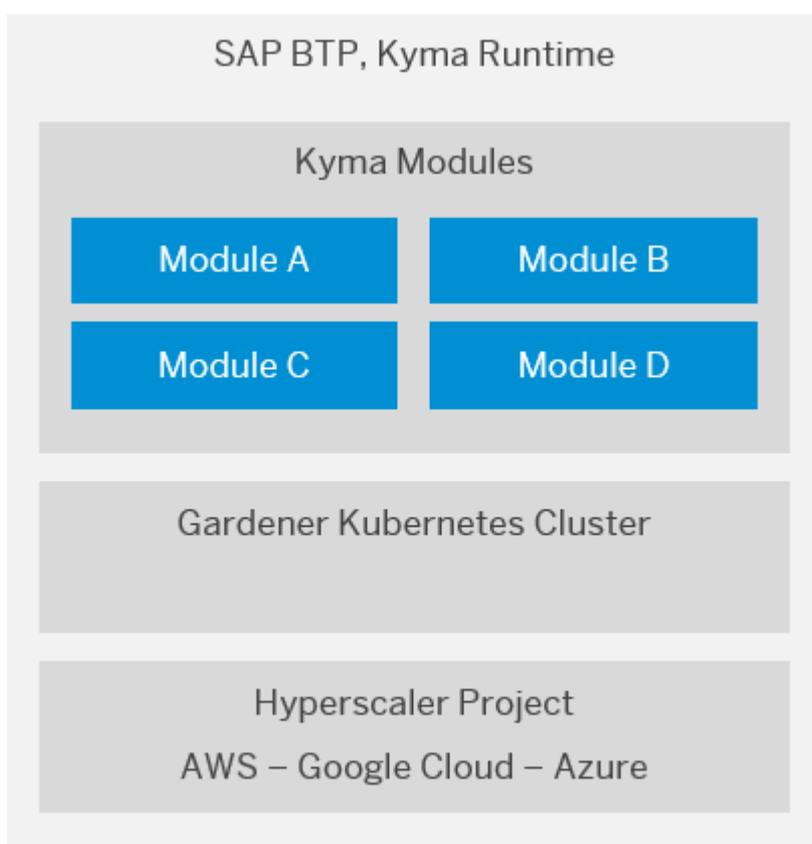

Kyama implements a dedicated application runtime to deploy highly scalable, robust, and secure containerized microservices.

### Note

Kyama as a managed service automatically checks all Kyama-managed resources. Any unexpected modifications are discarded, and the resource is reverted to the original state.

Every Kyama environment consists of:

- A Kubernetes cluster based on project "Gardener" on a cloud provider and region (data center) of your choice. To find out the available regions and providers, see [Regions for the Kyama Environment \[page 37\]](#).
- A set of Kyama modules picked by a user in the release channel of their choice installed on the provisioned cluster.

## Integration

Every Kyama environment runs on a single Kubernetes cluster created for a specific subaccount. The configuration of the Kyama environment enables you to connect it to a multitude of SAP systems. This way, you can build various formations that aggregate the SAP systems and environment according to your business use cases.

SAP systems connected to a Kyma environment expose APIs and events. To extend the existing logic of these SAP services, you can build serverless applications called “Functions”, and trigger them to react to particular events or calls to your application's API. You can also use the Kyma environment to deploy microservices or even build full-stack applications.

### 2.3.3.1 Kyma's Modular Approach

With Kyma's modular approach, you can install only the modules you need, instead of a predefined set of components.

#### Kyma Module or Component?

Classic Kyma runtime offered a fixed set of mandatory interdependent components whose development rhythm was synchronized and determined by the release schedule. One by one, all Kyma components are converted to modules that work independently from each other.

The modular approach boosts Kyma's extensibility and scalability and makes it more cost-effective. With fully modularized Kyma, you can choose from many of its modules to facilitate your business needs best. You can add or delete modules on demand and configure them, thus determining the costs generated by the infrastructure that your modules use.

You can decide which modules are needed for your workload, although some features may still require the presence of other modules or related capabilities. For example, the API Gateway module depends on Istio capabilities, but it doesn't require the Istio module from Kyma. Instead, the API Gateway module needs Istio custom resources, such as Gateway and VirtualService, to be present in the cluster. If you want to use your own Istio installation, the API Gateway module will use it as soon as the required resources are available.

Learn more about the available Kyma modules: [Kyma Modules \[page 57\]](#).

Learn how to add a module under [Add and Delete a Kyma Module \[page 2764\]](#).

#### Kyma Release Channels

Sets of Kyma modules are deployed in two release channels:

- *Regular channel* is the default release channel.
- *Fast channel* provides more frequent releases. It offers early previews of all new features and changes before they are promoted to the regular channel. It also allows you to test and provide feedback on the new features sooner.

According to the Kyma modules` release cycle, we first release a new module's major or minor version in the fast channel. After approximately two weeks, we promote the release to the regular channel.

### Note

In case of important functionality fixes or critical vulnerabilities identified by our security organization, the timeline doesn't apply, as we provide hotfixes between regular releases.

You can use one or both release channels in your Kyma cluster, but you can define only one release channel per module. For example, you can mix different modules from the regular and fast channels in your development cluster, but you cannot deploy the same module in the regular and fast versions in one cluster.

### Note

You can upgrade module versions, but you cannot downgrade them. To test the upstream versions, you can switch a module or an entire cluster from the regular channel to the fast one. To return to the regular channel, switch back to it, and wait until the upgrade is automatically applied in your cluster. Alternatively, you can delete and add your module from the regular channel.

To find out which module version is running in your cluster, go to [Kyma dashboard](#).

## Release Notes

A release of a new module's version is announced with a release note in [What's New for SAP Business Technology Platform](#) for both, the fast and regular channels. On the day of the release in the fast channel, a release note is published with the `preview` label. The `preview` label is removed after approximately two weeks when the module version becomes available in the regular channel.

## Related Information

[Kyma Functionalities \[page 60\]](#)

### 2.3.3.2 Kyma Modules

With Kyma's modular approach, you can install just the modules you need, instead of a predefined set of components.

You can choose to add any modules as required. To learn how, see [Add and Delete a Kyma Module \[page 2764\]](#). To find out which module version is running in your cluster, go to Kyma dashboard.

### → Tip

A release of a new module's version is announced with a release note in [What's New for SAP Business Technology Platform](#) for both, the fast and regular channels:

- On the day of the release in the fast channel, a release note is published with the *Preview* label.
- When the module version becomes available in the regular channel (after approximately two weeks), the *Preview* label is removed.

## Default Kyma Modules

When you create Kyma runtime in SAP BTP cockpit, it is provisioned with the default modules added. The default modules are not mandatory. If you don't need them, you can delete them in [Kyma dashboard](#).

Default Kyma Modules

### Module

Technical name	Purpose	Documentation
<a href="#">API Gateway</a> api-gateway	API Gateway provides functionalities that allow you to expose and secure APIs.	<a href="#">kyma-project.io: API Gateway module</a>
<a href="#">Istio</a> istio	Istio is a service mesh with Kyma-specific configuration.	<a href="#">kyma-project.io: Istio module</a>
<a href="#">SAP BTP Operator</a> btp-operator	Within the SAP BTP Operator module, BTP Manager installs the SAP BTP service operator that allows you to consume SAP BTP services from your Kubernetes cluster using Kubernetes-native tools.	<a href="#">Using SAP BTP Services in the Kyma Environment [page 1732]</a> <a href="#">kyma-project.io: SAP BTP Operator module</a> <a href="#">GitHub: BTP Manager releases</a> <a href="#">GitHub: SAP BTP service operator releases</a>

## Non-Default Kyma Modules

When you create Kyma runtime in SAP BTP cockpit, the following modules are not added by default, but you can choose to add (and delete) them anytime.

## Non-Default Kyma Modules

### Module

Technical name	Purpose	Documentation
<p><i>Application Connector</i></p> <p>application-connector</p>	<p>Application Connector allows you to connect with external solutions. No matter if you want to integrate an on-premise or a cloud system, the integration process doesn't change, which allows you to avoid any configuration or network-related problems.</p>	<p><a href="https://kyma-project.io/docs/next/what-is-application-connectivity-in-kyma/">kyma-project.io: What is Application Connectivity in Kyma?</a> </p> <p><a href="https://github.com/kyma-project/application-connector-manager">GitHub repository: Application Connector Manager</a> </p>
<p><i>Keda</i></p> <p>keda</p>	<p>The Keda module comes with Keda Manager, an extension to Kyma that allows you to install <a href="#">KEDA</a>  (Kubernetes Event Driven Autoscaler).</p>	<p><a href="https://kyma-project.io/docs/next/keda-module/">kyma-project.io: Keda module</a> </p>
<p><i>Serverless</i></p> <p>serverless</p>	<p>With the Serverless module, you can define simple code snippets (Functions) with minimal implementation effort.</p>	<p><a href="https://kyma-project.io/docs/next/deploy-workloads-in-the-kyma-environment-to-extend-sap-systems/">Deploy Workloads in the Kyma Environment to Extend SAP Systems [page 1735]</a></p> <p><a href="https://kyma-project.io/docs/next/what-is-serverless-in-kyma/">kyma-project.io: What is Serverless in Kyma?</a> </p> <p><a href="https://kyma-project.io/docs/next/serverless-configuration/">kyma-project.io: Serverless Configuration</a> </p> <p><a href="https://github.com/kyma-project/serverless">GitHub repository: Serverless</a> </p>
<p><i>Telemetry</i></p> <p>telemetry</p>	<p>The Telemetry module collects application logs and distributed traces for your application, and dispatches them to your preferred backends.</p>	<p><a href="https://kyma-project.io/docs/next/telemetry-module/">kyma-project.io: Telemetry module</a> </p> <p><a href="https://github.com/kyma-project/telemetry-manager/releases">GitHub: Telemetry manager releases</a> </p> <p><a href="https://github.com/kyma-project/telemetry">GitHub repository: Telemetry</a> </p>
<p><i>NATS</i></p> <p>nats</p>	<p>NATS deploys a NATS cluster within the Kyma cluster. You can use it as a backend for Kyma Eventing.</p>	<p><a href="https://kyma-project.io/docs/next/nats-module/">kyma-project.io: NATS module</a> </p> <p><a href="https://github.com/kyma-project/nats">GitHub repository: NATS</a> </p>
<p><i>Eventing</i></p> <p>eventing</p>	<p>Eventing provides functionality to publish and subscribe to CloudEvents.</p> <p>At the moment, the SAP Event Mesh default plan and NATS are supported. If you choose NATS, add the NATS module.</p>	<p><a href="https://kyma-project.io/docs/next/configure-sap-event-mesh-for-kyma-eventing/">Configure SAP Event Mesh for Kyma Eventing [page 1740]</a></p> <p><a href="https://kyma-project.io/docs/next/eventing-module/">kyma-project.io: Eventing module</a> </p> <p><a href="https://github.com/kyma-project/eventing">GitHub repository: Eventing</a> </p>

## Third-Party Modules

Third-Party Modules

### Module

Technical name	Purpose	Documentation
<i>Transparent Proxy</i> transparent-proxy	Use the transparent proxy for Kubernetes to connect workloads in a Kubernetes cluster to Internet and on-premise applications.	<a href="#">Transparent Proxy in the Kyma Environment</a>
<i>Connectivity Proxy</i> connectivity-proxy	Use the connectivity proxy for Kubernetes to connect workloads in a Kubernetes cluster to on-premise systems, exposed via the Cloud Connector.	<a href="#">On-Premise Connectivity in the Kyma Environment</a>

### 2.3.3.3 Kyma Functionalities

SAP BTP, Kyma runtime and open source project "Kyma" offer slightly different functionalities and install a different set of components.

For all functionalities that the Kyma environment offers, see the official [project "Kyma" documentation](#) .

Functionality Comparison

Functionality	open source project "Kyma"	SAP BTP, Kyma runtime
Service Level Agreements	×	✓
Managed Kubernetes	×	✓
Managed Kyma	×	✓
Kyma CLI	✓	limited (SAP BTP, Kyma runtime supports commands for serverless Functions, not the commands related to installation.)
Centrally hosted Kyma dashboard	×	✓
System landscape management in SAP BTP cockpit	×	✓
In-cluster system landscape management (Application Connector)	✓	×

### 2.3.3.4 Basic Concepts

This table explains basic concepts relating to the Kyma environment. It aims to give you an understanding of the Kyma environment before you actually start using it to build extensions for your SAP solutions.

## Note

For an overview of the basic Kubernetes concepts that the Kyma environment heavily relies on, see the official [Kubernetes documentation](#) .

Concept	Description
Kyma cluster	A Kubernetes cluster provisioned with the latest version of the open-source project "Kyma". You can enable such a cluster on a given subaccount through the SAP BTP cockpit. After creating a Kyma environment instance on your subaccount, the cluster is provisioned automatically through Gardener on your chosen cloud service provider. To access the cluster, you must have appropriate roles assigned to your subaccount.
Kyma module	An extension to the Kyma environment that can be added, deleted, or re-configured at runtime.
Role	Access to every cluster is managed by the roles assigned. Roles give the assigned users a different level of permissions suitable for different purposes. For more information, read <a href="#">Assign Roles in the Kyma Environment [page 2766]</a> .
Namespace	Namespaces are used to organize objects in a cluster and provide a way to divide cluster resources. This way, several users can share a cluster but have access only to resources within the namespace they have permissions for. This allows for increasing the security and organization of your cluster by dividing it into smaller units. Access to namespaces in the Kyma environment depends on your Kubernetes RBAC permissions.
Service operator	A service operator is a piece of software that provides a set of all necessary resources (such as CustomResourceDefinitions and controllers) needed to provision third-party services in your Kubernetes cluster.
Binding	The connection you create between a service instance and an SAP solution so that they can communicate with each other. You can also bind a service instance to any workload running in the Kyma environment, such as a Function or a microservice.
Credentials / Secrets	Sensitive data necessary for an SAP solution to call the service, connect to it, and authenticate it. Depending on whether you use Kyma dashboard or kubectl to create the binding between a service instance and an SAP solution, the Kubernetes Secret object that contains these credentials is either created automatically or you need to create it manually.
Function	A simple code snippet that you can run without provisioning or managing servers. It implements the exact business logic you define. A Function is based on the Function custom resource and can be written in either Node.js or Python. A Function can perform a business logic of its own. You can also bind it to an instance of a service and configure it to be

Concept	Description
Microservice	<p>triggered whenever it receives a particular event type from the service or a call is made to the service's API. Functions are executed only if they are triggered by an event or an API call.</p> <p>An architectural variant for extensions or applications, where you separate the tasks into smaller pieces that interact with each other as loosely coupled, independently deployable units of code. A failing microservice should not cause your whole application to fail. Microservices are packed in a container that is always running; it's idling if there is no load. The microservice should always be reachable even when the Pods move around. Microservices typically communicate through APIs.</p>

## 2.3.4 Neo Environment

The Neo environment lets you develop HTML5, Java, and SAP HANA extended application services (SAP HANA XS) applications. You can also use the UI Development Toolkit for HTML5 (SAPUI5) to develop rich user interfaces for modern web-based business applications.

See also:

- [Development, Neo Environment](#)
- [Extensions, Neo Environment](#)
- [Administration and Operations, Neo Environment](#)
- [Security, Neo Environment](#)
- [Getting Support, Neo Environment](#)

## Migration from the Neo to the Multi-Cloud Foundation

To learn more about why and how to migrate your scenarios on SAP BTP, see [Migrating from the SAP BTP Neo Environment to the Multi-Cloud Foundation](#).

## 2.4 Trial Accounts and Free Tier

Explore the different options for trying out SAP BTP.

### Trial Account or Free Tier Offering: When to Use Which?

Before setting up your account, you need to decide which free offering for SAP BTP is suitable for your needs:

- **Pay-As-You-Go or CPEA accounts with free tier service plans** are open to customers, partners, and let you try out SAP BTP in a per service defined time span for free. These account types enable you to test your scenarios and generally offer the option to upgrade to paid service plans. These accounts also allow you to store data long-term and move projects to production. You also get access to our community, including free technical resources such as tutorials and blog posts. For more information, see [Enterprise Accounts \[page 65\]](#) and [Using Free Service Plans \[page 72\]](#). You can self-register for an enterprise account with free tier service plans. For more information, see [Get an Account on SAP BTP to Try Out Free Tier Service Plans](#).

#### Note

Only community support is available for free tier service plans and these are not subject to SLAs.

#### Note

The option to upgrade from free tier service plans to paid service plans is not yet available for all services and runtimes, such as Kyma. See [Using Free Service Plans](#) to read more about upgrading from free tier service plans to paid service plans.

- A **trial account** lets you try out SAP BTP for free for 90 days. The services provided for the trial account allow restricted use of the platform resources and services. Access is open to everyone. Trial accounts are intended for personal exploration, your own non-productive testing, and evaluation of the services in accordance with [SAP BTP trial terms and conditions](#). A SAP BTP trial account must not be used for production use or team development. You are not permitted to use the trial account in any productive or commercial manner. You can self-register for a trial account. For more information on how to do that, see [Get a Free Account on SAP BTP Trial](#).

### Free Tier and Always Free Tags in the SAP Discovery Center

In the [SAP Discovery Center service catalog overview](#), some services display the tag *Free Tier*, which indicates the service is offering a free tier service plan. Some services display the tag *Always Free*, which indicates the service is offering a service plan that comes free of additional charges, as it is already included in your overall SAP BTP contract. You can use the filter function of the SAP Discovery Center to filter for services that offer *Free Tier* and *Always Free* plans. The *Always Free* service plans include the following note in their service plan description: "This service plan is included in the overall SAP Business Technology Platform contract".

## Note

*Always Free* service plans might not be available in all regions or for all providers.

## Trial Lifecycle

- **Use your SAP BTP trial account:**

Familiarize yourself with the [Trial Scope \[page 64\]](#) or try out one of our [Starter Scenarios](#) on the [Tutorial Navigator](#).

- **Extend your SAP BTP trial account in intervals:**

- Your 90-day trial period is divided in intervals. If you sign in to your trial account regularly, the intervals are extended automatically for you by up to 30 days or until your overall 90-day trial is finished.
- Extend your trial account interval by clicking [Extend Trial Account](#) in the pop-up window that appears once 30 days have passed.
- If you don't sign in to your trial account for 30 days or more, your account will be suspended. You won't be able to use applications or services. However, your account will not be deleted yet. To unsuspend your trial account, click [Extend Trial Account](#) in the pop-up window that appears when you try to sign in. You'll then be able to use your account again, provided that there are still days left in your overall 90-day trial period.

- **Delete your SAP BTP trial account:**

After 90 days, your trial account is automatically deleted. But if you want to proactively delete your SAP BTP trial account, you can navigate to the global accounts scope and select the Account Explorer page, then click the [Delete Trial Account](#) button.

- If you want to continue to use an SAP BTP trial account after deletion, you need to set up a new account.
- If you want to explore SAP BTP without time limit, create an enterprise account with free tier service plans allowing you to test your scenarios. See: [Get an Account on SAP BTP to Try Out Free Tier Service Plans](#).

## Caution

Environments enabled on your trial account may not be valid for your whole trial period. To learn about the validity period for the Kyma environment, see [About the Trial Account \[page 207\]](#).

## Trial Scope

- A trial account enables you to explore the basic functionality of SAP BTP.
- SAP BTP trial accounts use cloud management tools feature set B. For more information, see [Cloud Management Tools – Feature Set Overview \[page 111\]](#).
- SAP BTP trial accounts are available in several regions. For more information, see [Regions \[page 17\]](#).
- You can create directories in your trial account. For more information, see [Managing Directories Using the Cockpit \[Feature Set B\] \[page 1968\]](#)

- You can use productive and beta services. To consume beta services, you must enable the subaccount for beta features during the subaccount creation or when you edit the subaccount details.
- You can manage platform users by assigning them role collections. For more information, see [Working with Role Collections](#).
- A trial account includes 4 GB of memory for applications.
- You can use 8 GB of instance memory.
- There are 10 total routes and 40 total services available.
- You can use 2 configured on-premise systems with the Cloud connector.
- There's no service level agreement with regards to the availability of the platform.
- You can use HDI containers in a shared SAP HANA database (only available on cf-us10).
- For cleanup purposes, applications stop automatically on a daily basis. You need to manually restart them when needed.

#### Note

Applications are stopped at midnight (or some time later depending on server load) relative to the region in which you created your trial account. If you're working in a time zone that is far from the region where your trial account was created, then your applications may stop during business hours.

- You can have a trial tenant of SAP Cloud identity Services, see [Get Your Tenant](#).

## Related Information

[Getting Started with a Trial Account in the Cloud Foundry Environment \[page 130\]](#)

[Getting Started with a Trial Account in the Kyma Environment \[page 206\]](#)

## 2.5 Enterprise Accounts

Enterprise accounts are usually associated with SAP customer or partner contracts and contain their purchased entitlements to platform resources and services. However, it's also possible to create an enterprise account for personal exploration.

SAP BTP provides different types of global accounts, **enterprise** and **trial**. The type you choose determines pricing, conditions of use, resources, available services, and hosts.

If you want to start out using services for free, you can create a trial account and only use free tier service plans: The major benefit of using such an account for exploration purposes is that you can upgrade your services to productive use without losing any of your data. Check out the [Free Tier Services](#) in SAP Discovery Center and learn the details about [Using Free Service Plans \[page 72\]](#) in your enterprise account.

Another way to start out using services for free is to create a trial account. But keep in mind that when you want to use your global account productively, there's no way to migrate your data from the trial account to a productive enterprise account. For more information, see [Trial Accounts and Free Tier \[page 63\]](#).

## Enterprise Accounts

The main features of enterprise accounts are described for use by customers and by partners in the following table:

	Customer Account	Partner Account
<b>Use case</b>	<p>A global account that enables you to host productive, business-critical applications with 24/7 support.</p> <p>You can purchase a global account just like any other SAP software. You can upgrade and refine your resources later on. You can also contact your SAP sales representative and opt for a configuration, tailored to your needs.</p> <p>If you want to start out exploring services for free, you can sign up for a Pay-As-You-Go for SAP BTP global account and make use of the free tier services only. See <a href="#">Using Free Service Plans [page 72]</a>.</p>	<p>A global account that enables you to build applications and to sell them to your customers.</p> <p>If you want to start out exploring services for free, you can sign up for a Pay-As-You-Go for SAP BTP global account and make use of the free tier services only. See <a href="#">Using Free Service Plans [page 72]</a>.</p>
<b>Benefits</b>	Support for productive applications.	<ul style="list-style-type: none"> <li>• Includes SAP Application Development licenses that enable you to get started with scenarios across cloud and on-premise applications.</li> <li>• Offers the opportunity to certify applications and receive SAP partner logo package with usage policies.</li> <li>• Advertise and sell applications via the SAP Store</li> </ul>
<b>Services available</b>	Productive services.	Productive and beta services.
<b>Limitations</b>	Resources according to your contract.	Predefined resources according to your partner package. You can purchase additional resources if necessary.

	Customer Account	Partner Account
<b>Registration</b>	<p>For more information about SAP Integration Suite and SAP Extension Suite pricing, see <a href="https://www.sap.com/products/extension-suite/pricing.html">https://www.sap.com/products/extension-suite/pricing.html</a> and <a href="https://www.sap.com/products/integration-suite/pricing.html">https://www.sap.com/products/integration-suite/pricing.html</a>.</p> <p>Contact us on <a href="#">SAP BTP</a> or via an SAP sales representative.</p> <p>If you're located in China and want to buy a global account on SAP BTP you need to contact an SAP sales representative: <a href="https://www.sap.cn/registration/contact.html">https://www.sap.cn/registration/contact.html</a>.</p>	<p>Sign up to join the <a href="#">SAP Partner Program</a>.</p>
<b>Available Regions</b>	See <a href="#">Regions [page 17]</a> .	See <a href="#">Regions [page 17]</a> .

## Cancelling a SAP BTP Enterprise Account

As a business user, you can cancel your contract via your account executive. As an individual user with a trial account, you can cancel your account in your [SAP for Me account](#). You can also contact the SAP store via their "Contact Us" function.

For the commercial models available for enterprise accounts, see [Commercial Models \[page 67\]](#).

## Related Information

[Getting Started in the Kyma Environment \[page 204\]](#)

[Getting Started with a Customer Account in the ABAP Environment \[page 149\]](#)

[Getting Started with an Enterprise Account in the Cloud Foundry Environment \[page 141\]](#)

## 2.5.1 Commercial Models

SAP BTP offers two different commercial models for enterprise accounts.

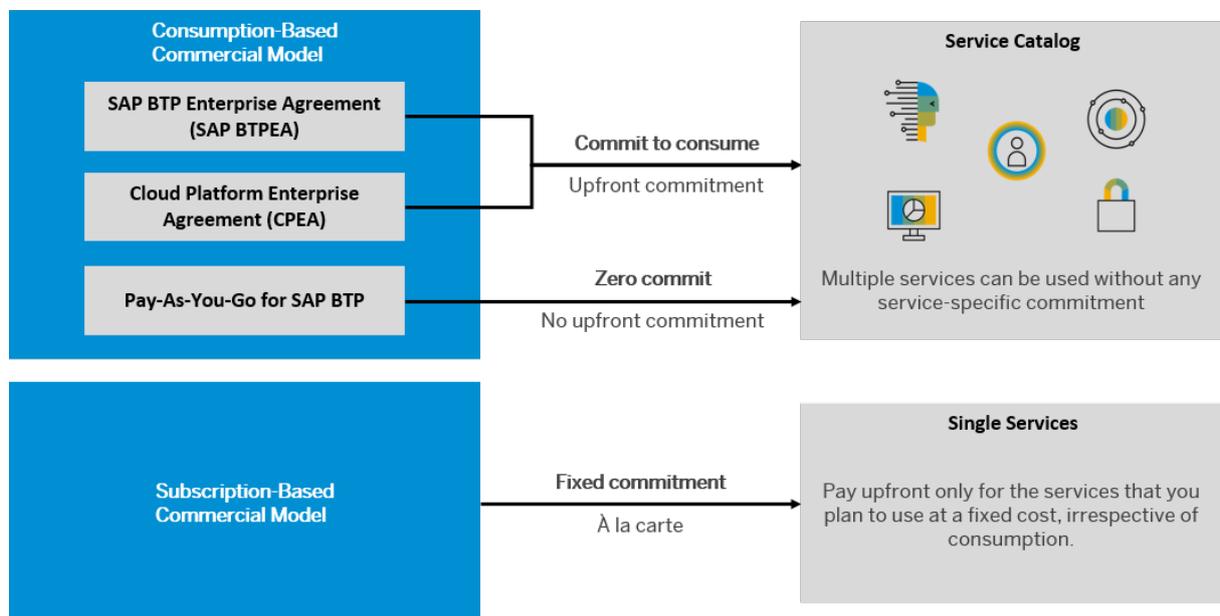

- Consumption-based commercial model:** Your organization receives access to all current and future services that are eligible for this model. You have complete flexibility to turn services on and off and to switch between services as your business requires throughout the duration of your contract. This commercial model is available in the following flavors: SAP BTP Enterprise Agreement (SAP BTPEA), Cloud Platform Enterprise Agreement (CPEA), and Pay-As-You-Go for SAP BTP. For more information, see [What Is the Consumption-Based Commercial Model? \[page 68\]](#)

- **Subscription-based commercial model:** Your organization subscribes only to the services that you plan to use. You can then use these services at a fixed cost, irrespective of consumption. For more information, see [What Is the Subscription-Based Commercial Model? \[page 71\]](#)

### Note

You can use both commercial models, either in separate global accounts or in the same global account depending on your business needs. Contact your SAP account executive or sales representative for more information. Note however that you cannot mix more than one flavor of the consumption-based commercial model in the same global account.

For information about service availability, prices, and estimators, see <https://www.sap.com/products/technology-platform/solutions.html> and <https://www.sap.com/products/technology-platform/integration-suite/pricing.html>. You can also view the service catalog via the [SAP Discovery Center](#).

## 2.5.1.1 What Is the Consumption-Based Commercial Model?

### Note

The use of the consumption-based commercial model is subject to its availability in your country or region.

With the consumption-based model, your organization purchases an entitlement to all current and future SAP BTP services that are eligible for this model. Throughout the duration of your contract, you have complete flexibility to turn services on and off and to switch between services as your business requires.

The consumption-based commercial model is available in the following flavors: the **SAP BTPEA (SAP BTP Enterprise Agreement)**, the **CPEA (Cloud Platform Enterprise Agreement)**, and **Pay-As-You-Go for SAP BTP**. Each option is suited to different business situations and levels of financial commitment, as described in the table below. For additional information and clarifications, please contact your account executive.

## SAP BTPEA

- Your organization makes a prepaid investment in cloud credits for the contract duration with an annual commitment to consume SAP BTP services.
- This model is suitable for customers that have well-established and planned use cases, and who want the flexibility of turning services on and off, and switching between services, without the commitment of being tied to a single service throughout the duration of the contract.
- You receive a monthly balance statement that provides information about the usage consumption of each service and the corresponding costs. The total monthly cost is deducted from your cloud credits balance.
- This model has a minimum investment entry, and volume-based discounts are available.
- You are billed annually in advance. Any overages are billed in arrears at list price.
- You can top up your cloud credits at any time to prevent overages.
- You get access to new SAP BTP services that are added to the consumption-based service catalog.

---

## CPEA

### Note

The service scope of CPEA will no longer be extended. All new services will be available with SAP BTPEA instead.

- Your organization makes a prepaid investment in cloud credits for the contract duration with an annual commitment to consume SAP BTP services.
- This model is suitable for customers that have well-established and planned use cases, and who want the flexibility of turning services on and off, and switching between services, without the commitment of being tied to a single service throughout the duration of the contract.
- You receive a monthly balance statement that provides information about the usage consumption of each service and the corresponding costs. The total monthly cost is deducted from your cloud credits balance.
- This model has a minimum investment entry, and volume-based discounts are available.
- You are billed annually in advance. Any overages are billed in arrears at list price.
- You can top up your cloud credits at any time to prevent overages.

## Pay-As-You-Go for SAP BTP

- You have the same access to all the services that are available in SAP BTPEA, but with a highly flexible zero-commitment model – you pay nothing upfront and there is no minimum usage requirement or annual commitment.
- You pay only for the SAP BTP services that you want, when you use them.
- You are billed monthly in arrears.
- Service charges are non-discountable.
- This low-risk model is suitable for customers with use cases that are not well defined, and are interested in running a proof-of-concept in a productive environment. This model provides the flexibility of turning services on and off, and switching between services, as needed throughout the duration of the contract.
- A seamless transition to the CPEA model is available, on the condition that you have no other CPEA-based global accounts.

If you want information about the **Pay-As-You-Go for SAP BTP for cloud test, demo, and development** commercial model, go to the [SAP Partner Portal](#).

### Note

- In global accounts that use the consumption-based commercial model, SAP BTP, Cloud Foundry Runtime is not listed in the *Entitlements* pages in the SAP BTP cockpit. A technical limit of 200 GB of Cloud Foundry Runtime memory is assigned by default to every subaccount. The limit defines the maximum amount of runtime memory that can be used in the subaccount. Note that the “Standard” plan in the consumption-based commercial model is a paid plan and that you are billed based on the amount of Cloud Foundry Runtime you consume. For more information on consumption monitoring, see [Consumption Monitoring](#).
- If you need to increase this limit, report an incident to [SAP support](#) on the BC-NEO-CIS component. This also applies to other services that have a technical quota limit.

### → Tip

You can monitor costs and service usage throughout the contract period. See [Monitoring Usage and Consumption Costs in Your Global Account \[page 1950\]](#).

For information about eligible services and pricing, see <https://www.sap.com/products/technology-platform/pricing.html>, or access the SAP BTP service catalog via the [SAP Discovery Center](#). The SAP BTP service catalog allows you to identify service availability per data center and to determine licensing model compatibility per available service plan.

As part of the free tier model for SAP BTP, some services offer free service plans that allow you to try out these services without any additional charge within your SAP BTPEA, CPEA, or Pay-As-You-Go for SAP BTP global account. For more information, see [Using Free Service Plans \[page 72\]](#).

To find frequently asked questions about the consumption-based commercial model, see the *Frequently Asked Questions* section in <https://www.sap.com/products/technology-platform/pricing.html>.

## Note

Depending on your business needs, you can combine the consumption-based commercial model with the subscription-based commercial model in the same global account, or you can use both commercial models in the same global account. Contact your SAP account executive or sales representative for more information. Note however that you cannot mix more than one flavor of the consumption-based commercial model in the same global account.

## Related Information

[Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#)

### 2.5.1.2 What Is the Subscription-Based Commercial Model?

Your organization receives a fixed price and period (typically a 1 to 3-year period) for access to your subscribed SAP BTP services.

Under this commercial agreement:

- You are entitled to use only the subscribed services.
- To access additional services, at an extra cost, you can modify your contract via your sales representative or account executive.
- You pay at a fixed cost, regardless of consumption of subscribed services.
- You pay in advance when the contract period starts.
- Your organization can renew the subscription at the end of the contract period.

For information about available services and pricing, see [SAP Store](#).

You can also access the SAP BTP service catalog via the [SAP Discovery Center](#) to identify the availability of services by data center, and also to determine licensing model compatibility per service plan.

Note that some services can be subscribed based on a user metric or a resource metric. For example, a Portal service can be based on the number of site visits or user metrics. A resource-based metric is more common when dealing with a large number of users; for example, suppliers accessing a portal to interact with your organization. Since it isn't always possible to predict how many resources would be required upfront for a three-year period, you can increase your original order if resource usage exceeds your subscribed quota. Using SAP BTP cockpit, you can view resource consumption within your global account on a monthly basis.

In the subscription-based model, you also get access to bundles or packages that comprise several related services and apps. Most of the time, this works out to be more cost effective when compared to subscribing to individual SAP BTP services.

## Can an existing global account under a consumption-based contract be transformed to the subscription-based model?

You can change your existing contract from the consumption-based commercial model to a subscription license. Keep in mind that not all services that are eligible for the consumption-based model are compatible with the subscription-based model. We recommend that you contact your SAP account executive or sales representative to discuss feasibility and terms of transforming your contract.

Note that you can use both consumption and subscription-based commercial models either in separate global accounts or in the same global account depending on your business needs. Contact your SAP account executive or sales representative for more information.

## 2.5.2 Using Free Service Plans

The free tier model for SAP BTP lets you try out services in global accounts without any additional cost using the consumption-based commercial model and an [enterprise account](#).

We offer free service plans for many services within SAP BTP. Free service plans are limited in scope and capacity. They are designed to allow you and your team to explore new SAP BTP capabilities before committing to subscribing to a full capacity paid service.

The free tier model for SAP BTP is added automatically to new and existing contracts using the consumption-based commercial model. There, the free service plans are visible.

### Note

The use of the consumption-based commercial model is subject to its availability in your country or region.

The consumption-based commercial model is available in the following flavors: the **SAP BTPEA (SAP BTP Enterprise Agreement)**, the **CPEA (Cloud Platform Enterprise Agreement)** and **Pay-As-You-Go for SAP BTP**. For more information, see [What Is the Consumption-Based Commercial Model? \[page 68\]](#).

To try out services that participate in the free tier model for SAP BTP, create a service instance using the **Free** service plan offered by the service.

#### → Tip

To find out which services offer the free plans, see [Discover Free Services \[page 73\]](#). Here, you also find information on how to identify the technical limitations of the free plan of each service. [Access Free Services \[page 74\]](#) by assigning entitlements to subaccounts and creating service instances.

Once you reach the technical limits of a service and want to continue using it, you must move to a paid service plan. Upgrading an existing service instance from free tier to paid usually doesn't require creating a new service instance. Find out how to upgrade a service plan at [Upgrade to a Paid Service Plan \[page 74\]](#).

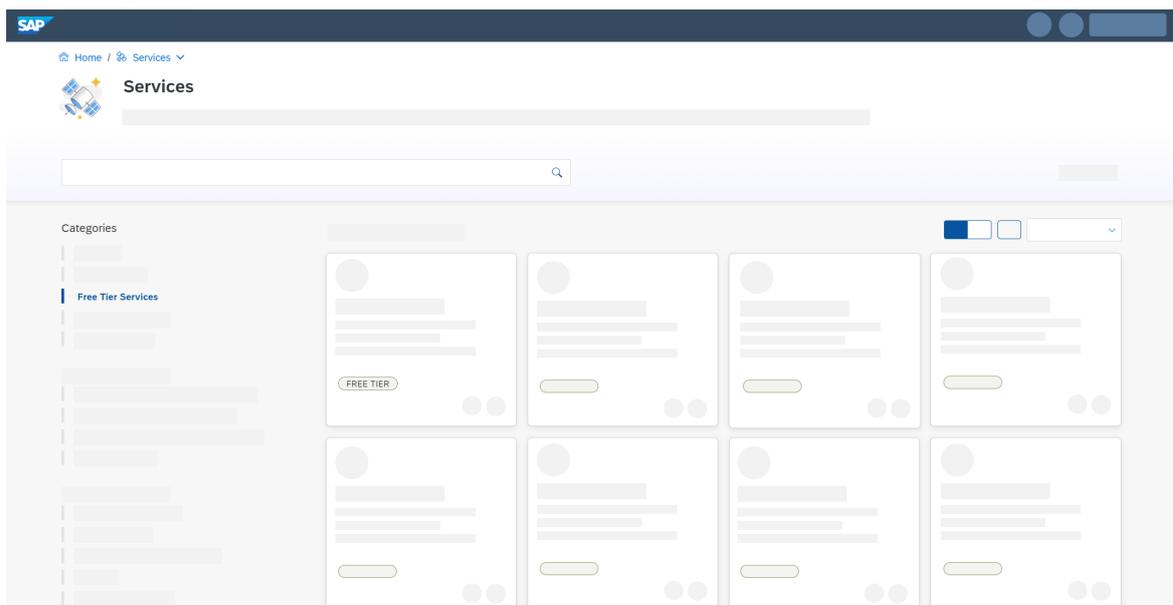

Use of free tier service plans is subject to additional terms and conditions as provided in the [Business Technology Platform Supplemental Terms and Conditions](#). Only community support is available for Free service plans and these aren't subject to SLAs.

## Discover Free Services

Find out which services offer Free plans and what the limitations are.

Free Tier services can be explored in the service catalog of SAP Discovery Center. A free tier service appears as a "Free" plan offering for a service.

1. Access the [Service Catalog](#) in the [SAP Discovery Center](#).
2. In the [Categories](#) section, select [Free Tier Services](#).

3. Select one of the services displayed in the catalog.
4. Navigate to the [Pricing](#) tab.

On this page, you can see all available plans for this service, including the limitations of each plan. Plans that participate in the free tier model for SAP BTP are labeled **Free**.

## Access Free Service Plans

To try out the free tier model for SAP BTP, you must entitle your subaccount for the free plan and create a service instance using this plan.

### Note

The free tier model for SAP BTP is available for accounts that use the consumption-based commercial model.

1. Enter your global account.  
For more information, see [Access the Cockpit](#).
2. Configure entitlements for the subaccount in which you want to use the free service plans. Select the service and choose the free plan.  
For more information, see [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#).
3. Navigate into the subaccount and go to the [Service Marketplace](#).
4. Find the service you want to try out and select it.  
You find a description of the available service plans, including the free service plan. By clicking [More](#), you find the scope and limitations of the free plan for this service.
5. Create an instance of the service and select the free service plan.  
For more information, see [View and Manage Services from the Service Marketplace](#).

You can now start using this service.

## Update to a Paid Service Plan

Once you've reached the limits of the free plan, you can upgrade the free service plan to a paid plan.

### Note

The option to upgrade from free tier service plans to paid service plans is not yet available for all services and runtimes, such as Kyma. To use a paid service plan for Kyma runtime, you will need a new Kyma cluster. It is possible to have both - free and paid clusters - in parallel.

### Note

It's not possible to switch from a paid plan to a free plan.

1. In your subaccount, navigate to the [Instances and Subscriptions](#) page.
2. Find the instance of the service and click **⋮ (Actions)** and [Update](#).
3. In the [Update Instance](#) dialog, change the plan to a paid service plan.
4. Click [Update Instance](#) to save your changes.

You can now use the service without the limitations of the free service plan.

## Scope

- The free tier model for SAP BTP is available for CPEA and Pay-As-You-Go for SAP BTP contracts. For more information, see [What Is the Consumption-Based Commercial Model? \[page 68\]](#).
- Services using the free tier service plans run on the same platform as paid services.
- Services are technically limited. This limit depends on the service. You can find a description of the service plans in the [Service Marketplace](#) in the cockpit or in the [SAP Discovery Center](#).

## 2.6 Account Model

Learn more about the different types of accounts on SAP BTP and how they relate to each other.

Accounts are structured according to global accounts, subaccounts, and directories [Feature Set B].

To learn more about managing your account model, see [Account Administration \[page 1935\]](#).

### 2.6.1 Global Accounts

A **global account** is the realization of a contract you or your company has made with SAP.

A global account is used to manage subaccounts, members, entitlements and quotas. You receive entitlements and quotas to use platform resources per global account and then distribute the entitlements and quotas to the subaccount for actual consumption. There are two types of commercial models for global accounts: consumption-based model and subscription-based model. See [Commercial Models \[page 67\]](#).

Global accounts are region- and environment-independent. Within a global account, you manage all of your subaccounts, which in turn are specific to one region.

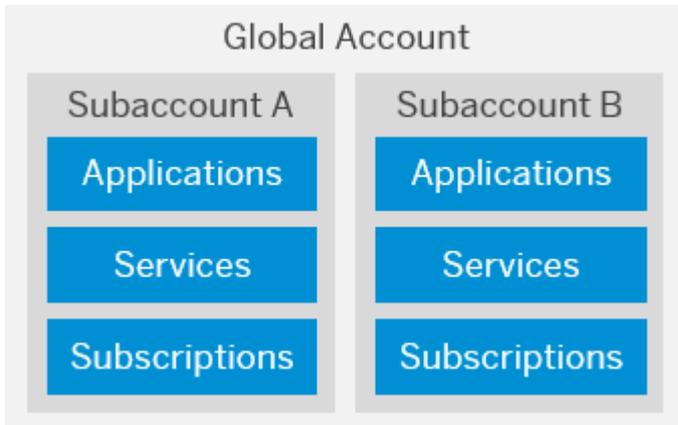

### 2.6.2 Subaccounts

**Subaccounts** let you structure a global account according to your organization's and project's requirements with regard to members, authorizations, and entitlements.

A global account can contain one or more subaccounts in which you deploy applications, use services, and manage your subscriptions. Subaccounts in a global account are independent from each other. This is

important to consider with respect to security, member management, data management, data migration, integration, and so on, when you plan your landscape and overall architecture.

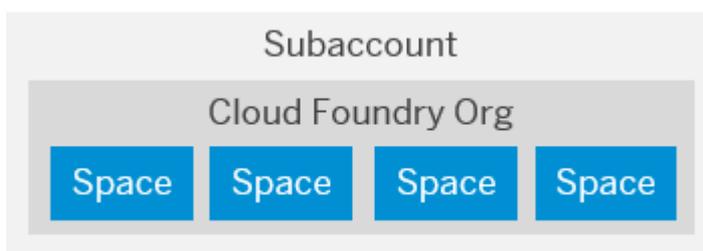

Each subaccount is associated with a region, which is the physical location where applications, data, or services are hosted. The specific region is relevant when you deploy applications and access the SAP BTP cockpit using the corresponding cockpit URL. The region assigned to your subaccount doesn't have to be directly related to your location. You could be located in the United States, for example, but operate your subaccount in Europe.

The entitlements and quotas that have been purchased for a global account have to be assigned to the individual subaccounts.

Global accounts and subaccounts are completely independent of user accounts. For more information, see [User and Member Management \[page 85\]](#).

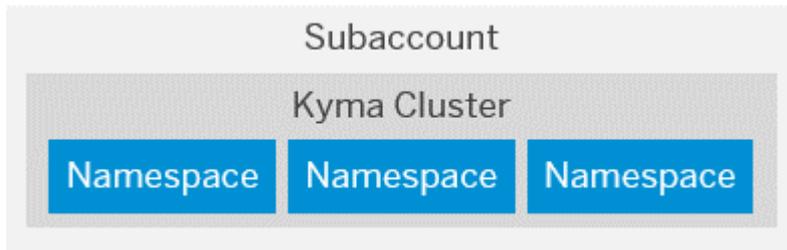

### Subaccounts, Cloud Foundry Orgs and Kyma Clusters

- When you enable the Cloud Foundry environment in one of your subaccounts, the system automatically creates a Cloud Foundry org for you. The subaccount and the org have a 1:1 relationship and the same navigation level in the cockpit (even though they may have different names). You can create spaces within that Cloud Foundry org. Spaces let you further break down your account model and use services and functions in the Cloud Foundry environment.

For more information about Cloud Foundry orgs and spaces, see the Cloud Foundry documentation at <https://docs.cloudfoundry.org/concepts/roles.html> .

- When you enable the Kyma environment in one of your subaccounts, the system automatically creates a Kubernetes cluster equipped with the latest version of the open-source project "Kyma" for you. The subaccount and the Kyma cluster have a 1:1 relationship. You can create namespaces within that Kyma cluster. Namespaces let you further break down your account model and use services and functions in the Kyma environment. For more information, see the Kubernetes documentation at <https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/> .

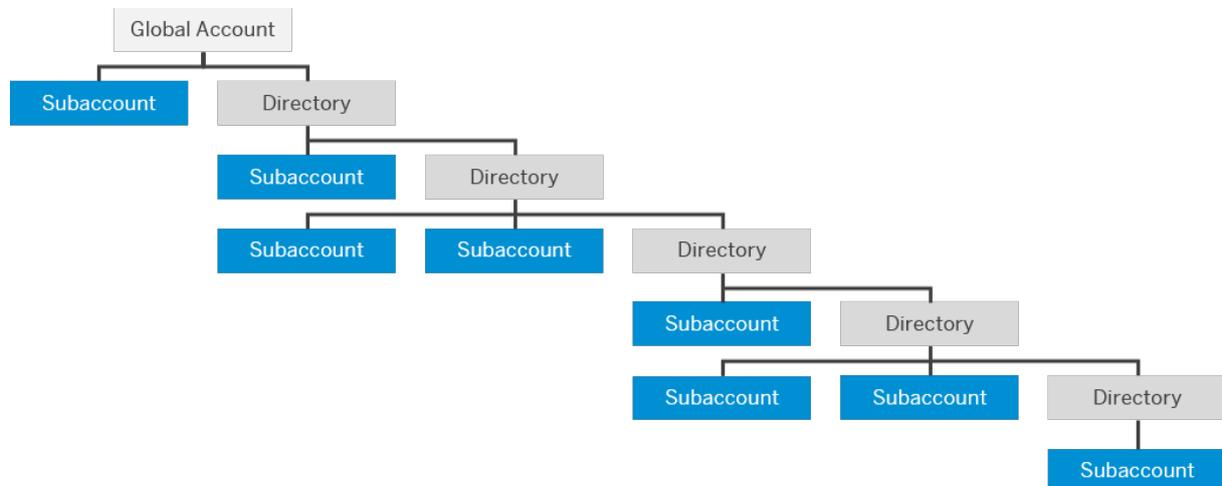

## 2.6.3 Directories [Feature Set B]

With **directories**, you can organize and manage your subaccounts according to your technical and business needs.

A directory can contain directories and subaccounts to create a hierarchy. Using directories to group other directories and subaccounts is optional - you can still create subaccounts directly under your global account.

You can create a hierarchical structure that is up to 7 levels deep. The highest level of a given path is always the global account and the lowest is a subaccount, which means that you can have up to 5 levels of directories between the global account and the lowest level subaccount.

Directories enable you to:

- Group and filter directories and subaccounts
- Monitor usage and costs for contracts that use the consumption-based commercial model

Optionally, you can also enable the following features in your directories:

- **Manage Entitlements:** Enables the assignment of a quota for services and applications to the directory from the global account quota, for distribution to the directory's subaccounts. When you assign entitlements to a directory, you express the entitlements and maximum quota that can be distributed across its children subaccounts. You also have the option to choose the auto-assignment of a set amount of quota to all subaccounts created or moved to that directory. Subaccounts that are already in the directory when you select that option will not be auto-assigned quota.

### Note

If you've enabled the Manage Entitlements feature for a given directory, you must first assign the necessary entitlements and maximum allowed quota from the global account to that directory. Then you can distribute this "reserved" quota to any of the directory's child subaccounts.

- **Manage Authorizations:** Enables authorization management for the directory. For example, it allows certain users to manage directory entitlements. You can only use this feature in combination with the *Manage Entitlements* feature.

[Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)

## 2.6.4 Relationship Between Global Accounts and Subaccounts [Feature Set A]

A global account can group together different subaccounts that an administrator makes available to users. Administrators can assign the available quotas of a global account to its different subaccounts and move it between subaccounts that belong to the same global account.

The hierarchical structure of global accounts and subaccounts lets you define an account model that accurately fits your business and development needs. For example, if you want to separate development, testing, and productive usage, you can create a subaccount for each of these scenarios in your global account. You can also create subaccounts for different development teams or departments in your organizations.

For more information about the relationship between a global account and its subaccounts, see the graphic in [Basic Platform Concepts](#). For best practices, see [Setting Up Your Account Model](#).

## 2.6.5 Relationship Between Global Accounts, Subaccounts, and Directories [Feature Set B]

A global account can group together different directories and subaccounts that an administrator makes available to users. Administrators can assign the available entitlements and quotas of a global account to its different subaccounts and move it between subaccounts that belong to the same global account.

### Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

The hierarchical structure of global accounts, directories, and subaccounts lets you define an account model that accurately fits your business and development needs. For example, if you want to separate development, testing, and productive usage for different departments in your organization, you can create a directory for each department, and within each directory, you group subaccounts for development, testing, and production.

## 2.6.6 Labels [Feature Set B]

Labels are user-defined words or phrases that you can assign to various entities in SAP BTP to categorize them in your global account, to identify them more easily.

For example, in the [Account Explorer](#) page in the cockpit, you can quickly filter for directories and subaccounts by label.

You can assign labels to these entities when you create or edit them using the SAP BTP cockpit, command line interface (btp CLI), or REST APIs:

- Directories
- Subaccounts
- Multitenant application subscriptions
- Service instances
- Environment instances

### Note

For environment instances, these custom labels are user defined and apply only to SAP BTP. They are not the same labels that might be defined by your environment broker.

Labels are made up of a *label name* (also referred to as a *key*) and up to 10 *values* associated with the label. You can apply label names and values in any way that suits your business and technical needs.

## Types of labels and examples

Types of Labels	Examples
Single-value labels are useful for labels that have an identifier, or for labels with fixed lists.	<ul style="list-style-type: none"><li>Label Name: <b>Cost Object</b> Value: The ID of a cost center number or internal order that is associated with the entity, such as: <b>000001134789</b></li><li>Label Name: <b>Status</b> Value: <b>Active</b> or <b>Inactive</b></li><li>Label Name: <b>Landscape</b> Value: <b>Dev</b> or <b>Test</b> or <b>Production</b></li></ul>
Multi-value labels make them useful for labels that typically have more than one value assigned to them.	<ul style="list-style-type: none"><li>Label Name: <b>Contacts</b> Value: The e-mail addresses or names of users that are responsible for the entity, such as: <b>admin-1@example.com</b> and <b>admin-2@example.com</b></li></ul>
Labels can also be assigned with a name only and no value. In such cases, the label behaves like tag.  Note that currently for service instances, labels must have at least value.	<ul style="list-style-type: none"><li>Label Name: <b>For demo only</b></li><li>Label Name: <b>Audited</b></li><li>Label Name: <b>Flagged for deletion</b></li></ul>

### Note

Labels replace what were previously called "custom properties". Custom properties supported only single values per label and were available only to directories and subaccounts. As a result of the move to labels, all relevant commands in the SAP BTP command line interface (btp CLI) and in the relevant REST APIs in the SAP Cloud Management service have been updated accordingly. The `custom-properties` parameter in the btp CLI and the `customProperties` field in the relevant REST APIs are deprecated.

You can assign labels when you create an entity, and then later add, change, or remove labels by editing the entity.

### → Tip

- In the *Account Explorer* and *Instances and Subscriptions* pages in the SAP BTP cockpit, assigned labels are shown in the *Labels* column. To display the column if it is not shown, click  (*Configure Table Columns*).
- In the *Account Explorer* page, you can view the labels that are assigned to a directory or subaccount by choosing the *More Info* option of each directory and subaccount. Assigned labels are also listed under the *Labels* tab when you display the *Overview* page of every directory and subaccount.
- In the *Account Explorer* and *Instances and Subscriptions* pages, you can filter the displayed entities by their assigned labels in the *Search* field.
- In the *Instances and Subscriptions* page, you can also view the labels that are assigned to a subscription or instance by expanding its details panel.

When working with labels, consider the following aspects:

- In the cockpit, each entity can have up to 10 labels assigned to it.
- You cannot add the same label name more than once to the same entity.
- Existing label names and values are offered as suggestions when you or anyone else assigns a label to other entities of the same type in your global account.  
When you view a subaccount in the cockpit, the subaccount also shows the labels that are assigned to its parent directory and to other directories that are above it in the same path in your account structure. And in the *Account Explorer*, when you filter by labels that are assigned to a directory, the subaccounts in that directory path are also listed. We refer to these as inherited labels.
- Label names and values are case-sensitive, which means you can create variants of the same label name with a different casing; for example, **My Label** and **My label** can coexist as separate labels. We recommend that you avoid using different casing or styling to create variants of the same names or values.

## 2.7 Entitlements and Quotas

When you purchase an enterprise account, you're entitled to use a specific set of resources, such as the amount of memory that can be allocated to your applications.

### Services and Service Plans

On SAP BTP, all external dependencies such as databases, messaging systems, files systems, and so on, are **services**. In this context, multitenant applications and environments are considered services.

Each service has one or more **service plans** available. A service plan is the representation of the costs and benefits for a given variant of a particular service. For instance, a database may be configured with various "T-shirt sizes", each of which is a different service plan.

## Entitlements

An **entitlement** is your right to provision and consume a resource. In other words, entitlements are **the service plans** that you're entitled to use.

## Quotas

A **quota** represents the numeric quantity of a service plan that you're entitled to consume in your global account and its subaccounts.

From the perspective of your SAP BTP global account contract, the global quota of a service plan can be defined as either fixed or unlimited:

- **Fixed quota:** The quota or allowance of the service plan is the upper limit at which the plan can be consumed collectively across your global account. This is typical of global accounts that have the **subscription-based** commercial model agreement.
- **Unlimited quota:** There is no upper limit to how much the service plan can be used collectively across your global account. This is typical of most services that are eligible to global accounts with a **consumption-based** commercial model agreement (Cloud Platform Enterprise Agreement (CPEA) and Pay-As-You-Go for SAP BTP). At the end of the month, the number of units used determines how much you are charged.

Regardless of whether the global quota of a plan on the global account level is fixed or unlimited, the specifics and properties of each plan determines how its quota can be distributed by the global account admin to the subaccounts in your global account. There are two types of quota assignments:

- **Numeric assignments:** The global account admin assigns the plan to a subaccount and specifies the maximum quantity of units from the global quota that can be consumed by the subaccount. Admins can use this assignment to limit users from exceeding a specific quota for cost-controlling purposes. Typically, but not always, the assigned quota is directly related to the number of instances that can be created in subaccounts for the assigned plan.
- **Non-numeric assignments:** The global account admin does not assign a specific quantity but simply grants access to the specific plan by assigning the plan to the subaccount. When the plan is assigned, it's available for use by the subaccount. SaaS application assignments are typically non-numeric, whereby a subaccount can either subscribe to the app or not. For services that fall into this category of non-numeric assignments, there is usually no limit to the number of instances that can be created.

See also the sections below and [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#).

## Distribution and Usage of Entitlements and Quotas [Feature Set A]

Entitlements and quotas are purchased and managed at global account level, from where they're distributed to subaccounts, which consume them.

When you remove quotas or assignments from a subaccount, they become available again at global account level and can be assigned to other subaccounts.

For example, let's say you've purchased 10 units of service plan <x> for your global account. If you have 3 subaccounts in your global account and you assign all 10 units to only one of them, the other 2 subaccounts won't be able to use that service plan at all. You would have to remove some quota from that one subaccount and then entitle that service plan to the other subaccount, distributing the globally available quota among them.

For more information, see [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#).

## Distribution and Usage of Entitlements and Quotas [Feature Set B]

Entitlements and quotas are purchased and managed at global account level, from where they're distributed to subaccounts, which consume them.

### → Tip

You can also distribute entitlements to directories, and then redistribute to the subaccounts under the directories; however, this is optional. By default, directories are not enabled to manage entitlements. This feature needs to be enabled per directory by the global account administrator.

When assigning entitlements and quotas to directories, you also have the option to automatically assign a set amount of quota to each new subaccount added to the directory. This option doesn't apply to subaccounts that are already in the directory when you select this option. The quota you assigned to the directory is then gradually distributed to all subaccounts that you add to that directory, until it runs out. Once the directory quota runs out, if you add a new subaccount to that directory it won't get any quota automatically anymore.

Since directories are only a way of grouping subaccounts, you can't consume a service at directory level. However, when you assign entitlements and quotas from the global account to a directory, the quota you assigned is shown as used, even if there are no subaccounts in that directory to consume the quota. You can think of it as a way to "reserve" quota and make sure it's not assigned to other subaccounts or directories.

When you remove quotas or assignments from a directory or subaccount, they become available again at global account level and can be assigned to other directories or subaccounts; unless the quota is reserved for a given directory then the freed quota remains available only to that directory and its subaccounts.

### ⓘ Note

Before a subaccount admin can enable a quota-based environment, such as Kyma, the subaccount admin must first assign the environment as an entitlement to the subaccount. Other environments, such as Cloud Foundry, are available by default to all subaccounts, and therefore are not available as entitlements.

For more information, see:

- [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)
- [Configure Entitlements and Quotas for Directories \[Feature Set B\] \[page 1998\]](#)

## Quota Plans

In the Cloud Foundry environment, you can further distribute the quotas that are allocated to a subaccount. This is done by creating space quota plans and assigning them to the spaces.

Space quota plans are optional and are used to limit how much each space can use, not to enable. If you don't create any space quota plans, all spaces in a subaccount using the Cloud Foundry environment have access to all entitlements and quotas in that subaccount. This means that one space could use up all the quota in a subaccount. If you want to prevent that from happening and set a limit to how much each space can use from the total quota available in the subaccount, you can use quota plans and assign them to spaces.

For more information on space quota plans in the Cloud Foundry environment, see:

- <https://docs.cloudfoundry.org/adminguide/quota-plans.html> 
- [Managing Space Quotas \[page 2254\]](#)

## Resource Providers

SAP BTP allows you to connect your global account in the SAP BTP Cockpit to your provider account from a non-SAP cloud vendor, and consume remote service resources that you already own and which are supported by SAP through this channel.

For example, if you're subscribed to Amazon Web Services (AWS) and have already purchased services, such as PostgreSQL, you can register the vendor as a resource provider in SAP BTP and consume this service across your subaccounts together with other services offered by SAP.

SAP BTP currently supports the following vendors and their consumable services:

Cloud Vendor	Supported Services
Amazon Web Services	<a href="#">Amazon Relational Database Service (RDS) - PostgreSQL</a>
Microsoft Azure	<a href="#">Azure Database for PostgreSQL</a>

After you configure a new resource provider, its supported services are added as entitlements in your global account. In the  [Entitlements](#)  page in the cockpit, you can then allocate the required services and quotas to the relevant directories and subaccounts in your global account.

For more information, see [Managing Resource Providers \[page 1947\]](#).

## Related Information

[Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#)

[Tutorial: Manage Entitlements on SAP BTP Trial](#)

[Troubleshooting: Entitlement and Quota Problems](#)

## 2.8 User and Member Management

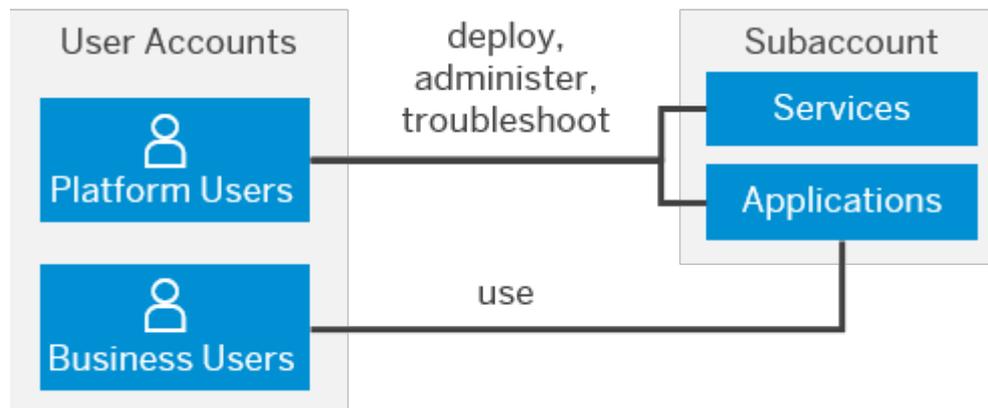

On SAP BTP, member management happens at all levels from global account to environment, while user management is done for business applications.

### User Accounts

A user account corresponds to a particular user in an identity provider, such as the default identity provider or a custom tenant of the Identity Authentication service.

**User accounts** enable users to log on to SAP BTP and access subaccounts and use services according to the permissions given to them.

Before diving into the different user and member management concepts, it's important to understand the difference between the different types of users we're referring to: **Platform users** and **business users**.

## Related Information

[Working with Users \[page 2078\]](#)

[Roles and Role Collections \[page 2099\]](#)

[Attributes \[page 2102\]](#)

[Trust and Federation with Identity Providers \[page 2014\]](#)

## 2.8.1 Platform Users

**Platform users** are usually developers, administrators or operators who deploy, administer, and troubleshoot applications and services on SAP BTP. They're the users that have full access and give certain permissions for instance at global account, directory, or subaccount level. Members only have basic access.

Platform users who have administrative permissions can view or manage the list of global accounts, subaccounts, and environments, such as Cloud Foundry orgs and spaces. Members have basic access to them using the SAP BTP cockpit, the SAP BTP command-line interface (btp CLI), or environment-specific CLI, such as the Cloud Foundry (CF) CLI.

For platform users, there's a [default identity provider \[page 2072\]](#). We expect that you have your own identity provider. We recommend that you configure your custom tenant of Identity Authentication as the identity provider and connect Identity Authentication to your own corporate identity provider.

### Note

For China (Shanghai) and Government Cloud (US) regions, a different default identity provider is used. You can't use Identity Authentication as identity provider in the global account.

For more information on the China (Shanghai) region, see this [blog article](#) on *SAP Community*.

## Member Management

**Member management** refers to managing permissions for platform users. Members have only basic access to SAP BTP.

Member management happens at global account, directory, subaccount, and environment level. Members' permissions apply to all operations that are associated with the global account, the organization, or the space, irrespective of the tool used. Depending on the scope and the cloud management tools feature set you're using, you manage members in different ways:

	Global Accounts	Directories	Subaccounts
<b>Feature Set A</b>	<p>You add global account administrators on the <a href="#">Members</a> page at global account level in the SAP BTP cockpit. All members/administrators of the lower levels (for example, subaccounts or spaces) are automatically global account members.</p> <p>On the <a href="#">Members</a> page at the global account level in the SAP BTP cockpit, all global account members can view the global account administrators.</p> <p>You can only manage global account administrators using the SAP BTP cockpit.</p> <p>See <a href="#">Add Members to Your Global Account [page 1944]</a>.</p>	Not available	<p>You don't have member management at subaccount level directly.</p> <p>The person who created the subaccount is automatically a security administrator of that subaccount. That person can assign additional subaccount security administrators on the <a href="#">Security Administrators</a> page at subaccount level in the SAP BTP cockpit.</p> <p>As a security administrator, you can manage authentication and authorization in the subaccount for business users, such as configuring trust to application identity providers, and assigning role collections to business users.</p> <p>You can only manage subaccount security administrators using the SAP BTP cockpit.</p> <p>See <a href="#">Managing Security Administrators in Your Subaccount [Feature Set A] [page 1980]</a></p>

	Global Accounts	Directories	Subaccounts
<b>Feature Set B</b>	<p>You manage global account members by assigning role collections to platform users. Use the following predefined role collections:</p> <ul style="list-style-type: none"> <li>• Global Account Administrator</li> <li>• Global Account Viewer</li> </ul> <p>Assign these role collections from the SAP BTP cockpit or the btp CLI.</p> <p>See:</p> <p><a href="#">Role Collections and Roles in Global Accounts, Directories, and Subaccounts [Feature Set B] [page 89]</a></p> <p><a href="#">Add Members to Your Global Account [page 1944]</a></p> <p><a href="#">Create Users [page 2083]</a></p>	<p>You manage directory members by assigning role collections to platform users. Use the following predefined role collections:</p> <ul style="list-style-type: none"> <li>• Directory Administrator</li> <li>• Directory Viewer</li> </ul> <p>Assign these role collections from the SAP BTP cockpit or the btp CLI.</p> <p>See:</p> <p><a href="#">Role Collections and Roles in Global Accounts, Directories, and Subaccounts [Feature Set B] [page 89]</a></p> <p><a href="#">Create Users [page 2083]</a></p> <p><a href="#">Manage Users in Directories [Feature Set B] [page 1973]</a></p>	<p>You manage subaccount members by assigning role collections to platform users.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px; margin: 5px 0;"> <p><b>Note</b></p> <p>Neo subaccounts don't use role collections.</p> <p>For more information, see <a href="#">Managing Member Authorizations in the Neo Environment</a>.</p> </div> <p>Use the predefined role collections, such as:</p> <ul style="list-style-type: none"> <li>• Subaccount Administrator</li> <li>• Subaccount Viewer</li> </ul> <p>Assign these role collections from the SAP BTP cockpit or the btp CLI.</p> <p>See:</p> <p><a href="#">Role Collections and Roles in Global Accounts, Directories, and Subaccounts [Feature Set B] [page 89]</a></p> <p><a href="#">Add Members to Your Subaccount [Feature Set B] [page 1984]</a></p> <p><a href="#">Create Users [page 2083]</a></p>

Member management in the Cloud Foundry or Kyma environment environment is independent of the feature set you use. For more information on the Kyma environment, see [Getting Started in the Kyma Environment \[page 204\]](#).

## Member Management in the Cloud Foundry Environment

Orgs	Spaces
Manage org members on the <a href="#">Members</a> page at environment level in the SAP BTP cockpit or with the Cloud Foundry CLI.	Manage space members on the <a href="#">Members</a> page at space level in the SAP BTP cockpit or with the Cloud Foundry CLI.
A platform user added as an org member can be either an <b>Org Manager</b> or an <b>Org Auditor</b> or implicitly as an <b>Org User</b> .	A platform user added as a space member can be either a <b>Space Manager</b> , <b>Space Developer</b> , <b>Space Auditor</b> , or <b>Space Supporter</b> .
See: <a href="#">About Roles in the Cloud Foundry Environment [page 2244]</a> <a href="https://docs.cloudfoundry.org/concepts/roles.html#roles">https://docs.cloudfoundry.org/concepts/roles.html#roles</a>  <a href="#">Add Org Members Using the Cockpit [page 2248]</a>	See: <a href="#">About Roles in the Cloud Foundry Environment [page 2244]</a> <a href="https://docs.cloudfoundry.org/concepts/roles.html#roles">https://docs.cloudfoundry.org/concepts/roles.html#roles</a>  <a href="#">Add Space Members Using the Cockpit [page 2252]</a>

See also [About User Management in the Cloud Foundry Environment \[page 2243\]](#).

### 2.8.1.1 Role Collections and Roles in Global Accounts, Directories, and Subaccounts [Feature Set B]

In the cloud management tools feature set B, SAP BTP provides a set of role collections to set up administrator access to your global account and subaccounts.

#### Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

Role collections group authorizations for resources and services. Your administrators assign these role collections to other platform users to create new administrators. Role collections consist of individual roles. For more information on role collections, roles, see the related link.

Role collections are account-specific. Role collections that exist in the global account don't exist in the subaccounts. Likewise, role collections in subaccounts aren't available in the global account.

#### Note

Neo subaccounts don't use role collections.

For more information, see [Managing Member Authorizations in the Neo Environment](#).

## Role Collections

You can use the default role collections, but you can't change or delete them. SAP BTP provides the following administrator role collections:

- [Global Account Administrator](#)
- [Subaccount Administrator](#)
- [Directory Administrator](#)
- [Cloud Connector Administrator](#)
- [Connectivity and Destination Administrator](#)
- [Destination Administrator](#)
- [Subaccount Service Administrator](#)

SAP BTP provides also viewer role collections for the global account and for subaccounts. In contrast to the administrator role collections, viewer role collections only grant read access.

- [Global Account Viewer](#)
- [Subaccount Viewer](#)
- [Directory Viewer](#)

## Administrator Role Collections

If you assign the [Global Account Administrator](#) role collection to a user, this user can perform administration tasks for subaccounts, role collections, identity providers, entitlements, and regions on the level of the global account. If you assign the [Global Account Viewer](#) role collection, this user can view subaccounts, role collections, identity providers, entitlements, and regions on the level of the global account.

### Note

You can also use the command-line interface (CLI) for SAP BTP to assign authorizations. For more information on managing authorizations, see the related link.

### Global Account Administrator Role Collection

Roles Included	Description
Global Account Admin	<p>Role for global account members with read-write authorizations for core commercialization operations, such as updating global accounts, setting entitlements, and creating, updating, and deleting subaccounts.</p> <p>The <a href="#">GlobalAccount_Admin</a> role template contains this role. You find the role template in the SAP BTP Cockpit if you choose the <a href="#">cis-central&lt;suffix&gt;</a> application identifier.</p>

### Example

[cis-central!b1](#)

Roles Included	Description
Global Account Usage Reporting Viewer	<p>Role for global account members with read-only authorizations for core commercialization operations, such as viewing global account usage information.</p> <p>The <i>GlobalAccount_Usage_Reporting_Viewer</i> role template provides this role. You find the role template in the SAP BTP Cockpit if you chose the <i>uas!&lt;suffix&gt;</i> application identifier</p>
User and Role Administrator	<p>Manage authorizations, trusted identity providers, and users.</p> <p>The <i>xsuaa_admin</i> role template provides this role. You find the role template in the SAP BTP Cockpit if you choose the <i>xsuaa!&lt;suffix&gt;</i> application identifier.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px; margin-top: 10px;"> <p> <b>Example</b></p> <p><i>xsuaa!tl</i></p> </div>

System Landscape Administrator	<p>Administrative access to systems and scenario-related resources.</p> <p>The <i>GlobalAccount_System_Landscape_Administrator</i> role template provides this role. You find the role template in the SAP BTP Cockpit if you choose the <i>cmp!&lt;suffix&gt;</i> application identifier.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px; margin-top: 10px;"> <p> <b>Example</b></p> <p><i>cmp!b7</i></p> </div>
--------------------------------	---

If you assign the *Subaccount Administrator* role collection to a user, you grant a user administration permission for a subaccount.

#### Subaccount Administrator Role Collection

Roles Included	Description
Cloud Connector Administrator	Operate the data transmission tunnels used by the Cloud connector.
Destination Administrator	Manage destination configurations, certificates and subaccount trust via the Destination editor in the SAP BTP cockpit.
Subaccount Admin	Role for subaccount members with read-write authorizations for core commercialization operations, such as viewing subaccount entitlements, and creating and deleting environment instances.

Roles Included	Description
Subaccount Service Administrator	Administrative access to service brokers and environments on a subaccount level.
User and Role Administrator	Manage authorizations, trusted identity providers, and users.

If you assign the *Cloud Connector Administrator* role collection to a user, you grant the user administration permissions for the Cloud Connector in a subaccount.

Cloud Connector Administrator Role Collection

Roles Included	Description
Cloud Connector Administrator	Operate the data transmission tunnels used by the Cloud connector.

If you assign the *Connectivity and Destination Administrator* role collection to a user, you grant the user administration permissions for the Cloud Connector and SAP Destination service in a subaccount.

Connectivity and Destination Administrator Role Collection

Roles Included	Description
Cloud Connector Administrator	Operate the data transmission tunnels used by the Cloud connector.
Destination Administrator	Manage destination configurations, certificates and subaccount trust via the Destination editor in the SAP BTP cockpit.

If you assign the *Destination Administrator* role collection to a user, you grant the user administration permissions for the SAP Destination service in a subaccount.

Destination Administrator Role Collection

Roles Included	Description
Destination Administrator	Manage destination configurations, certificates and subaccount trust via the Destination editor in the SAP BTP cockpit.

If you assign the *Subaccount Service Administrator* role collection to a user, you grant the user administration permissions for the Service Manager in a subaccount.

Subaccount Service Administrator Role Collection

Roles Included	Description
Subaccount Service Administrator	Administrative access to service brokers and environments on a subaccount level.

## Viewer Role Collections

If you assign the *Global Account Viewer* role collection to a user, you grant read access to the same information as the Global Account Administrator role collection.

### Global Account Viewer Role Collection

Roles Included	Description
Global Account Viewer	Role for global account members with read-only authorizations for core commercialization operations, such as viewing global accounts, subaccounts, entitlements, and regions.
Global Account Usage Reporting Viewer	Role for global account members with read-only authorizations for core commercialization operations, such as viewing global account usage information.
User and Role Auditor	Read-only access for authorizations, trusted identity providers, and users.
System Landscape Viewer	Viewer access to systems and scenario-related resources.

If you assign the *Subaccount Viewer* role collection to a user, you restrict a user's viewer permission to the subaccounts.

### Subaccount Viewer Role Collection

Roles Included	Description
Cloud Connector Auditor	View the data transmission tunnels used by the Cloud connector to communicate with back-end systems.
Destination Viewer	View destination configurations, certificates and subaccount trust via the Destination editor in the SAP BTP cockpit.
Subaccount Service Auditor	Read-only access to service brokers and environments on a subaccount level
Subaccount Viewer	Role for subaccount members with read-only authorizations for core commercialization operations, such as viewing subaccount entitlements, details of environment instances, and job results.
User and Role Auditor	Read-only access for authorizations, trusted identity providers, and users.

## Directory Role Collections

The role collections *Directory Administrator* and *Directory Viewer* can be assigned during the creation of a directory. If you select the checkbox *Manage Authorizations* in the creation wizard, you can assign users the role collections during the step *Manage Authorizations*. You can't create custom role collections for directories.

The *Directory Administrator* role collection grants a user administration permission for directories.

### Directory Administrator Role Collection

Roles Included	Description
Directory Admin	Role for directory members with read-write authorizations for core commercialization operations, such as updating directories, setting entitlements, and creating, updating, and deleting subaccounts.
Directory Usage Reporting Viewer	Role for directory members with read-only authorizations for core commercialization operations, such as viewing directory usage information.
User and Role Administrator	Manage authorizations, trusted identity providers, and users.

The *Directory Viewer* role collection grants a user read access to the same information as the Directory Administrator role collection.

### Directory Viewer Role Collection

Roles Included	Description
Directory Usage Reporting Viewer	Role for directory members with read-only authorizations for core commercialization operations, such as viewing directory usage information.
Directory Viewer	Role for directory members with read-only authorizations for core commercialization operations, such as viewing directories, subaccounts, entitlements, and regions.
User and Role Auditor	Read-only access for authorizations, trusted identity providers, and users.

## Roles

Create your own role collections by using the roles of the default role collections. The roles are based on role templates, which are provided by applications. The application identifier refers to the application, which provides the role templates.

### ❁ Example

The *GlobalAccount\_Admin* role template provides the *Global Account Admin* role. You find the role template in the cockpit if you choose the *cis-central!<suffix>* application identifier.

## Example

cis-central!b1

The following table provides the information about the roles that are available.

### Role Details

Roles	Available in	Role Templates	Application Identifier
Cloud Connector Administrator	Subaccount	Cloud_Connector_Administrator	connectivity!<suffix>
Cloud Connector Auditor	Subaccount	Cloud_Connector_Auditor	connectivity!<suffix>
Destination Administrator	Subaccount	Destination_Administrator	destination-xsappname! <suffix>
Destination Viewer	Subaccount	Destination_Viewer	destination-xsappname! <suffix>
Directory Admin	Directory	Directory_Viewer	cis-central!<suffix>
Directory Usage Reporting Viewer	Directory	Directory_Usage_Reporting_Viewer	uas!<suffix>
Directory Viewer	Directory	Directory_Admin	cis-central!<suffix>
Global Account Admin	Global account	GlobalAccount_Admin	cis-central!<suffix>
Global Account Viewer	Global account	GlobalAccount_Viewer	cis-central!<suffix>
Global Account Usage Reporting Viewer	Global account	GlobalAccount_Usage_Reporting_Viewer	uas!<suffix>
System Landscape Administrator	Global account	GlobalAccount_System_Landscape_Administrator	cmp!<suffix>
System Landscape Viewer	Global account	GlobalAccount_System_Landscape_Viewer	extension-service-cmp! <suffix>
Subaccount Admin	Subaccount	Subaccount_Admin	cis-local!<suffix>
Subaccount Viewer	Subaccount	Subaccount_Viewer	cis-local!<suffix>
Subaccount Service Administrator	Subaccount	Subaccount_Service_Administrator	service-manager!<suffix>
Subaccount Service Auditor	Subaccount	Subaccount_Service_Auditor	service-manager!<suffix>
User and Role Administrator	Global account and subaccount	xsuaa_admin	xsuaa!<suffix>

Roles	Available in	Role Templates	Application Identifier
User and Role Auditor	Global account and subaccount	xsuaa_auditor	xsuaa!<suffix>

## Roles in Environments

If you've enabled environments in your subaccount, manage the roles for those environments. For more information, see:

- [About Roles in the Cloud Foundry Environment \[page 2244\]](#)
- [Assign Roles in the Kyma Environment \[page 2766\]](#)

### Note

The ABAP environment uses the roles of the SAP BTP, Cloud Foundry Environment.

## Related Information

[Mapping Role Collections in the Subaccount \[page 2094\]](#)

[Managing Users and Their Authorizations Using the btp CLI \[page 2177\]](#)

### 2.8.1.2 Bringing Your Corporate Identity Provider for Platform Users [Feature Set A]

SAP BTP supports the use of your own identity provider for platform users.

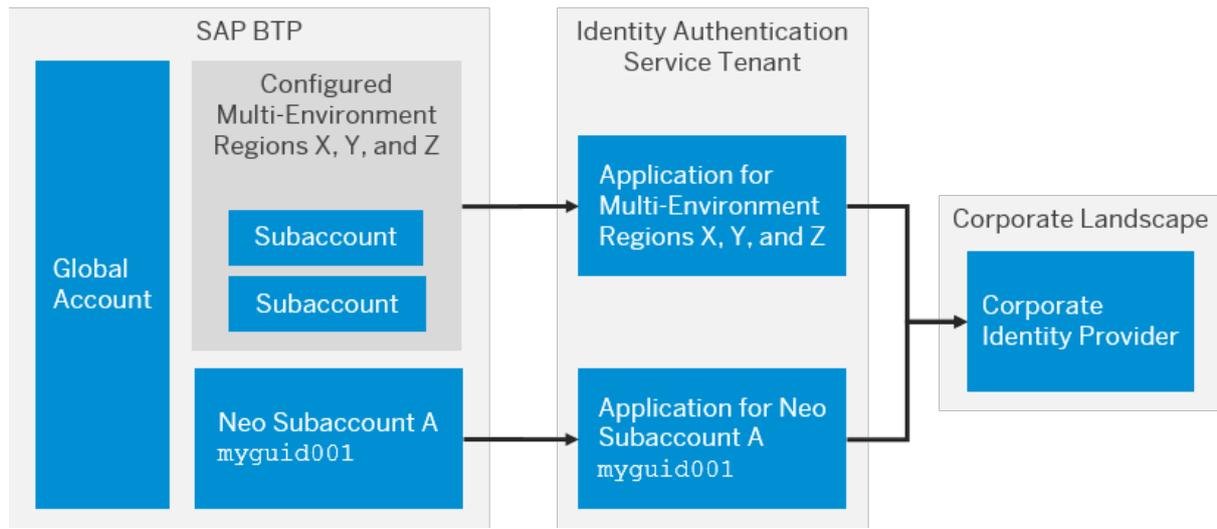

### Note

The content in this section is only relevant for cloud management tools feature set A. For more information, see [Cloud Management Tools - Feature Set Overview](#).

Platform users perform technical development, deployment, and administration tasks. They perform subaccount administration in the SAP BTP cockpit or access the Cloud Foundry command-line interface (CF CLI). By hosting these users in your own identity provider, you gain a number of advantages over hosting them in SAP ID service.

- Integrate the management of these users with your broader identity management strategy, hosted on your own identity providers. You control your own user lifecycle and single sign-on strategies throughout the entire landscape.
- Enforce your own password and authentication policies, such as stronger passwords or multifactor authentication.

The following figure illustrates the architecture required for platform users. This configuration is independent of the default configuration with SAP ID service. You can continue to use SAP ID service in parallel for platform users.

Architecture Required for Custom User Base of Platform Users

In the preceding figure, you enable trust between SAP BTP and your corporate identity provider over your tenant of SAP Cloud Identity Services - Identity Authentication. For each Neo subaccount, you choose the Identity Authentication tenant to use as the platform identity provider. The Identity Authentication tenant automatically configures an application within the tenant and generates an identifier to establish the connection between the two entities. When you log on to a platform resource, such as the cockpit, you indicate the Neo subaccount you want to log on with using this identifier in the subdomain, for example, `https://cockpit.eu10.hana.ondemand.com/cockpit/?idp=bs8ibxkn.accounts.ondemand.com`. Once you've logged on with your platform user, the cockpit displays any global accounts and subaccounts your platform user is a member of.

### Note

An e-mail address alone isn't enough to determine membership in an account. For Neo subaccounts the identifier is the user base (identity provider) and a configurable identifier with the user base; usually the user ID. For multi-environment subaccounts, the identifier is the origin (your Cloud Foundry-specific alias for the identity provider) and e-mail address. For example, you can have a platform user in the default identity provider, SAP ID service, and another user in your corporate identity provider with the same e-mail address. You can log on to the cockpit with both, but the cockpit displays different user information. This difference is because you've logged on with different identity providers.

You also see this difference when assigning roles or membership in subaccount. You must provide the user base or origin in addition to the e-mail address of the user. You can choose your own origin for multi-environment accounts, but the origin must be unique across all SAP customers. We recommend using the subdomain of your Identity Authentication tenant or your organization's name. All your users

must be able to remember or type the origin when they use the Cloud Foundry command-line interface or service dashboards. A string of random characters isn't useful.

To use a corporate identity provider for platform users of a multi-environment subaccount, you need a Neo subaccount set up for the same corporate identity provider. This requirement exists, because logon to the cockpit is dependent on a Neo subaccount. You're extending the existing configuration of your Neo subaccount to add the trust of your corporate identity provider to your multi-environment subaccounts.

For Neo subaccounts, there's a 1:1 relationship between its applications in your Identity Authentication tenant. Multi-environment subaccounts are handled differently. During configuration, you submit a support ticket in which you state all the regions you want to apply this corporate identity provider configuration. This trust then applies to **all** your multi-environment subaccounts in those regions. So, all your multi-environment subaccounts share the same application in your Identity Authentication tenant.

Configuring platform users for multi-environment subaccounts has no impact on your existing Neo configuration. You need the Neo configuration to log on to resources like the cockpit.

#### → Recommendation

While support of multiple corporate identity providers is possible, we recommend using your Identity Authentication tenant as a proxy and use conditional authentication to separate them.

## Related Information

[Establish Trust and Federation of Custom Identity Providers for Platform Users in Multi-Environment Subaccounts \[Feature Set A\] \[page 2050\]](#)

[Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#)

### 2.8.1.3 Bringing Your Corporate Identity Provider for Platform Users Feature Set B

SAP BTP supports the use of your own identity provider for platform users.

#### 📘 Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

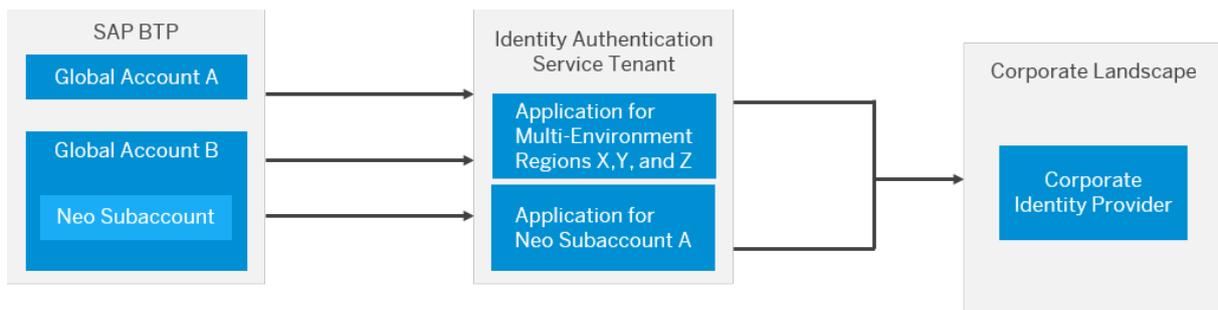

Platform users perform technical development, operations, and administration tasks. They manage global accounts, directories, and subaccounts using the SAP BTP cockpit and the BTP CLI. They also develop and operate custom applications. By hosting these users in your own identity provider, you gain a number of advantages over hosting them in SAP ID service or in SAP Universal ID.

- Integrate the management of these users with your broader identity management strategy, hosted on your own identity providers. You control your own user lifecycle and single sign-on strategies throughout the entire landscape.

- Enforce your own password and authentication policies, such as stronger passwords or multifactor authentication.

The following figure illustrates the architecture required for platform users. This configuration is independent of the default configuration with SAP ID service. You can continue to use SAP ID service in parallel.

**Authentication Architecture for Platform Users with a Corporate Identity Provider**

In the preceding figure, you enable trust between the SAP BTP global account and your corporate identity provider over your tenant of SAP Cloud Identity Services - Identity Authentication. For each global account, you choose the Identity Authentication tenant to use as the identity provider for platform users. For the platform identity provider, you can have up to three Identity Authentication tenants per global account. Multiple global accounts can share the same Identity Authentication tenant. When you log on to a platform resource, such as the cockpit, you indicate the Identity Authentication tenant that you want to log on with. For example, to log on to the cockpit, copy a URL parameter from the cockpit to identify the tenant:

```
https://cockpit.btp.cloud.sap/cockpit/?idp=<tenant>.accounts.ondemand.com
```

For example: `https://cockpit.btp.cloud.sap/cockpit/?idp=cidppuxhm.accounts.ondemand.com`

Once you've logged on, the cockpit displays any global accounts and subaccounts of which your platform user is a member.

Typically, a user is identified by email and origin (your alias for the identity provider). However, to most accurately identify a user, you need both user identifier and an identifier from an identity provider. The reason is that the system treats users with the same name but from different identity providers as separate users. For example, you can have a platform user in the default identity provider, SAP ID service, and another user in your corporate identity provider with the same e-mail address. This behavior applies to global accounts, directories, multi-environment subaccounts, and Cloud Foundry orgs and spaces.

For Neo subaccounts a user is uniquely identified by the user base (hostname of the Identity Authentication tenant) and a configurable subject identifier. You can log on to the cockpit with both, but the cockpit displays different user information. This difference is because you've logged on with different identity providers.

### **Note**

With enhancements of cloud management tools feature set B, the trust configuration between SAP BTP and Identity Authentication changes for platform users (for example, administrators, developers, operators) in the Neo environment. The change only applies to global accounts in cloud management tools feature set B which have custom trust configurations for platform users.

For more information, see [SAP Note 3330671](#).

You also see this difference when assigning roles. You must provide the origin or user base in addition to the e-mail address or user ID of the user. When platform users use the Cloud Foundry command-line interface or service dashboards, they need to remember the origin. You can choose your own origin, but the origin must be unique across all customers. We recommend that you use a meaningful name that helps identify the target it points to.

In Identity Authentication, there's one application that represents SAP BTP overall. So, if you have multiple global accounts with the same Identity Authentication tenant, they all share the same application in your Identity Authentication tenant that is where customers typically configure settings such as the corporate identity provider used for authentication and user attribute mapping between systems. For more information, see [Map User Attributes from a Corporate Identity Provider for Platform Users \[page 2059\]](#).

## Related Information

[Log On with a Custom Identity Provider to the Cloud Foundry Environment Using the Cloud Foundry Command-Line Interface \[page 2065\]](#)

[Establish Trust and Federation of Custom Identity Providers for Platform Users \[Feature Set B\] \[page 2053\]](#)

### 2.8.1.4 Impact of Upgrading from Feature Set A to Feature Set B on User and Account Management

While we've tried to make upgrading your account management feature set as simple as possible, we've had to make a few adjustments. To help you find your way, we've gathered a summary of changes you can expect in your accounts.

#### Note

For more information about the upgrade process itself, see SAP Note [3027721](#).

## Reactivation of the Default Identity Provider for Applications

If you deactivated the default identity provider, SAP ID service, for business users in multi-environment subaccounts in cloud management tools feature set A, the process of upgrading to cloud management tools feature set B reactivates the default identity provider. We reactivate the default identity provider because cloud management tools feature set B also uses it for platform users.

#### Recommendation

Keep at least one user from the default identity provider in each account to still have access if there are ever issues with a custom identity provider.

Even though the default identity provider has been reactivated, the option to authenticate with the default identity provider is hidden from business users. Business users are redirected to your custom identity provider.

Hiding the default identity provider ensures that the user experience for your business users remains the same. Users from the default identity provider can log on, only if the users are authorized, in other words, users with existing shadow users.

For more information about shadow users, see [Working with Users \[page 2078\]](#).

#### Note

Whether the default identity provider was reactivated or not, applications that share the default identity provider, such as SAP Support Portal or your demo application in your subaccount, no longer require reauthentication, when you switch from one application to the other. This change improves the single sign-on experience.

## Custom Identity Providers for Platform Users

In cloud management tools feature set B, you're free to integrate custom identity providers for platform users. If you use custom identity providers for platform users in cloud management tools feature set A, see SAP Note [3264627](#) .

## Global Account Users Identified by E-Mail Address

With cloud management tools feature set B, global account users from the SAP ID service are identified by their e-mail address and not their user ID. If you've multiple user accounts that share the same e-mail address, they all get the same authorizations.

## Mapping Account Authorizations Between Feature Set A and Feature Set B

The following table lists the role collections for account administration that a user has in cloud management tools feature set B, based on the role memberships the user had in cloud management tools feature set A.

Account Authorization Mappings Between Feature Set A and Feature Set B

Authorizations in Feature Set A	Authorizations in Feature Set B	More Information
Administrator of global account	<i>Global Account Administrator</i> in global account and <i>Subaccount Administrator</i> in multi-environment subaccounts	In cloud management tools feature set A, members of the global account have global account administrator privileges. Such users can create and manage subscriptions for subaccounts.  <div data-bbox="1007 562 1394 987" style="border: 1px solid #0070C0; padding: 5px;"> <p>→ Tip</p> <p>To ensure that your global account administrators still have these authorizations, these users are also assigned subaccount administrator authorizations in <b>all</b> multi-environment subaccounts of the global account. After the move, consider if your global account administrators really need subaccount administrator access to all your subaccounts.</p> </div>
Security administrator in multi-environment subaccount	<i>Subaccount Administrator</i> in multi-environment subaccount	Security administrators rely mostly on the <i>User &amp; Role Administrator</i> role for their authorizations. In cloud management tools feature set B, these authorizations are bundled in the <i>Subaccount Administrator</i> role collection.

## Mapping Cloud Foundry Authorizations Between Feature Set A and Feature Set B

The following table lists the roles and role collections a user receives, based on the Cloud Foundry roles the user had in cloud management tools feature set A.

## Mappings of Cloud Foundry Authorizations Between Feature Set A and Feature Set B

Authorizations in Feature Set A	Authorizations in Feature Set B	More Information
<i>Org Manager</i>	<i>Org Manager</i>	In cloud management tools feature set A, a user with the <i>Org Manager</i> , <i>Space Manager</i> , or <i>Space Developer</i> roles could also manage cloud connectors and destinations. To make sure that such users don't lose any authorizations, we check the users authorizations and add the required role collections.
<i>Space Manager</i>	<i>Space Manager</i>	
<i>Space Developer</i>	<i>Space Developer</i>	
<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin: 10px 0;"> <p><b>Note</b></p> <p>If the user doesn't already have the <i>Subaccount Administrator</i> role collection, the user receives the <i>Connectivity and Destination Administrator</i> role collection.</p> </div>		
<i>Org Auditor</i>	<i>Org Auditor</i>	No change.
<i>Space Auditor</i>	<i>Space Auditor</i>	

## Role Collection Names

Any role collection that you created in cloud management tools feature set A with a name that is a reserved role collection name in cloud management tools feature set B, will have the suffix "(Custom)" appended to your role collection's name. For example, *Subaccount Administrator* will be renamed to *Subaccount Administrator (Custom)* after the upgrade.

## No Impact on Neo Subaccounts

The authorization model of Neo subaccounts remains the same in both feature sets.

## 2.8.2 Business Users

**Business users** use the applications that are deployed to SAP BTP. For example, the end users of SaaS apps or services, such as SAP Workflow service or SAP Cloud Integration, or end users of your custom applications are business users.

Application developers (platform users) create and deploy application-specific security artifacts for business users, such as scopes. Administrators use these artifacts to assign roles, build role collections, and assign these role collections to business users or user groups. In this way, they control the users' permissions in the application.

For business users, there's a [default identity provider \[page 2072\]](#), too. We expect that you have your own identity provider. We recommend that you configure your custom tenant of Identity Authentication as the identity provider and connect Identity Authentication to your own corporate identity provider.

## User Management

**User management** refers to managing authentication and authorization for your business users.

To manage your business users:

1. Configure trust to an application identity provider in your subaccount.
2. Create shadow users in your subaccount for your business users in your identity provider.  
When a user accesses a resource, SAP BTP redirects the user to the identity provider for authentication. You assign authorizations to shadow users in SAP BTP.
3. Assign role collections either directly to users or map them to user groups.  
The role collections were either delivered from the applications to which you subscribed or custom developed by your team.

To learn more about user management, see [Security Administration: Managing Authentication and Authorization \[page 2012\]](#).

## 2.9 Tools, Programming Models, Programming Languages, and APIs

SAP BTP provides various programming languages and tools for your development project.

### [Tools \[page 105\]](#)

SAP BTP includes many tools to help you develop and manage applications, and connect them to your on-premise systems.

### [Programming Languages \[page 106\]](#)

SAP BTP supports many different programming languages; the availability of each depends on the development environment you're using.

### [SAP Cloud Application Programming Model \[page 107\]](#)

The SAP Cloud Application Programming Model offers a consistent end-to-end programming model that includes languages, libraries, and APIs that are tailored for full-stack development on SAP BTP.

### [Continuous Integration and Delivery \(CI/CD\) \[page 107\]](#)

Configure and run predefined continuous integration and delivery (CI/CD) pipelines that automatically build, test, and deploy your code changes to speed up your development and delivery cycles.

### [APIs \[page 110\]](#)

Discover and consume APIs to manage, build, and extend the core capabilities of SAP BTP.

### [Cloud Management Tools — Feature Set Overview \[page 111\]](#)

Cloud management tools represent the group of technologies designed for managing SAP BTP.

### [Prerequisites and Restrictions \[page 124\]](#)

Find a list of the product prerequisites and restrictions for SAP BTP.

## 2.9.1 Tools

SAP BTP includes many tools to help you develop and manage applications, and connect them to your on-premise systems.

The availability of tools can depend on the cloud management tools feature set that you are running on. For more information, see [Cloud Management Tools — Feature Set Overview \[page 111\]](#).

Tool	Description
<a href="#">Account Administration in the Cockpit [page 1936]</a>	The SAP BTP cockpit is the web-based administration interface of SAP BTP and provides access to a number of functions for configuring and managing applications, services, and subaccounts. Use the cockpit to manage resources, services, security, monitor application metrics, and perform actions on cloud applications.
<a href="#">Cloud Connector</a>	The Cloud Connector serves as the link between on-demand applications in SAP BTP. This is the browser-based and existing on-premise systems. You can control the resources available for the cloud applications in those systems.
<a href="#">Command Line Interface for Cloud Foundry [page 2259]</a>	The Cloud Foundry command line interface enables you to work with the Cloud Foundry environment to deploy and manage your applications.
<a href="#">SAP BTP Command Line Interface [Feature Set B] [page 2136]</a>	The SAP BTP command line interface (btp CLI) is the command line tool for convenient account management, such as managing global accounts, directories, subaccounts, entitlements, environment instances, multitenant application subscriptions, and users and their authorizations.
<a href="#">kubectl</a> 	The Kubernetes command line tool to communicate with a Kubernetes cluster's control plane, using the Kubernetes API.
<a href="#">kubelogin</a> 	A <code>kubectl</code> plugin for Kubernetes OpenID Connect (OIDC) authentication.
<a href="#">Helm</a> 	The package manager for Kubernetes, used for installing and managing Kubernetes applications in form of Helm charts.
<a href="#">ABAP RESTful Application Programming Model</a>	The programming model that defines the architecture for efficient end-to-end development of intrinsically SAP HANA-optimized OData services (such as SAP Fiori apps) in the ABAP environment.
<a href="#">SAP BTP SDK for iOS</a>	The SAP BTP SDK for iOS is based on the Apple Swift programming language for developing apps in the Xcode IDE and includes well-defined layers (SDK frameworks, components, and platform services) that simplify development of enterprise-ready mobile native iOS apps. The SDK is tightly integrated with SAP Mobile Services for Development and Operations.

Tool	Description
<a href="#">SAP BTP SDK for Android</a>	The SAP BTP SDK for Android provides development tools for creating native Android mobile applications that use SAP Mobile Services. The SDK is based on the Java programming language and is built on top of Google's Android SDK.
<a href="#">SAP Cloud SDK</a>	SAP Cloud SDK provides a layer of abstractions for features of SAP BTP such as logging, multitenancy, and connectivity. It also includes project templates for different execution environments and implementations.
<a href="#">Eclipse Tool for the Cloud Foundry Environment</a> 	The Eclipse plug-in for the Cloud Foundry environment is a Java-based toolkit for Eclipse IDE that enables you to develop and deploy Java and Spring applications in the Cloud Foundry environment from Eclipse or Spring Tool Suite, as well as perform operations such as logging, managing user roles, creating connectivity destinations, and so on.
<a href="#">SAP Web IDE</a>	With SAP Web IDE Full-Stack, you can easily develop, test, build, deploy, and extend role-based, consumer-grade apps for business users. Create applications rapidly and deliver an outstanding user experience. You can extend or build SAP Fiori apps, create SaaS solutions, extend SAP S/4HANA cloud services, develop hybrid mobile apps, and build IoT apps for SAP Leonardo, using the UI development toolkit for HTML5, the SAP HANA toolset, and Java programming language and technologies.
<a href="#">SAP Business Application Studio</a>	SAP Business Application Studio is the next generation of SAP Web IDE - Develop, debug, test, and deploy SAP business applications.
<a href="#">SAP Build</a>	SAP Build enables everyone, no matter the skill level, to create and augment enterprise applications, process automations, and business sites with drag-and-drop simplicity.
Service-Specific Tools	The services that run on SAP BTP can come with service-specific tools. For an overview of the services and their tools, see the <a href="#">SAP Discovery Center</a>  .

## 2.9.2 Programming Languages

SAP BTP supports many different programming languages; the availability of each depends on the development environment you're using.

The following programming languages are available in the environments:

Supported Environments and Programming Languages

Environment	Programming Language
Cloud Foundry environment	<a href="#">SAP HANA [page 533]</a>
	<a href="#">Java [page 242]</a>

Environment	Programming Language
	<a href="#">Node.js [page 311]</a>
	<a href="#">Python [page 322]</a>
	<a href="#">SAPUI5 [page 355]</a>
	<a href="#">HTML5 [page 212]</a>
ABAP environment	<a href="#">ABAP [page 651]</a>
Kyma environment	<a href="#">Serverless Functions: Node.js and Python [page 1735]</a>
	Microservices: Any cross-platform programming language

### 2.9.3 SAP Cloud Application Programming Model

The SAP Cloud Application Programming Model offers a consistent end-to-end programming model that includes languages, libraries, and APIs that are tailored for full-stack development on SAP BTP.

It simplifies the development process by enabling you to create concise and comprehensive data and service models at a conceptual level, which are then used as input for the data, service, and UI layers. The SAP Cloud Application Programming Model is compatible with any development environment, but we recommend SAP Business Application Studio.

For more information, see [Developing with the SAP Cloud Application Programming Model \[page 224\]](#) and [SAP Business Application Studio](#).

### 2.9.4 Continuous Integration and Delivery (CI/CD)

Configure and run predefined continuous integration and delivery (CI/CD) pipelines that automatically build, test, and deploy your code changes to speed up your development and delivery cycles.

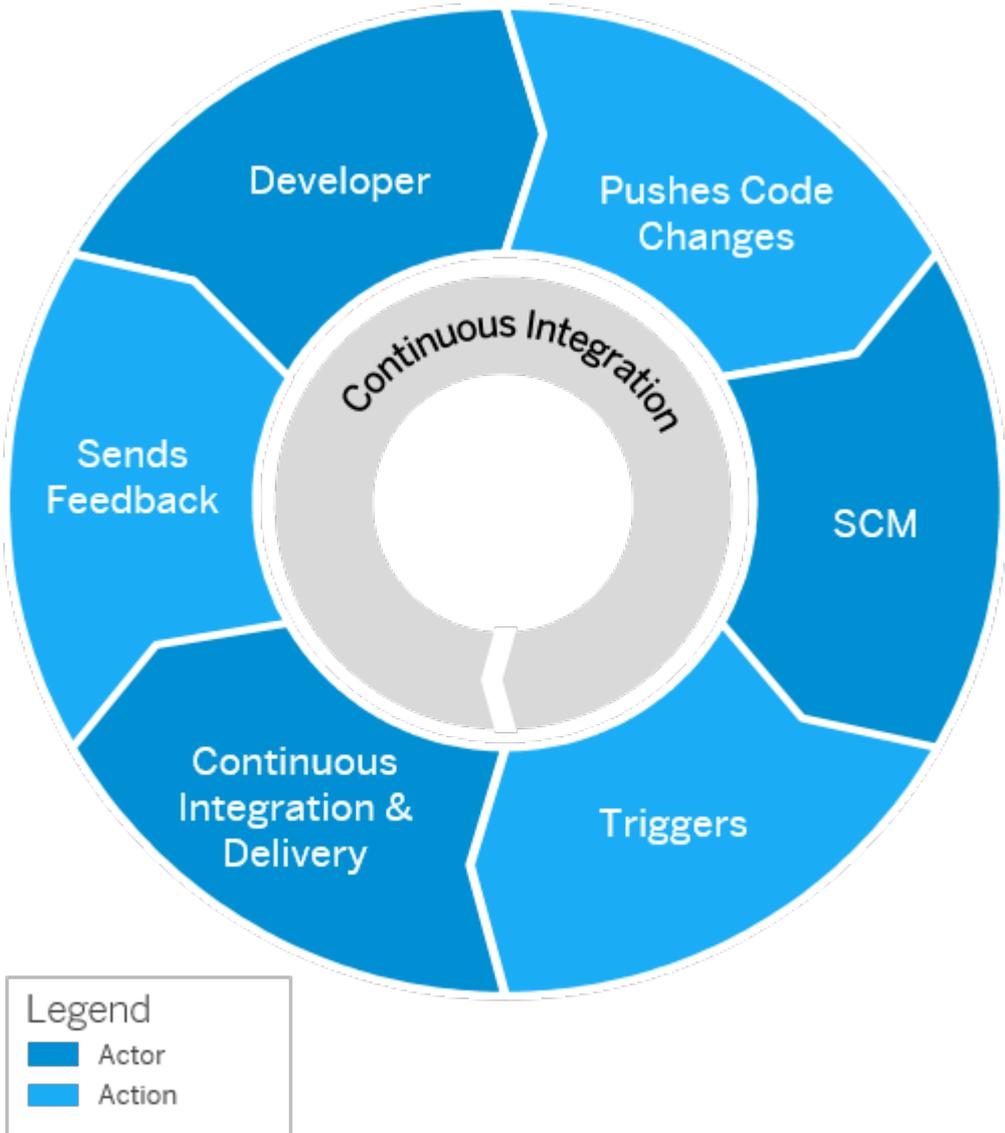

#### Note

For links to all SAP solutions for CI/CD, blog posts, presentations, and tutorials, have a look at our [Continuous Integration and Delivery by SAP](#) overview.

**Continuous integration (CI)** describes a software development process, in which various team members integrate their contributions frequently into a single main line. Before each integration, the changes are verified through builds and automated testing. Thereby, you can detect errors as quickly as possible and prevent integration problems before completing the development.

The **continuous delivery (CD)** concept expands on the one of continuous integration. It adds the aspect that any change that has successfully passed the tests is immediately ready to be deployed to production, both from a technical and a qualitative point of view.

The following graphic shows the basic flow for continuous integration and delivery:

Continuous Integration Basic Flow

For more information about the continuous integration and continuous delivery concepts, see [What Are Continuous Integration and Continuous Delivery?](#).

### Use

Depending on your use case, you can choose between different CI/CD pipelines to help you implement continuous integration and delivery in your software development.

SAP Continuous Integration and Delivery lets you configure and run predefined pipelines for the development of the following applications:

- [SAP Cloud Application Programming Model](#)

Configure a CI/CD pipeline for the development of applications that follow the SAP Cloud Application Programming Model in the Cloud Foundry runtime.

- [SAP Fiori in the Cloud Foundry Environment](#)  
Configure a CI/CD pipeline for the development of SAPUI5/SAP Fiori applications in the Cloud Foundry runtime.
- [SAP Fiori in the Neo environment](#)  
Configure a CI/CD pipeline for the development of SAPUI5/SAP Fiori applications in the Neo environment.
- [SAP Fiori for the ABAP Platform](#)  
Configure a CI/CD pipeline for the development of SAPUI5/SAP Fiori applications for the ABAP platform.
- [SAP Integration Suite Artifacts](#)  
Configure a CI/CD pipeline for the development of SAP Cloud Integration artifacts in the Cloud Foundry runtime.
- [Container-Based Applications](#)  
Configure a CI/CD pipeline for the development of container-based applications.

To learn more about the CI/CD pipelines supported by SAP Continuous Integration and Delivery and the stages each pipeline can comprise, see [Supported Pipelines](#).

## Get Started with CI/CD

SAP Continuous Integration and Delivery provides an easy, UI-guided way to set up the service and configure and run your pipelines, without hosting your own Jenkins instance.

To set up SAP Continuous Integration and Delivery:

1. Enable the service in the SAP BTP cockpit.
2. Assign either the [Administrator](#) or [Developer](#) role to your user.
3. Enable the API usage to connect SAP Continuous Integration and Delivery to other services, if necessary.

To configure SAP Continuous Integration and Delivery:

### Note

Only administrators of SAP Continuous Integration and Delivery can configure the service.

1. Configure credentials for connecting SAP Continuous Integration and Delivery to other services (for example, GitHub, GitLab, Bitbucket Server, or Azure Repos to clone your sources, and SAP BTP to deploy your built application).
2. Add your repository.

Now you can create and modify your CI/CD jobs and monitor their outcome. If you want to automate your builds, you can configure a webhook between your repository and the service. You can create and modify timed triggers for your jobs, if necessary.

For more information, see [Initial Setup](#) and [Configuration](#), or follow the tutorial [Configure and Run a Predefined SAP Continuous Integration and Delivery \(CI/CD\) Pipeline](#).

## Learn and Get Certified

Depending on your learning goals and level of expertise, you can choose from the following offerings:

- **Efficient DevOps with SAP**  This openSAP course introduces general DevOps approaches and key principles. Learn about the basic CI/CD principles (week 1) and how to deliver cloud applications using CI/CD (week 3).
- **Continuous Integration and Delivery Introduction Guide** The CI/CD Introduction Guide provides you with basic knowledge for setting up and implementing continuous integration and delivery processes. It gives an overview of the concepts and principles of CI/CD, explains both procedures and their relation, and helps you plan your own CI/CD process.

## 2.9.5 APIs

Discover and consume APIs to manage, build, and extend the core capabilities of SAP BTP.

An Application Programming Interface or API is an **interface provided by an application for interacting with other applications**. APIs specify how software programs are able to exchange information with each other, even if designed and run by different organizations. They facilitate interaction by selectively exposing certain functionality, allowing different apps, websites, and devices to communicate effectively with each other. More importantly, APIs allow businesses to reach beyond regular business channels and share data, content, and services directly to both B2B (business to business) and B2C (business to consumer) clients, making UI development easy.

### API Offerings on SAP BTP

SAP BTP enables you to consume APIs and publish your own ones through the following offerings:

Offering	Description
<a href="#">SAP BTP on SAP Business Accelerator Hub</a> 	The SAP Business Accelerator Hub provides you with one central repository for browsing and accessing APIs from SAP and selected partners. Test APIs and try out mock data in your systems.  It is also the official place where REST and OData REST API references are published.
<a href="#">SAP BTP API Management</a>	API Management allows you to build, manage, publish, and monetize your own APIs within one secure and scalable environment.

Offering	Description
SDKs	<p>The software development kits (SDKs) available for SAP BTP offer APIs to, for example, accelerate enterprise app development.</p> <p>For an overview on the available SDKs, see <a href="#">Tools [page 105]</a>.</p>

## Related Information

[SAP API Style Guide](#)

## 2.9.6 Cloud Management Tools — Feature Set Overview

Cloud management tools represent the group of technologies designed for managing SAP BTP.

We're currently renovating and adding core functionalities to SAP BTP. As part of this process, we're upgrading enterprise accounts from the existing cloud management tools feature set A to the renovated cloud management tools feature set B. We're doing this upgrade as a phased rollout, so cloud management tools feature sets A and B will coexist for some time. For more information about the account upgrade process and frequently-asked questions, see [3027721](#).

### How can I know which cloud management tools feature set I'm using?

There's an easy way to check if you're currently using cloud management tools feature set A or B. Access the SAP BTP cockpit and choose your username from the top right-hand corner of the screen. From the menu, select **About** to get information about the cloud management tools feature set you're using.

## Access the SAP BTP cockpit

Feature sets A and B don't share the same cockpit. So in your feature set A cockpit, you'll only see feature set A global accounts, while in your feature set B cockpit, you'll only see your feature set B global accounts.

When using cloud management tools feature set A: Choose <https://account.eu1.hana.ondemand.com> to access the SAP BTP cockpit.

When using cloud management tools feature set B:

Choose <https://cockpit.btp.cloud.sap> to access the cockpit. Depending on your own geo location this URL will redirect you to the closest regional Cockpit URL.

For more information, see [Access the Cockpit \[page 1937\]](#).

## What are the differences between the two cloud management tools feature sets?

New/Changed Features and Behaviors	Feature Set A	Feature Set B
Directories — NEW	<i>Not applicable</i>	<p>Summary:</p> <ul style="list-style-type: none"><li>Group and filter directories and subaccounts</li><li>Monitor usage and costs for contracts that use the consumption-based commercial model</li></ul> <p>With <b>directories</b>, you can organize and manage your subaccounts according to your technical and business needs.</p> <p>A directory can contain directories and subaccounts to create a hierarchy. Using directories to group other directories and subaccounts is optional - you can still create subaccounts directly under your global account.</p> <p>See:</p> <p><a href="#">Directories [Feature Set B] [page 77]</a></p> <p><a href="#">Create a Directory [Feature Set B] [page 1969]</a></p> <p><a href="#">Manage the Account Explorer Hierarchy [Feature Set B] [page 1971]</a></p>

**New/Changed Features and Behaviors**

	<b>Feature Set A</b>	<b>Feature Set B</b>
<b>Labels — NEW</b>	<i>Not applicable</i>	<p>Summary:</p> <ul style="list-style-type: none"><li>• Set labels for categorization and identification purposes</li><li>• Additional filtering options</li></ul> <p>Labels allow you to categorize your directories, subaccounts, multitenant application subscriptions, service instances, and environment instances so that you identify them more easily within your global account. For example, the <a href="#">Account Explorer</a> and <a href="#">Instances and Subscriptions</a> pages in the cockpit allow you search by label name or value.</p> <p>Labels are user-defined so you can apply them as you wish according to your own business and technical needs.</p> <p>You can manage labels for the supported entities using the SAP BTP cockpit, command line interface (btp CLI), or REST APIs.</p> <p>See <a href="#">Labels [Feature Set B] [page 79]</a>.</p>

New/Changed Features and Behaviors	Feature Set A	Feature Set B
APIs for SAP BTP — NEW	<i>Not applicable</i>	<p data-bbox="1007 376 1110 398">Summary:</p> <p data-bbox="1007 427 1374 555">Discover and consume REST APIs to manage, build, and extend the cloud operation capabilities of SAP BTP. For example:</p> <ul data-bbox="1007 577 1390 1070" style="list-style-type: none"> <li data-bbox="1007 577 1374 636">• Manage global accounts, directories, and subaccounts</li> <li data-bbox="1007 651 1390 741">• Assign entitlements for services and applications to directories and subaccounts</li> <li data-bbox="1007 757 1374 884">• Manage the provisioning of environment instances and get information relating to provisioned services</li> <li data-bbox="1007 900 1390 965">• Manage subaccount subscriptions to multitenant applications</li> <li data-bbox="1007 981 1358 1070">• Generate reports based on the resource and cost consumption within your accounts.</li> </ul> <p data-bbox="1007 1099 1404 1294">See <a href="#">Account Administration Using APIs of the SAP Cloud Management Service [Feature Set B] [page 2190]</a> and <a href="#">Monitoring Usage Information Using APIs of the SAP Usage Data Management Service [Feature Set B] [page 2222]</a>.</p>

**New/Changed Features and Behaviors**

**Feature Set A**

**Feature Set B**

**SAP BTP command line interface (btp CLI) – NEW** *Not applicable*

Summary:

Use the btp CLI for convenient account management tasks on the command line and to automate these procedures. For example:

- Manage global accounts, directories, and subaccounts
- Set entitlements
- Work with environments
- Work with multitenant applications
- Manage users and their authorizations

To log in to a global account, you need the CLI server URL `https://cpcli.cf.eu10.hana.ondemand.com` and the global account subdomain. Only global accounts on feature set B have global account subdomains (see cockpit).

See:

[Account Administration Using the SAP BTP Command Line Interface \(btp CLI\) \[page 2136\]](#)

[btp CLI Command Reference](#)

[Setting Up a Global Account via the Command Line \[page 145\]](#)

New/Changed Features and Behaviors

	Feature Set A	Feature Set B
<b>Global account navigation — CHANGED</b>	<p>Summary:</p> <ul style="list-style-type: none"><li>• "Home" scope outside the global account in the cockpit</li><li>• <a href="#">Global Accounts</a> page in the cockpit</li><li>• Switching between global accounts via breadcrumbs (second element)</li><li>• <a href="#">Overview</a> page is the first in the global account scope</li></ul> <p>With feature set A, your cockpit contains a number of general views <b>outside</b> of the global account scope. These include a <a href="#">Global Accounts</a> page, where you can find all your global accounts listed as tiles, and from where you can navigate to your desired global account.</p> <p>Since it has several views outside of the global account scope, your cockpit contains an additional "home" scope, which is represented by the first element in the breadcrumbs. Your global account is therefore represented by the second element in the breadcrumbs. You can also use that second element to navigate from one global account to another.</p> <p>Once you're in a global account, the first page you see is the global account overview page. To navigate to a sub-account, you have to navigate to the <a href="#">Subaccounts</a> page from the left hand-side navigation.</p> <p>See <a href="#">Navigate in the Cockpit [page 1938]</a></p>	<p>Summary:</p> <ul style="list-style-type: none"><li>• Global accounts selection dialog displayed before entering the cockpit</li><li>• Option to set a default global account</li><li>• "Home" scope removed from the cockpit</li><li>• Switching between global accounts via the selection dialog or breadcrumbs (first element)</li><li>• <a href="#">Subaccounts</a> page is the first in the global account scope</li></ul> <p>With feature set B, there's no scope beyond the global account in the cockpit anymore. Therefore, after logging on to the cockpit and before actually entering it, if you have more than one global account, you're asked to choose which of the available cloud management tools feature set B global accounts you want to enter. Only feature set B global accounts are visible here. This is done via a global account selection dialog, where you also have the option to remember your selection. Doing that sets the global account you chose as default, so that next time you access the cockpit you're automatically taken to your default global account instead of seeing the selection dialog.</p> <p>As the cockpit doesn't have a "home" scope anymore, the global account becomes the outermost scope and is therefore represented by the first element in the breadcrumbs. You can still navigate from one global account to another either by using the breadcrumbs, or by choosing <a href="#">Switch Global Accounts</a> to launch the global account selection dialog, where you can also modify or remove your default global account.</p> <p>Once you're in a global account, the first page you see is the <a href="#">Subaccounts</a> page, from where you can directly nav-</p>

**New/Changed Features and Behaviors**

**Feature Set A**

**Feature Set B**

---

avigate to your subaccount — one less click needed. Usage and cost information for your global account is displayed in the global account's *Usage Analytics* page.

See [Navigate in the Cockpit \[page 1938\]](#).

Feature Set B

(Trial Only) Trial Account Extension - CHANGED

*Not applicable*

Summary:

- You cannot access a suspended trial global account.
- You can still see the counter with the remaining number of days in the same place, but you cannot extend your trial from there.
- You extend your trial account from a dialog similar to the global account selection dialog described previously in this table under global account navigation.

With feature set B, it's not possible anymore to access suspended trial global accounts. Before your trial interval expires, you can still see the counter with the remaining number of days in the same place. However, once your trial interval expires and you try to access it, you will instead be prompted by a dialog asking you to extend your trial first.

**Note**

The overall trial period is 90 days and is divided in intervals.

If you don't log in to your account for 30 days or more, your account will be suspended. During suspension, your applications may be stopped and you won't be able to access them. However, your data will not be deleted yet. You can unsuspend your account as long as there are days left in your trial period.

When your 90-day trial period is finished, your account will be deleted, and you will no longer be able to access your data. You can then set up a new trial account.

## New/Changed Features and Behaviors

	Feature Set A	Feature Set B
(Trial Only) Deletion of SAP BTP Trial - NEW	<i>Not applicable</i>	<p>Summary:</p> <ul style="list-style-type: none"><li>• Possible to easily delete only your SAP BTP trial account.</li></ul> <p>With feature set B, you can delete your SAP BTP trial account. Simply navigate into your trial global account by choosing <i>Enter Your Trial Account</i> on the trial home page. Once you're on the <i>Subaccounts</i> page of your global account, you will see a new button giving you the option to delete your trial account.</p>

### Note

Cloud management tools feature set B applies also to the Neo environment. For more information about the scope offered with the enhanced capabilities, see [Working with Cloud Management Tools Feature Set B in the Neo Environment](#).

## 2.9.7 Prerequisites and Restrictions

Find a list of the product prerequisites and restrictions for SAP BTP.

### General Constraints

- For information on constraints and default settings to consider when you deploy an application in the Cloud Foundry environment, see [http://docs.cloudfoundry.org/devguide/deploy-apps/large-app-deploy.html#limits\\_table](http://docs.cloudfoundry.org/devguide/deploy-apps/large-app-deploy.html#limits_table).
- SAP BTP exposes applications only via HTTPS. For security reasons, applications can't be accessed via HTTP.

### SAP BTP Tools

- SAP BTP Tools for Java and SDK have been tested with Java 7, and Java 8.
- SAP BTP Tools for Java and SDK run in many operating environments with Java 7, and Java 8 that are supported by Eclipse. However, SAP doesn't systematically test all platforms.
- SAP BTP Tools for Java must be installed on Eclipse IDE for Java EE developers.

For the platform development tools, SDK, Cloud connector, and SAP JVM, see <https://tools.hana.ondemand.com/#cloud>.

## Browser Support

For a list of supported browsers for the SAP BTP cockpit, see [Feature Scope Description](#).

For a list of supported browsers for developing SAPUI5 applications, see [Browser and Platform Support](#).

To find out the browser support for a specific service, refer to the corresponding feature scope description.

For security reasons, SAP BTP doesn't support TLS1.1 and older, SSL 3.0 and older, and RC4-based cipher suites. Make sure that your browser supports at least TLS1.2 and modern ciphers (for example, AES).

# 3 Getting Started

Once you're familiar with the basic concepts of SAP BTP, you can start your first workflows or check out further resources that help you get started quickly.

## Onboarding Guide

The guide [Best Practices for SAP BTP](#) helps you plan your development projects on SAP BTP from setting up the correct organizational structure to creating an account and security model, to developing and operating applications.

## Getting Started Workflows

Learn how to get a global account and get started with a trial or an enterprise account on SAP BTP. A trial account lets you try out SAP BTP for free, and within an enterprise account, you can use so-called free tier service plans for free. See [Trial Accounts and Free Tier \[page 63\]](#).

Depending on your use case, follow the appropriate workflow:

- [Getting a Global Account \[page 127\]](#)
- [Getting Started in the Cloud Foundry Environment \[page 129\]](#)
- [Getting Started in the ABAP Environment \[page 149\]](#)
- [Getting Started in the Kyma Environment \[page 204\]](#)

## Additional Resources

The SAP Developer Center provides further resources to get you started:

- [SAP Discovery Center](#) 
- [SAP BTP in SAP Developer Center](#) 
- [Start Developing on SAP BTP Tutorials](#) 

## Related Information

[Best Practices for SAP BTP](#)  
[Access the Cockpit \[page 1937\]](#)

## 3.1 Getting a Global Account

SAP BTP offers two types of global accounts: Trial accounts (completely free of charge) and enterprise accounts. Within an enterprise account, you can use both free and paid plans.

A **global account** is the realization of a contract you or your company has made with SAP. A global account is used to manage subaccounts, members, entitlements and quotas. You receive entitlements and quotas to use platform resources per global account and then distribute the entitlements and quotas to the subaccount for actual consumption. There are two types of commercial models for global accounts: consumption-based model and subscription-based model. See [Commercial Models \[page 67\]](#)

- [Trial Accounts and Free Tier \[page 63\]](#)
- [Enterprise Accounts \[page 65\]](#)
- [Try Out SAP BTP for Free \[page 127\]](#)
- [Get an Enterprise Account \[page 127\]](#)

### 3.1.1 Try Out SAP BTP for Free

There are two ways to try out SAP BTP services and applications for free.

#### Context

A **free trial** account is intended for individuals, for example students, who want to explore SAP BTP for free. It is an isolated account and subaccount, with preallocated service entitlements that can be used for a limited number of days.

**Free tier** is not an account type, but it's a set of free services that can be used within an enterprise account.

To learn which is best for your needs, see the [Set Up an SAP BTP Account for Tutorials](#) group in the SAP Developer Center.

### 3.1.2 Get an Enterprise Account

To use an enterprise account, you can either purchase a customer account, join the partner program to purchase a partner account, or self-register for an enterprise account to try out free tier service plans.

For more information about the scope of our enterprise offering, see [Enterprise Accounts \[page 65\]](#). For more information about free tier within an enterprise account, see [Trial Accounts and Free Tier \[page 63\]](#) and [Using Free Service Plans \[page 72\]](#).

## Related Information

[Get an Account on SAP BTP to Try Out Free Tier Service Plans](#)

### 3.1.2.1 Sign up for a Customer Account

A customer account is an enterprise account that allows you to host productive, business-critical applications with 24x7 support.

When you want to purchase a customer account, you can select from a set of predefined packages. For information about service availability, prices, and estimators, see <https://www.sap.com/products/extension-suite/pricing.html> and <https://www.sap.com/products/integration-suite/pricing.html>. You can also view the service catalog via the [SAP Discovery Center](#). Contact us on [SAP BTP](#) or via an SAP sales representative.

#### Free Tier

If you want to try out services for free, with the option of easily upgrading them later, you can get an enterprise account and use free tier service plans only. See [Get an Account on SAP BTP to Try Out Free Tier Service Plans](#). When you sign up for a global account to try out free tier service plans, you need to select either an existing global account of your company, or create a new global account. If you choose an existing global account, make sure to contact the global account admin of this global account, as they'll receive the communication emails. In this case, we recommend to have them add you as Global Account Administrator. See [Assign Users to Role Collections \[page 2092\]](#) and [SAP BTP Onboarding Resource Center](#).

You can upgrade and refine your resources later on. You can also contact your SAP sales representative and opt for a configuration, tailored to your needs.

#### Onboarding

After you have purchased a new customer account, you will receive an email confirming the provisioning of resources from the platform services team and a second email with the URL and login ID to obtain access. Note, only the person who receives the access email has initial access to SAP BTP.

If you chose an add-on to an existing global account, the initial access email will not be sent to you. You will need to contact the Global Account Administrator from the initial BTP order. If you're unsure who this person is, please contact your SAP Sales representative. If you need to add a new global admin because the person with initial access is no longer available to grant you access, then you can contact the SAP Support Portal, by creating a ticket at component BC-NEO-CIS-OPS.

#### → Tip

Check out the [Live Onboarding Webinars](#).

## Getting a Customer Account in China

If you are located in China and want to buy a global account on SAP BTP, you need to contact an SAP sales representative: <https://www.sap.cn/registration/contact.html> .

## Related Information

[Commercial Models \[page 67\]](#)

[Using Free Service Plans \[page 72\]](#)

[Access the Cockpit \[page 1937\]](#)

### 3.1.2.2 Join the Partner Program

A partner account is an enterprise account that enables you to build applications and to sell them to your customers.

To become a partner, you need to fill in an application form and then sign your partner contract. You will be assigned to a partner account with the respective resources. To apply for the partner program, visit [https://partneredge.sap.com/content/partnerregistration/en\\_us/registration.html?partnertype=BLD&engagement=0002&build=1](https://partneredge.sap.com/content/partnerregistration/en_us/registration.html?partnertype=BLD&engagement=0002&build=1) . You will receive a welcome mail with further information afterwards.

General information about the partner program is available on <https://www.sap.com/partner/become/partneredge-build/plan-design.html> .

## Next Steps

- [Getting Started in the Cloud Foundry Environment \[page 129\]](#)
- [Getting Started in the ABAP Environment \[page 149\]](#)
- [Getting Started in the Kyma Environment \[page 204\]](#)

## 3.2 Getting Started in the Cloud Foundry Environment

Get onboarded in the Cloud Foundry environment of SAP BTP. Follow the workflows for trial or customer accounts or subscribe to business applications.

[Getting Started with a Trial Account in the Cloud Foundry Environment \[page 130\]](#)

Quickly get started with a trial account.

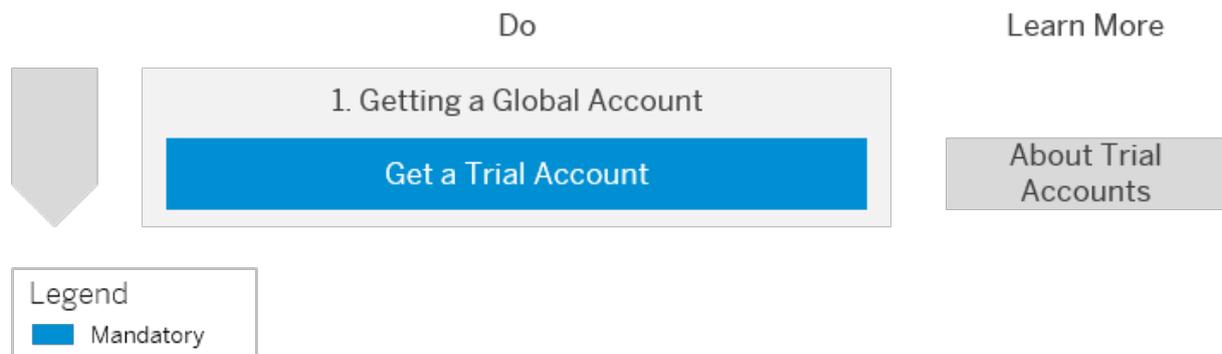

[Getting Started with an Enterprise Account in the Cloud Foundry Environment \[page 141\]](#)

Quickly get started with an enterprise account in the Cloud Foundry Environment.

## 3.2.1 Getting Started with a Trial Account in the Cloud Foundry Environment

Quickly get started with a trial account.

### 1. Getting a Global Account

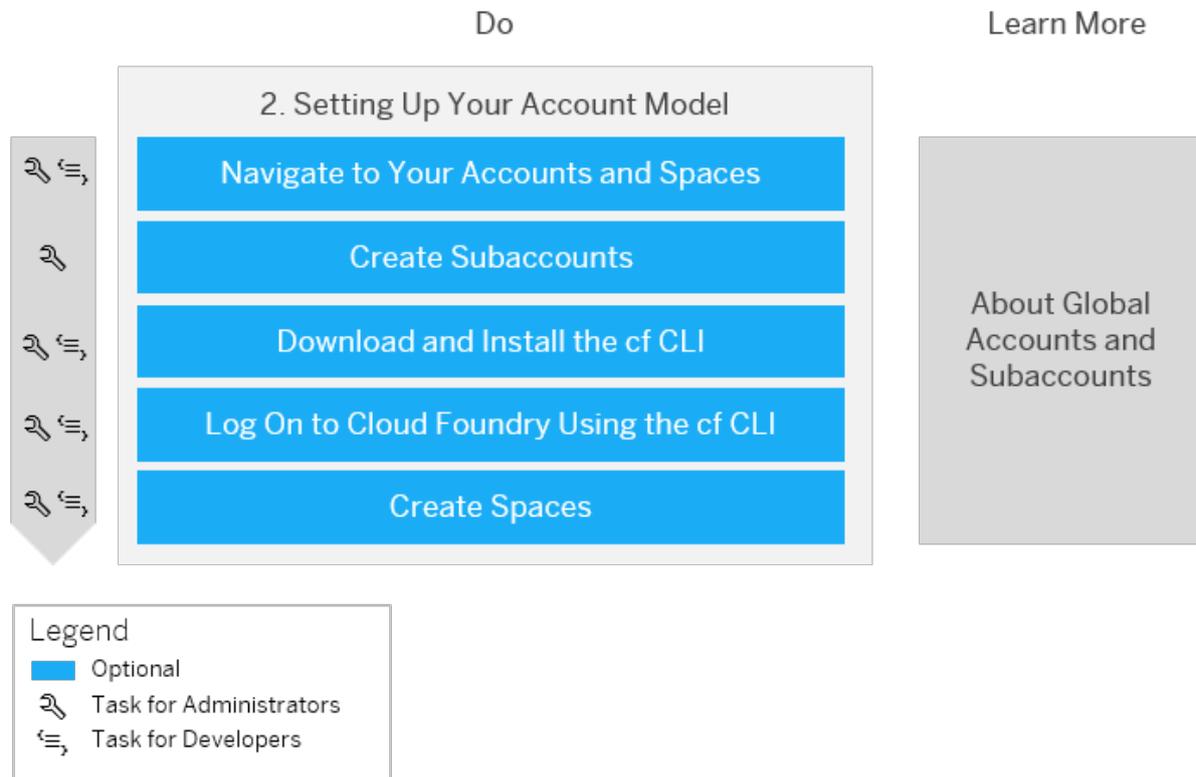

- [Try Out SAP BTP for Free \[page 127\]](#)
- [Trial Accounts and Free Tier \[page 63\]](#)

Before you begin, sign up for a free trial account. See [Get a Free Trial Account \[page 127\]](#). For more information about the scope of our trial offering, see [Trial Accounts and Free Tier \[page 63\]](#).

If you want to familiarize yourself with the Cloud Foundry environment, see [Cloud Foundry Environment \[page 44\]](#).

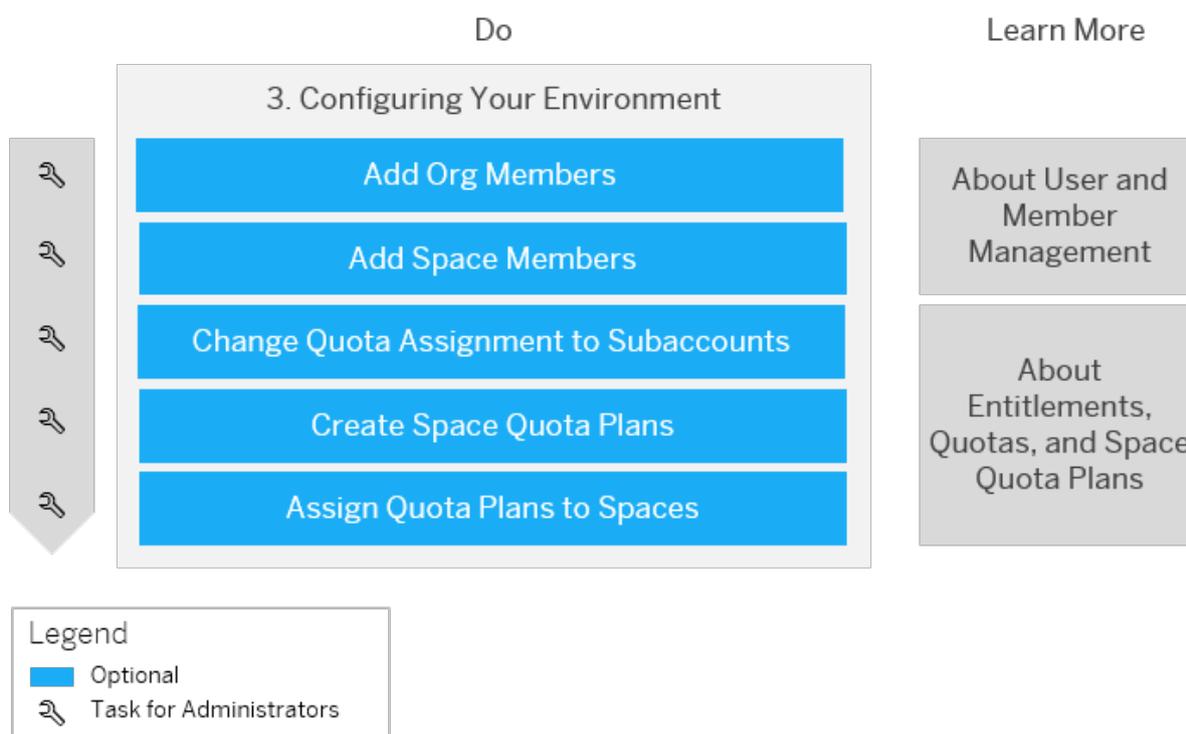

## 2. Setting Up Your Account Model

- [Navigate to Orgs and Spaces \[page 2246\]](#)
  - [Create a Subaccount \[page 1977\]](#)
  - [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
  - [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)
  - [Create Spaces \[page 2251\]](#)
  - [Relationship Between Global Accounts and Subaccounts \[Feature Set A\] \[page 78\]](#)
1. When you register for a trial account, a subaccount and a space are created for you. You can create additional subaccounts and spaces, thereby further breaking down your account model and structuring it according to your development scenario, but first it's important you understand how to navigate to your accounts and spaces using the SAP BTP cockpit. See [Navigate to Orgs and Spaces \[page 2246\]](#).
  2. If you like, create further subaccounts. See [Create a Subaccount \[page 1977\]](#). You can also download and use the CLI for SAP BTP to create new subaccounts. See [Download and Start Using the btp CLI Client \[page 2138\]](#) and [Working with Global Accounts, Directories, and Subaccounts Using the btp CLI \[page 2168\]](#).
  3. If you haven't done so already, now is a good time to download and install the Cloud Foundry Command Line Interface (cf CLI). This tool allows you to administer and configure your environment, enable services, and deploy applications. See [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#). But don't worry, you can also perform all the necessary task using the SAP BTP cockpit, which you don't need to install.

4. If you'd like to use the cf CLI, log on to your environment. See [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
5. If you like, create further spaces. See [Create Spaces \[page 2251\]](#). If you want to learn more about subaccounts, orgs, and spaces, and how they relate to each other, see [Account Model \[page 75\]](#).

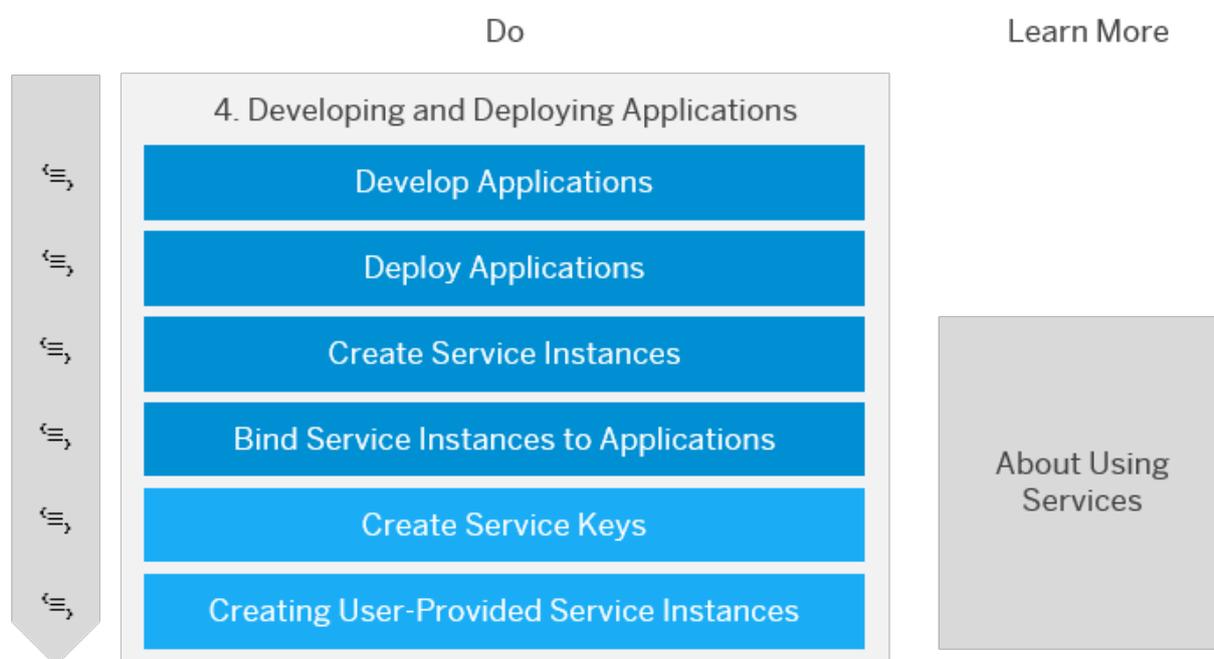

### 3. Configuring Your Environment

- [Add Org Members Using the Cockpit \[page 2248\]](#)
  - [Add Space Members Using the Cockpit \[page 2252\]](#)
  - [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)
  - [Create Space Quotas \[page 2254\]](#)
  - [Create Space Quota Plans Using the Cloud Foundry Command Line Interface \[page 2292\]](#)
  - [User and Member Management \[page 85\]](#)
  - [Entitlements and Quotas \[page 81\]](#)
1. Now that you've set up your account model, it's time to think about member management. You can add members at different levels. For example, you can add members at the org level. See [Add Org Members Using the Cockpit \[page 2248\]](#). For more information about the roles that are available on the different levels, see [User and Member Management \[page 85\]](#).
  2. You can also add members at the space level. See [Add Space Members Using the Cockpit \[page 2252\]](#).

3. In a trial account, quotas are automatically assigned to your subaccounts, but you can change that assignment. See [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#). To learn more about entitlements and quotas, see [Entitlements and Quotas \[page 81\]](#).
4. You can also assign quotas to different spaces within a subaccount. To do so, first create a space quota plan. See [Create Space Quotas \[page 2254\]](#) or [Create Space Quota Plans Using the Cloud Foundry Command Line Interface \[page 2292\]](#).
5. Then assign the quota plan to your space. See [Assign Space Quotas to Spaces \[page 2256\]](#) or [Assign Quota Plans to Spaces Using the Cloud Foundry Command Line Interface \[page 2293\]](#).

## 4. Developing and Deploying Applications

Legend

- Mandatory
- Optional
- ☰, Task for Developers

- [Development \[page 212\]](#)
- [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#)
- [Creating Service Instances \[page 231\]](#)
- [Binding Service Instances to Applications \[page 234\]](#)
- [Creating Service Keys \[page 236\]](#)

- [About Services \[page 230\]](#)
  - [Creating User-Provided Service Instances \[page 233\]](#)
1. Develop your application. Check out the Developer Guide for tutorials and more information. See [Development \[page 212\]](#).
  2. Deploy your application. See [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#).
  3. Integrate your application with a service. To do so, first create a service instance. See [Creating Service Instances \[page 231\]](#).
  4. Bind the service instance to your application. See [Binding Service Instances to Applications \[page 234\]](#).
  5. Alternatively, you can also create and use service keys. See [Creating Service Keys \[page 236\]](#). For more information on using services and creating service keys, see [About Services \[page 230\]](#).
  6. You can also create instances of user-provided services. See [Creating User-Provided Service Instances \[page 233\]](#).

#### → Tip

Also check out the tutorial [Create Your First App on Cloud Foundry](#) to see how you can deploy a pre-bundled set of artifacts using the SAP BTP cockpit, access the app from your web browser, and create an instance of a service available on Cloud Foundry and bind it to your app.

## 3.2.1.1 Setting Up Your Trial Account

Your trial account is set up automatically, so that you can start using it right away. However, if one or more of the automatic steps fail, you can also finalize the setup manually, by following the steps below.

### 3.2.1.1.1 Create Your Trial Subaccount

The first thing that is needed in the setup of your trial account is the creation of a subaccount. If this step was successful in the SAP BTP cockpit, you can directly skip to the next section.

#### Procedure

1. Navigate into your global account by choosing [Enter Your Trial Account](#).
2. Choose [New Subaccount](#).
3. Configure it as follows:

Field	Input
Display Name	<code>trial</code>
Description	(Optional) Any text that describes your subaccount
Provider	Desired infrastructure provider
Region	Desired region
Subdomain	<code>&lt;your_id&gt;trial</code> Example: <code>P0123456789trial</code>
[Advanced] Enable beta features	(Optional) Enables the use of beta services and applications.
[Advanced] Labels	(Optional) You can assign labels to help identify and organize the subaccounts in your global account. For example, you can filter subaccounts by custom property in the <a href="#">Account Explorer</a> page. See <a href="#">Labels [Feature Set B] [page 79]</a> .

#### Results

You have successfully set up your trial subaccount.

### 3.2.1.1.2 Create Your Trial Org and Configure Entitlements

Once you have a subaccount (whether it was created automatically or you followed the steps described above), you need an org and entitlements.

#### Procedure

1. Navigate to your subaccount by choosing its tile.
2. Choose [Enable Cloud Foundry](#) to create your org.
3. Once your org is created, choose [Entitlements](#) from the left hand-side navigation.
4. Choose [Configure Entitlements](#) to enter edit mode.
5. Choose [Add Service Plans](#) and select all the service plans available for your subaccount.

#### Note

To select a service plan, choose a service from the left and tick all the service plans that appear on the right. Do that for all services.

6. Once you've added all the service plans, you see them all in a table. Before you choose Save, for all the plans with numerical quota, choose **+** to increase the amount to the maximum (until the icon becomes disabled).
7. Finally, choose [Save](#) to save all your changes and exit edit mode.

#### Results

You now have an org and all the entitlements for your subaccount. The last thing you need is a space where you can use the services you've configured entitlements for and deploy applications.

### 3.2.1.1.3 Create Your Trial Space

#### Procedure

1. In your *trial* subaccount, navigate to [Cloud Foundry](#) [Spaces](#) using the left hand-side navigation.
2. Choose [Create Space](#) and name it **dev**.
3. Choose [Create](#).

## Results

You now have your trial set up all done and ready to go.

To get some guidance on how you can get started, navigate back to your Trial Home by choosing the first item in your breadcrumbs at the top. There, you can find several guided tours to walk you through the basics of SAP Business Technology Platform and the cockpit, as well as some more complex starter scenarios.

### 3.2.1.2 Setting Up a Trial Account via the Command Line [Feature Set B]

If your trial account is running on the cloud management tools feature set B, you can use the command-line interfaces to set it up. For all tasks on global account and subaccount level, you use the **SAP BTP command line interface (btp CLI)**. Once you've created a Cloud Foundry environment instance (a Cloud Foundry org), you use the Cloud Foundry CLI (cf CLI). This procedure works without the SAP BTP cockpit (except that you need the global account subdomain to log in, which you may have to look up in the cockpit).

#### Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

For all tasks on global account and subaccount level, you can use the **the btp CLI** instead of the SAP BTP cockpit. Once you've created a Cloud Foundry environment instance (a Cloud Foundry org), you use the Cloud Foundry CLI (cf CLI).

## Prerequisites

- You have created a trial account on cloud management tools feature set B.
- You have downloaded and extracted the following command-line tools:
  - SAP BTP command line interface (btp CLI). See [Download and Start Using the btp CLI Client \[page 2138\]](#)
  - Cloud Foundry CLI (cf CLI). See [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)

## Procedure

#### → Tip

In the btp CLI, you can view the command help of each command to get information about how to use the command, its syntax, and input parameters. See [Get Help \[page 2148\]](#).

Step No.	Task	Performed By	Do This	More Information
1.	Log in to your global account using the subdomain of your global account.	Global account administrator or viewer	Run this command in the <code>btp</code> CLI: <code>btp login</code>	See <a href="#">Log in [page 2149]</a> .
2.	View details of your global account.	Global account admin or viewer	Run this command in the <code>btp</code> CLI: <code>btp get accounts/global-account</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the <code>btp</code> CLI [page 2168]</a> .
4.	View all the regions that are available to your global account and subaccounts.	Global account admin or viewer	Run this command in the <code>btp</code> CLI: <code>btp list accounts/available-region</code>	This command also provides information about the environments and infrastructure provider of each region.
5.	Create subaccounts in your global account.	Global account admin	Run this command in the <code>btp</code> CLI: <code>btp create accounts/subaccount --display-name &lt;my-subaccount&gt; --region &lt;my-region&gt; --subdomain &lt;my-subaccount-subdomain&gt;</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the <code>btp</code> CLI [page 2168]</a> and <a href="#">Relationship Between Global Accounts and Subaccounts [Feature Set A] [page 78]</a> .
6.	View the details of the subaccounts in your global account.	Global account admin or viewer	Run this command in the <code>btp</code> CLI: <code>btp get accounts/subaccount &lt;ID of new subaccount&gt;</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the <code>btp</code> CLI [page 2168]</a> .
7.	Add admins to your subaccounts.	Subaccount admin	Assign the role collection <code>Subaccount Administrator</code> to the user by running the following command in the <code>btp</code> CLI: <code>btp assign security/role-collection "Subaccount Administrator" --to-user &lt;user&gt; --create-user-if-missing</code>	See <a href="#">Managing Users and Their Authorizations Using the <code>btp</code> CLI [page 2177]</a> and <a href="#">Security Administration: Managing Authentication and Authorization [page 2012]</a> .
8.	View all the services and applications that are entitled to your global account, including quota information per service plan.	Global account admin or viewer	Run this command in the <code>btp</code> CLI: <code>btp list accounts/entitlement</code>	See <a href="#">Setting Entitlements Using the <code>btp</code> CLI [page 2171]</a> .

Step No.	Task	Performed By	Do This	More Information
9.	Assign quotas to your subaccounts.	Global account admin	<p>Run this command in the btp CLI:</p> <pre>btp assign accounts/entitlement --to- subaccount &lt;my-subaccount- id&gt; --for-service &lt;my- service&gt; --plan &lt;my- service-plan&gt; --amount &lt;number&gt;</pre> <p>Validate with this command:</p> <pre>btp list accounts/ entitlement</pre>	See <a href="#">Setting Entitlements Using the btp CLI [page 2171]</a> .
10.	View all the entitlements in your subaccounts.	Subaccount admin or viewer	<p>Run this command in the btp CLI:</p> <pre>btp list accounts/ entitlement --subaccount &lt;my-subaccount-id&gt;</pre>	See <a href="#">Setting Entitlements Using the btp CLI [page 2171]</a> .
11.	Create a Cloud Foundry org (environment instance) in your subaccounts.	Subaccount admin	<p>Run this command in the btp CLI:</p> <pre>btp create accounts/ environment-instance -- subaccount &lt;my-subaccount- id&gt; --display-name &lt;my- environment&gt; --environment &lt;cloudfoundry&gt;</pre>	See <a href="#">Working with Environments Using the btp CLI [page 2172]</a> .
12.	View details of the environment instances in your subaccounts.	Subaccount admin or viewer	<p>Run this command in the btp CLI:</p> <pre>btp list accounts/ environment-instance -- subaccount &lt;my-subaccount- id&gt;</pre>	See <a href="#">Working with Environments Using the btp CLI [page 2172]</a> .
13.	Create a Cloud Foundry space.	Org manager	<p>Run these cf CLI commands:</p> <pre>cf login cf create-space</pre>	See <a href="#">Create Spaces Using the Cloud Foundry Command Line Interface [page 2289]</a> .

Step No.	Task	Per- formed By	Do This	More Information
14.	Add Cloud Foundry org and space members.	Org manager	Run these cf CLI commands:  <pre>cf set-org-role &lt;USERNAME&gt; &lt;ORG&gt; &lt;ROLE&gt;  cf set-space-role &lt;USERNAME&gt;&lt;ORG&gt;&lt;SPACE&gt;&lt;ROLE&gt;</pre>	See <a href="#">Add Organization Members Using the Cloud Foundry Command Line Interface [page 2288]</a> and <a href="#">Add Space Members Using the Cloud Foundry Command Line Interface [page 2291]</a> .
15.	Display all available services in the Cloud Foundry marketplace.	Org manager	Run this cf CLI command:  <pre>cf marketplace</pre>	See <a href="#">Using Services in the Cloud Foundry Environment [page 229]</a> .

Using the `btp` CLI, you can perform additional account maintenance tasks, such as updating global account and subaccount details, deleting subaccounts, and deleting environment instances.

Subaccount members can also use the `btp` CLI to work with multitenant applications. See [Working with Multitenant Applications Using the `btp` CLI \[page 2173\]](#).

## Next Steps

Org/space members can create service instances, which are entitled to the subaccount, using also the `cf create-service <allowed-service-plan>` command in the `cf` CLI. Use the `cf services` command to verify that the service instances exist.

For further documentation about developer tasks, see [Development in the Cloud Foundry Environment \[page 214\]](#).

## 3.2.2 Getting Started with an Enterprise Account in the Cloud Foundry Environment

Quickly get started with an enterprise account in the Cloud Foundry Environment.

This topic focuses on how to get started with a customer or partner account using the SAP BTP cockpit. However, you can also perform these tasks using the CLI. See [Setting Up a Global Account via the Command Line](#) [page 145].

### 1. Setting Up Your Account Model

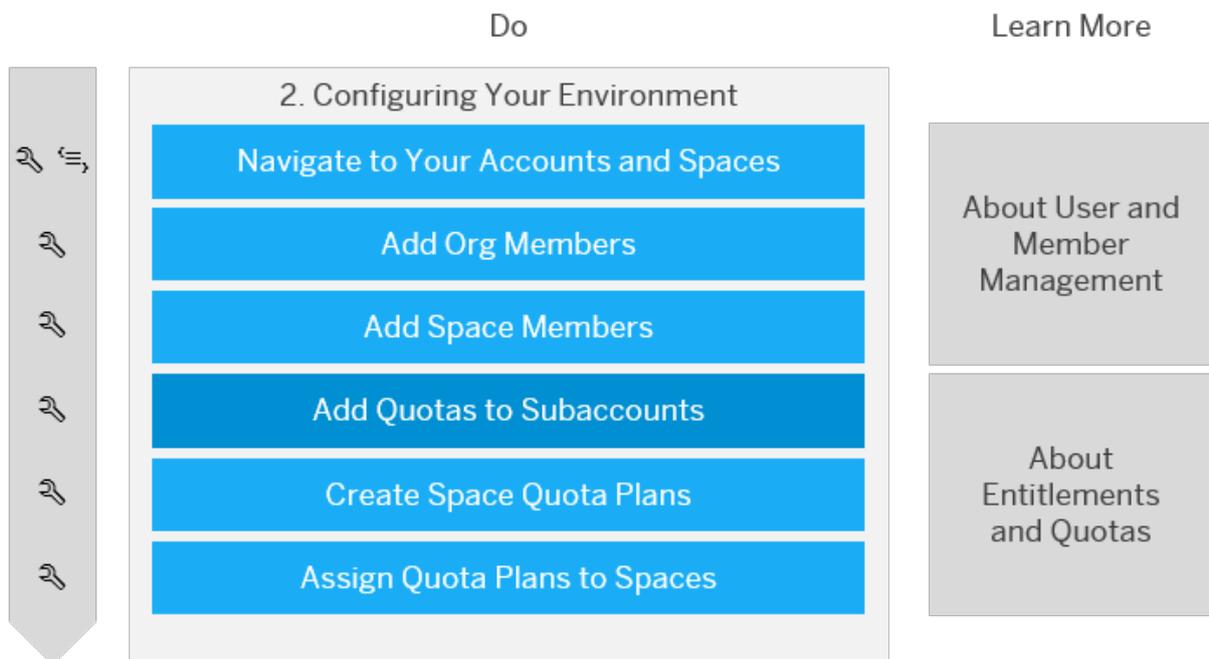

- [Download and Install the Cloud Foundry Command Line Interface](#) [page 2259]
  - [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface](#) [page 2260]
  - [Create Spaces](#) [page 2251]
  - [Global Accounts](#) [page 75]
  - [Create a Subaccount](#) [page 1977]
  - [Create Orgs](#) [page 2247]
1. After you've received your logon data by email, create subaccounts in your global account. This allows you to further break down your account model and structure it according to your business needs. See [Create a Subaccount](#) [page 1977].
  2. If you haven't done so already, now is a good time to download and install the Cloud Foundry Command Line Interface (cf CLI). This tool allows you to administer and configure your environment, enable services, and deploy applications. See [Download and Install the Cloud Foundry Command Line Interface](#) [page 2259].

But don't worry, you can also perform all the necessary task using the SAP BTP cockpit, which you don't need to install.

3. If you'd like to use the cf CLI, log on to your environment. See [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
4. Create a Cloud Foundry organization in each of your subaccounts. See [Create Orgs \[page 2247\]](#)
5. Create spaces. See [Create Spaces \[page 2251\]](#).

## 2. Configuring Your Environment

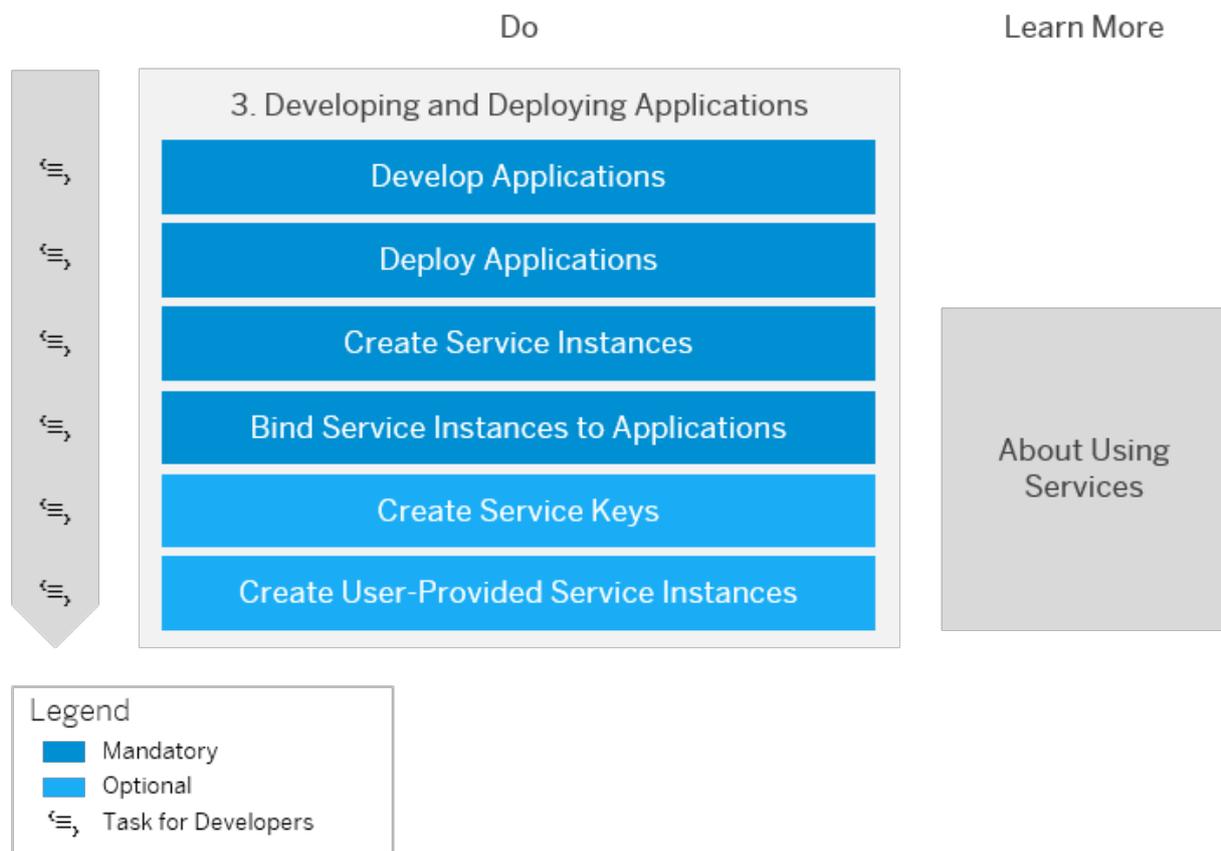

Legend	
<span style="display: inline-block; width: 15px; height: 10px; background-color: #0070C0; margin-right: 5px;"></span>	Mandatory

<span style="vertical-align: middle;">Task for Developers</span>	

- [User and Member Management \[page 85\]](#)
- [Navigate to Orgs and Spaces \[page 2246\]](#)
- [Add Org Members Using the Cockpit \[page 2248\]](#)
- [Add Space Members Using the Cockpit \[page 2252\]](#)

- [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#)
  - [Create Space Quotas \[page 2254\]](#)
  - [Assign Space Quotas to Spaces \[page 2256\]](#)
  - [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#)
1. You can either use the cockpit or the cf CLI to configure your environment. If you'd like to use the cockpit, it's important you understand how you can navigate to your accounts and spaces. See [Navigate to Orgs and Spaces \[page 2246\]](#).
  2. It's time to think about member management. You can add members at different levels. For example, you can add members at an org level. See [Add Org Members Using the Cockpit \[page 2248\]](#). For more information about roles, see [User and Member Management \[page 85\]](#).
  3. You can also add members at a space level. See [Add Space Members Using the Cockpit \[page 2252\]](#).
  4. Before you can start using resources such as services or application runtimes, you need to manage your entitlements and add quotas to your subaccounts. See [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#). To learn more about entitlements and quotas, see [Managing Entitlements and Quotas Using the Cockpit \[page 1995\]](#). Note that if you want to try out services for free, you need to select free tier service plans if available. For a list of free services, check the [SAP Discovery Center](#) .
  5. You can also assign quotas to different spaces within a subaccount. To do so, first create a space quota plan. See [Create Space Quotas \[page 2254\]](#) or [Create Space Quota Plans Using the Cloud Foundry Command Line Interface \[page 2292\]](#).
  6. Then assign the quota plan to your space. See [Assign Space Quotas to Spaces \[page 2256\]](#) or [Assign Quota Plans to Spaces Using the Cloud Foundry Command Line Interface \[page 2293\]](#).

### 3. Developing and Deploying Applications

- [Creating Service Instances \[page 231\]](#)
  - [Binding Service Instances to Applications \[page 234\]](#)
  - [Creating Service Keys \[page 236\]](#)
  - [Using Services in the Cloud Foundry Environment \[page 229\]](#)
  - [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#)
  - [Development \[page 212\]](#)
  - [Creating User-Provided Service Instances \[page 233\]](#)
1. Develop your application. Check out the Developer Guide for tutorials and more information. See [Development \[page 212\]](#).
  2. Deploy your application. See [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#).
  3. Integrate your application with a service. To do so, first create a service instance. See [Creating Service Instances \[page 231\]](#)
  4. Bind the service instance to your application. See [Binding Service Instances to Applications \[page 234\]](#).
  5. Alternatively, you can also create and use service keys. See [Creating Service Keys \[page 236\]](#). For more information on using services and creating service keys, see [About Services \[page 230\]](#).

6. You can also create instances of user-provided services. See [Creating User-Provided Service Instances \[page 233\]](#).

### 3.2.2.1 Setting Up a Global Account via the Command Line

Your global account is the entry point for managing the resources, landscape, and entitlements for your departments and projects in a self-service manner in SAP BTP. You can use the command-line tool **btp CLI** to set it up, and the **cf CLI** to manage Cloud Foundry instances.

#### ⓘ Note

The content in this section is only relevant for cloud management tools feature set B. For more information, see [Cloud Management Tools - Feature Set Overview](#).

Set up your account model using the btp CLI by creating subaccounts in your enterprise account that is running on the cloud management tools feature set B. You can create any number of subaccounts in the Cloud Foundry environment and region.

To manage Cloud Foundry, i.e. for managing service instances and members in orgs and spaces, creating spaces, as well as assigning quota to orgs and spaces, you use the cf CLI.

### Prerequisites

- You have purchased an enterprise global account.
- You have downloaded and extracted the following command-line tools:
  - SAP BTP command line interface (btp CLI). See [Download and Start Using the btp CLI Client \[page 2138\]](#)
  - Cloud Foundry CLI (cf CLI). See [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)

### Procedure

#### → Tip

In the btp CLI, you can view the command help of each command to get information about how to use the command, its syntax, and input parameters. See [Get Help \[page 2148\]](#).

Step No.	Task	Performed By	Do This	More Information
1.	Log in to your global account using the URL of the btp CLI server and the subdomain of your global account.	Global account administrator or viewer	Run this command in the btp CLI: <code>btp login</code>	See <a href="#">Log in</a> [page 2149].
2.	View details of your global account.	Global account admin or viewer	Run this command in the btp CLI: <code>btp get accounts/global-account</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the btp CLI</a> [page 2168].
3.	Add admins to your global account.	Global account admin	Assign the role collection <code>Global Account Administrator</code> to a user by running the following command in the btp CLI:  <code>btp assign security/role-collection "Global Account Administrator" --to-user &lt;user&gt; --create-user-if-missing</code>	See <a href="#">Managing Users and Their Authorizations Using the btp CLI</a> [page 2177] and <a href="#">Security Administration: Managing Authentication and Authorization</a> [page 2012].
4.	View all the regions that are available to your global account and subaccounts.	Global account admin or viewer	Run this command in the btp CLI: <code>btp list accounts/available-region</code>	This command also provides information about the environments and infrastructure provider of each region.
5.	Create subaccounts in your global account.	Global account admin	Run this command in the btp CLI: <code>btp create accounts/subaccount --display-name &lt;my-subaccount&gt; --region &lt;my-region&gt; --subdomain &lt;my-subaccount-subdomain&gt;</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the btp CLI</a> [page 2168] and <a href="#">Relationship Between Global Accounts and Subaccounts</a> [Feature Set A] [page 78].
6.	View the details of the subaccounts in your global account.	Global account admin or viewer	Run this command in the btp CLI: <code>btp get accounts/subaccount &lt;ID of new subaccount&gt;</code>	See <a href="#">Working with Global Accounts, Directories, and Subaccounts Using the btp CLI</a> [page 2168].

Step No.	Task	Performed By	Do This	More Information
7.	Add admins to your subaccounts.	Subaccount admin	Assign the role collection Subaccount Administrator to the user by running the following command in the btp CLI:  <pre>btp assign security/role-collection "Subaccount Administrator" --to-user &lt;user&gt; --create-user-if-missing</pre>	See <a href="#">Managing Users and Their Authorizations Using the btp CLI [page 2177]</a> and <a href="#">Security Administration: Managing Authentication and Authorization [page 2012]</a> .
8.	View all the services and applications that are entitled to your global account, including quota information per service plan.	Global account admin or viewer	Run this command in the btp CLI:  <pre>btp list accounts/entitlement</pre>	See <a href="#">Setting Entitlements Using the btp CLI [page 2171]</a> .
9.	Assign quotas to your subaccounts.	Global account admin	Run this command in the btp CLI:  <pre>btp assign accounts/entitlement --to-subaccount &lt;my-subaccount-id&gt; --for-service &lt;my-service&gt; --plan &lt;my-service-plan&gt; --amount &lt;number&gt;</pre> <p>Validate with this command:</p> <pre>btp list accounts/entitlement</pre>	See <a href="#">Setting Entitlements Using the btp CLI [page 2171]</a> .
10.	View all the entitlements in your subaccounts.	Subaccount admin or viewer	Run this command in the btp CLI:  <pre>btp list accounts/entitlement --subaccount &lt;my-subaccount-id&gt;</pre>	See <a href="#">Setting Entitlements Using the btp CLI [page 2171]</a> .
11.	Create a Cloud Foundry org (environment instance) in your subaccounts.	Subaccount admin	Run this command in the btp CLI:  <pre>btp create accounts/environment-instance --subaccount &lt;my-subaccount-id&gt; --display-name &lt;my-environment&gt; --environment &lt;cloudfoundry&gt; --plan standard --parameters "{ \"instance_name\" : \"myOrg\" }"</pre>	See <a href="#">Working with Environments Using the btp CLI [page 2172]</a> and <a href="#">Org Management Using the SAP BTP Command Line Interface (btp CLI) [Feature Set B] [page 2238]</a> .

Step No.	Task	Performed By	Do This	More Information
12.	View details of the environment instances in your subaccounts.	Subaccount admin or viewer	Run this command in the <code>btcp</code> CLI:  <pre>btcp list accounts/ environment-instance -- subaccount &lt;my-subaccount- id&gt;</pre>	See <a href="#">Working with Environments Using the <code>btcp</code> CLI</a> [page 2172].
13.	Create a Cloud Foundry space.	Org manager	Run these <code>cf</code> CLI commands:  <pre>cf login cf create-space</pre>	See <a href="#">Create Spaces Using the Cloud Foundry Command Line Interface</a> [page 2289].
14.	Add Cloud Foundry org and space members.	Org manager	Run these <code>cf</code> CLI commands:  <pre>cf set-org-role &lt;USERNAME&gt; &lt;ORG&gt; &lt;ROLE&gt; cf set-space-role &lt;USERNAME&gt;&lt;ORG&gt;&lt;SPACE&gt;&lt;ROL E&gt;</pre>	See <a href="#">Add Organization Members Using the Cloud Foundry Command Line Interface</a> [page 2288] and <a href="#">Add Space Members Using the Cloud Foundry Command Line Interface</a> [page 2291].
15.	Display all available services in the Cloud Foundry marketplace.	Org manager	Run this <code>cf</code> CLI command:  <pre>cf marketplace</pre>	See <a href="#">Using Services in the Cloud Foundry Environment</a> [page 229].

Using the `btcp` CLI, you can perform additional account maintenance tasks, such as updating global account and subaccount details, deleting subaccounts, and deleting environment instances.

Subaccount members can also use the `btcp` CLI to work with multitenant applications. See [Working with Multitenant Applications Using the `btcp` CLI](#) [page 2173].

## Next Steps

Org/space members can create service instances, which are entitled to the subaccount, using also the `cf create-service <allowed-service-plan>` command in the `cf` CLI. Use the `cf` CLI command `cf services` to verify that the service instances exist.

For further documentation about developer tasks, see [Development in the Cloud Foundry Environment](#) [page 214].

## 3.3 Getting Started in the ABAP Environment

Get onboarded in the SAP BTP, ABAP environment. Follow the workflows for trial or customer accounts.

[Getting Started with a Customer Account in the ABAP Environment \[page 149\]](#)

After you have purchased a customer account, learn how to get started in the ABAP environment.

### 3.3.1 Getting Started with a Customer Account in the ABAP Environment

After you have purchased a customer account, learn how to get started in the ABAP environment.

#### 📌 Note

This documentation informs you about the first steps as an administrator in the ABAP environment. For more information about getting started as a developer, see [Getting Started as a Developer in the ABAP Environment \[page 198\]](#).

#### 1. Logging on to SAP BTP

1. After you have purchased your customer account, you will receive an e-mail with a link to the home page of SAP BTP and the logon data as administrator for the global account.
2. Log on to SAP BTP.  
You are now in the SAP BTP cockpit.
3. Navigate to your global account.

## 2. Automated Initial Setup Using a Booster (Optional)

Do

Learn More

Set Up ABAP Environment Automatically

Run Booster

About Boosters

Legend

Optional

- [Using a Booster to Automate the Setup of the ABAP Environment \(Optional\) \[page 156\]](#)
- <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/fb1b56148f834749a2bf51127421610b.html> [<https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/fb1b56148f834749a2bf51127421610b.html>]

To set up a development system quickly, you can use the booster *Prepare an Account for ABAP Development*. The interactive booster guides you through the process of setting up your subaccounts, configuring entitlements, assigning members, and so on. For more information, see [Using a Booster to Automate the Setup of the ABAP Environment \(Optional\) \[page 156\]](#).

Using a booster is optional. If you don't use the booster, you must perform more steps manually.

## 3. Manual Setup

Even if you have used the booster, some manual setup steps are still required. In the following, steps that are performed by the booster are indicated.

## a. Setting Up Your Account Model

Do

**Set Up Your Account Model**

▶ Create a Subaccount

▶ Create Organizations and Spaces

Learn More

About Global  
Accounts,  
Subaccounts,  
Orgs, and Spaces

### Legend

Performed by booster

Mandatory if you don't use the booster

- [Creating a Cloud Foundry Subaccount for the ABAP Environment \[page 158\]](#)
  - [Creating a Cloud Foundry Organization and Space \[page 159\]](#)
  - <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/8ed4a705efa0431b910056c0acdbf377.html> [<https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/8ed4a705efa0431b910056c0acdbf377.html>]
1. (Not required if you have used the booster):  
Create a subaccount for ABAP environment in your global account (see [Creating a Cloud Foundry Subaccount for the ABAP Environment \[page 158\]](#) ).  
This allows you to further break down your account model and structure it according to your business needs.
  2. (Not required if you have used the booster):  
Create organizations and spaces (see [Creating a Cloud Foundry Organization and Space \[page 159\]](#)).  
If you want to learn more about subaccounts, orgs, and spaces, and how they relate to each other, see [Account Model](#).

## b. Setting Up the ABAP System

Do

Learn More

### Set Up Your ABAP System

-  Increase Quota for ABAP Environment
-  Increase Quota for Cloud Foundry Runtime
-  Create an ABAP System
-  Subscribe to Web Access for ABAP

### Managing Entitlements and Quotas Using the Cockpit

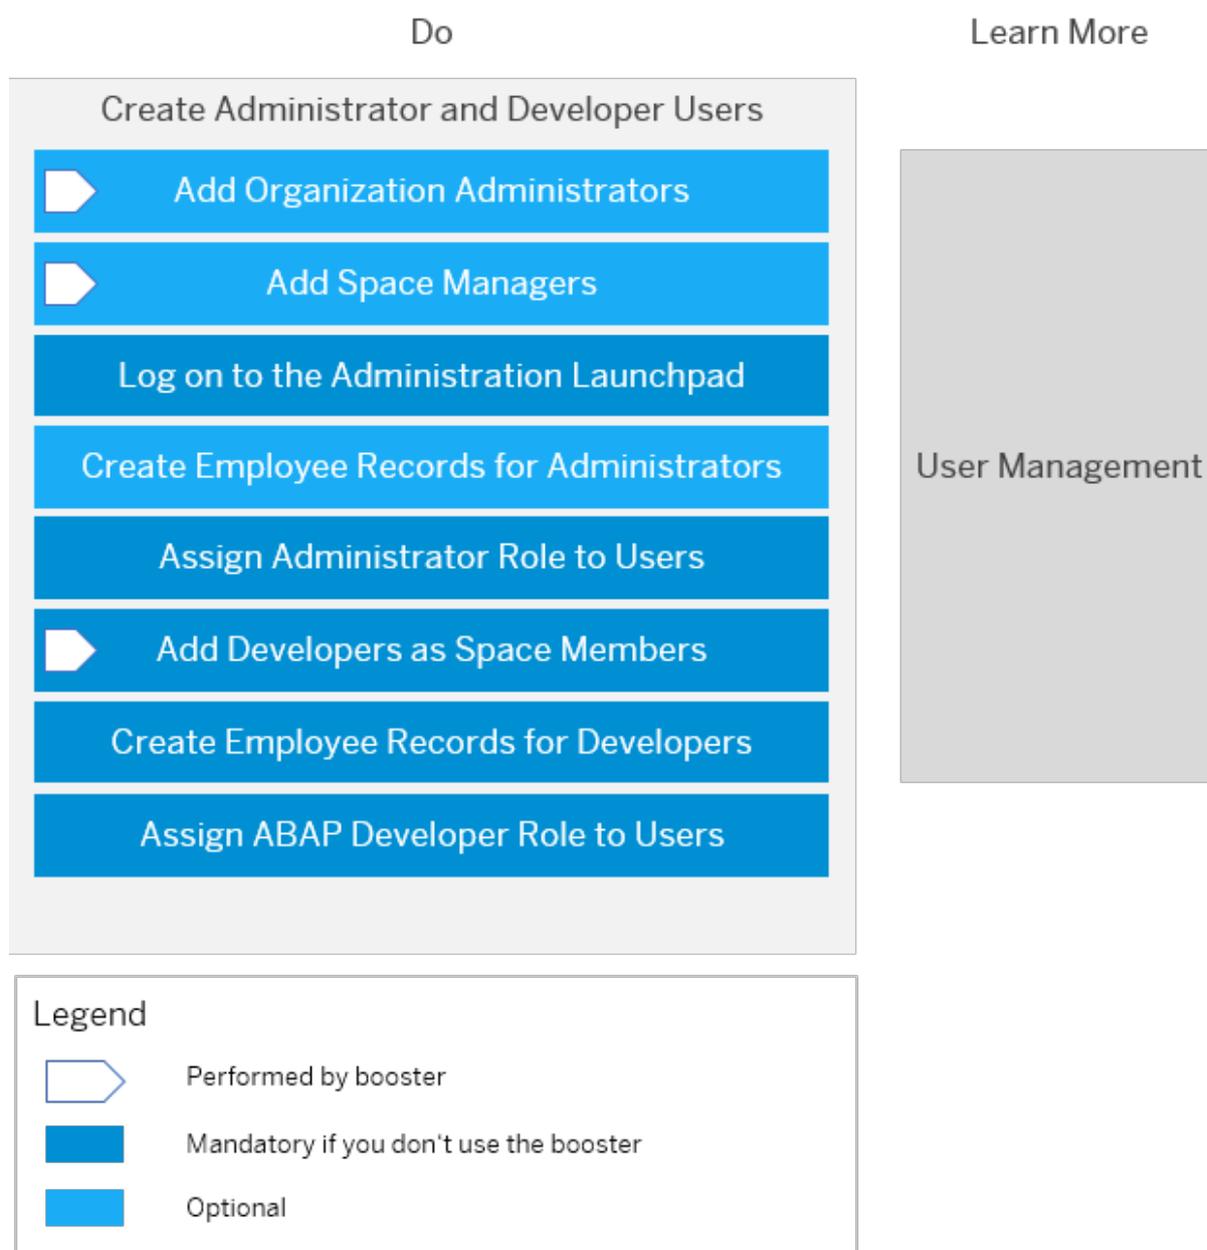

### Legend

-  Performed by booster
-  Mandatory if you don't use the booster
-  Optional if you don't use the booster

- [Increasing the Quota for the ABAP Environment \[page 160\]](#)
  - [Increasing the Quota for the Cloud Foundry Runtime \(Optional\) \[page 161\]](#)
  - [Creating an ABAP System \[page 163\]](#)
  - [Subscribing to the Web Access for ABAP \[page 168\]](#)
  - <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/c8248745dde24afb91479361de336111.html> [<https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/c8248745dde24afb91479361de336111.html>]
1. (Not required if you have used the booster):  
Before you can start using resources such as services or application runtimes, you must manage your entitlements and add quotas to your subaccount (see [Increasing the Quota for the ABAP Environment \[page 160\]](#) ).
  2. (Not required if you have used the booster):  
Optionally, if your developers want to deploy their own apps in Cloud Foundry, increase the quota for the Cloud Foundry runtime (see [Increasing the Quota for the Cloud Foundry Runtime \(Optional\) \[page 161\]](#) ).
  3. (Not required if you have used the booster):  
Create your ABAP system (see [Creating an ABAP System \[page 163\]](#) ).

4. (Not required if you have used the booster):  
 Subscribe to the Web access for ABAP SaaS application to get direct browser access to your instances in the ABAP environment (see [Subscribing to the Web Access for ABAP \[page 168\]](#)).  
 This also allows you to access the administration launchpad including your own SAP Fiori applications. You only have to subscribe once for each subaccount.

### c. Creating Administrator and Developer Users

- [Adding a User as Org Manager for the Cloud Foundry Organization \[page 169\]](#)
- [Adding a User as Space Manager for the Cloud Foundry Space \[page 169\]](#)

- [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)
  - [Creating an Employee Record for a New Administrator \[page 171\]](#)
  - [Assigning the ABAP Environment Administrator Role to the New Administrator User \[page 172\]](#)
  - [Creating New Space Members and Assigning Space Developer Roles to Them \[page 173\]](#)
  - [Creating an Employee Record for a New Developer \[page 173\]](#)
  - <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/cc1c676b43904066abb2a4838cbd0c37.html> [<https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/cc1c676b43904066abb2a4838cbd0c37.html>]
  - [Assigning the ABAP Developer User to the ABAP Developer Role \[page 174\]](#)
1. Optionally, you can create additional administrator users for the ABAP environment as follows:
    1. (Not required if you have used the booster):  
Add users as administrators of the Cloud Foundry organization that you created for the ABAP environment (see [Adding a User as Org Manager for the Cloud Foundry Organization \[page 169\]](#)).
    2. (Not required if you have used the booster):  
Add the users as managers for the Cloud Foundry space that you created for the ABAP environment (see [Adding a User as Space Manager for the Cloud Foundry Space \[page 169\]](#)).
    3. Log on to the administration launchpad (see [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)).
    4. Create employee records for the new administrators (see [Creating an Employee Record for a New Administrator \[page 171\]](#)).
    5. Assign the administrator role for the ABAP environment to the new users (see [Assigning the ABAP Environment Administrator Role to the New Administrator User \[page 172\]](#)).
  2. For your developers, create business users and assign them to the developer business role as follows:
    1. (Not required if you have used the booster):  
Create new members for the space that you created for the ABAP environment and assign developer roles to the new members (see [Creating New Space Members and Assigning Space Developer Roles to Them \[page 173\]](#)).
    2. Create employee records for the new developer users (see [Creating an Employee Record for a New Developer \[page 173\]](#)).
    3. Assign the ABAP developer users to the ABAP developer role (see [Assigning the ABAP Developer User to the ABAP Developer Role \[page 174\]](#)).

## 4. What's Next

After the initial setup of the ABAP environment, your developers can now develop applications using ABAP Development Tools. You can tell your developers to get started (see [Getting Started as a Developer in the ABAP Environment \[page 198\]](#)).

As next steps, you can optionally set up additional tools for your developers or ensure the integration with other systems:

- If your developers need a UI development tool, set up SAP Business Application Studio (see [Setup of UI Development in SAP Business Application Studio \(Optional\) \[page 175\]](#)).
- As a default identity service in the ABAP environment, you get SAP ID. You might want to set up a custom identity service (see [Setup of a Custom Identity Service \[page 183\]](#)).

- As an alternative to SAP Business Application Studio, you can also set up SAP Web IDE (see [Setup of UI Development in SAP Web IDE \(Optional\)](#) [page 189]).

Setup of UI  
Development in SAP  
Business Application  
Studio

Setup of a Custom  
Identity Provider

Setup of UI  
Development in SAP  
Web IDE

- [Setup of UI Development in SAP Business Application Studio \(Optional\)](#) [page 175]

[Video Tutorials](#) 

### 3.3.1.1 Using a Booster to Automate the Setup of the ABAP Environment (Optional)

You can use a booster to automate some of the required steps for setting up the ABAP environment. Automation includes creating a subaccount and space, configuring the required entitlements, and assigning administrators and developers to the subaccount.

#### Context

A booster is a set of guided interactive steps that enable you to select, configure, and consume services on SAP BTP. For more information, see [Boosters](#).

#### ⚠ Caution

The booster is only intended to create development systems. For non-development systems, follow the steps to set up the ABAP environment manually (see [Getting Started with a Customer Account in the ABAP Environment \[page 149\]](#)).

#### Procedure

1. Log on to the SAP BTP cockpit and choose the global account for the Cloud Foundry environment as administrator.
2. From the navigation menu, choose [Boosters](#).
3. Choose the booster [Prepare an Account for ABAP Development](#).

The tab pages [Overview](#), [Components](#), and [Additional Resources](#) are displayed, where you get more information about the booster.

4. Choose [Start](#).
5. After the system has successfully checked the prerequisites, choose [Next](#) to continue.
6. On the [Prepare an Account for ABAP Development](#) dialog, entitlements and quotas for the new subaccount are proposed, but you can change them if needed:
  - For the [ABAP environment](#) service, the service plan [standard](#) enables you to size ABAP server and persistence independently from each other in 16 GB units. These units are represented in the quota plans [abap\\_compute\\_unit](#) and [hana\\_compute\\_unit](#).  
As part of the default quota assignment, you get at least 1 compute unit in the [abap\\_compute\\_unit](#) service plan and at least 2 compute units in the [hana\\_compute\\_unit](#) service plan. This corresponds to the minimum configuration for an instance of the ABAP Environment service. You can also choose higher quotas in the dialog of the booster.
  - For the [Web Access to ABAP](#) service, a default plan is chosen that you cannot change. You need the service and the quota for direct browser access to your instances in the ABAP environment, including access to the administration launchpad for ABAP.

- Depending on what you have ordered for your account, additional entitlements for the services [Cloud Foundry Runtime](#), [Launchpad](#), and [SAP Business Application Studio](#) might be shown. They are optional; you can remove the entitlements if you don't need them right now and want to add them later:
    - A quota for the Cloud Foundry runtime is only needed for the ABAP environment if your developers want to deploy their own apps in Cloud Foundry.
    - The SAP Build Work Zone, standard edition enables organizations to establish a central point of access to SAP, custom-built, and third party applications and extensions, both in the cloud and on premise.
    - SAP Business Application Studio is a UI development environment.
7. On the [Prepare an Account for ABAP Development](#) dialog, follow the instructions on the screen to enter subaccount name, provider, region, and so on.
  8. On the [Add Users](#) dialog, add the e-mail addresses of new users in the ABAP environment.
 

This step allows you to quickly create additional administration users for the ABAP environment, if needed, and developer users. In the [Origin](#) field, you can see the identity provider for the ABAP environment. By default, this is SAP ID service ([sap.ids](#)), but if you have set up a custom identity provider, you can choose this provider from the dropdown list.
  9. On the [Configure ABAP Environment Instance](#) dialog, enter a 3-character ID for your ABAP system.
  10. Review your settings and finish the booster.

## Results

After the booster has run successfully, the following tasks have been performed automatically:

- A new Cloud Foundry subaccount for the ABAP environment is created and enabled.
- A space and an organization for the ABAP environment are available.
- A service instance for the ABAP environment has been created.
- A system ID of your choice has been assigned to the ABAP system.
- An identity provider (SAP ID service or a custom identity provider) has been set up for the ABAP environment.
- For the [ABAP environment](#) service, quotas have been distributed for the ABAP server and the SAP HANA persistence. The quotas that you have chosen are deducted from the available quota for each service in your global account..
- If you have entitlements for SAP Build Work Zone, standard edition and SAP Business Application Studio, then you have subscribed to these services and standard quotas have been assigned accordingly. ([Feature Set B]: Entitlements for subscription services are assigned to the subaccount.)
- You're subscribed to the Web access for ABAP SaaS application and get direct browser access to your instances in the ABAP environment. ([Feature Set B]: Entitlements for subscription services are assigned to the subaccount.)
- Additional users with Cloud Foundry organization manager and space manager roles have been added. If you have ordered the launchpad as a service, the additional administration users have also been assigned to the role collection [Launchpad\\_Admin](#).
- Additional users for developers with space developer role have been added. If you have ordered SAP Business Application Studio as a service, the additional developer users have also been assigned to the role collection [Business\\_Application\\_Studio\\_Developer](#).

### 📘 Note

The booster speeds up the initial setup, but there are still some tasks that you need to perform after the booster has run.

In the following, you can find documentation for all necessary initial tasks, including the tasks that you don't need to perform if you have run the booster successfully. A note at the beginning of each task indicates that you can skip it if you've used the booster.

## 3.3.1.2 ABAP Environment: Initial Settings

With the initial settings, you as an administrator and your ABAP developers can get started in the ABAP environment.

After the initial settings are done, the ABAP environment is ready for your ABAP developers so they can implement business services using ABAP Development Tools (ADT).

### 3.3.1.2.1 Creating a Cloud Foundry Subaccount for the ABAP Environment

Create a Cloud Foundry subaccount for the ABAP environment in your global account using the cockpit.

#### Context

### 📘 Note

If you have run the booster [Prepare an Account for ABAP Development](#), you can skip these steps.

For the ABAP environment, you need a Cloud Foundry subaccount as a technical environment. If you want to reuse an existing Cloud Foundry subaccount, make sure that it uses the providers and regions that are available for provisioning an ABAP environment. For more information about the providers and regions for ABAP environment, see [Regions](#).

#### Procedure

1. From your global account, choose [New Subaccount](#).
2. Specify a display name, for example, **ABAP**.
3. **Optional:** Enter a description.
4. Leave the [Neo Environment](#) checkbox deselected.

5. Choose the desired infrastructure provider and region for your subaccount.

You can find the available providers and regions for the ABAP environment in [Regions](#).

6. Enter a subdomain for your subaccount. The subdomain will become part of the URL for accessing applications that you subscribe to from this subaccount.

#### Note

You can choose any string of your choice. However, note that the subdomain can contain only letters, digits and hyphens (not allowed in the beginning or at the end), and must be unique across all subaccounts in the same region. Uppercase and lowercase letters can be used, however that alone does not qualify as a means to differentiate subdomains (for example, **SUBDOMAIN** and **subdomain** are considered to be the same).

7. If your subaccount is to be used for production purposes, select the *Used for production* option.
8. Choose *Create*.

## 3.3.1.2.2 Creating a Cloud Foundry Organization and Space

Create a Cloud Foundry organization and Cloud Foundry space that will correspond to the instance of the ABAP environment.

### Context

#### Note

If you have already created an organization and space for the ABAP environment, you can skip these steps. If you have run the booster *Prepare an Account for ABAP Development*, you can also skip these steps.

For more information about creating Cloud Foundry spaces, see [Create Spaces](#).

### Procedure

1. Log on to the SAP BTP cockpit in the global account for the Cloud Foundry environment as administrator.
2. Choose the tile of the Cloud Foundry subaccount.
3. Check whether Cloud Foundry is enabled: If it's enabled, the Cloud Foundry organization name appears as organization on the screen area *Cloud Foundry*.
4. If Cloud Foundry is not enabled yet, proceed as follows:
  - a. Choose *Enable Cloud Foundry*.
  - b. On the *Create Cloud Foundry Organization* dialog, enter a name for the Cloud Foundry organization and choose *Create*.
  - c. Choose the free or standard plan for the Cloud Foundry runtime according to your needs.

5. On the *Cloud Foundry* screen area, choose the link for spaces.
6. If the Cloud Foundry space in the Cloud Foundry organization does not exist yet, proceed as follows:
  - a. Choose *New Space*.
  - b. On the *New Space* dialog, enter a name for the new Cloud Foundry space, for example, **dev**, and leave the checkboxes for space manager and space developer checked.
  - c. Choose *Create*.

### 3.3.1.2.3 Increasing the Quota for the ABAP Environment

Before you can create a service instance for the ABAP environment, you must assign some of the available quota to the subaccount for the ABAP environment.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

If you are working in an enterprise account, you need to add quotas to the services that you purchased in your subaccount before they can appear in the service marketplace. For more information, see [Configure Entitlements and Quotas for Subaccounts](#).

#### Procedure

1. Log on to the SAP BTP cockpit as administrator.
2. Go to your global account.
3. From the navigation area, choose ► *Entitlements* ► *Entity Assignments* ►.
4. Enter the subaccount for the ABAP environment and choose *Go*.
5. Choose *Configure Entitlements*.
6. Choose *Add Service Plans*.

In the following popup, the available entitlements for this subaccount are shown.

7. For the *ABAP environment* entitlement, select the plans *abap\_compute\_unit*, *standard*, and *hana\_compute\_unit*.

With the selection of the *standard* service plan, you can size the ABAP runtime and the SAP HANA memory independently from each other. To be able to do your sizing, you must also select the quota plans *abap\_compute\_unit* and *hana\_compute\_unit*.

8. Choose *Add 3 Service Plans*.
9. On the following screen, increase the quotas in the *abap\_compute\_unit* service plan at least by 1 and in the *hana\_compute\_unit* service plan at least by 2.

The minimum configuration of 1 ABAP compute unit and 2 HANA compute units is sufficient in many cases to create one service instance for the ABAP environment. If you need more resources, choose higher quotas. Keep in mind that increasing the SAP HANA Cloud storage using the parameter `size_of_persistence_disk` consumes 0.002 HANA compute units for each GB that exceeds the minimal size of the persistence disk.

10. Choose *Save*.

## Results

After you have assigned an entitlement for the three plans with respective quotas to your subaccount, you can create an ABAP system. This is the point where you can then decide how many blocks of ABAP compute units and HANA compute units you want to assign to your new system. See [Creating an ABAP System \[page 163\]](#).

## Related Information

[ABAP Compute Units \[page 2739\]](#)

### 3.3.1.2.4 Increasing the Quota for the Cloud Foundry Runtime (Optional)

Check if your subaccount has a quota for the Cloud Foundry runtime and increase it, if needed.

## Context

### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

A quota for the Cloud Foundry runtime is optional. It's only needed for the ABAP environment if your developers want to deploy their own apps in Cloud Foundry.

## Procedure

1. Log on to the SAP BTP cockpit as Cloud Foundry administrator.
2. Go to your global account.
3. From the navigation area, choose [► Entitlements](#) [► Entity Assignments](#) [►](#).

4. If there is no entry for the Cloud Foundry runtime, choose [Configure Entitlements](#) and [Add Service Plans](#).
5. In the following popup, proceed as follows:
  - a. Choose [Cloud Foundry Runtime](#).
  - b. Under [Available Service Plans](#), select the checkbox [MEMORY](#).
  - c. Choose [Add 1 Service Plan](#).
6. Choose [+](#) to add at least 1 to the subaccount.
7. Choose [Save](#).

### 3.3.1.2.5 Selecting a Service Plan for the Web Access for ABAP

Before you can subscribe to the Web Access for the ABAP environment, you must select the relevant service plan.

#### Context

##### Note

If you have run the booster [Prepare an Account for ABAP Development](#), you can skip this step.

If you are working in an enterprise account, you need to add quotas to the services that you purchased in your subaccount before they can appear in the service marketplace.

#### Procedure

1. Log on to the SAP BTP cockpit as administrator.
2. Go to your global account.
3. From the navigation area, choose [Entitlements](#) [Entity Assignments](#).
4. Enter the subaccount for the ABAP environment and choose [Go](#).
5. Choose [Configure Entitlements](#).
6. Choose [Add Service Plans](#).

In the following popup, the available entitlements for this subaccount are shown.

7. For the [Web Access for ABAP](#) entitlement, select the plan [default \(Application\)](#).
8. Choose [Add 1 Service Plan](#).
9. Choose [Save](#).

## 3.3.1.2.6 Creating an ABAP System

Create a service instance for the ABAP environment from the Service Marketplace.

### Prerequisites

You have increased the quota for the ABAP environment. See [Increasing the Quota for the ABAP Environment \[page 160\]](#).

### Context

#### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can also skip this step.

For more information about creating service instances, see [Create Service Instances Using the Cockpit](#).

### Procedure

1. Log on to the SAP BTP cockpit and navigate to the Cloud Foundry subaccount. See [Navigate in the Cockpit](#).
2. From the navigation area, choose ► [Services](#) ► [Service Marketplace](#).  
You see a list of all services that are available to you.
3. Choose [ABAP environment](#).
4. Choose [Create](#).

A wizard opens that helps you create your instance.

#### → Tip

To see a list of all instances that have already been created in your subaccount, choose ► [Services](#) ► [Instances and Subscriptions](#) from the navigation area. Here, you can also create a new ABAP environment instance.

5. Select the `standard` service plan.
6. Choose [Cloud Foundry](#) as your runtime environment.
7. Select a space.
8. Enter a CLI-friendly instance name, and choose [Next](#).

The instance name identifies the service instance in the Cloud Foundry environment. Specify an instance name that is unique among all the service instances in a space and only contains alphanumeric characters (A-Z, a-z), periods, underscores, and hyphens.

9. Provide additional instance parameters for the configuration by either using the default **form** or by uploading a **JSON file** from your computer or by specifying the parameters in JSON format. Here is a list of all parameters:

Parameter (technical name in parenthesis)	Note
<b>Admin Email Address</b> (admin_email)	The <b>admin email address</b> is used to create the initial user for the ABAP system automatically, including the assignment of the administrator role to this user. You can access the ABAP environment system only with this specified user. By default, the email address is used as subject name identifier.
<b>ABAP System Description</b> (description)	The <b>ABAP system description</b> is optional.
<b>Development System</b> (is_development_allowed)	The <b>development system</b> checkbox is checked by default. By using this setting, you can control the changeability of development objects in the system. If you want to protect all your customer-related software components and ABAP namespaces against manual changes via ABAP Development Tools, uncheck the box. This setting is used for test and productive systems, where changes must be imported only. For information about which business catalogs are available in development systems only, see <a href="#">Business Catalogs for Development Tasks [page 2348]</a> .
<b>ABAP System ID</b> (sapsystemname)	The <b>ABAP system ID</b> must consist of exactly three alphanumeric characters. Only uppercase letters are allowed. The first character must be a letter (not a digit). The ID does not have to be technically unique.
<b>ABAP Runtime Size</b> (size_of_runtime)	The <b>ABAP runtime size</b> refers to the runtime size of the ABAP environment service instance. The size is specified in number of ABAP compute units that should be used from the quota plan <i>abap_compute_unit</i> , with one ABAP compute unit representing 16 GB. The supported number of abap_compute_unit is 1, 2, 4, 6, 8, 16, 24, or 32. For more information, see <a href="#">ABAP Compute Units [page 2739]</a> .
<b>Elastic Scaling of the ABAP Application Server</b> (elastic)	<p>The <b>elastic scaling of the ABAP application server</b> parameter defines whether or not to adapt the number of ABAP application servers dynamically, depending on the system load.</p> <p>By default, the checkbox is not checked (<code>elastic = false</code>), and the service instance will have a fixed number of ABAP application servers with a total ABAP runtime size as defined by the parameter <b>ABAP Runtime Size</b> (see above).</p> <p>If you enable elastic scaling by checking the checkbox (<code>elastic = true</code>), application servers will be automatically added to the service instance when the load increases and removed when the load decreases. More specifically, the number of application servers will scale between 1 ACU (ABAP Compute Unit), using two application servers, as a minimum and the number of ACUs configured in the <b>ABAP Runtime Size</b> parameter (see above) as a maximum.</p>

Parameter (technical name in parenthesis)	Note
	<p>This feature considerably helps in cost-saving as charges are only levied based on the actually allocated ACUs, and not on the configured maximum. Still, to ensure that defined quotas are not exceeded, the maximum number of ACUs that is set in the <b>ABAP Runtime Size</b> parameter is allocated from the available ACU quota for the entire duration that the service instance is provisioned.</p> <p>The scaling typically occurs within a couple of minutes. Especially when a service instance is scaled down, there is a grace period of a few minutes to allow the completion of short-lived requests. Before enabling elastic scaling in production, we advise to test your typical workload patterns and monitor the embedded <a href="#">Health Monitoring</a> app to verify the suitability of this cost-saving measure. Maintaining a higher number of statically configured ACUs might be better for handling sudden large spikes in the system load.</p>
<b>HANA Cloud Memory Size</b> (size_of_persistence)	<p>The <b>HANA Cloud memory size</b> refers to the memory size of the SAP HANA Cloud database used by the ABAP environment service instance. The size is specified in number of HANA compute units that should be used from the quota plan <i>hana_compute_unit</i>, with one HANA compute unit representing the suitable block size for the underlying SAP HANA Cloud instance (16 GB on Microsoft Azure and Google Cloud Platform, or 15 GB on AWS). The supported number of hana_compute_unit per HANA instance is 2, 4, 8, 16, 32, or 64.</p>
<b>HANA Cloud Disk Size</b> (size_of_persistence_disk)	<p>The <b>HANA Cloud disk size</b> refers to the disk size in GB of the SAP HANA Cloud database used by the ABAP environment service instance. If the parameter is set to <code>auto</code>, the SAP HANA Cloud storage size is set to the minimal value <math>40 * \text{size\_of\_persistence} + 40</math>. The maximum allowed value is <math>120 * \text{size\_of\_persistence} + 40</math>. If you set a higher value, it will consume 0.002 HANA compute units (HCU) for any GB exceeding the minimal default size of the persistence disk. Therefore, the HCU ratio of additional storage disk to RAM is 1 : 31.25 per GB on Microsoft Azure and on Google Cloud Platform (as 1 HCU = 16 GB) or 1 : 33.33 per GB on AWS (as 1 HCU = 15 GB).</p>
<b>Admin User Name</b> (admin_user_name)	<p>The <b>admin user name</b> is an optional parameter used to provide the user name for the initial user. It must be provided if the <b>login attribute</b> is set to <code>user_name</code> (see below).</p>
<b>Login Attribute</b> (login_attribute)	<p>Using an email address as subject name identifier might not be possible if the e-mail address is ambiguous across users or if the trusted identity provider configured for authentication in the ABAP Environment instance's subaccount already is configured with the subject name identifier <code>Login Name</code>. In this case, you can change the <b>login attribute</b> to <code>user_name</code> and in addition also provide the user name for the initial user in the <b>admin user name</b> (see above).</p>

### Note

Make sure that you don't choose more compute units than you have assigned to your subaccount for the ABAP environment (see [Increasing the Quota for the ABAP Environment \[page 160\]](#)).

For more information about ABAP system sizing and Native Storage Extension for selected SAP HANA tables, see [ABAP System Sizing \[page 2727\]](#) and [Native Storage Extension for the ABAP Environment \[page 2731\]](#).

### Caution

Be aware that not all parameters can be changed if you update your ABAP system. For a list of updatable parameters, see [Updating an ABAP System \[page 166\]](#).

10. Choose [Next](#) to review and verify your instance details.
11. Choose [Create](#).

The ABAP environment instance is being set up, which might take a while. Wait for an email that is sent when the setup is completed and the system up and running. The email is sent to the email address that you specified as admin email in the previous steps.

## 3.3.1.2.6.1 Updating an ABAP System

Learn how to update your ABAP environment instance.

### Context

#### Note

After you have created an ABAP environment instance, you can change the following properties:

- ABAP System Description
- ABAP Runtime Size (size\_of\_runtime)
- Elastic Scaling of the ABAP Application Server
- HANA Cloud Memory Size (size\_of\_persistence)
- HANA Cloud Disk Size (size\_of\_persistence\_disk)

#### Note

The updates of these properties are done without any downtime, or - in case of updating the HANA memory or disk size - with near zero downtime (meaning that the database is not accessible for a few seconds only).

To change the initial admin, you have to use the [Maintain Employees](#) SAP Fiori app. See [Maintain Employees \[page 2419\]](#).

### ⚠ Restriction

A downsizing of the HANA Cloud memory size is only possible down to the minimum amount of memory required for a stable performance of the HANA Cloud database. Before the memory size is decreased, an SQL query (as described on [SAP HANA Database Downsizing](#)) is automatically run on the database to make sure the downsizing is possible based on the already consumed memory.

The HANA Cloud memory size cannot be decreased while a system is stopped. To decrease the HANA Cloud memory size of a stopped instance, the instance has to be started via the [Landscape Portal](#) first.

The HANA Cloud disk size can currently only be increased, and not decreased.

Both the HANA Cloud memory and the disk size can only be resized once every 24 hours.

## Procedure

1. In the SAP BTP cockpit, choose your Cloud Foundry subaccount and navigate to the space, in which you have created your ABAP environment instance. See [Navigate in the Cockpit](#).
2. From the navigation area, choose **Services > Instances and Subscriptions**.
- You see a list of all instances that have been created.
3. Select your *ABAP environment* instance and choose *Update* by clicking on **⋮** at the end of the row. If you'd like to check the values that are currently configured first, please select *View Parameters* instead.
4. In the *Update Instance* wizard, you can update the parameters listed above. See [Increasing the Quota for the ABAP Environment \[page 160\]](#). The currently configured values are prefilled in the *Update Wizard*, so you can keep the values that you don't want to change as they are.
5. Choose *Update Instance* to save your changes.

## Results

Your ABAP environment instance is being updated. This might take a while.

### 3.3.1.2.7 Subscribing to the Web Access for ABAP

You need to subscribe to the [Web access for ABAP](#) SaaS application to get direct browser access to your instances in the ABAP environment, including access to the administration launchpad for ABAP.

#### Context

##### Note

If you have run the booster [Prepare an Account for ABAP Development](#), you can skip this step.

This subscription is required to access the SAP Fiori launchpad for the administrator and to access developed SAP Fiori applications. Subscription is required only once per subaccount (for all systems to be created in all spaces of this subaccount). After subscribing to the application, you have access to the administration launchpad, where you can configure application roles and assign those roles to your users.

#### Procedure

1. Log on to the SAP BTP cockpit in the Cloud Foundry subaccount of the global account for Cloud Foundry as administrator.
2. In the navigation area, choose ► [Services](#) ► [Service Marketplace](#) ▾.
3. Choose the SaaS application tile [Web access for ABAP](#).
4. If the application is not shown as active, choose [Create](#) and wait for the subscription to be provisioned.

### 3.3.1.2.8 Creation of Additional Administrator Users (Optional)

After you have set up the ABAP environment for administration, add more administrator users for the ABAP environment.

After you have completed the administrative setup, only your user is available as administrator in the ABAP environment. You will probably want to create more administration users for your ABAP environment. Creating more administration users also helps you verify that your administrative setup is correct and complete.

### 3.3.1.2.8.1 Adding a User as Org Manager for the Cloud Foundry Organization

After you have created a Cloud Foundry organization for the ABAP environment, you can add more users as organization managers.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development* and entered additional administrators, you can skip these steps.

#### Procedure

1. Log on to the SAP BTP cockpit as administration user for Cloud Foundry.
2. Go to your subaccount for the ABAP environment.
3. From the navigation area, choose *Org Members*.
4. Choose *Add Members*.
5. Enter the user's e-mail address in the *E-mails* field.
6. Select the checkbox for org manager.
7. Choose *OK*.

### 3.3.1.2.8.2 Adding a User as Space Manager for the Cloud Foundry Space

After you have created a Cloud Foundry space for the ABAP environment, you can add more users as space managers.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development* and entered users as additional administrators, you can skip these steps.

## Procedure

1. Log on to the SAP BTP cockpit as administration user for Cloud Foundry.
2. Go to your subaccount for the ABAP environment.
3. Choose *Spaces*.
4. Choose the Cloud Foundry space in the Cloud Foundry org.
5. In the navigation area, choose *Members*.
6. Choose *Add Members*.
7. Enter the user's e-mail address in the *E-mails* field.
8. Select the checkbox for space manager.
9. Choose *OK*.

### 3.3.1.2.8.3 Logging on to the Administration Launchpad of the ABAP Environment

To add another user as administrator for the ABAP instance, log on to the administration launchpad of the ABAP environment.

## Prerequisites

You are the administrator who has created the ABAP system (see [Creating an ABAP System \[page 163\]](#)).

## Procedure

1. In the SAP BTP cockpit, go to the Cloud Foundry subaccount for the ABAP environment as administrator.
2. Choose the space in the Cloud Foundry subaccount.
3. In the navigation area, choose  *Services*  *Service Instance* .
4. Choose the service instance for the ABAP environment.
5. Choose *View Dashboard*.

The logon window for the administration launchpad of the ABAP environment opens.

6. If you are using the custom Identity Authentication service for SAP BTP, you don't need to enter your user and password, but choose the available link of the custom Identity Authentication service and log on.
7. If you need to enter your user and password, remember to log on with the right user that was defined before (see [Creating an ABAP System \[page 163\]](#)).

## Results

The administration launchpad opens. You can now proceed with creating an employee record for the administrator.

### 3.3.1.2.8.4 Creating an Employee Record for a New Administrator

To be able to create a new administration user, you first need to create an employee record for the new administrator.

## Prerequisites

You have logged on to the administration launchpad of the ABAP environment as administrator user (see [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)).

## Procedure

1. From the SAP Fiori launchpad, open the *Maintain Employees* app.
2. Choose *Create*.
3. Enter the data for the new administrator, including employee ID, name, and e-mail address.  
The entered e-mail is important because it is the default approach to authorization and represents the mapping between the user in the identity provider and in the ABAP environment.
4. Choose *Create*.

## Results

You can now create a business user and assign administration roles to the business user.

### 3.3.1.2.8.5 Assigning the ABAP Environment Administrator Role to the New Administrator User

Add the new administration user as administrator to the ABAP instance.

#### Prerequisites

You have logged on to the administration launchpad of the ABAP environment as administrator (see [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)). You have created an employee record for another, new administrator.

#### Procedure

1. On the SAP Fiori launchpad, choose the *Maintain Business Users* tile.
2. Choose *New*.
3. In the following dialog, choose the employee record of the new administrator from the list.
4. Confirm the system message that you want to create a new user.
5. Add the time zone to the business user data.
6. On the *Assigned Business Roles* tab, choose *Add*.
7. Select the checkbox for the predefined administrator business role `SAP_BR_ADMINISTRATOR`.
8. Select the checkbox for other administrator roles that are available for your organization and choose *OK*.
9. Choose *OK*.
10. Choose *Save*.

### 3.3.1.2.9 Creation of Developer Users

After you have set up the ABAP environment for development, create developer users for the ABAP environment.

Creating developer users also helps you verify that your development setup is correct and complete.

### 3.3.1.2.9.1 Creating New Space Members and Assigning Space Developer Roles to Them

For your developers, create new members in the space for the ABAP environment and assign developer roles to them.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

#### Procedure

1. Log on to the SAP BTP cockpit as Cloud Foundry administrator.
2. Choose the tile for the Cloud Foundry subaccount.
3. In the navigation area, choose *Spaces*.
4. Choose the space for the ABAP environment.
5. In the navigation area, choose *Members*.  
All members currently assigned to the space are shown in a list.
6. Choose *Add Members*.
7. Enter e-mail addresses of your developer users.
8. You can use commas, spaces, semicolons, or line breaks to separate members.
9. Select the space developer role for the users and save your changes.

### 3.3.1.2.9.2 Creating an Employee Record for a New Developer

Create an employee record for a new developer user for the ABAP environment.

#### Procedure

1. Log on to the administration launchpad of the ABAP environment as administrator (see [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)).
2. Choose the *Maintain Employees* tile.
3. Choose *Create*.

4. Enter the data for the new developer, including employee ID, name, and e-mail address.

The entered e-mail is important because it represents the mapping between the user in the identity provider and in the ABAP environment.

5. Choose *Save*.

### 3.3.1.2.9.3 Assigning the ABAP Developer User to the ABAP Developer Role

Add the developer user as business user to the ABAP instance.

#### Prerequisites

You have created an employee record for the new developer user (see [Creating an Employee Record for a New Developer \[page 173\]](#)).

You have created an ABAP developer role based on the business role template `SAP_BR_DEVELOPER`, which provides developers with unrestricted read and write access in the ABAP environment. Alternatively, you have created a business role based on a development-related business catalog (see [Business Catalogs for Development Tasks \[page 2348\]](#)).

#### Procedure

1. Log on to the administration launchpad of the ABAP environment as administrator (see [Logging on to the Administration Launchpad of the ABAP Environment \[page 170\]](#)).
2. On the SAP Fiori launchpad, choose the *Maintain Business Users* tile.
3. Choose *New*.
4. In the following dialog, choose the employee record of the new developer user from the list.
5. Confirm the system message that you want to create a new user.
6. On the *Assigned Business Roles* tab, choose *Add*.
7. Select the checkbox for the ABAP developer role that you have created before (see *Prerequisites*).
8. Choose *OK* and save your entries.

### 3.3.1.2.10 Creating a Service Key (Optional)

In the SAP BTP cockpit, you can create a service key for the ABAP system. You can later use this service key, for example, to log on to the ABAP system from ABAP development tools (ADT) for test purposes.

#### Context

You can use service keys to generate credentials to communicate directly with a service instance. After you have configured the service keys for your service, local clients, apps in other spaces, or entities outside your deployment can access your service with these keys. Using a service key is one option how you can access the service instance of the ABAP environment, for example, as administrator for test purposes. Note, however, that there's also another option for users of ABAP development tools (ADT): instead of using an existing service key, developers and other users with a user and password for the ABAP system can also use the project creation wizard in ADT to log on to the ABAP service instance and use the service key that is automatically provided by the service instance. For more information about service keys, see [Using a Service Key Provided by the Service Instance](#).

#### Procedure

1. As Cloud Foundry administration user, log on to the SAP BTP cockpit.
2. Go to your Cloud Foundry subaccount for the ABAP environment.
3. In the navigation area, choose [Spaces](#).
4. Choose the tile for the ABAP environment space.
5. From the navigation area, choose [Services](#) > [Instances and Subscriptions](#).
6. Choose the service instance of the ABAP system.
7. In the [Service Keys](#) section of the details area, choose [Create](#).
8. Enter a name for the service key, for example, **ABAP Development**.
9. Choose [Save](#).
10. Copy the created service key for later reuse.

### 3.3.1.3 Setup of UI Development in SAP Business Application Studio (Optional)

If developers want to use SAP Business Application Studio to create and deploy SAP Fiori application UIs, you need to perform some administrative activities to set it up.

In the Cloud Foundry environment, SAP Business Application Studio is a service that provides a modular development environment, including the development of SAP Fiori applications. As an alternative to SAP Business Application Studio, you can also use SAP Web IDE. We recommend that you use SAP Business Application Studio.

## Prerequisites

For setting up SAP Business Application Studio, you need the following:

- You are a member of the global account.
- You are an organization manager in your Cloud Foundry subaccount (see also [Adding a User as Org Manager for the Cloud Foundry Organization \[page 169\]](#)).
- You have created an ABAP service instance (see also [Creating an ABAP System \[page 163\]](#)).
- You are a security administrator. If you have created a subaccount for the ABAP environment in the Cloud Foundry environment, your user automatically has the security administration role.

## Setting Up SAP Business Application Studio

### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip the first two steps.

### Do

#### Set Up SAP Business Application Studio

Subscribe to SAP Business Application Studio

Assign Role Collection to Developers

Create Service Key

Create Service Destination to ABAP System

- [Subscribing to SAP Business Application Studio \[page 177\]](#)
  - [Assigning Permissions for SAP Business Application Studio \[page 178\]](#)
  - [Creating a Service Key for the ABAP System \[page 179\]](#)
  - [Creating a Destination to the ABAP System for SAP Business Application Studio \[page 180\]](#)
1. To enable the creation and deployment of SAP Fiori application UIs, subscribe to SAP Business Application Studio in the same subaccount in which you've created your ABAP service instance (see [Subscribing to SAP Business Application Studio \[page 177\]](#)).

2. To allow developers to develop applications using SAP Business Application Studio, assign developers to the `Business_Application_Studio_Developer` role collection (see [Assigning Permissions for SAP Business Application Studio \[page 178\]](#)).
3. Create a service key for your ABAP system, which you will need to set up a service destination (see [Creating a Service Key for the ABAP System \[page 179\]](#)).
4. To connect your ABAP system with SAP Business Application Studio, set up a destination in the same subaccount in which you have subscribed to SAP Business Application Studio (see [Creating a Destination to the ABAP System for SAP Business Application Studio \[page 180\]](#)).

### 3.3.1.3.1 Subscribing to SAP Business Application Studio

If developers want to use SAP Business Application Studio as development environment for UIs, you need to subscribe to SAP Business Application Studio in your subaccount.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

For more information about SAP Business Application Studio and how to subscribe to it, see also [Subscribe to SAP Business Application Studio](#).

#### Procedure

1. Log on to the SAP BTP cockpit as Cloud Foundry administrator.
2. Choose the tile of the global account of the Cloud Foundry environment.
3. From the global account, navigate to the same subaccount where the ABAP instance is present.
4. From the navigation area, choose  *Services*  *Service Marketplace* .
5. Search for **studio**.  
The *SAP Business Application Studio* tile is displayed.
6. Choose the application name.
7. Choose *Create*.

### 3.3.1.3.2 Assigning Permissions for SAP Business Application Studio

Use the available role collection `Business_Application_Studio_Developer` to assign the relevant permissions to your developers to work in SAP Business Application Studio.

#### Context

Developers using SAP Business Application Studio must be assigned to developer roles based on the `Business_Application_Studio_Developer` role template. When you subscribe to SAP Business Application Studio, a role collection containing the relevant developer permissions is automatically created. You must assign the role collection to your developers.

#### Note

In the following steps, you can assign a role collection to an individual user. If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

As an alternative, if you are using a custom identity service and identity provider groups, you can also assign the role collection to the identity provider group for your developers. For more information, see [Setup of a Custom Identity Service \[page 183\]](#) and [Mapping a Role Collection to the Identity Provider Group for Developers \[page 188\]](#).

#### Procedure

1. In the SAP BTP cockpit, navigate to your subaccount for the ABAP environment.
2. From the navigation area, choose ► [Security](#) ► [Role Collections](#) ▾.
3. Choose the role collection `Business_Application_Studio_Developer`.
4. Go to the [Users](#) section and choose [Edit](#).
5. Enter the user ID of the user that you want to assign to the role collection.
6. Save your changes.

### 3.3.1.3.3 Creating a Service Key for the ABAP System

Create a service key for the ABAP system, which will later be needed to configure a destination from SAP Business Application Studio to the ABAP system.

#### Context

You can use service keys to generate credentials to communicate directly with a service instance. After you have configured the service keys for your service, local clients, apps in other spaces, or entities outside your deployment can access your service with these keys. For more information about service keys, see [Creating Service Keys](#).

#### Procedure

1. As Cloud Foundry administration user, log on to the SAP BTP cockpit.
2. Go to your Cloud Foundry subaccount for the ABAP environment.
3. In the navigation area, choose [Spaces](#).
4. Choose the tile for the ABAP environment space.
5. From the navigation area, choose [Services](#) [Instances](#).
6. Choose the service instance for the ABAP system.
7. In the [Service Keys](#) section of the details area, choose [Create](#).
8. Enter a service key name, for example, **ABAP Destination**, and save.
9. From the service key, copy the following for later reuse:
  - The URL of the ABAP system from the `url` element
  - The client ID from the `clientId` element in the `uaa` section
  - The content of the `clientsecret` element in the `uaa` section
  - The URL from the `url` element in the `uaa` section

### 3.3.1.3.4 Creating a Destination to the ABAP System for SAP Business Application Studio

Learn how to set up a destination in the same Cloud Foundry subaccount in which you have subscribed to SAP Business Application Studio to establish communication between the ABAP environment and SAP Business Application Studio.

#### Procedure

1. Log on to the SAP BTP cockpit as administrator.
2. From your global account, navigate to your Cloud Foundry subaccount.
3. In the navigation area, choose *Destinations*.
4. Choose *New Destination*.
5. Enter the following data:

Field	User Input
<i>Name</i>	Enter a name for the destination, for example, <b>SAP_Business_Application_Studio</b> .
<i>Type</i>	<b>HTTP</b>
<i>Description</i>	
<i>URL</i>	Enter the URL of the ABAP system that you copied from the <code>&lt;url&gt;</code> element in the service key (see <a href="#">Creating a Service Key for the ABAP System [page 179]</a> ).
<i>Proxy Type</i>	<b>Internet</b>
<i>Authentication</i>	<b>OAuth2UserTokenExchange</b>
<i>Client ID</i>	Enter the content of the <code>&lt;clientId&gt;</code> element that you copied from the <code>uaa</code> section of the service key (see <a href="#">Creating a Service Key for the ABAP System [page 179]</a> ).
<i>Client Secret</i>	Enter the content of the <code>&lt;clientsecret&gt;</code> element that you copied from the <code>uaa</code> section of the service key (see <a href="#">Creating a Service Key for the ABAP System [page 179]</a> ).
<i>Token Service URL Type</i>	Choose <b>Dedicated</b> .
<i>Token Service URL</i>	Enter <code>&lt;uaa-url&gt;/oauth/token</code> , where <code>&lt;uaa-url&gt;</code> is the content of the <code>&lt;url&gt;</code> element that you copied from the <code>uaa</code> section of the service key (see <a href="#">Creating a Service Key for the ABAP System [page 179]</a> ).

6. Choose *New Property* and add the following properties:

Property	Value
<i>HTML5.DynamicDestination</i>	<b>true</b>
<i>HTML5.Timeout</i>	<b>60000</b>
<i>WebIDEEnabled</i>	<b>true</b>
<i>WebIDEUsage</i>	<b>odata_abap,dev_abap,abap_cloud</b>

7. Make sure that the *Use default JDK truststore* checkbox is checked.

8. Choose *Save*.

## Related Information

[Creating a Destination for Cross-Subaccount Communication \[page 181\]](#)

### 3.3.1.3.5 Creating a Destination for Cross-Subaccount Communication

Learn how to create a destination with SAML assertion authentication to establish communication between an ABAP environment system and SAP Business Application Studio when they are set up in different subaccounts.

## Procedure

1. Log on to the SAP BTP cockpit as an administrator.
2. From your global account, navigate to your Cloud Foundry subaccount.
3. In the navigation area, choose **Connectivity > Destinations**.
4. Choose *New Destination*.
5. Enter the following data:

Field	User Input
<i>Name</i>	Enter a name for the destination, for example <b>SAP_Business_Application_Studio</b> .
<i>Type</i>	<i>HTTP</i>
<i>Description</i>	Optionally, enter a description.
<i>URL</i>	Enter the URL of your system by copying the <i>Host Name</i> from the <i>Communications Systems</i> app, for example <b>1a354373-d200-46f6-9d5c-daab9a65d9b6.abap.eu10.hana.ondemand.com</b>
<i>Proxy Type</i>	<i>Internet</i>
<i>Authentication</i>	<i>SAMLSAssertion</i>
<i>Audience</i>	Enter the URL of your system and add <b>-web</b> as follows <b>1a354373-d200-46f6-9d5c-daab9a65d9b6.abap-web.eu10.hana.ondemand.com</b>
<i>AuthnContextClassRef</i>	<i>urn:oasis:names:tc:SAML:2.0:ac:classes:PreviousSession</i>

6. Choose *New Property* and add the following properties:

Property	Value
<i>HTML5.DynamicDestination</i>	<b>true</b>
<i>HTML5.Timeout</i>	<b>60000</b>
<i>WebIDEEnabled</i>	<b>true</b>
<i>WebIDEUsage</i>	<b>odata_abap,dev_abap</b>
<i>nameIdFormat</i>	<b>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</b> or urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified depending on the login_attribute configuration chosen during ABAP system provisioning (see <a href="#">Creating ABAP System</a> )

7. Make sure that the *Use default JDK truststore* checkbox is ticked.
8. Choose *Save*.

## Related Information

[Creating a Destination to the ABAP System for SAP Business Application Studio \[page 180\]](#)

### 3.3.1.3.5.1 Creating a Communication System for SAP Business Application Studio

Create a communication system to set up communication between your ABAP environment system and SAP Business Application Studio.

## Procedure

1. In the SAP BTP cockpit, download your subaccount-specific trust certificate by navigating to [Connectivity > Destinations > Download Trust](#).
2. In the SAP Fiori launchpad of your ABAP environment system, create a communication system by using the *Communication Systems* app. See [How to Create Communication Systems](#).
3. Navigate to section [General > SAML Bearer Assertion Provider](#) and switch the toggle button to *ON*.
4. Upload the *Signing Certificate* first and then enter the following data:

#### Note

The signing certificate is the trust certificate that you have downloaded from your destination.

Field	User Input
User ID Mapping Mode	User Name
SAML Bearer Issuer	From the <i>Signing Certificate Subject</i> , copy the common name (the string after <i>CN=</i> ) and paste it in the <i>SAML Bearer Issuer</i> field.

### 3.3.1.4 Setup of a Custom Identity Service

For your business users in the ABAP environment, you set up a custom identity service.

#### Custom Identity Service for the ABAP Environment

For platform users such as the administrator, the default identity provider is SAP ID Service, which is set up by default. For the business users in the ABAP environment, you must set up a custom identity service. For example, the users of your deployed application or users of subscribed apps or services, such as SAP Business Application Studio, are business users. For more information about platform and business users in the ABAP environment, see [User Types](#).

In this documentation, a custom trust configuration is described using SAP Cloud Identity Services - Identity Authentication. The Identity Authentication service is a cloud solution for identity lifecycle management for SAP BTP applications. You can set up SAP BTP as a service provider, and Identity Authentication service as an identity provider.

#### Identity Authentication Service as Proxy

If you have your own custom identity providers at your company, you can use SAP Cloud Identity Services - Identity Authentication as a proxy. For more information about setting up the Identity Authentication service as a proxy, see [Establish Trust and Federation Between UAA and Identity Authentication](#) and [Configure Trust with Corporate Identity Provider](#).

#### More Information

This documentation describes the basic trust concepts and helps you to get started with a simple landscape. To learn more about trust setup with custom identity providers, check the following, more detailed documentation:

- For more information about trust in SAP BTP, see [Trust and Federation with Identity Providers](#).
- For more information about the Identity Authentication service, see [Overview](#) and [Initial Setup](#).

### 3.3.1.4.1 Establishing Trust of Type OpenID Connect

If you want to use a custom identity provider, you must set up trust between the subaccount and the SAP Cloud Identity Services - Identity Authentication service.

#### Context

##### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

If you have custom identity provider, you can use a function in SAP BTP cockpit to set up trust between your subaccount and the Identity Authentication service for SAP BTP automatically. The trust configuration is of type *OpenID Connect*.

For more information, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication](#).

#### Procedure

1. In the SAP BTP cockpit, go to the subaccount for your ABAP system.
2. From the navigation area, choose ► *Security* ► *Trust Configuration* ►.
3. Choose *Establish Trust*.
4. In the following popup, select a identity provider from the dropdown list.

Only identity providers that are associated with your customer ID are shown.

5. Choose *Establish Trust*.

Trust of type *OpenID Connect* between your subaccount and the identity provider is generated.

6. Log on to the Identity Authentication service.
7. From the navigation area, choose ► *Applications & Resources* ► *Applications* ►.
8. Search for the application that has been created as part of the trust setup.

The name of the application has the format *SAP BTP subaccount <Subaccount Name>*, but you can change it if needed.

##### Note

Older application names have the format *XSUAA\_<Subaccount Name>*.

9. Verify that the subject name identifier matches the login\_attribute chosen during ABAP system provisioning.

ABAP login_attribute	SAP Cloud Identity Services Subject Name Identifier
email	email
user_name	login name

## 3.3.1.4.2 Creating Identity Provider Users and Groups

Learn how you create identity provider users and groups in the Identity Authentication service.

### Context and Use Cases

This configuration is needed for easier developer authentication using Identity Authentication service. With the creation of identity provider groups, you can also more easily map role collections to entire user groups instead of single users, or map identity provider groups to groups in the Neo environment, for example.

This documentation illustrates the basic concepts and helps you to get started with users and groups in a simple landscape for the ABAP environment.

### Prerequisites

You have already created developer users in the ABAP environment (see [Creation of Developer Users \[page 172\]](#)).

### 3.3.1.4.2.1 Creating an Identity Provider Group for Developers

In the administration console of the Identity Authentication service, you can create an identity provider group for the developers.

### Context

An identity provider group for developers is useful, for example, if you want to assign a role collection to all developers in one step, such as the *Application\_Studio* role collection for SAP Business Application Studio.

You also use identity provider groups for developers if you want to assign all developers to a corresponding group in the Neo environment, which is necessary if your developers want to use SAP Web IDE as UI development tool.

For more information about creating user groups in the Identity Authentication service, see [Create a New User Group](#).

## Procedure

1. Log on to the tenant's administration console for the Identity Authentication service at <https://<tenant ID>.accounts.ondemand.com/admin> as administration user.
2. In the navigation area, choose ► [Users & Authorizations](#) ► [User Groups](#) ▾.
3. If no user group for developers exists, choose [+ Add](#).
4. Enter a name, for example, **Developers**.
5. Enter a display name and a description.
6. Choose [Save](#).
7. Note down the group name for later reference.

### 3.3.1.4.2.2 Creating Identity Provider Users for Developers

In the administration console of the Identity Authentication service, you can create identity provider users for the developers working in the ABAP environment.

## Context

You create identity provider users if you work with your own custom identity provider, such as the Identity Authentication service for SAP BTP. You can use the identity provider users, for example, for developers who develop UIs and services using SAP Web IDE or SAP Business Application Studio.

For more information about creating users in the Identity Authentication service, see [Create a New User](#).

## Procedure

1. Log on to the tenant's administration console for the Identity Authentication service at <https://<tenant ID>.accounts.ondemand.com/admin> as administration user.
2. In the navigation area, choose ► [Users & Authorizations](#) ► [User Management](#) ▾.
3. Choose [+ Add User](#).
4. Enter the name, e-mail address and login name of the developer.
5. Leave the account type set to [Employee](#).
6. Make sure that the account activation is set to [Send activation e-mail](#).
7. Choose [Save](#).

### 3.3.1.4.2.3 Assigning the Identity Provider User Group to the Identity Provider Users for Developers

Assign the identity provider user group for developers to the identity provider users that you have created for the developers.

#### Prerequisites

You have already created identity provider users. You have also already created identity provider user groups, for example, for SAP Web IDE, for SAP Business Application Studio, or for both.

#### Context

You now assign these identity provider user groups to the identity provider users for the developers.

For more information about assigning user groups, see [Assign Groups to a User](#).

#### Procedure

1. Log on to the tenant's administration console for the Identity Authentication service at <https://<tenant ID>.accounts.ondemand.com/admin> as administration user.
2. In the navigation area, choose **Users & Authorizations** > **User Management**.
3. Choose the identity provider user that you have created for the developer.
4. Choose the *User Group* tab.
5. Choose *Assign Groups*.
6. Choose the identity provider group for developers that you have created (for example, *Developers* for SAP Web IDE, or *BAS\_DEVELOPERS* for SAP Business Application Studio).
7. Choose *Save*.

## 3.3.1.4.2.4 Mapping a Role Collection to the Identity Provider Group for Developers

For developers to be able to work with SAP Business Application Studio, you can use a predefined role collection and assign it to the identity provider group that you created for the developers.

### Prerequisites

#### Note

If you have run the booster *Prepare an Account for ABAP Development*, you can skip this step.

You have subscribed to SAP Business Application Studio (see [Subscribing to SAP Business Application Studio \[page 177\]](#)).

### Context

#### Note

These steps are only relevant if developers want to use SAP Business Application Studio as development environment for UIs.

Developers who want to load, develop, and deploy applications in SAP Application Studio must be assigned to developer roles based on the *Business\_Application\_Studio\_Developer* role template. There's no need to create these roles for SAP Business Application Studio. When you subscribe to SAP Business Application Studio, role collections together with these business role templates are created automatically.

This procedure briefly describes how to assign the role collections to the developer user group in your custom identity provider. For more information about managing authorizations, see [Manage Authorizations](#).

### Procedure

1. Log on to the SAP BTP cockpit as Cloud Foundry administrator.
2. Choose the tile of the global account of the Cloud Foundry environment.
3. In the SAP BTP cockpit, navigate to your subaccount for the ABAP environment.
4. From the navigation area, choose ► **Security** ► **Role Collections** ▾.
5. Choose the *Business\_Application\_Studio\_Developer* role collection.
6. Go to the *User Groups* section and choose *Edit*.
7. Select the identity provider where the user group is stored.
8. Enter the name of the user group that you created before, for example, **Developers**.

9. Save your entries.

### 3.3.1.5 Setup of UI Development in SAP Web IDE (Optional)

If your developers want to use SAP Web IDE as a development tool for creating UIs, you as an administrator need to perform some additional settings.

If your developers want to use SAP Web IDE, which is part of the Neo environment, they need to work in the Cloud Foundry and the Neo environments. To enable an easier authentication of the developers in the Cloud Foundry and Neo environments, set up SAP BTP as a service provider, and Identity Authentication service as an identity provider. For the integration, you must set the trust on both sides and map the identity provider group for developers to its corresponding Neo group.

#### → Recommendation

We recommend that you use SAP Business Application Studio as a UI development environment instead of SAP Web IDE.

### 3.3.1.5.1 Neo Environment: Trust Setup

To enable an easier authentication of the developers in the Cloud Foundry and Neo environments, set up SAP BTP as a service provider, and Identity Authentication service as an identity provider.

Before you follow the steps outlined here for setting up trust between the Neo application and the Identity Authentication service, make sure that you have already set up the Identity Authentication service as custom identity provider for the Cloud Foundry account. For more information, see [Setup of a Custom Identity Service \[page 183\]](#).

#### 3.3.1.5.1.1 Exporting SAML Identity Provider Metadata

Export the SAML metadata of the identity provider for the SAML trust setup on the service provider side.

#### Context

You need this step only if the SAML metadata file for the Identity Authentication service tenant has not been downloaded already. For more information about tenant SAML 2.0 configuration, see [Tenant SAML 2.0 Configuration](#).

## Procedure

1. Log on to the tenant's administration console for the Identity Authentication service at <https://<Your custom Identity Authentication service tenant>.accounts.ondemand.com/admin> as administration user.
2. In the navigation area, choose **Applications & Resources > Tenant Settings**.
3. Choose **SAML 2.0 Configuration**.
4. Choose **Download Metadata File** (or download it directly from <https://<Your custom Identity Authentication service tenant>.accounts.ondemand.com/saml2/metadata>).
5. Specify a file name and save it locally to your hard drive.

### Note

Specify a file name that you can easily recognize later, for example, `metadataIDP<tenant-id>.xml`, because you need to download and upload multiple SAML metadata files later.

## 3.3.1.5.1.2 Configuring the Neo Account as SAML Service Provider and Export SAML Metadata

Configure the Neo account as local SAML service provider.

## Context

### Note

The following steps are only relevant if your developers will use SAP Web IDE in the Neo environment for UI development.

This configuration is needed for developer authentication in the Neo environment (Web IDE runs in the Neo environment).

In the SAML 2.0 communication, each account acts as a service provider. In this documentation, we use the term “local service provider” to describe the account in SAP BTP as a service provider in the SAML 2.0 communication. You need to configure how the local service provider communicates with the identity provider. This includes, for example, setting a signing key and certificate to verify the service provider’s identity and encrypt data.

For more information, see [Configure SAP BTP as a Local Service Provider](#).

## Procedure

1. Log on to the SAP BTP cockpit as Neo administrator.
2. Go to the subaccount for the Neo environment.
3. In the SAP BTP cockpit, choose ► *Security* ► *Trust* ▾.
4. On the *Local Service Provider* tab, choose *Edit*.
5. Change the configuration type from *Default* to *Custom*.
6. If the fields for the signing key and the signing certificate are already filled, leave them as they are and don't generate a new key pair.
7. If the fields for the signing key and the signing certificate are empty, choose *Generate Key Pair*.
8. Set principal propagation to *Enabled*.
9. Leave the settings for force authentication as they are.
10. Choose *Save* and confirm the alert message.
11. If you haven't downloaded the SAML metadata file yet: Choose *Get Metadata*.

The metadata file is downloaded automatically.

12. Rename the downloaded file so that you can easily recognize it later on, for example, to `metadataNeo<tenant-id>.xml`,

You must download and upload multiple SAML metadata files. Renaming the file helps you distinguishing the metadata files from each other.

## Results

You can now switch to the *Application Identity Provider* tab to import the SAML identity provider metadata.

### 3.3.1.5.1.3 Establishing Trust to the SAML Identity Provider for the Neo Account

Import the SAML identity provider metadata to the Neo account to configure SAML trust to the identity provider (that is, the Identity Authentication service tenant).

## Prerequisites

You have downloaded the SAML identity provider metadata file from the Identity Authentication service tenant (see [Exporting SAML Identity Provider Metadata \[page 189\]](#)).

## Context

### Note

The following steps are only relevant if your developers will use SAP Web IDE in the Neo environment for UI development.

You want to use Identity Authentication service as an SAML 2.0 identity provider. For more information, see [Configure Trust to the SAML Identity Provider](#).

## Procedure

1. Log on to the SAP BTP cockpit as Neo administrator.
2. In the SAP BTP cockpit, navigate to the subaccount for the Neo environment.
3. In the navigation area, choose **Security > Trust**.
4. Choose the *Application Identity Provider* tab.
5. Choose *Add Trusted Identity Provider*.
6. Choose *Browse*.
7. Upload the metadata file of the custom Identity Authentication service tenant.

### Note

During the setup of the ABAP environment, you need to upload multiple SAML metadata files. Make sure that you upload the correct file. If you have followed the naming conventions suggested in this documentation, the file needed here is `metadataIDP<tenant-id>.xml`.

8. Enter a description.
9. Choose *Save*.

### 3.3.1.5.1.4 Creating a Neo Application as Trusted Service Provider

Create and configure an application to represent the Neo account in the Identity Authentication Service tenant as SAML 2.0 service provider.

### Note

The following steps are only relevant if your developers will use SAP Web IDE in the Neo environment for UI development.

## Creating an SAML Application for the Neo Account

As a first step, you need to create the application for the Neo account.

1. Log on to the tenant's administration console for the Identity Authentication service at `https://<tenant ID>.accounts.ondemand.com/admin` as administration user.
2. In the navigation area, choose **Application & Resources > Applications**.
3. Choose **+ Add**.
4. Enter an application name for the Neo account (the service provider) in the Identity Authentication service.
5. Choose **Save**.

## Configuring the Neo Application as Trusted Service Provider

Import the SAML service provider metadata from the Neo environment to the Identity Authentication service tenant (that is, the SAML identity provider). This configures SAML trust to the Neo account as SAML service provider.

1. Under **Applications**, choose the entry for the Neo application that you have just created.
2. Choose **SAML 2.0 Configuration**.
3. Choose **Browse**.
4. Upload the metadata file of the SAML service provider from the Neo account that you have downloaded before (see also [Configuring the Neo Account as SAML Service Provider and Export SAML Metadata \[page 190\]](#)).

### Note

During the setup of the ABAP environment, you need to upload multiple SAML metadata files. Make sure that you upload the correct file. If you have followed the naming conventions suggested in this documentation, the file needed here is `metadataNeo<tenant-id>.xml`.

5. Choose **Save**.

## Configuring the Subject Name Identifier Sent to Cloud Foundry

Configure the subject name identifier that the Identity Authentication service (as identity provider) sends to the Neo application. Use the email address as user identifier for the Neo account.

1. Under **Applications**, choose the entry for the Neo application.
2. Choose **Subject Name Identifier**.
3. Choose **Basic Configuration** and select **E-Mail** from the dropdown list.
4. Choose **Save**.

## Configuring the Default Name ID Format for the Neo Application (Optional)

Optionally, you can configure the default name ID attribute of the identity provider for Neo. Use the email address as user identifier for the Neo account.

1. Under *Applications*, choose the entry for the Neo application in the Identity Authentication service.
2. Choose *Default Name ID Format*.
3. Choose the *E-Mail* radio button.
4. Choose *Save*.

## Configuring the SAML Assertion Attributes for Cloud Foundry

Include the attributes `first_name`, `last_name`, `mail`, and `Groups` for the SAML assertion.

1. Under *Applications*, choose the entry for the Neo application.
2. Choose *Attributes*.
3. Choose *Add* to enter the following attributes (if they don't already exist):

Name	Value
<code>first_name</code>	<i>First Name</i>
<code>last_name</code>	<i>Last Name</i>
<code>mail</code>	<i>E-Mail</i>
<code>Groups</code>	<i>Groups</i>

### Note

Make sure that you enter **Groups** (with upper case **G**), not **groups**, in the *Name* field, so that it matches the assertion attribute used for the Neo environment.

4. Choose *Save*.

## More Information

[Configuring Applications](#)

[Configure Trust](#)

[Configure the Subject Name Identifier Sent to the Application](#)

## 3.3.1.5.2 Enabling SAP Web IDE Full-Stack in the Neo Account

Enable the SAP Web IDE Full-Stack service in the Neo account if it is not yet enabled.

### Context

#### ⓘ Note

You only need this step if your developers want to use SAP Web IDE as environment for UI development. As an alternative, you can also use SAP Business Application Studio.

SAP Web IDE Full-Stack is a development environment to create new or extend existing SAP Fiori, SAPUI5, or hybrid applications. For more information about the SAP Web IDE Full-Stack, see [SAP Web IDE Full-Stack](#).

### Procedure

1. Log on to the SAP BTP cockpit for the Neo environment as Neo administration user.
2. In the navigation area, choose [Services](#).
3. Scroll down to the [Web IDE Full-Stack](#) tile.
4. If the service is not yet enabled, choose the [Web IDE Full-Stack](#) tile.
5. On the [Service: Web IDE Full-Stack: Overview](#) screen, choose [Enable](#).
6. Wait for the status to change to the green [Enabled](#) status.

This may take a few minutes.

## 3.3.1.5.3 Creation of Developer Users for SAP Web IDE

If your developers want to use SAP Web IDE, use identity provider users for them to ease log on to the Neo environment.

If you have followed the steps for setting up a custom identity provider, you have already created a developer group in the tenant for the Identity Authentication service (see also [Setup of a Custom Identity Service \[page 183\]](#)). Now you need to create a developer group in the Neo environment and map this group to the developer group in the tenant for the Identity Authentication service.

### 3.3.1.5.3.1 Creating a Neo Group for Developers

Define a Neo group to map the developer group of the identity provider to the `DiDeveloper` role of SAP Web IDE.

#### Context

##### Note

The following steps are only relevant if your developers will use SAP Web IDE in the Neo environment for UI development.

For more information about roles, see [Managing Roles](#).

#### Procedure

1. Log on to the SAP BTP cockpit (Neo account) as Neo administration user.
2. In the navigation area, choose **Security > Authorizations**.
3. Choose the *Groups* tab.
4. Choose *New Group*.
5. Enter a group name, for example, **Developers**, and choose *Save*.
6. In the *Roles* screen area, choose *Assign*.
7. As subaccount, select the service provider account of the Web IDE, for example, **sapwebide EU1**.
8. As application, select the Web IDE application (*di*).
9. As role, select the predefined Web IDE developer role *DiDeveloper*.
10. Choose *Save*.

## 3.3.1.5.3.2 Mapping the Identity Provider Group Developers to the Neo Group

Map the developer group of the identity provider to the Neo developer group with the Web IDE `DiDeveloper` role.

### Context

#### Note

The following steps are only relevant if your developers will use SAP Web IDE in the Neo environment for UI development.

The mapping is part of the trust configuration to the SAML identity provider. For more information, see [Configure Trust to the SAML Identity Provider](#).

### Procedure

1. Log on to the SAP BTP cockpit (Neo account) as Neo administration user.
2. In the navigation area, choose **Security > Trust**.
3. Choose the *Application Identity Provider* tab.
4. Choose the link for the custom identity authentication service tenant.
5. Choose the *Groups* tab.
6. If no group for Neo developers exists, choose *Add Assertion-Based Group*.
7. Enter the following data:

Option	Description
<i>Group</i>	Select <i>Developers</i> .
<i>Mapping Rules (part 1)</i>	Enter <i>Groups</i> .
<i>Mapping Rules (part 2)</i>	Select <i>equals</i> .
<i>Mapping Rules (part 3)</i>	Enter the developer group name from the Identity Authentication service that was created by the administrator for the Identity Authentication service, for example, <i>Developers</i> .  If you are not the responsible administrator for the Identity Authentication service, make sure that you are informed about the group name (see also <a href="#">Creating an Identity Provider Group for Developers [page 185]</a> ).

8. Choose *Save*.

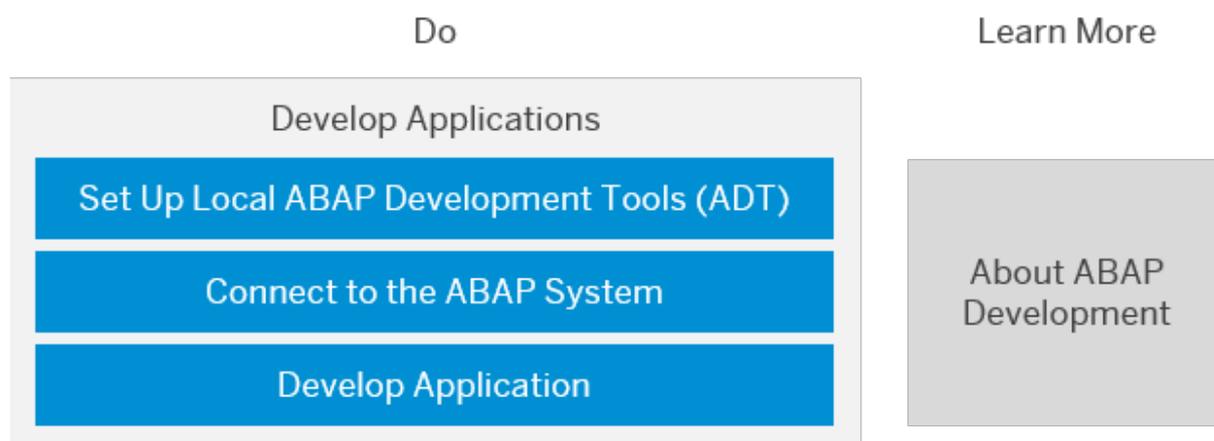

### 3.3.1.6 Getting Started as a Developer in the ABAP Environment

Learn about your first steps to get started as a developer in the ABAP environment.

#### Note

This documentation informs you about the first steps as a developer and assumes that the necessary steps for setting up the ABAP environment are done. For more information about how to set up the ABAP environment and getting started as an administrator, see [Getting Started with a Customer Account in the ABAP Environment \[page 149\]](#).

### Developing Applications: Overview

1. Download and install ABAP Development Tools (ADT) from <https://tools.hana.ondemand.com/#abap>. See [Video Tutorial: Configure ABAP Development Tools](#) .

#### Note

SAP GUI is not supported in the ABAP environment. You can only use ADT as your development environment.

2. Create an ABAP cloud project with ADT to connect to the ABAP system in the ABAP environment (see [Connect to the ABAP System \[page 654\]](#)).
3. Develop your application (see [Development in the ABAP Environment](#)). To learn more about how to develop applications, see [Tutorial: Create Your First ABAP Console Application](#) and [Video Tutorial: Create Application](#) .

## More Information About Development in the ABAP Environment

For more information about ABAP development, see [Development in the ABAP Environment](#).

### 3.3.1.7 Tutorial Overview

## Getting Started

### Mission

[Build an SAP Fiori app Using the ABAP RESTful Application Programming Model](#)

- [Create Database Table and Generate UI Service](#)
- [Enhance the Business Data Model and Enable OData Streams](#)
- [Enhance the Business Object Behavior With Unmanaged Internal Numbering](#)
- [Enhance the Business Object Behavior With Determinations](#)
- [Enhance the Business Object Behavior With Validations](#)
- [Enhance the Business Object Behavior With Instance Action](#)
- [Enhance the Business Object Behavior With Factory Action](#)
- [Enhance the Business Object Behavior With Dynamic Feature Control](#)
- [Write an ABAP Unit Test for the RAP Business Object](#)

*Group:* [Create and Expose CDS Views \(Unmanaged Scenarios\)](#)

- [Create a Simple Database Table for ABAP Environment](#)
- [Create and Expose Core Data Services Based on a Database Table](#)
- [Add Transactional Behavior to Your Core Data Services](#)

*Group:* [Create an ABAP Core Data Services \(CDS\) View in SAP BTP, ABAP Environment](#)

- [Enhance an ABAP Core Data Services \(CDS\) View in SAP Business Technology Platform \(BTP\) ABAP Environment](#)

## ABAP Dictionary and ABAP Language

*Group: Start Developing ABAP Tables*

- [Create an ABAP Database Table and Relevant ABAP Dictionary Objects](#)
- [Create ABAPDoc Comments in Your Class in ABAP Environment](#)
- [Create an ABAP Managed Database Procedure \(AMDP\) and Analyze Its Performance](#)

## Analytics

- [Develop and Consume Queries on SAP Analytics Cloud](#)
- [Develop Queries Based on Booking Supplement and Consume on SAP Analytics Cloud](#)

## Authorization Model

*Group: Create Authorization Model with SAP BTP, ABAP Environment*

- [Create Data Model and Lock Object in SAP BTP, ABAP Environment](#)
- [Create Behavior and Service in SAP BTP, ABAP Environment](#)
- [Create Authorization Model and App in SAP BTP, ABAP Environment](#)
- [Maintain Business Roles and Access Restrictions in SAP BTP, ABAP Environment](#)

## Business Configuration

*Group: Create a SAP Fiori based Table Maintenance App*

- [Create Business Configuration Maintenance Object](#)
- [Providing Authorization Control for a Business Configuration Maintenance Object](#)
- [Use Custom Business Configurations app](#)
- [Explore additional features of the Business Configurations app](#)

## Lifecycle Management and CI/CD

- [Transfer Your ABAP Source Code With SAP Cloud Platform ABAP Environment via abapGit](#)
- [Create Branches with SAP BTP, ABAP Environment](#)
- [Use Checkout Functionality of Branches to Switch Between Different Versions of Code](#)
- [Transport a Software Component Between two Systems](#)
- [Use abapGit to Transfer ABAP Source Code to the Cloud](#)
- [Connect ABAP On-Premise to a Central Check System for Custom Code Migration Using ABAP Test Cockpit \(ATC\)](#)

## Cloud Operations

- [Monitor an SAP BTP, ABAP Environment Service Using SAP Focused Run \(FRUN\)](#)
- [Monitor an SAP BTP, ABAP Environment Service Using SAP Cloud ALM \(CALM\)](#)

## Eventing

- [How to Create RAP Business Events in SAP BTP, ABAP Environment](#)
- [Event Consumption in ABAP Development Tools for Eclipse](#)
- [How to Create RAP Business Events in an On-Premise System \(In Progress\)](#)

## Integration

*Group:* [Expose an ABAP CDS View Externally Using a Communication Scenario](#)

- [Expose a Standard Core Data Service for ABAP Environment](#)
- [Maintain a Communication Arrangement for Inbound Communication](#)

*Mission:* [Get Data From an On-Premise System Using a Remote Function Call \(RFC\)](#)

- [Get Data from an On-Premise System Using a Remote Function Call \(RFC\) Scenario](#)
- [Remote Function Call \(RFC\) - Connect to Your On-Premise System from SAP BTP, ABAP Environment](#)
- [Test the Business API \(BAPI\) with an ABAP Console App](#)
- [Get Data from an On-Premise System Using a Custom Entity](#)
- [RFC: Inspect Your Class in the ABAP Debugger](#)
- [RFC: Enhance the Handler Class With Filtering](#)

*Mission:* [Get Data from a Remote System Using an OData Service](#)

- [Enable Connection From a Remote Instance of SAP BTP, ABAP Environment](#)
- [Prepare Consuming System and Create Service Consumption Model](#)

- [Create Remote Client Proxy and ABAP Console App](#)
- [Implement Custom Entity and Query Implementation Class](#)

*Mission:* [Connect to SAP S/4HANA Cloud with SAP BTP, ABAP Environment](#)

- [Create Communication System to Connect to SAP BTP, ABAP Environment](#)
- [Create Service Consumption Model for Business Partner and Sales Order Item Cube](#)
- [Create Service Binding for Bonus Plan Scenario with SAP BTP, ABAP Environment](#)

without group/mission:

- [Call an External API and Parse the Response in SAP BTP, ABAP Environment](#)
- [Create RFC Proxy Class](#)
- [Create Business Partner in S/4HANA Cloud Using ABAP Environment Data](#)
- [Connect ABAP On-Premise to a Central Check System for Custom Code Migration Using ABAP Test Cockpit \(ATC\)](#)
- [Using ODBC driver for SQL Service](#)
- [Consume SOAP Based Web Services with SAP BTP, ABAP Environment](#)

## Tools, User, Identity Management

*Mission:* [SAP BTP, ABAP Environment: Create and Expose a CDS-Based Data Model](#)

*Group:* <https://developers.sap.com/group.abap-env-expose-cds-travel-model.html>

- [Create an SAP Cloud Platform ABAP Environment Trial User](#)

without group/mission:

- [Install ABAP Development Tools \(ADT\) and abapGit Plugin](#)
- [Create a Developer User in SAP Cloud ABAP Environment](#)
- [Provision Users into your SAP BTP, ABAP Environment](#)

## UI Development

*Mission:* [SAP BTP, ABAP Environment: Create and Expose a CDS-Based Data Model](#)

- [Develop and Run SAP Fiori Application With SAP Business Application Studio](#)
- [Integrate List Report into ABAP FLP](#)
- [Add SAP BTP ABAP environment App to Portal Site](#)
- [Developing and extending SAP Fiori Elements Apps](#)
- [RAP Feature Showcase App](#)
- [Create a Travel App with SAP Fiori Elements Based on OData V4 RAP Service](#)

*Group:*

- [Implement a Custom Shell-Plugin in the SAP BTP, ABAP Environment](#)

- [Enrich Your Shell-Plugin with O-Data Services](#)

without group/mission:

- [Develop and Run SAP Fiori Application With Visual Studio Code](#)
- [Develop SAP Fiori App & Deploy to Cloud Foundry Using SAP-managed App Router](#)
- [Add Cloud Foundry to Portal Side](#)
- [Set SAP BTP ABAP Environment as a ContentProvider for SAP Build Workzone, standard edition](#)
- [Use Custom Themes in the SAP BTP, ABAP Environment](#)

## SAP S/4HANA Cloud, ABAP Environment

*Group:* [Develop an SAP Fiori App to Trigger Purchase Requisitions API](#)

- [Create a Shopping Cart Business Object](#)
- [Create Value Help, Enhance the Behaviour Definition and Behaviour Implementation of the Shopping Cart Business Object](#)
- [Integrate released Purchase Requisition API into Online Shop Business Object](#)
- [Develop a Custom UI with SAP S/HANA Cloud ABAP Environment](#)
- [Integrate List Report into Fiori Launchpad](#)

### Without group/mission

- [Implement a Business Add-In \(BAdI\) to Check a Purchase Requisition](#)
- [Implement a Field Control Using a Business Add-In \(BAdI\)](#)
- [Create Custom Logic Using Key User Extensibility and Perform Trace](#)
- [Create and Debug a BAdI Implementation in ABAP Development Tools \(ADT\)](#)

## Badges

Taster: [Get Started with SAP BTP, ABAP Environment](#)

Level 1: [Get to know the ABAP RESTfulApplication Programming Model](#)

Level 2: [Level up with SAP BTP, ABAP Environment](#)

Level 3: [SAP BTP, ABAP Environment: Intermediate Topics](#)

## 3.4 Getting Started in the Kyma Environment

As an administrator, you must perform several steps to set up a fully operational Kyma environment to which you can connect the chosen SAP solutions.

### Prerequisites

- To perform administrative and development tasks, you need a global account and one or several subaccounts for which you can provision the Kyma environment. For details, see [Create the Kyma Instance \[page 2749\]](#).
- The subaccount must have the following entitlements assigned:
  - Kyma environment (added by the subaccount manager)
  - Service Manager (added by default). However, if you removed the entitlement, you must add it again in your subaccount

For details, see [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#).

### Procedure

1. Set up a Kubernetes cluster with the project "Kyma" to connect and extend SAP systems: [Create the Kyma Instance \[page 2749\]](#)
2. Add the modules you'd like to use: [Kyma Modules \[page 57\]](#).
3. Assign the roles to users to allow the administrators to manage Kyma and the developers to create Functions: [Assign Roles in the Kyma Environment \[page 2766\]](#)

#### ⚠ Caution

Assign the roles before the users start using the Kyma dashboard. Not granting the roles results in an error.

4. Use the Kyma environment to integrate external systems: [Register an SAP Customer Experience System](#)

You have the following options:

- Integrate a CX system and the Kyma environment, so that the Functions you develop can use the system's API and receive business events.
- Integrate an SAP S/4 HANA Cloud system to use the services it provides to extend your applications.

After you've integrated external systems, the developers can start working on their Functions.

5. Extend SAP S/4HANA Cloud by developing event-driven extensions and applications: [Extending SAP S/4HANA Cloud in the Cloud Foundry and Kyma Environment](#)
6. Group several solutions into one formation to meet the requirements of your business scenario: [Including SAP Systems in a Formation](#)

## Results

You have set up the Kyma environment and connected it as required.

## Next Steps

After the administrator has set up the Kyma environment, the developers can access it through the Kyma dashboard. After logging on, developers can start creating extensions for the SAP systems either from the Kyma dashboard or from the terminal after downloading the kubeconfig file with the cluster configuration. For details, see [Development in the Kyma Environment \[page 1729\]](#).

### 3.4.1 Getting Started with an Enterprise Account in the Kyma Environment

Quickly get started with an enterprise account in the Kyma environment using the SAP BTP cockpit.

#### Procedure

1. Get a global account.

After you've signed up for your enterprise account, you get an e-mail with a link to SAP BTP and the logon data as administrator for the global account.

Log on to SAP BTP and navigate to your global account.

#### Note

For more information on available plans, including free tier, see [Available Plans in the Kyma Environment \[page 2750\]](#).

2. Set up your subaccount. For more information, see [Create a Subaccount \[page 1977\]](#).

You can create more subaccounts to break down your account model and structure it according to your development scenario. But first it's important you understand how to navigate to your accounts using the SAP BTP cockpit.

You can also download and use the SAP BTP command line interface (btp CLI) to create new subaccounts. See [Download and Start Using the btp CLI Client \[page 2138\]](#) and [Working with Global Accounts, Directories, and Subaccounts Using the btp CLI \[page 2168\]](#).

3. Create your Kyma environment. For more information, see [Create the Kyma Instance \[page 2749\]](#).
4. Configure your Kyma environment.

Now that you've set up your account model, it's time to think about member management. You can add members at different levels:

- For Kyma-specific role assignment, see [Assign Roles in the Kyma Environment \[page 2766\]](#).
  - To learn more about how user roles are assigned in SAP BTP, have a look at [User and Member Management \[page 85\]](#).
5. Develop your applications and extend SAP solutions.
- Check out [Development in the Kyma Environment \[page 1729\]](#) to learn more.

## Related Information

[Available Plans in the Kyma Environment \[page 2750\]](#)

### 3.4.2 Getting Started with a Trial Account in the Kyma Environment

Quickly get started with a trial account in the Kyma environment.

#### Procedure

1. Get a global account.

Sign up for a free trial account. See [Get a Free Trial Account \[page 127\]](#). For more information about the scope of our trial offering, see [Trial Accounts and Free Tier \[page 63\]](#).

For more information on available plans, including free tier, see [Available Plans in the Kyma Environment \[page 2750\]](#).

2. Set up your subaccount.

When you register for a trial account, a subaccount is created for you.

If you want to create more subaccounts to break down your account model and structure it according to your development scenario, see [Create a Subaccount \[page 1977\]](#). But first it's important you understand how to navigate to your accounts using the SAP BTP cockpit.

You can also download and use the SAP BTP command line interface (btp CLI) to create new subaccounts. See [Download and Start Using the btp CLI Client \[page 2138\]](#) and [Working with Global Accounts, Directories, and Subaccounts Using the btp CLI \[page 2168\]](#).

3. Create your Kyma environment. For details, see [Create the Kyma Instance \[page 2749\]](#) and [Enable Trial Kyma Environment \[page 210\]](#).
4. Configure your Kyma environment.

Now that you've set up your account model, it's time to think about member management. You can add members at different levels:

- For Kyma-specific role assignment, see [Assign Roles in the Kyma Environment \[page 2766\]](#).
- To learn more about how user roles are assigned in SAP BTP, have a look at [User and Member Management \[page 85\]](#).

5. Develop your applications and extend SAP solutions.

Check out [Development in the Kyma Environment \[page 1729\]](#) to learn more.

You can also provide extensions for the SAP Commerce Cloud, SAP Cloud for Customer, and SAP Field Service Management systems. For more information, read [Extending SAP Solutions Using Automated Configurations \[page 1744\]](#).

### 3.4.2.1 About the Trial Account

A trial account lets you try out the Kyma environment for free with a restricted use of the platform resources and services. Access is open to everyone. Trial accounts are intended for personal exploration, and not for production use or team development.

#### Trial Period

The trial account is valid for 90 days. During this time, you can explore and use the basic functionality of SAP BTP, Kyma runtime for 14 days. After 90 days, your account is automatically deleted, and you'll no longer be able to access your data. See [Trial Accounts and Free Tier](#) to learn more about the trial periods.

Note that while your trial account is valid for 90 days, the Kyma environment that you create with it expires **14 days** after its creation and is then deleted permanently. To create a new Kyma environment, you must first disable the expired Kyma on your subaccount. To learn how to do that, see [Disable Expired Trial Kyma Environment \[page 210\]](#).

#### ⚠ Caution

Once your account has expired, your cluster is deleted and all the cluster resources are removed. We recommend that you back up your cluster configuration to restore it quickly if you choose to create a new Kyma environment.

#### Scope and Limitations

- It's possible to provision only one Kyma environment per global account.
- You can manage members in your trial account.
- Kyma trial accounts are available in all SAP BTP regions.
- A trial account provides you with a 1-node cluster with 4 vCPU and 16 GB of memory. An idle cluster without any customer workload uses around 33% of vCPU and 33% of memory.
- A trial account comes with a cluster with built-in eventing.
- Events are processed in-memory and are not persisted to disk. Not delivered events will be lost on restart of the eventing infrastructure.
- There's no service level agreement with regards to the availability of the platform.

## Related Information

[Trial Accounts and Free Tier \[page 63\]](#)

[Assign Roles in the Kyma Environment \[page 2766\]](#)

### 3.4.2.2 Setting Up Your Trial Account

Your global trial account is set up automatically, so that you can start using it right away. However, if one or more of the automatic steps fail, you can also finalize the setup manually by following the steps below.

#### 3.4.2.2.1 Create Your Trial Subaccount

The first thing that is needed in the setup of your trial account is the creation of a subaccount. If this step was successful in the SAP BTP cockpit, you can directly skip to the next section.

#### Procedure

1. Navigate into your global account by choosing [Enter Your Trial Account](#).
2. Choose [New Subaccount](#).
3. Configure your trial account:

Field	Input
Display Name	<code>trial</code>
<div><p> Note</p><p>The value for this parameter is a sample one, you can provide a name of your choice.</p></div>	
Description	Optional
Provider	Desired infrastructure provider
Region	Desired region
Subdomain	<code>&lt;your_id&gt;trial</code> Example: <code>P0123456789trial</code>
Enable beta features	Optional Enables the use of beta services and applications.
Custom Properties	Optional

Field	Input
	You can use custom properties to identify and organize the subaccounts in your global account. For example, you can filter subaccounts by custom property in some cockpit pages.

## Results

You have successfully set up your trial subaccount.

### 3.4.2.2.2 Add Entitlements

Once you have a subaccount (whether it was created automatically or you followed the steps described above), you need entitlements to get your trial up and running.

## Procedure

1. Navigate to your subaccount by choosing its tile.
2. Choose *Entitlements* from the left-hand side navigation.
3. Choose *Configure Entitlements* to enter edit mode.
4. Choose *Add Service Plans* and select all the service plans available for your subaccount.

#### Note

To select a service plan, choose a service from the left and tick all the service plans that appear on the right. Do that for all services.

5. Once you've added all the service plans, you see them all in a table. Before you choose Save, for all the plans with numerical quota, choose **+** to increase the amount to the maximum (until the icon becomes disabled).
6. Finally, choose *Save* to save all your changes and exit edit mode.

### 3.4.2.2.3 Enable Trial Kyma Environment

After you've successfully added the entitlements, you can enable your trial Kyma environment and start developing.

#### Procedure

1. Navigate to your subaccount.
2. Create your Kyma environment. For details, see [Create the Kyma Instance \[page 2749\]](#).
3. Provide the name of your cluster and, optionally, a description.

Wait until the cluster is provisioned and you see the link to the Kyma dashboard.

4. Access the Kyma dashboard. For further information on the development options, see [Development in the Kyma Environment \[page 1729\]](#).

#### Results

Your trial Kyma environment is ready to use.

### 3.4.2.2.4 Disable Expired Trial Kyma Environment

After your trial Kyma environment has expired, you must disable it to remove all the data connected to the cluster from SAP systems.

#### Procedure

1. Navigate to your subaccount.
2. In the *Kyma Environment* section of your subaccount overview, click *Disable Kyma*.

#### Note

On deletion of the expired cluster, we attempt to delete the Service Instances that you created with the cluster. If we cannot do that, you have to [remove the Service Instances yourself](#) before you disable such a *Kyma Environment*.

### 3.4.2.2.5 Extend Trial Kyma Environment

You cannot extend your trial Kyma environment. After your trial Kyma environment has expired, you must disable it on your subaccount and enable it again to create a new cluster.

#### Procedure

1. Navigate to your subaccount.
2. [Disable your expired Kyma environment. \[page 210\]](#)
3. After your Kyma environment has been successfully disabled, [create a new Kyma environment. \[page 210\]](#)

# 4 Development

Develop and run business applications on SAP Business Technology Platform (SAP BTP) using our cloud application programming model, APIs, services, tools, and capabilities.

SAP BTP supports multiple environments. It features a number of tools and programming languages that increase your flexibility and freedom when developing applications. You can choose the environment that best suits your use cases and skill set and get to work. You also have the possibility to integrate applications you've built with other solutions by SAP.

Environment options

	Cloud Foundry	Kyma	ABAP
Benefits	<ul style="list-style-type: none"> <li>Simplified developer experience for business application development</li> <li>Large choice of programming languages</li> <li>Intuitive “code-to-container” packaging and deployment, managed by the platform</li> <li>Platform-managed application security patching and updates</li> <li>Automatic application routing, load balancing, health checks, and multilevel self-healing</li> <li>Support for CAP – an opinionated business app development framework</li> </ul>	<ul style="list-style-type: none"> <li>Take full advantage of the advanced features and rich ecosystem of Kubernetes</li> <li>Free choice of programming languages and models (containerized deployments)</li> <li>Combines microservices and serverless functions</li> <li>Built-in, managed service mesh based on Istio, and other cloud-native open-source modules to reduce the development effort</li> <li>Built-in, managed event mesh</li> <li>Managed infrastructure: day-2 operations, security patches, and updates</li> <li>Full administrator access</li> <li>Refined horizontal and vertical automatic scalability</li> <li>Dedicated application runtime</li> <li>Zero downtime infrastructure setup by default</li> <li>Support for CAP – an opinionated business app development framework</li> <li>Support for on-premise connectivity</li> </ul>	<ul style="list-style-type: none"> <li>ABAP programming language</li> <li>Fast prototyping with ABAP RESTful Programming Model (RAP)</li> <li>Integrated development lifecycle</li> <li>Reuse existing on-prem ABAP assets</li> </ul>

## 4.1 Development in the Cloud Foundry Environment

Learn more about developing applications on the SAP BTP, Cloud Foundry environment.

### Overview

SAP BTP, Cloud Foundry environment is an open Platform-as-a-Service (PaaS) targeted at microservice development and orchestration.

#### Develop polyglot applications

Build on open standards with SAP Java, Node.js, and Python buildpacks or bring your own language with community buildpacks for PHP, Ruby, Go.

#### Manage the lifecycle of applications

Start, stop, scale, and configure distributed cloud applications using standard Cloud Foundry tools, our web-based administration user interface for SAP BTP, and dev-ops capabilities.

**Optimize development and operations**

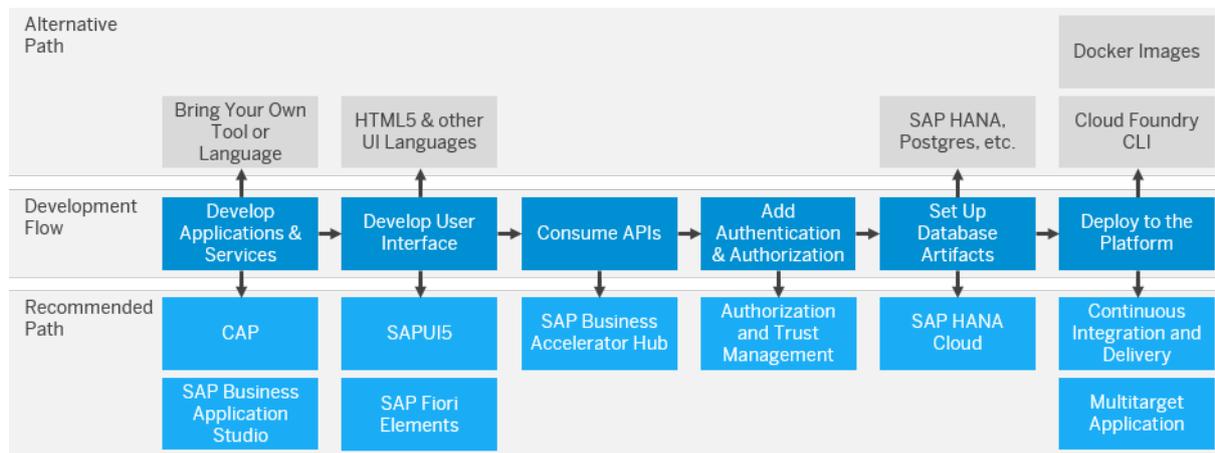

Use the rich set of SAP BTP services including messaging, persistence, and many other capabilities.

**Use the application programming model**

Use programming languages, libraries, and APIs tailored for full-stack application development.

The following graphic is designed to help you find the information you need for your programming purposes. The bottom row represents the tools, frameworks, services, and deployment options recommended by SAP. If you want full flexibility you can also bring your own development tools and languages, as shown in the top row.

## The Recommended Path

This development approach offers guidance for important development decisions and features proven best practices recommended by SAP. You can follow a model path for application and service development that is based on the Cloud Application Programming Model (CAP). When working with CAP, we recommend using Java and Node.js because they receive the highest level of tool support and are well suited for most use cases. This path provides you with a list of key aspects to consider, but the order shown in these steps isn't mandatory. You can adapt the steps as you wish to better fit your use case.

## Choose Your Own Path

Because of the polyglot nature of the Cloud Foundry environment, you're also free to choose your own approach. You're not forced to use one language exclusively, but can choose between Java, Node.js, and Python. Concerning tools you can either use the Cloud Foundry Command Line Interface (CF CLI) or other tools to develop and deploy your application. You're also free to decide if you want to develop and deploy your applications in the multitarget format (MTA).

For more information on the supported programming languages, see:

- [Developing Java in the Cloud Foundry Environment \[page 242\]](#)
- [Developing Node.js in the Cloud Foundry Environment \[page 311\]](#)
- [Developing Python in the Cloud Foundry Environment \[page 322\]](#)

If you already have monolithic applications running on SAP BTP and are looking for a way to run them in the Cloud Foundry environment, read our migration best practice guide. See [Migrating from the Neo Environment to the Multi-Cloud Foundation \(Cloud Foundry and Kyma\)](#).

[SAP BTP, Cloud Foundry Runtime](#)

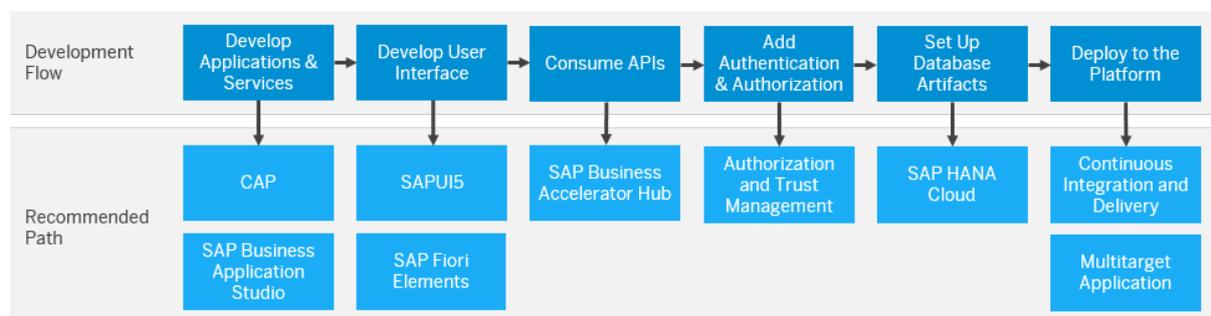

## 4.1.1 Best Practices

Choose the development environment, tools, APIs, and programming model that best suit your needs with recommendations from SAP.

Navigating the large portfolio of solutions, services, tools, and frameworks can be difficult. That's why we want to provide you with recommendations based on our years of experience in helping customers achieve their goals. The best practices listed here are targeted at developers. If you're looking for recommendations on general development planning and setting up SAP BTP, see [Best Practices for SAP BTP](#). If you're interested in extending existing applications, see [Extensions \[page 1743\]](#).

The following graphic offers an overview of the most important considerations to take when starting development on SAP BTP for the Cloud Foundry environment. The steps are recommendations, you're free to complete them in a different order if you feel it suits your needs better.

### Development Options

- [Developing Applications and Services \[page 219\]](#)
- [Developing User Interface \[page 354\]](#)
- [Consuming APIs \[page 464\]](#)
- [Adding Authentication and Authorization \[page 465\]](#)
- [Setting Up Database Artifacts \[page 532\]](#)
- [Deploying to the Cloud Foundry Environment \[page 535\]](#)
- [Developing with the SAP Cloud Application Programming Model \[page 224\]](#)
- [Developing SAPUI5 \[page 355\]](#)
- <https://api.sap.com/> [<https://api.sap.com/>]
- [Protecting Your Application \[page 467\]](#)
- [SAP HANA Cloud \[page 534\]](#)
- [SAP Business Application Studio \[page 220\]](#)
- [Continuous Integration and Delivery \[page 644\]](#)
- [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#)

## The Recommended Path: The SAP Cloud Application Programming Model

We recommend using the SAP Cloud Application Programming Model (CAP) for full-stack development. CAP is a framework of languages, libraries, APIs, and tools that guide developers along a proven path of best practices. It was designed with a business domain focus in mind, relying on common patterns and reuse models for programming. With CAP you can develop multitarget applications or automate tasks such as authorization, integration, or localization to make applications and services easier to fix and maintain. CAP is compatible with any development environment, but we recommend SAP Business Application Studio.

For more information, see [Developing with the SAP Cloud Application Programming Model \[page 224\]](#) and [SAP Business Application Studio](#).

## Multitarget Applications

One of the challenges of programming in a cloud environment is the deployment and management of applications consisting of multiple, interdependent components. The agility, flexibility, and resilience of cloud applications brings with it an increased complexity. For example, your application could be targeted at multiple runtimes or consist of interconnected modules created in different tools and programming languages.

To reduce this complexity, we recommend programming multitarget applications (MTA). That means packaging all the components of your application into a single archive file. Doing so makes managing the application's lifecycle easier and enables you to automate processes, for example through the Continuous Integration and Delivery service.

For more information, see [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#).

## SAP Alert Notification Service

Applications running in the Cloud Foundry environment are constantly monitored through health checks. If an application doesn't respond, for example because it crashed, it fails the health check and is automatically restarted. Because the system restarts applications quickly to avoid major disruptions, it can be difficult to identify underlying problems. For more information about configuring Health Checks, see <https://docs.cloudfoundry.org/devguide/deploy-apps/healthchecks.html> 

To support the smooth operation of your applications and services, we recommend using the SAP Alert Notification Service. Using a standardized environment-agnostic model, the service collects any update from the application checks as well as crucial technical information from other services on SAP BTP. It also handles custom scenarios that only occur in your specific application and environment. Each piece of information is translated into a common event model.

You can subscribe to events that are of interest to you and use a delivery channel of your choice, for example email or a custom webhook allowing you to send events to any REST API endpoint in the public internet. SAP Alert Notification Service also natively supports integration with external systems, such as Slack, Microsoft Teams, VictorOps, ServiceNow. For more information on events, see [SAP Alert Notification Service Events](#).

## Related Information

[What Is SAP Alert Notification Service for SAP BTP](#)

### 4.1.2 Developing Your First Application

Follow any of these tutorials to develop your first application on SAP BTP. Choose your preferred programming model and technology.

Name	Technology
<a href="#">Build a Business Application Using CAP for Node.js</a>	SAP Cloud Application Programming Model (CDS and Node.js)
<a href="#">Develop a Simple Hello World Application Using SAPUI5</a>	SAPUI5
<a href="#">Create an Application with SAP Java Buildpack</a>	Java
<a href="#">Create an Application with Cloud Foundry Python Buildpack</a>	Python
<a href="#">Create an Application with Cloud Foundry Node.js Buildpack</a>	Node.js

### 4.1.3 Developing Applications and Services

Get started with developing applications and services in the Cloud Foundry environment.

#### Basic Considerations

At the outset of every development project stand questions about the goal you want to achieve, which skills, tools, and programming languages are required, and how the finished application or service is deployed and maintained. This topic provides an overview of the programming models, development languages, tools, and services you can leverage in the SAP BTP, Cloud Foundry environment to help you address those questions.

#### SAP Business Application Studio

Learn about the SAP Business Application Studio, the environment tailored for efficient development of business applications. For more information, see [SAP Business Application Studio \[page 220\]](#).

## Business Application Pattern

To find information about the recommended development architecture for business applications in the SAP BTP, Cloud Foundry environment, see [Business Application Pattern \[page 221\]](#).

## SAP Cloud Application Programming Model

The SAP Cloud Application Programming Model (CAP) is the recommended framework for application and service development in the Cloud Foundry environment. To learn more, see [Developing with the SAP Cloud Application Programming Model \[page 224\]](#).

## Services in the Cloud Foundry Environment

In a PaaS environment, external dependencies such as databases, messaging systems, and file systems are services. To use a service, you need to create a service instance and bind it to your application, using either the cockpit or the Cloud Foundry Command Line Interface (CF CLI). To learn more, see [Using Services in the Cloud Foundry Environment \[page 229\]](#).

## Development Languages

Find information and tutorials for the main development languages supported in the SAP BTP, Cloud Foundry environment: Java, Node.js, and Python. See [Development Languages \[page 241\]](#).

## Multitenant Applications

If you want to make your applications and services available for use to other SAP BTP users, you can design them as multitenant applications. This allows consumers, who are called tenants in this scenario, to access what you've created through dedicated URLs. For more information, see [Developing Multitenant Applications in the Cloud Foundry Environment \[page 327\]](#).

### 4.1.3.1 SAP Business Application Studio

SAP Business Application Studio is a new cloud service in the SAP BTP, Cloud Foundry environment offering a modern development environment tailored for efficient development of business applications.

SAP Business Application Studio provides a desktop-grade IDE experience in the cloud, including command line functionalities and optimized editors.

It features dev spaces that function like isolated virtual machines. They contain tailored tools and pre-installed runtimes that can save you time and effort when setting up your development environment and that allow you to efficiently develop, test, build, and run your solutions both locally or in the cloud.

SAP Business Application Studio is the recommended environment when working with the Cloud Application Programming Model (CAP).

For more information, see [SAP Business Application Studio](#).

## 4.1.3.2 Business Application Pattern

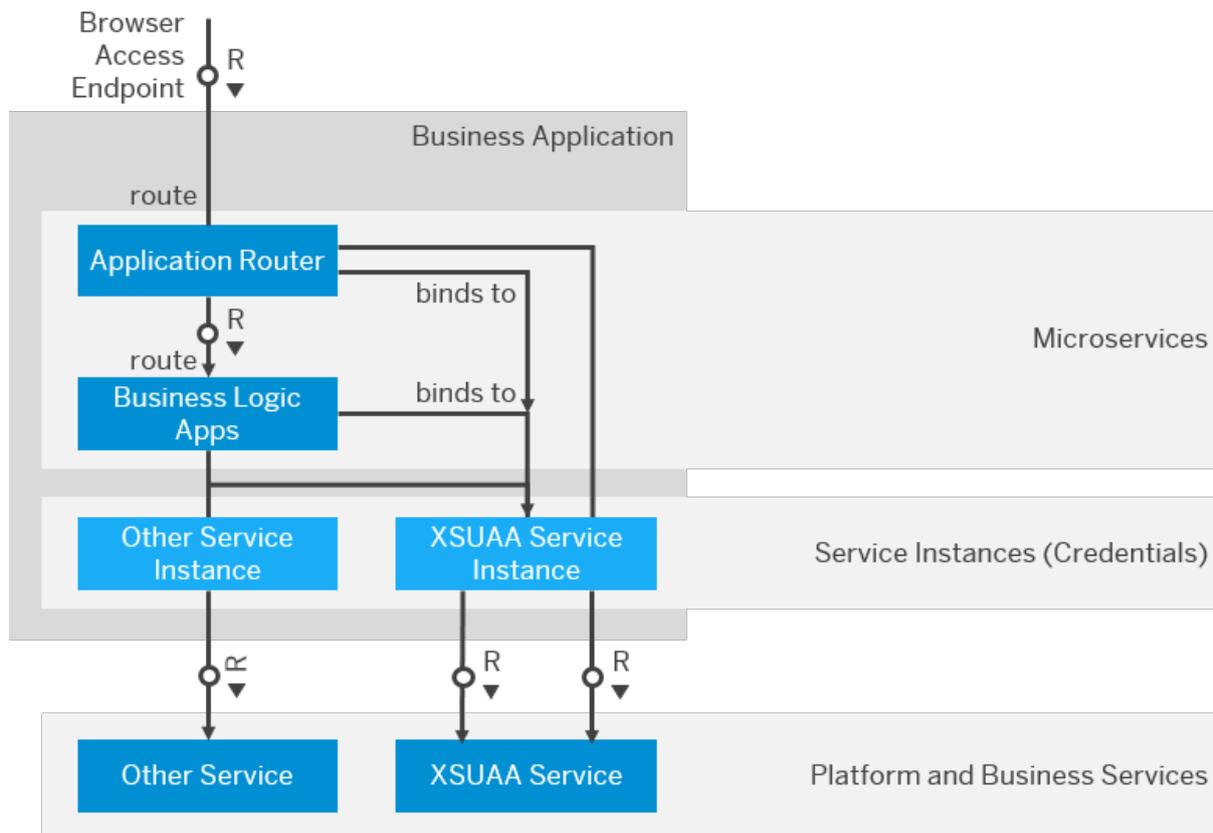

In the Cloud Foundry environment, SAP is promoting a pattern for building applications. We use the term **Business Application** to distinguish from single applications in the context of the Cloud Foundry environment.

This topic covers the following:

- [Application Patterns \[page 221\]](#)
- [Application Router \[page 222\]](#)
- [UAA Service \[page 223\]](#)
- [Platform and Business Services \[page 223\]](#)
- [Application Deployment \[page 223\]](#)

### Application Patterns

The diagram below is a logical view, abstracting from numerous details like the CF router, CF controller, and represents architecture of a business application. In general, a business application consists of multiple microservices which are deployed as separate applications to SAP BTP, Cloud Foundry environment.

Microservices, service instances, bindings, services, and routes are entities known to the platform.

Create Microservices from "pushing" code and binaries to the platform resulting in a number of application instances each running in a separate container.

Services are exposed to apps by injecting access credentials into the environment of the applications via service binding. Applications are bound to service instances where a service instance represents the required configuration and credentials to consume a service. Services instances are managed by a service broker which has to be provided for each service (or for a collection of services).

Routes are mapped to applications and provide the actual application access points / URLs.

A business application is a collection of microservices, service instances, bindings, and routes, which together represent a usable web application from an end user point of view. These microservices, services instances, bindings, and routes are created by communicating with the CF / XSA Controller (for example, using a command line interface).

SAP provides a set of libraries, services, and component communication principles, which are used to implement (multi-tenant) business applications according to this pattern.

## Application Router

Business applications embracing a microservice architecture, consist of multiple services that can be managed independently. Still this approach brings some challenges for application developers, like handling security in a consistent way and dealing with same origin policy.

Application router is a separate component that addresses some of these challenges. It provides three major functions:

- Reverse proxy - provides a single entry point to a business application and forwards user requests to respective backend services
- Serves static content from the file system
- Security – provides security-related functionality like logon, logout, user authentication, authorization, and CSRF protection in a central place

The application router exposes the endpoint accessed by a browser to access the application.

## UAA Service

The User Account and Authentication (UAA) service is a multi-tenant identity management service, used in the SAP BTP, Cloud Foundry environment. Its primary role is as an OAuth2 provider, issuing tokens for client applications to use when they act on behalf of the users of the Cloud Foundry environment. It can also authenticate users with their credentials for the Cloud Foundry environment, and can act as an SSO service using those credentials (or others). It has endpoints for managing user accounts and for registering OAuth2 clients, as well as various other management functions.

## Platform and Business Services

The platform provides a number of backing services like SAP HANA, MongoDB, PostgreSQL, Redis, RabbitMQ, Audit Log, Application Log, and so on. Also, the platform provides various business services, like retrieving currency exchange rates. In addition, applications can use user-provided services, which are not managed by the platform.

In all these cases applications can bind and consume required services in a similar way. See [Services Overview documentation](#) for general information about services and their consumption.

## Application Deployment

There are two options for a deployer (human or software agent), how to deploy and update a business application:

- Native deployment: Based on the native controller API of the Cloud Foundry environment, the `deployer` deploys individual applications and creates service instances, bindings, and routes. The `deployer` is responsible for performing all these tasks in an orchestrated way to manage the lifecycle of the entire business application.
- [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#) (MTA): Based on a declarative model the `deployer` creates an MTA archive and hands over the model description together with all application artifacts to the SAP Deploy Service. This service is performing and orchestrating all individual (native) steps to deploy and update the entire business application (including blue-green deployments).

### 4.1.3.3 Developing with the SAP Cloud Application Programming Model

The SAP Cloud Application Programming Model (CAP) is a framework of languages, libraries, and tools for building enterprise-grade services and applications. It guides developers along a 'golden path' of proven best practices and a great wealth of out-of-the-box solutions to recurring tasks.

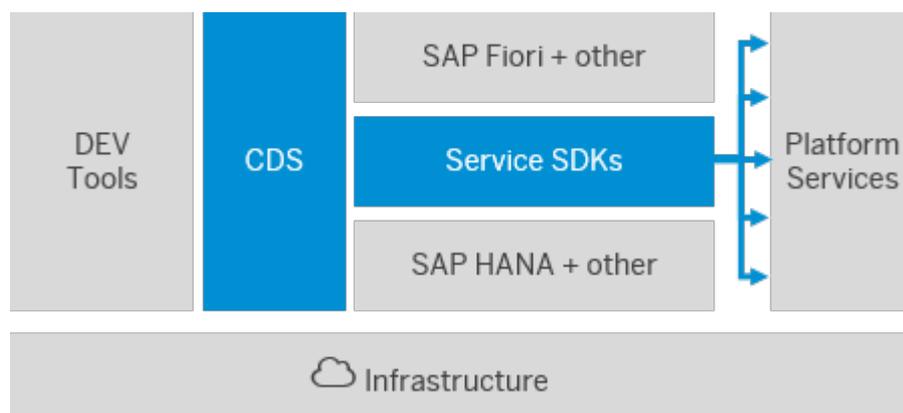

Use Core Data & Services (CDS) to build data models and service definitions on a conceptual level. These CDS models are used as inputs for the data, service, and UI layers. They're then translated to native artifacts, for example SQL database schemas, and interpreted to automatically serve requests at runtime.

In summary, CDS is used as a business level data definition source, and to generate the artifacts at the persistence layer. It's used to define visual aspects relating to the data, with those definitions (annotations) defining the UI layer. And it's used to generate the application service layer.

We provide seamless integration with the Cloud Foundry environment on SAP Business Technology Platform. This makes it easier for you to deploy your application and consume platform services.

The programming model is compatible with any development environment, but we recommend using the SAP Business Application Studio.

The following graphic shows the relationship between CAP, SAP Business Technology Platform, platform services, and development tools:

Overview of the SAP Cloud Application Programming Model

#### [Best Practices \[page 225\]](#)

To help you create concise and comprehensible models with CDS, we have put together a list of best practices.

#### [Core Data and Services \(CDS\) Language Reference Documentation \[page 225\]](#)

CDS is the backbone of the SAP Cloud Application Programming Model (CAP). It provides the means to declaratively capture service definitions and data models, queries, and expressions in plain (JavaScript) object notations. CDS features to parse from a variety of source languages and to compile them into various target languages.

#### [Developing Business Applications Using Java \[page 226\]](#)

The CAP Java SDK enables developing SAP Cloud Application Programming Model (CAP) applications in Java. While the SAP Business Application Studio provides excellent support to develop CAP Java applications, you can also develop locally with your tool of choice, for example Eclipse.

#### [Developing Business Applications Using Node.js \[page 227\]](#)

Develop a sample business service using Core Data & Services (CDS), Node.js, and SQLite, by using the SAP Cloud Application Programming Model (CAP). Develop on your local environment and deploy to the Cloud.

- [Serving Fiori UIs](#) - Explains how to add one or more SAP Fiori Elements apps to a CAP project and how to add SAP Fiori Elements annotations to respective service definitions.
- [Deploy to Cloud](#) - How to deploy your services to the cloud.
- [Native SAP HANA](#) - How to use existing database objects with CDS.

### 4.1.3.3.2 Core Data and Services (CDS) Language Reference Documentation

CDS is the backbone of the SAP Cloud Application Programming Model (CAP). It provides the means to declaratively capture service definitions and data models, queries, and expressions in plain (JavaScript) object

notations. CDS features to parse from a variety of source languages and to compile them into various target languages.

CDS models are plain JavaScript objects complying to the Core Schema Notation (CSN), an open specification derived from JSON Schema. You can easily create or interpret these models, which foster extensions by 3rd-party contributions. Models are processed dynamically at runtime and can also be created dynamically.

For further information, please refer to the following sections:

- [Upgrade to Compiler v2](#) - CDS compiler version 2 (cv2) brings numerous improvements, which allow us to significantly streamline model processing going forward.
- [Definition Language \(CDL\)](#) - A reference and overview of all CDS concepts and features in the form of compact examples.
- [Schema Notation \(CSN\)](#) - Specification of CSN, CDS' canonical format for representing CDS models as plain JavaScript objects, similar to JSON Schema.
- [Query Language \(CQL\)](#) - Documents the CDS Query Language (aka CQL) which is an extension of the standard SQL SELECT statement.
- [Query Notation \(CQN\)](#) - Specification of the Core Query Notation (CQN) format that is used to capture queries as plain JavaScript objects.
- [Expression Notation \(CXN\)](#) - Specification of the Core Expression Notation (CXN) used to capture expressions as plain JavaScript objects.
- [Built-in Types](#) - List of provided built-in types.
- [Common Types & Aspects](#) - Introduces `@sap/cds/common` a prebuilt CDS model shipped with `@sap/cds` that provides common types and aspects.
- [Common Annotations](#) - A reference and glossary of common annotations intrinsically supported by the CDS compiler and runtimes.
- [Compiler Messages](#) - This page lists selected error messages and explanations on how to fix them.
- [The Nature of Models](#) - Introduces the fundamental principles of CDS models.
- [Node.js API](#) - The CDS compiler is implemented in Node.js. Find here the reference documentation for the respective APIs which can be used in CLI tools as well at runtime in CDS service implementations.

### 4.1.3.3 Developing Business Applications Using Java

The CAP Java SDK enables developing SAP Cloud Application Programming Model (CAP) applications in Java. While the SAP Business Application Studio provides excellent support to develop CAP Java applications, you can also develop locally with your tool of choice, for example Eclipse.

The CAP Java SDK supports lean application design by its modular architecture, that means you pick the required features and add them to your application dependencies on demand.

It enables local development by supporting in-memory or file-based SQLite databases. At the same time, the CAP Java SDK enables switching to a productive environment, using, for example, SAP HANA as a database, easily by simply switching the application deployment configuration.

The following sections help you get started.

### 4.1.3.3.5.1 What's New

Find out what is new and what has changed in CAP since the last release.

- [Release Notes](#)
- [Changelog](#)

### 4.1.3.3.5.2 Learning Content

Learn about the golden path that CAP gives users to create service-based applications. Get to know the principles that enable you to focus on your domain and avoid boilerplate code. With CAP you focus on what you can do best: Solving business problems.

Try out the [Learning Sources](#) we collected on this page.

### 4.1.3.3.5.3 Sample Projects

CAP enables you to quickly create business applications by allowing you to focus on your domain logic. It offers a consistent end-to-end programming model that includes languages, libraries, and tools tailored for full-stack development on SAP BTP.

Get started with samples and reusable packages created based on CAP for [Node.js](#) and [Java](#) provided can be run in a local setup on, for example, a SQLite database.

## 4.1.3.3.5.4 Tutorials

- Learn how to create a business service using CAP for Java and deploy it to SAP BTP: [Build a Business Application Using CAP for Java](#).
- Learn how to create a business service with CDS using Node.js and deploy it to SAP BTP: [Create a Business Service with Node.js using Visual Studio Code](#).
- Find more tutorials using the SAP Cloud Application Programming Model (CAP) in the [Tutorial Navigator](#).

## 4.1.3.3.5.5 Community, Blogs & Q&A

Learn more about CAP by visiting SAP Community.

- Find more samples, openSAP course material, podcasts, and other related resources in the [SAP Cloud Application Programming Model community](#).
- Read the [blogs](#) including the [original introduction](#) by Daniel Hutzler and a great collection of [starting points](#) by DJ Adams.
- Ask [questions](#) related to CAP to get help from developers and other community members.

## 4.1.3.3.5.6 Troubleshooting

If you run into issues working with CAP samples or tutorials, please refer to the [Troubleshooting](#) guide. There you can find a collection of frequently asked questions and provided solutions.

Furthermore, you can get support as mentioned in section [Resources](#).

## 4.1.3.4 Using Services in the Cloud Foundry Environment

Learn more about using services in the Cloud Foundry environment, how to create (user-provided) service instances and bind them to applications, and how to create service keys.

- [About Services \[page 230\]](#)
- [Binding Service Instances to Applications \[page 234\]](#)
- [Creating Service Instances \[page 231\]](#)
- [Creating Service Keys \[page 236\]](#)
- [Creating User-Provided Service Instances \[page 233\]](#)
- [Deleting Service Instances \[page 237\]](#)
- [Updating Service Instances \[page 239\]](#)

## SAP Service Manager

You can also access services for the Cloud Foundry environment through SAP Service Manager, the central registry for service brokers and platforms. It's tightly integrated with SAP BTP and allows you to consume services in connected runtime environments and to manage platforms, service brokers, service instances, and service bindings.

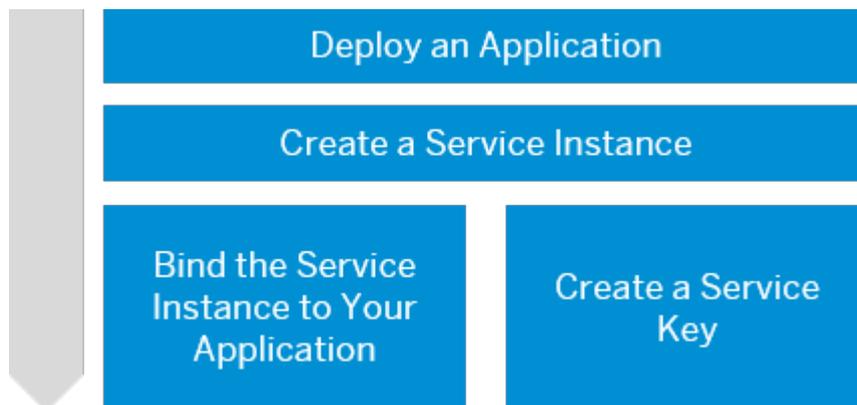

- For more information, see [SAP Service Manager](#).
- To find out if SAP Service Manager is available in your desired region, search for it in the [SAP Discovery Center - Service Catalog](#). In the *Pricing* tab, choose the globe icon to display a map of available regions for this service.

### 4.1.3.4.1 About Services

In the Cloud Foundry environment, you usually enable services by creating a service instance using either the SAP BTP cockpit or the Cloud Foundry command line interface (cf CLI), and binding that instance to your application.

In a PaaS environment, all external dependencies, such as databases, messaging systems, files systems, and so on, are services. In the Cloud Foundry environment, services are offered in a marketplace, from which users can create service instances on-demand. A service instance is a single instantiation of a service running on SAP BTP. Service instances are created using a specific service plan. A service plan is a configuration variant of a service. For example, a database may be configured with various "t-shirt sizes", each of which is a different service plan.

To integrate services with applications, the service credentials must be delivered to the application. To do so, you can bind service instances to your application to automatically deliver these credentials to your application. Or you can use service keys to generate credentials to communicate directly with a service instance. As shown in the figure below, you can deploy an application first and then bind it to a service instance:

Using Services in the Cloud Foundry Environment

Alternatively, you can also bind the service instance to your application as part of the application push via the application manifest. For more information, see <https://docs.cloudfoundry.org/devguide/deploy-apps/manifest.html#services-block>.

### Note

Have in mind that you need to create a service instance first before you integrate it into your application manifest.

The Cloud Foundry environment also allows you to work with user-provided service instances. User-provided service instances enable developers to use services that are not available in the marketplace with their applications running in the Cloud Foundry environment. Once created, user-provided service instances behave in the same manner as service instances created through the marketplace. For more information, see [Creating User-Provided Service Instances \[page 233\]](#).

For more conceptual information about using services in the Cloud Foundry environment, see <https://docs.cloudfoundry.org/devguide/services/>.

## Related Information

[Creating User-Provided Service Instances \[page 233\]](#)

[Solutions and Services \[page 16\]](#)

## 4.1.3.4.2 Creating Service Instances

Use the SAP BTP cockpit or the Cloud Foundry Command Line Interface to create service instances:

- [Create Service Instances Using the Cockpit \[page 231\]](#)
- [Create Service Instances Using the Cloud Foundry Command Line Interface \[page 232\]](#)

You can also create service instances by declaring them as part of your multitarget application (MTA). To learn how to do that, have a look at the service creation parameters.

- [Service Creation Parameters \[page 597\]](#)

### 4.1.3.4.2.1 Create Service Instances Using the Cockpit

#### Note

The content of this page has moved to a new location.

To learn how to create service instances using the cockpit, see

[Creating Service Instances](#).

## 4.1.3.4.2.2 Create Service Instances Using the Cloud Foundry Command Line Interface

You can use the Cloud Foundry Command Line Interface (cf CLI) to create service instances.

### Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry.  
For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
- If you are working in an enterprise account, you need to add quotas to the services you purchased in your subaccount before they appear in the service marketplace. Otherwise, only default free-of-charge services are listed. Quotas are automatically assigned to the resources available in trial accounts.  
For more information, see [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#).

### Procedure

1. (Optional) Open a command line and enter the following string to list all services and service plans that are available in your org:

```
cf marketplace
```

2. Run the following command to create a service instance:

```
cf create-service SERVICE PLAN SERVICE_INSTANCE
```

Specify the following parameters:

- **SERVICE**: The name of the service you want to create an instance of.
- **PLAN**: The name of the service plan you want to use.
- **SERVICE\_INSTANCE**: The new name for your service instance. Use only alphanumeric characters, hyphens, and underscores.

### Related Information

[Binding Service Instances to Applications \[page 234\]](#)

[Creating User-Provided Service Instances \[page 233\]](#)

[About Services \[page 230\]](#)

### 4.1.3.4.3 Creating User-Provided Service Instances

User-provided service instances enable you to use services that are not available in the marketplace with your applications running in the Cloud Foundry environment.

You can create user-provided service instances using the SAP BTP cockpit or the Cloud Foundry Command Line Interface:

- [Create User-Provided Service Instances Using the Cockpit \[page 233\]](#)
- [Create User-Provided Service Instances Using the Cloud Foundry Command Line Interface \[page 233\]](#)

For more information on user-provided service instances, see <https://docs.cloudfoundry.org/devguide/services/user-provided.html>.

#### 4.1.3.4.3.1 Create User-Provided Service Instances Using the Cockpit

##### Note

The content of this page has moved to a new location.

To learn how to create user-provided service instances using the cockpit, see [Creating User-Provided Service Instances in Cloud Foundry](#).

#### 4.1.3.4.3.2 Create User-Provided Service Instances Using the Cloud Foundry Command Line Interface

Use the Cloud Foundry Command Line Interface to make a user-provided service instance available to Cloud Foundry applications.

##### Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry. For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
- Obtain a URL, port, user name, and password for communicating with a service that is not available in the marketplace.

## Context

For more information on user-provided service instances, see <https://docs.cloudfoundry.org/devguide/services/user-provided.html>.

## Procedure

Open a command line and enter the following string to create a user-provided service instance:

```
cf create-user-provided-service SERVICE_INSTANCE [-p CREDENTIALS]
```

Specify the following parameters:

- `SERVICE_INSTANCE`: The new name for your service instance.
- `CREDENTIALS`: Credentials as JSON

## Next Steps

To bind your application to the user-provided service instance, follow the steps described in [Bind Service Instances to Applications Using the Cloud Foundry Command Line Interface \[page 235\]](#).

## Related Information

[Creating Service Instances \[page 231\]](#)

[About Services \[page 230\]](#)

### 4.1.3.4.4 Binding Service Instances to Applications

Use the SAP BTP cockpit or the Cloud Foundry Command Line Interface to bind service instances to applications:

- [Bind Service Instances to Applications Using the Cockpit \[page 235\]](#)
- [Bind Service Instances to Applications Using the Cloud Foundry Command Line Interface \[page 235\]](#)

You can also bind service instances by declaring them as part of your multitarget application (MTA). To learn how to do that, have a look at the service binding parameters.

- [Service Binding Parameters \[page 599\]](#)

## 4.1.3.4.4.1 Bind Service Instances to Applications Using the Cockpit

### Note

The content of this page has moved to a new location.

To learn how to bind service instances to applications using the cockpit, see [Binding Service Instances to Cloud Foundry Applications](#).

## 4.1.3.4.4.2 Bind Service Instances to Applications Using the Cloud Foundry Command Line Interface

You can bind service instances to applications using the Cloud Foundry Command Line Interface (cf CLI).

### Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry. For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
- Deploy an application in the same space in which you plan to create the service instance. For more information, see [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#).
- Create a service instance. For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface \[page 232\]](#).

### Procedure

Open a command line and enter the following string:

```
cf bind-service APP-NAME SERVICE_INSTANCE [-c PARAMETERS_AS_JSON]
```

Specify the following parameters:

- `APP_NAME`: Name of the application.
- `SERVICE_INSTANCE`: Name of the service instance.
- `-c`: (Optional) Provide service-specific configuration parameters either in a valid JSON object in-line or in a parameters file. This file reference can be an absolute or relative path to a file.

## Related Information

[Creating Service Keys \[page 236\]](#)

[About Services \[page 230\]](#)

### 4.1.3.4.5 Creating Service Keys

You can use service keys to generate credentials to communicate directly with a service instance. Once you configure them for your service, local clients, apps in other spaces, or entities outside your deployment can access your service with these keys.

You can use the SAP BTP cockpit or the Cloud Foundry Command Line Interface to create service keys:

- [Creating Service Keys Using the Cockpit](#)
- [Create Service Keys Using the Cloud Foundry Command Line Interface \[page 236\]](#)

For more information on service keys, see <https://docs.cloudfoundry.org/devguide/services/service-keys.html> .

#### 4.1.3.4.5.1 Create Service Keys Using the Cockpit

##### Note

The content of this page has moved to a new location.

To learn how to create service keys using the cockpit, see [Creating Service Keys in Cloud Foundry](#).

#### 4.1.3.4.5.2 Create Service Keys Using the Cloud Foundry Command Line Interface

Use the Cloud Foundry Command Line Interface to create a service key.

### Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry. For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).
- Create a service instance. For more information, see [Create Service Instances Using the Cloud Foundry Command Line Interface \[page 232\]](#).

## Procedure

Run the following command to create a service key:

```
cf create-service-key SERVICE_INSTANCE SERVICE_KEY [-c PARAMETERS_AS_JSON]
```

Specify the following parameters:

- `SERVICE_INSTANCE`: Name of the service instance.
- `SERVICE_KEY`: Name for the service key.
- `-c`: (Optional) Provide service-specific configuration parameters either in a valid JSON object in-line or in a parameters file. This file reference can be an absolute or relative path to a file.

## Results

Local clients, apps in other spaces, or entities outside your deployment can now access your service instance with this key.

### 4.1.3.4.6 Deleting Service Instances

Use the SAP BTP cockpit or the Cloud Foundry Command Line Interface to delete service instances:

#### ⚠ Caution

Be aware that instances will be deleted ultimately. There is no way to revoke this step.

- [Delete Service Instances Using the Cockpit \[page 238\]](#)
- [Delete Service Instances Using the Cloud Foundry Command Line Interface \[page 238\]](#)

You can also delete service instances using the Multitarget Application plug-in for the Cloud Foundry command line interface. This works with the command `deploy`, `bg-deploy`, and `undeploy` with specifying the `--delete-services` option. To learn how to do that, have a look at the multitarget application commands.

- [Multitarget Application Commands for the Cloud Foundry Environment \[page 2263\]](#)

## 4.1.3.4.6.1 Delete Service Instances Using the Cockpit

### Note

The content of this page has moved to a new location.

To learn how to delete service instances using the cockpit, see [Deleting Service Instances](#).

## 4.1.3.4.6.2 Delete Service Instances Using the Cloud Foundry Command Line Interface

You can use the Cloud Foundry Command Line Interface (cf CLI) to delete service instances.

### Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry.  
For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).

### Procedure

1. Open a command line and log in.

```
cf l -a <API endpoint>
```

2. (Optional) List all services and bound apps in your org:

```
cf services
```

3. Unbind the service from any application.

```
cf unbind-service APP_NAME SERVICE_INSTANCE
```

4. (Optional) List all service keys for your service instance.

```
cf service-keys SERVICE_INSTANCE
```

5. Delete any service key from the service instance.

```
cf delete-service-key SERVICE_INSTANCE SERVICE_KEY
```

6. Run the following command to delete a service instance:

```
cf delete-service SERVICE_INSTANCE
```

Specify the following parameters:

- `SERVICE_INSTANCE`: The name of your service instance.
- `APP_NAME`: The name of an application your service instance is connected to.
- `SERVICE_KEY`: The name of the service key of your service instance.

## Related Information

[About Services \[page 230\]](#)

### 4.1.3.4.7 Updating Service Instances

Use the Cloud Foundry Command Line Interface to update service instances:

- [Update Service Instances Using the SAP BTP Cockpit or Cloud Foundry Command Line Interface \[page 239\]](#)

You can also update service instances inside a multitarget application if the service broker supports updates. Change the deployment descriptor file or a configuration file for a service instance inside your multitarget application and deploy your application to trigger an update of the respective service instance.

#### 4.1.3.4.7.1 Update Service Instances Using the SAP BTP Cockpit or Cloud Foundry Command Line Interface

##### Note

We have redesigned SAP BTP cockpit screens to view and manage service instances.

For more information about the procedure to update service instances using the cockpit, see [Updating Service Instances](#).

To learn how to update service instances using the Cloud Foundry Command Line Interface, continue reading this document.

Use Cloud Foundry Command Line Interface to update service instances:

## Prerequisites

- Download and install the cf CLI and log on to Cloud Foundry.

For more information, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#) and [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#).

## Context

You are using a service instance, for which you want to change the plan or the service-specific configuration.

## Procedure

1. (Optional) Open a command line and enter the following string to list all services in your space:

```
cf services
```

2. (Optional) Enter the following string to list the details of your service:

```
cf service SERVICE_INSTANCE
```

3. Run the following command to update your service instance:

```
cf update-service SERVICE_INSTANCE [-p NEW_PLAN] [-c PARAMETERS_AS_JSON] [-t TAGS]
```

Specify the following parameters:

- `SERVICE_INSTANCE`: The name of your service instance as shown when executing `cf services`.

### 4.1.3.4.8 Boosters

Boosters are a set of guided interactive steps that enable you to select, configure, and consume services on SAP BTP to achieve a specific technical goal.

You can access them directly from your desired global account in the SAP BTP cockpit, by choosing [Boosters](#) in the navigation menu. This leads to a page where you can find an overview of all available boosters, grouped by capability. From this overview page, you can get quick information about a booster, start a booster, or choose a tile to access the booster details.

## Booster Details

The details of boosters are organized in 3 tabs:

- [Overview](#)  
Here, you can get information about what the booster does, its key features and how that particular booster can help you.

- [Components](#)  
Here, you can see all the components that are required for the booster to run.
- [Additional Resources](#)  
Here, you find a list of additional information resources where you can learn more about the concepts and components mentioned in the booster.

Boosters automate processes and always achieve a technical goal, often in the form of an artifact. Artifacts are entities that you develop which may consume technical components (for example, services). Examples of artifacts include applications, content for integration and workflows, or even documents.

When you start a booster, a wizard opens up which guides you through a set of steps. Following these steps enables you to reach the result described in the booster overview.

### 4.1.3.5 Development Languages

Learn about the development languages supported in the SAP BTP, Cloud Foundry environment.

The polyglot nature of SAP BTP means that you have the freedom to choose between various development languages. While we do recommend using Java and Node.js for most use cases, you're free to use the language that best suits your development needs.

Find more information on the three main languages supported by SAP by following the links below:

- [Developing Java in the Cloud Foundry Environment \[page 242\]](#)
- [Developing Node.js in the Cloud Foundry Environment \[page 311\]](#)
- [Developing Python in the Cloud Foundry Environment \[page 322\]](#)

#### Note

Please be informed that the SAP BTP, Cloud Foundry runtime Cloud Service is an open Platform-as-a-Service targeted at microservice development and orchestration. SAP is a member of the Cloud Foundry Foundation, which provides Cloud Foundry, a model for cloud-native application delivery. SAP allows use of certain, publicly available, system buildpacks that are supported by the Cloud Service. However, SAP is not in possession or control of, and cannot be responsible for the content, operation, or use of such system buildpacks, which are not part of the Cloud Service (including SAP Business Technology Platform).

SAP may, without notice, remove any system buildpacks at any time and at SAP's own discretion.

## Tutorials

Tutorial Navigator: [Build an Application in the Cloud Foundry Runtime](#) 

## Guided Answers

## Related Information

[Best Practices \[page 217\]](#)

### 4.1.3.5.1 Developing Java in the Cloud Foundry Environment

Find selected information for Java development on SAP BTP, Cloud Foundry and references to more detailed sources.

## Usage

To use a buildpack, specify its name when deploying a Java application to SAP BTP, Cloud Foundry. For example:

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack_jakarta
```

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack
```

```
cf push -f <PATH_TO_APP_MANIFEST> -b java_buildpack
```

You can also use the *buildpack* or *buildpacks* attribute to specify it in the `manifest.yml` file:

```
---
applications:
- name: <APP_NAME>
  buildpacks:
  - sap_java_buildpack_jakarta
  ...
```

or in the `mtad.yml` file of your archive:

```
...
modules:
  - name: <APP_NAME>
    type: java.tomcat
    path: <path_to_archive>
    properties:
      ...
    parameters:
      ...
      memory: 512M
      buildpack: sap_java_buildpack_jakarta
  ...
```

## What's New

To see the latest news and updates about SAP Java Buildpack, regularly check the release notes on the [What's New portal](#).

## Troubleshooting

If you encounter an issue while using SAP Java Buildpack, you can create an incident for your specific problem, using support component **BC-CP-CF-BLDP**.

## Related Information

### 4.1.3.5.1.1 Buildpacks

You can choose to deploy applications by using the following Java buildpacks:

- [SAP Java Buildpack 1 \[page 244\]](#) – an SAP-managed buildpack that supports Java 8, 11, 17, TomEE 7 and Tomcat 9
- [SAP Java Buildpack 2 \[page 248\]](#) – an SAP-managed buildpack that supports Java 17, 21 and Tomcat 10
- [Community Java Buildpack \[page 251\]](#) – an open-source product maintained by the [java-buildpack](#) 🐙 community

## 4.1.3.5.1.1.1 SAP Java Buildpack 1

SAP Java Buildpack is a Cloud Foundry buildpack for running JVM-based applications.

This buildpack supports the following runtimes:

- [TomEE 7 \[page 253\]](#)
- [Tomcat 9 \[page 256\]](#)
- [Java Main \[page 262\]](#)

### Usage

To use this buildpack, specify its name when deploying a Java application to the SAP BTP, Cloud Foundry environment:

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack
```

You can also use the buildpack attribute to specify it in the `manifest.yml` file:

```
---
applications:
- name: <APP_NAME>
  buildpacks:
  - sap_java_buildpack
  ...
```

or in the `mtad.yml` file of your archive:

```
...
modules:
- name: <APP_NAME>
  type: java.tomcat
  path: <path_to_archive>
  properties:
  ...
  parameters:
  ...
  memory: 512M
  buildpack: sap_java_buildpack
...
```

### Buildpack Versioning

The SAP BTP, Cloud Foundry environment provides four versions of SAP Java Buildpack 1 as part of its system buildpacks:

- [sap\\_java\\_buildpack](#) – Holds the latest available version of SAP Java Buildpack 1. All new features and fixes are provided with this version.
- [sap\\_java\\_buildpack\\_<version\\_latest>](#) – Holds the latest available version of SAP Java Buildpack 1. It's available for a limited timeframe (4 to 6 weeks).

- [sap\\_java\\_buildpack\\_<version\\_previous>](#) – This version used to be latest in the previous update of the SAP BTP, Cloud Foundry environment. It's available for a limited timeframe (4 to 6 weeks).
- [sap\\_java\\_buildpack\\_<version\\_before\\_previous>](#) – This version used to be latest before two updates of the SAP BTP, Cloud Foundry environment. It's available for a limited timeframe (4 to 6 weeks).

To check these versions, proceed as follows:

1. Log in to a particular SAP BTP region and subaccount. For example, if your region is **eu10**, run:

```
cf api https://api.cf.eu10.hana.ondemand.com
```

2. Then run:

```
cf buildpacks
```

## How to use versions of SAP Java Buildpack 1?

- **Option 1:** Use the default one – [sap\\_java\\_buildpack](#)  
You take advantage of all latest features and fixes in SAP Java Buildpack 1. This way, it's guaranteed that the buildpack is always available. The drawback in this case is the limited time for adoption, if it's needed. In such a scenario, applications can fall back to an older version temporarily to avoid any downtime.
- **Option 2:** Set a particular version – [sap\\_java\\_buildpack\\_<version\\_suffix>](#)  
Bear in mind that this version will only exist for a limited amount of time. This may lead to the situation where application restage is failing because the used version of the buildpack is no longer available. To avoid this, we recommend that you follow the updates of the buildpack and test your applications with its latest version. Developers should never allow their applications to run on an outdated buildpack version.

### Example:

Let's say that the latest version of SAP Java Buildpack 1 is **1.80.0**. Then, the output of the `cf buildpacks` command would be:

```
buildpack      position  enabled  locked  filename
sap_java_buildpack      1          true    false
sap_java_buildpack-1.80.0.zip
sap_java_buildpack_1_80      2          true    false
sap_java_buildpack-1.80.0.zip
sap_java_buildpack_1_79      3          true    false
sap_java_buildpack-1.79.0.zip
sap_java_buildpack_1_78      4          true    false
sap_java_buildpack-1.78.0.zip
```

When SAP Java Buildpack 1 is updated on the SAP BTP, Cloud Foundry environment from version **1.80.0** to **1.81.0**, the list will change to:

```
- You take advantage of all latest features and fixes in SAP
JavaBuildpack      position  enabled  locked  filename
sap_java_buildpack      1          true    false
sap_java_buildpack-1.81.0.zip
sap_java_buildpack_1_81      2          true    false
sap_java_buildpack-1.81.0.zip
sap_java_buildpack_1_80      3          true    false
sap_java_buildpack-1.80.0.zip
sap_java_buildpack_1_79      4          true    false
sap_java_buildpack-1.79.0.zip
```

This means that [sap\\_java\\_buildpack\\_1\\_78](#) will no longer be available for applications.

### Note

No fixes will be provided to older versions of the buildpack. Fixes, including security ones, will be part of the latest version.

## How to switch to a specific buildpack version?

To use `sap_java_buildpack_<version_suffix>`, specify its name when pushing an application to SAP BTP, Cloud Foundry environment:

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack_<version_suffix>
```

Alternatively, you can specify the buildpack in the `manifest.yml` file.

For example:

```
---
applications:
- name: myapp
  memory: 128M
  path: ./target/myapp.war
  instances: 1
  buildpacks:
  - sap_java_buildpack_1_80
```

You can do the same in the `mtad.yml` of your **mtar** archive:

```
...
modules:
- name: myapp
  type: java.tomcat
  path: ./target/myapp.war
  properties:
  ...
  parameters:
  ...
  memory: 512M
  buildpack: sap_java_buildpack_1_80
...
```

## Supported Java Versions

SAP Java Buildpack 1 (`sap_java_buildpack`) supports the following Java versions:

- Java **8** – default version when you use SAP JVM (*it provides a JRE and JDK with Java 8*)
- Java **11** – default version when you use SapMachine (*it provides a JRE with Java 11*)
- Java **17** – possible version when you use SapMachine (*it provides a JRE with Java 17*)

To learn how to configure your application to use SapMachine JRE and JDK, see: [SapMachine \[page 268\]](#)

## Components

SAP Java Buildpack 1 provides the following components in the application container (<APP\_ROOT\_DIR>/app/META-INF/.sap\_java\_buildpack):

- Runtimes – Tomcat 9 [page 256], TomEE 7 [page 253], and Java Main [page 262]
- SapMachine [page 268]
- Memory Calculator V2 [page 273] - default
- Memory Calculator V1 (SAP JVM Memory Calculator) [page 277] - optional
- SAP BTP Security Services Integration Libraries  – version 2.x

To check all the components regularly updated in the SAP Java Buildpack 1.x releases, see: [SAP Java Buildpack BOM !\[\]\(e21ed573f24a8266194504b214259f53\_img.jpg\)](#)

## Async Servlets

In the current version of the SAP Java Buildpack 1, the async servlets are *not supported*.

**Reason:** Some of the [valves !\[\]\(58825044599a067d4cdedde1c01503b1\_img.jpg\)](#) that SAP Java Buildpack 1 brings to Tomcat and TomEE 7 are not "async enabled".

## What's New

To see the latest news and updates about SAP Java Buildpack 1, regularly check the release notes on the [What's New portal](#).

## Troubleshooting

If you encounter an issue while using SAP Java Buildpack 1, you can:

- Search for your problem in our Guided Answers: [SAP Java Buildpack !\[\]\(eb6b70ee6082a17d1d78fb49d4e58420\_img.jpg\)](#)
- Create an incident for your specific problem, using support component **BC-CP-CF-BLDP**. To provide the necessary details, use the following template: [Initial Problem-Related Data !\[\]\(4ec57221df33d228679c71d3fe869704\_img.jpg\)](#)

See also:

- SAP Note: [3261748 !\[\]\(77a0e3ca78137234d57b13c2b219f2e9\_img.jpg\)](#) SapMachine is replacing OpenJDK 11 & 17 in java\_buildpack

## Java Tutorial

The following tutorial will guide you through creating a Java application in Cloud Foundry Command Line Interface (cf CLI), consuming Cloud Foundry services, and setting up authentication and authorization checks. See: [Create an Application with SAP Java Buildpack](#) 

### 4.1.3.5.1.1.2 SAP Java Buildpack 2

SAP Java Buildpack 2 is a Cloud Foundry buildpack for running SapMachine-based applications.

This buildpack supports the following runtimes:

- [Tomcat 10 \[page 259\]](#)
- [Java Main \[page 262\]](#)

## Usage

To use this buildpack, specify its name when deploying a Java (Jakarta) application to the SAP BTP, Cloud Foundry environment:

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack_jakarta
```

You can also use the buildpack attribute to specify it in the `manifest.yml` file:

```
---
applications:
- name: <APP_NAME>
  buildpacks:
  - sap_java_buildpack_jakarta
  ...
```

or in the `mtad.yml` file of your archive:

```
...
modules:
- name: <APP_NAME>
  type: java.tomcat
  path: <path_to_archive>
  properties:
  ...
  parameters:
  ...
  memory: 512M
  buildpack: sap_java_buildpack_jakarta
...
```

## Buildpack Versioning

The SAP BTP, Cloud Foundry environment provides four versions of SAP Java Buildpack 2 as part of its system buildpacks:

- [sap\\_java\\_buildpack\\_jakarta](#) – Holds the latest available version of SAP Java Buildpack 2. All new features and fixes are provided with this version.
- [sap\\_java\\_buildpack\\_jakarta\\_<version\\_latest>](#) – Holds the latest available version of SAP Java Buildpack 2. It's available for a limited timeframe (4 to 6 weeks).
- [sap\\_java\\_buildpack\\_jakarta\\_<version\\_previous>](#) – This version used to be latest in the previous update of the SAP BTP, Cloud Foundry environment. It's available for a limited timeframe (4 to 6 weeks).
- [sap\\_java\\_buildpack\\_jakarta\\_<version\\_before\\_previous>](#) – This version used to be latest before two updates of the SAP BTP, Cloud Foundry environment. It's available for a limited timeframe (4 to 6 weeks).

To check these versions, proceed as follows:

1. Log in to a particular SAP BTP region and subaccount. For example, if your region is **eu10**, run:

```
cf api https://api.cf.eu10.hana.ondemand.com
```

2. Then run:

```
cf buildpacks
```

### How to use versions of SAP Java Buildpack 2?

- **Option 1:** Use the default one – [sap\\_java\\_buildpack\\_jakarta](#)  
You take advantage of all latest features and fixes in SAP Java Buildpack 2. This way, it's guaranteed that the buildpack is always available. The drawback in this case is the limited time for adoption, if it's needed. In such a scenario, applications can fall back to an older version temporarily to avoid any downtime.
- **Option 2:** Set a particular version – [sap\\_java\\_buildpack\\_jakarta\\_<version\\_suffix>](#)  
Bear in mind that this version will only exist for a limited amount of time. This may lead to the situation where application restage is failing because the used version of the buildpack is no longer available. To avoid this, we recommend that you follow the updates of the buildpack and test your applications with its latest version. Developers should never allow their applications to run on an outdated buildpack version.

#### Example:

Let's say that the latest version of SAP Java Buildpack 2 is **2.10.0**. Then, the output of the `cf buildpacks` command would be:

```
buildpack      position  enabled  locked  filename
sap_java_buildpack_jakarta      1        true    false
sap_java_buildpack_jakarta-2.10.0.zip 2        true    false
sap_java_buildpack_jakarta_2_10      3        true    false
sap_java_buildpack_jakarta-2.9.0.zip  4        true    false
sap_java_buildpack_jakarta_2_8      4        true    false
sap_java_buildpack_jakarta-2.8.0.zip
```

When SAP Java Buildpack 2 is updated on the SAP BTP, Cloud Foundry environment from version **2.10.0** to **2.11.0**, the list will change to:

```
buildpack      position  enabled  locked  filename
```

sap_java_buildpack_jakarta	1	true	false
sap_java_buildpack_jakarta-2.11.0.zip			
sap_java_buildpack_jakarta_2_11	2	true	false
sap_java_buildpack_jakarta-2.11.0.zip			
sap_java_buildpack_jakarta_2_10	3	true	false
sap_java_buildpack_jakarta-2.10.0.zip			
sap_java_buildpack_jakarta_2_9	4	true	false
sap_java_buildpack_jakarta-2.9.0.zip			

This means that `sap_java_buildpack_jakarta_2_8` will no longer be available for applications.

### Note

No fixes will be provided to older versions of the buildpack. Fixes, including security ones, will be part of the latest version.

## How to switch to a specific buildpack version?

To use `sap_java_buildpack_jakarta_<version_suffix>`, specify its name when pushing an application to the SAP BTP, Cloud Foundry environment:

```
cf push -f <PATH_TO_APP_MANIFEST> -b sap_java_buildpack_jakarta_<version_suffix>
```

Alternatively, you can specify the buildpack in the `manifest.yml` file.

For example:

```
---
applications:
- name: myapp
  memory: 128M
  path: ./target/myapp.war
  instances: 1
  buildpacks:
  - sap_java_buildpack_jakarta_2_9
```

You can do the same in the `mtad.yml` of your **mtar** archive:

```
...
modules:
- name: myapp
  type: java.tomcat
  path: ./target/myapp.war
  properties:
  ...
  parameters:
  ...
  memory: 512M
  buildpack: sap_java_buildpack_jakarta_2_9
...
```

## Supported Java Versions

SAP Java Buildpack 2 (`sap_java_buildpack_jakarta`) supports the following Java versions:

- Java **17** – default version. You can obtain it by using SapMachine 17 (*it provides a JRE with Java 17*)
- Java **21** – you can obtain it by using SapMachine 21 (*it provides a JRE with Java 21*)

To learn how to configure your application to use SapMachine JRE and JDK, see: [SapMachine \[page 268\]](#)

## Components

SAP Java Buildpack 2 provides the following components in the application container (<APP\_ROOT\_DIR>/app/META-INF/.sap\_java\_buildpack\_jakarta):

- Runtimes – [Tomcat 10 \[page 259\]](#) and [Java Main \[page 262\]](#)
- [SapMachine \[page 268\]](#)
- [Memory Calculator V2 \[page 273\]](#)
- [SAP BTP Security Services Integration Libraries](#) – version 3.x

To check all the components regularly updated in the SAP Java Buildpack 2.x releases, see: [SAP Java Buildpack BOM](#)

## What's New

To see the latest news and updates about SAP Java Buildpack 2, regularly check the release notes on the [What's New portal](#).

## Troubleshooting

If you encounter an issue while using SAP Java Buildpack 2, you can:

- Search for your problem in our Guided Answers: [SAP Java Buildpack](#)
- Create an incident for your specific problem, using support component **BC-CP-CF-BLDP**. To provide the necessary details, use the following template: [Initial Problem-Related Data](#)

### 4.1.3.5.1.1.3 Community Java Buildpack

Find SAP-managed Cloud Foundry Java components and updates that belong to the community [java-buildpack](#).

## Buildpack Versioning

The SAP BTP, Cloud Foundry environment provides one recent version of `java_buildpack` as part of its system buildpacks. To check this version, proceed as follows:

1. Log in to a particular SAP BTP region and subaccount. For example, if your region is **eu10**, run:

```
cf api https://api.cf.eu10.hana.ondemand.com
```

2. Then run:

```
cf buildpacks
```

To learn about changes in Node.js versions and features, regularly check the latest [buildpack releases](#) in the GitHub community page.

## Updates

- **SapMachine** – as of [v4.55](#) of the `java-buildpack`, SAP provides SapMachine 11 and 17 instead of OpenJDK 11 and 17 in the offline `java_buildpack`.  
See SAP Note: [3261748](#) *SapMachine is replacing OpenJDK 11 & 17 in java\_buildpack*

### 4.1.3.5.1.2 Runtimes and Containers

Find out which application runtimes and containers you can use, depending on the Java buildpack your application is using.

- [TomEE 7 \[page 253\]](#) – use this runtime only with SAP Java Buildpack 1
- [Tomcat 9 \[page 256\]](#) – use this runtime only with SAP Java Buildpack 1
- [Tomcat 10 \[page 259\]](#) – use this runtime only with SAP Java Buildpack 2
- [Java Main \[page 262\]](#) – use the Java Main container with all Java buildpacks

#### ⚠ Restriction

Currently, SAP Java Buildpack 2 does not support Apache TomEE. For this reason, we've temporarily forbidden deploying Java applications running on TomEE. That means, if you set **tomee** as a target runtime, your application will fail during the *staging* phase of the `cf push` command execution.

This restriction will be revoked when we provide a compatible Apache TomEE version for SAP Java Buildpack 2.

## Related Information

## 4.1.3.5.1.2.1 TomEE 7

Web applications deployed with SAP Java Buildpack 1 can run in an TomEE 7 container, which is compatible with Apache Tomcat 8.5 and 9.

Applications can explicitly define the target application container by using the `TARGET_RUNTIME` environment variable in the application's `manifest.yml` file

### ❁ Example

```
---
applications:
- name: myapp
  ...
  env:
    TARGET_RUNTIME: tomee7
```

## Provided APIs

The **tomee7** application runtime container provides the following standard APIs:

Runtime	Full Name	Supported Specifications
tomee7	<b>Apache TomEE 7</b> ( <i>Java EE 7 Web Profile</i> )	Java Servlet 3.1 Java Server Pages (JSP) 2.3 Java Expression Language (EL) 3.0 Java WebSocket 1.1 Java Standard Tag Library (JSTL) 1.2 Java RESTful Web Services (JAX-RS) 2.0 Java Server Faces (JSF) 2.2 Java Debugging Support for Other Languages 1.0 Java Enterprise Beans (EJB) Lite 3.2 Java Transactions API (JTA) 1.2 Java Persistence API (JPA) 2.1 Java Bean Validation 1.1 Java Managed Beans 1.0 Java Interceptors 1.2 Java Annotations 1.2 Java Dependency Injection 1.0 Java Contexts and Dependency Injection 1.1
	<b>Note</b> Only relevant for SAP Java Buildpack 1	For a full list of specification versions, see: <a href="#">Apache TomEE 7</a> 🐘

## Customizing the SAP Java Buildpack Defaults

SAP Java Buildpack 1 provides some default configurations for the Apache TomEE 7 application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature.

Below is a list of all the placeholders that can be customized by the application, along with their default values:

Placeholder	Description	Default Value
<code>connector.maxHttpHeaderSize</code>	The maximum size of the request and response HTTP header, specified in bytes	<b>8192</b>
<code>connector.maxThreads</code>	The maximum number of request processing threads to be created by this Connector, which therefore determines the maximum number of simultaneous requests that can be handled	<b>200</b>
<code>connector.allowTrace</code>	A Boolean value that enables or disables the TRACE HTTP method	<b>false</b>

To configure the HTTP header size, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomEE7/conf/server.xml':
  { 'connector.maxHttpHeaderSize': 1024 } ]"
```

To configure the maximum number of threads, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomEE7/conf/server.xml':
  { 'connector.maxThreads': 800 } ]"
```

To enable the TRACE HTTP method, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomEE7/conf/server.xml':
  { 'connector.allowTrace': true } ]"
```

## Configure the maximum number of active sessions

SAP Java Buildpack 1 provides the default configurations for unlimited sessions for the Apache TomEE 7 application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature. To limit the number of active sessions, set the `maxActiveSessions` attribute on a `Manager` element. For example:

### ❁ Example

```
<Context>
  <Manager maxActiveSessions="500" />
</Context>
```

## Configure the session timeout value

To set session timeout value of active sessions, set the `<session-config>` tag in the application's `web.xml` file:

### ❁ Example

```
<session-config>
  <session-timeout>1</session-timeout>
</session-config>
```

## Configure the context path attribute

The default value of context path in `server.xml` is "" (Empty String). You can override this default value by using `app_context_root` in the application's `manifest.yml` file. For example:

### ❁ Example

```
...
  env:
    JBP_CONFIG_TOMCAT: "[tomcat7:{app_context_root: test_context_path}]"
  ...
```

## 4.1.3.5.1.2.2 Tomcat 9

By default, web applications pushed with SAP Java Buildpack 1 are running in an Apache Tomcat 9 container.

Applications can explicitly define the target application container by using the `TARGET_RUNTIME` environment variable in the application's `manifest.yml` file.

### ❁ Example

```
---
applications:
- name: myapp
  ...
  env:
    TARGET_RUNTIME: tomcat
```

## Provided APIs

The **tomcat** application runtime container provides the following standard APIs:

Runtime	Full Name	Supported Specification Version
tomcat	<b>Apache Tomcat 9.0</b>	Java 8 and later
	<b>Note</b> Only relevant for SAP Java Buildpack 1	Java Servlets 4.0
		Java Server Pages (JSP) 2.3
		Expression Language (EL) 3.0
		Debugging Support for Other Languages 1.0
		Java API for WebSocket 1.1
		Java Authentication Service Provider Interface for Containers (JASPIC) 1.1
		For more information, see <a href="#">Apache Tomcat: Tomcat Versions</a> ➔

## Customizing the SAP Java Buildpack Defaults

SAP Java Buildpack 1 provides some default configurations for the Apache Tomcat application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature.

Below is a list of all the placeholders than can be customized by the application, along with their default values:

Placeholder	Description	Default Value
<code>connector.maxHttpHeaderSize</code>	The maximum size of the request and response HTTP header, specified in bytes	<b>8192</b>
<code>connector.maxThreads</code>	The maximum number of request processing threads to be created by this Connector, which therefore determines the maximum number of simultaneous requests that can be handled	<b>200</b>
<code>connector.allowTrace</code>	A Boolean value that enables or disables the TRACE HTTP method	<b>false</b>

To configure the HTTP header size, use:

```
env:  
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':  
  { 'connector.maxHttpHeaderSize': 1024 } ]"
```

To configure the maximum number of threads, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':
  { 'connector.maxThreads': 800} ]"
```

To enable the TRACE HTTP method, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':
  { 'connector.allowTrace': true} ]"
```

## Configure the maximum number of active sessions

SAP Java Buildpack 1 provides the default configurations for unlimited sessions for the Apache Tomcat application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature. To limit the number of active sessions, set the `maxActiveSessions` attribute on a `Manager` element. For example:

### ❁ Example

```
<Context>
  <Manager maxActiveSessions="500" />
</Context>
```

## Configure the session timeout value

To set session timeout value of active sessions, set the `<session-config>` tag in the application's `web.xml` file:

### ❁ Example

```
<session-config>
  <session-timeout>1</session-timeout>
</session-config>
```

## Configure the context path attribute

The default value of context path in `server.xml` is "" (Empty String). You can override this default value by using `app_context_root` in the application's `manifest.yml` file. For example:

### ❁ Example

```
...
env:
  JBP_CONFIG_TOMCAT: "[tomcat:{app_context_root: test_context_path}]"
```

...

## Configure the cookie processor

In Tomcat 8.5.84, a custom cookie processor has been created, based on the RFC 6265 Cookie Processor. If the `PROCESS_COOKIE` environment variable is set to **true**, then this new cookie processor will override the default one.

**Reason:** In Tomcat Apache 8.5.84, the date format used with the `expires` attribute of HTTP cookies was corrected to be compliant with RFC 6265. A single space rather than a single dash is now used to separate the day, month, and year components. For more information, see [Apache Tomcat: Tomcat 8 Changelog](#) 📄

The purpose of the new cookie processor is to set the `Cookie Expire` date to format with '-' (*dash*) delimiter instead of ' ' (*space*) so that no errors would be thrown.

Below is a sample error message thrown when **not** using the new customization:

### ❁ Example

```
Sample error: "Invalid cookie header: "set-cookie: username=John; Max-Age=21; Expires=Thu, 17 Aug 2023 13:31:55 GMT". Invalid 'expires' attribute: Thu, 17 Aug 2023 13:31:55 GMT "
```

## 4.1.3.5.1.2.3 Tomcat 10

By default, web applications pushed with SAP Java Buildpack 2 are running in an Apache Tomcat 10 container.

Applications can explicitly define the target application container by using the `TARGET_RUNTIME` environment variable in the application's `manifest.yml` file.

### ❁ Example

```
---
applications:
- name: myapp
  ...
  env:
    TARGET_RUNTIME: tomcat
```

## Provided APIs

The **tomcat** application runtime container provides the following standard APIs:

Runtime	Full Name	Supported Specification Version
tomcat	<b>Apache Tomcat 10.1.x</b>	Java 11 and later
	<b>Note</b> Only relevant for SAP Java Buildpack 2	Java Servlets 6.0
		Java Server Pages (JSP) 3.1
		Expression Language (EL) 5.0
		Debugging Support for Other Languages 2.0
		Java API for WebSocket 2.1
		Java Authentication Service Provider Interface for Containers (JASPIC) 3.0
		For more information, see <a href="#">Apache Tomcat: Tomcat Versions</a>

## Customizing the SAP Java Buildpack Defaults

SAP Java Buildpack 2 provides some default configurations for the Apache Tomcat application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature.

Below is a list of all the placeholders than can be customized by the application, along with their default values:

Placeholder	Description	Default Value
<code>connector.maxHttpHeaderSize</code>	The maximum size of the request and response HTTP header, specified in bytes	<b>8192</b>
<code>connector.maxThreads</code>	The maximum number of request processing threads to be created by this Connector, which therefore determines the maximum number of simultaneous requests that can be handled	<b>200</b>
<code>connector.allowTrace</code>	A Boolean value that enables or disables the TRACE HTTP method	<b>false</b>

To configure the HTTP header size, use:

```
env:  
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':  
  { 'connector.maxHttpHeaderSize': 1024 } ]"
```

To configure the maximum number of threads, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':
  { 'connector.maxThreads': 800} ]"
```

To enable the TRACE HTTP method, use:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/server.xml':
  { 'connector.allowTrace': true} ]"
```

## Configure the maximum number of active sessions

SAP Java Buildpack 2 provides the default configurations for unlimited sessions for the Apache Tomcat application container. They can be customized by the application with the [Resource Configuration \[page 283\]](#) feature. To limit the number of active sessions, set the `maxActiveSessions` attribute on a `Manager` element. For example:

### ❁ Example

```
<Context>
  <Manager maxActiveSessions="500" />
</Context>
```

## Configure the session timeout value

To set session timeout value of active sessions, set the `<session-config>` tag in the application's `web.xml` file:

### ❁ Example

```
<session-config>
  <session-timeout>1</session-timeout>
</session-config>
```

## Configure the context path attribute

The default value of context path in `server.xml` is "" (Empty String). You can override this default value by using `app_context_root` in the application's `manifest.yml` file. For example:

### ❁ Example

```
...
env:
  JBP_CONFIG_TOMCAT: "[tomcat:{app_context_root: test_context_path}]"
```

...

## Configure the cookie processor

In Tomcat 8.5.84, a custom cookie processor was created, based on the RFC 6265 Cookie Processor. If the `PROCESS_COOKIE` environment variable is set to **true**, then this new cookie processor will override the default one.

**Reason:** In Tomcat Apache 8.5.84, the date format used with the `expires` attribute of HTTP cookies was corrected to be compliant with RFC 6265. A single space rather than a single dash is now used to separate the day, month, and year components. For more information, see [Apache Tomcat: Tomcat 8 Changelog](#) 🗨️

The purpose of the new cookie processor is to set the `Cookie Expire` date to format with '-' (*dash*) delimiter instead of ' ' (*space*) so that no errors would be thrown.

Below is a sample error message thrown when **not** using the new customization:

### ❄️ Example

```
Sample error: "Invalid cookie header: "set-cookie: username=John; Max-Age=21; Expires=Thu, 17 Aug 2023 13:31:55 GMT". Invalid 'expires' attribute: Thu, 17 Aug 2023 13:31:55 GMT "
```

## 4.1.3.5.1.2.4 Java Main

You can create a Java application that starts its own runtime. This allows the usage of frameworks and Java runtimes, such as Spring Boot, Jetty, Undertow, or Netty.

## Prerequisites

- You are **not** using the [Resource Configuration \[page 283\]](#) feature of the buildpack.

### 📌 Note

The resource configurations needed for the database connection are not applicable for Java Main applications. For more information about database connections, see: [Configuring a Database Connection \[page 297\]](#)

## Context

In this section, applications like this are referred as *Java Main applications*. The application container provided by SAP Java/Jakarta Buildpack for running Java Main applications is referred as *Java Main container*.

## Procedure

1. Make sure your built JAR archive is configured properly.

Regardless of the tool you use to build your Java application, you have to make sure that the following tasks are performed:

- a. You have built a JAR archive.
- b. You have specified a main class in the `META-INF/MANIFEST.MF` file of the JAR archive.

### Sample Code

Manifest.MF

```
Manifest-Version: 1.0
Archiver-Version: Plexus Archiver
Built-By: p1234567
Created-By: Apache Maven 3.3.3
Build-Jdk: 1.8.0_45
Main-Class: com.company.xs.java.main.Controller
```

- c. You have packaged all your dependent libraries in the JAR file, also known as creating an [uber JAR](#) or a *flat JAR*.

If you are using Maven as your build tool, you can use the `maven-shade-plugin` to perform the above tasks.

### Sample Code

Sample configuration for the `maven-shade-plugin`

```
<build>
<finalName>java-main-sample</finalName>
<plugins>
  <plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-shade-plugin</artifactId>
    <version>2.4.3</version>
    <configuration>
      <createDependencyReducedPom>>false</createDependencyReducedPom>
      <filters>
        <filter>
          <artifact>*:*</artifact>
          <excludes>
            <exclude>META-INF/*.SF</exclude>
            <exclude>META-INF/*.DSA</exclude>
            <exclude>META-INF/*.RSA</exclude>
          </excludes>
        </filter>
      </filters>
    </configuration>
  </plugin>
</plugins>
<executions>
  <execution>
```

```

    <phase>package</phase>
    <goals>
      <goal>shade</goal>
    </goals>
    <configuration>
      <transformers>
        <transformer
implementation="org.apache.maven.plugins.shade.resource.ServicesResourceTra
nsformer" />
        <transformer
implementation="org.apache.maven.plugins.shade.resource.ManifestResourceTra
nsformer">
          <manifestEntries>
            <Main-Class>com.sap.xs.java.main.Controller</Main-Class>
          </manifestEntries>
        </transformer>
      </transformers>
    </configuration>
  </execution>
</executions>
</plugin>
</plugins>
</build>

```

2. Configure the `manifest.yml`.

To be able to push the Java Main application, you need to specify the path to the `.jar` archive in the `manifest.yml` file.

#### Sample Code

`manifest.yml`

```

---
applications:
- name: java-main
  memory: 128M
  path: ./target/java-main-sample.jar
  instances: 1

```

3. (Optional) If you use SAP HANA JDBC, we recommend that you include the dependent JAR files in the uber JAR. Then refer these files, as a space separated list, in the `Class-Path` header field of the `MANIFEST.MF` file. For example:

#### Sample Code

```

Class-Path: jar1-name jar2-name directory-name/jar3-name

```

4. Deploy the application on Cloud Foundry. Execute:

```

cf push

```

## Example

To create a Java Main application that is using its own runtime, proceed as follows:

1. Create an application, named `sample_main`. Use Spring Boot for that purpose.

2. Navigate to the `sample_main` directory of the application, using the command line tool, and build it. To do that, execute:

```
mvn clean install
```

3. After the successful build, check that the `sample_main` directory of the application contains a **sample\_main.jar** file.
4. Open the **sample\_main.jar** file and check that the `META-INF/MANIFEST.MF` file contains the `Main-Class` header, whose value is the name of the main class.
5. Add the path to the JAR file in the **manifest.yml** file.  
You need to do this to make sure that the application can be pushed to the Cloud Foundry environment. For that purpose, add the following line in the **manifest.yml** file:

```
path: ./target/sample_main.jar
```

6. Finally, deploy the Java Main application. Execute:

```
cf push sample_main
```

### 4.1.3.5.1.3 Customizing the Java Virtual Machine (JVM) Settings

- [Java Options \[page 265\]](#)
- [Java Memory Assistant \[AWS, Azure, or GCP Regions\] \[page 266\]](#)
- [Java Out Of Memory Behavior \[page 267\]](#)
- [Using an Agent \[page 268\]](#)
- [SapMachine \[page 268\]](#)
- [Memory Calculator \[page 272\]](#)

#### 4.1.3.5.1.3.1 Java Options

You can configure the Java properties by defining the `JBP_CONFIG_JAVA_OPTS` environment variable.

Defining the `JBP_CONFIG_JAVA_OPTS` environment variable in the `manifest.yml` file of the application.

##### Sample Code

manifest.yml

```
---
applications:
- name: <app-name>
  memory: 512M
  ...
  env:
    JBP_CONFIG_JAVA_OPTS: 'java_opts: '-DtestJBPCConfig=^%PATH^%
-DtestJBPCConfig1="test test" -DtestJBPCConfig2="%PATH%"'''
```

Defining the JBP\_CONFIG\_JAVA\_OPTS environment variable by using the `cf set-env` command of the Cloud Foundry Command Line Interface (cf CLI).

```
cf set-env myapp JBP_CONFIG_JAVA_OPTS "[java_opts: '-DtestJBPCConfig=^%PATH^%  
-DtestJBPCConfig1=\"test test\" -DtestJBPCConfig2=\"^%PATH^%\"']"
```

## Escaping Strings

### When defining the JBP\_CONFIG\_JAVA\_OPTS in the manifest.yml file

A single quote `'` is used to enclose the JBP\_CONFIG\_JAVA\_OPTS environment variable in the manifest.yml file. Strings containing the following characters must be quoted: `:`, `{`, `}`, `[`, `]`, `,`, `&`, `*`, `#`, `?`, `|`, `-`, `<`, `>`, `=`, `!`, `%`, `@`, `\`.

When a single quote `'` is used, other single quotes `'` in the string must be escaped by doubling it `''`.

### When defining the JBP\_CONFIG\_JAVA\_OPTS by using the `cf set-env` command

The string must be enclosed in the double quotes `"`. If there are other double quotes in the string, you have to escape them using the backslash `\`.

### When defining java options with values containing spaces

In case you need to specify a option value, which has blank spaces in it, you need to surround it with quotes `"`. If the value contains special characters like for example `$`, you have to escape them using the escape character specific for the operating system shell where the application is pushed. In the example below the `$` in the `$PATH` string is escaped using the `\` escape character for Linux. Otherwise, if the `$` sign is not escaped, the value of the variable `PATH` is substituted in the property value.

#### Sample Code

manifest.yml

```
---  
applications:  
- name: <app-name>  
  memory: 512M  
...  
  env:  
    JBP_CONFIG_JAVA_OPTS: 'java_opts: ''-DtestJBPCConfig=\$PATH  
-DtestJBPCConfig1="test test" -DtestJBPCConfig2="\$PATH"'''
```

## 4.1.3.5.1.3.2 Java Memory Assistant [AWS, Azure, or GCP Regions]

### Note

The content in this section is not relevant for China (Shanghai) and Government Cloud (US) regions.

Java Memory Assistant is a Java agent that generates heap dumps based on preconfigured conditions in the memory usage of the application. See: [Java Memory Assistant](#) ↗

### Note

This public repository went out of maintenance on **Sept 21, 2023**. Nevertheless, its latest version [0.5.0](#) ↗ is working fine so you can keep using it.

When enabled in the buildpack, the agent generates two files – `*.hprof` (heap dump) and `*.addons`, when the configured memory limits are met.

The `*.addons` file contains:

- Command-line parameters
- Implemented interfaces for the classes
- Information (name) about transient fields for the classes
- Class and metaspace statistics
- Stack traces of the last OOM errors

See also: [Java Memory Assistant Framework](#) ↗

## 4.1.3.5.1.3.3 Java Out Of Memory Behavior

SAP Java Buildpack prints a histogram of the heap to the logs when the JVM encounters a terminal failure.

### Output Code

```
ERR Stopping VM due to OutOfMemoryError
ERR Resource exhaustion event: the JVM was unable to allocate memory from the
heap.
ERR ResourceExhausted! (1/0)
OUT | Instance Count | Total Bytes | Class
Name |
OUT | 30130 | 5556616 |
[C |
OUT | 866 | 2485600 |
[B |
OUT | 29215 | 701160 | Ljava/lang/
String;
OUT | 3971 | 449528 | Ljava/lang/
Class;
OUT | 9998 | 319936 | Ljava/util/
HashMap$Node;
OUT | 3624 | 318912 | Ljava/lang/reflect/
Method;
OUT | 6429 | 205728 | Ljava/util/concurrent/
ConcurrentHashMap$Node;
OUT | 2821 | 171472 | [Ljava/lang/

[J |
OUT | 750 | 111096 | [Ljava/util/
HashMap$Node;
OUT | 5618 | 89888 | Ljava/lang/
Object;
OUT | 1054 | 74048 | [Ljava/lang/
String;
```

```

OUT | 696          | 62552          |
[I
OUT | 59           | 51920          | [Ljava/util/concurrent/
ConcurrentHashMap$Node;|
OUT | 1063          | 51024          | Ljava/util/
HashMap;
OUT | 854           | 40992          | Lorg/apache/tomcat/util/modeler/
AttributeInfo;|
...

```

This functionality is **activated** by default.

If you want to deactivate it, add property `-XX:+ExitVMOnOutOfMemoryError` through the `JBP_CONFIG_JAVA_OPTS` property in the application's `manifest.yml` file:

#### Sample Code

```
JBP_CONFIG_JAVA_OPTS: 'false, java_opts: '-XX:+ExitVMOnOutOfMemoryError''
```

See also: [Cloud Foundry jvmskill](#) ➔

### 4.1.3.5.1.3.4 Using an Agent

You can use any agent with the SAP Java Build pack. The agent must be included in the `.jar` or `.war` archive of your application. The SAP Java Build pack extracts the agent when the application is deployed. You can check if the agent is extracted to the expected location by using the `cf ssh` command.

To use an agent with the SAP Java Build pack, set the `<JBP_CONFIG_JAVA_OPTS>` environment variable as shown in the following example:

```

env:
  JBP_CONFIG_JAVA_OPTS: 'java_opts: "-javaagent:<PathToYourAgent>" '

```

The Java agent is platform-agnostic, but must be compatible to the version of the JVM you are using.

You can also use a native agent. Since a native agent is a dynamic library, it must be compatible with the architecture of the platform. For Cloud Foundry, this is Linux x86\_64. As the application developer you must make sure that the correct agent is used and apply updates whenever they are needed. To use a native agent, set the `<JBP_CONFIG_JAVA_OPTS>` as follows:

```

env:
  JBP_CONFIG_JAVA_OPTS: 'java_opts: "-agentpath:<PathToYourAgent>" '

```

### 4.1.3.5.1.3.5 SapMachine

SapMachine is an alternative to SAP JVM, and provides a Java Runtime Environment (JRE) with Java 11 and 17.

SapMachine works with the following application containers:

- [TomEE 7 \[page 253\]](#)
- [Tomcat 9 \[page 256\]](#)
- [Tomcat 10 \[page 259\]](#)
- [Java Main \[page 262\]](#)

### ⚠ Caution

#### Only relevant to SAP Java Buildpack 1:

Bear in mind that TomEE 7 supports only Java 7 and 8. Thus, even if your TomEE 7 application runs successfully with SapMachine JRE 17, at some point it might crash. Also, TomEE 7 has already [reached end of life](#) 🦋. See: [Discontinued TomEE versions](#) 🦋.

## Activation Using JRE

### SapMachine 11

To activate SapMachine **JRE** in SAP Java Buildpack, you have to add the following environment variable:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
  ...
```

This will make your application use the SapMachine JRE 11, bundled with SAP Java Buildpack.

Alternatively, you can direct the buildpack to download any published SapMachine patch version by adding additional configuration parameters, like the following:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: '{ use_offline_repository: false, version:
11.0.13 }'
  ...
```

Setting `use_offline_repository` to `false` will direct the buildpack to attempt a download of the SapMachine JRE of version "`<version>`" from the GitHub asset repository. This will only work if your Cloud Foundry instance has access to [GitHub: SapMachine](#) 🦋.

You can also point to the major version of the SapMachine JRE 11, in order to always get the latest patch versions. In this case, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
```

```
JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
JBP_CONFIG_SAP_MACHINE_JRE: "{ version: 11.+ }"
```

## SapMachine 17

Use environment variable JBP\_CONFIG\_SAP\_MACHINE\_JRE in analogical way. For example:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: '{ version: 17.0.10 }'
  ...
```

To point to the major version of the SapMachine JRE 17, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: "{ version: 17.+ }"
```

## SapMachine 21

Use environment variable JBP\_CONFIG\_SAP\_MACHINE\_JRE in analogical way. For example:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: '{ version: 21.0.2 }'
  ...
```

To point to the major version of the SapMachine JRE 21, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: "{ version: 21.+ }"
```

## Activation Using JDK

To use a full SapMachine **JDK**, use the following configurations:

```
---
```

```

applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
  ...

```

To specify the JDK version, use environment variable JBP\_CONFIG\_SAP\_MACHINE\_JDK. For example:

## SapMachine 11

```

---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: '{ version: 11.0.22 }'
  ...

```

To point to the major version of the SapMachine JDK 11, specify it the following way:

```

---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "{ version: 11.+ }"

```

## SapMachine 17

Use environment variable JBP\_CONFIG\_SAP\_MACHINE\_JDK in analogical way. For example:

```

---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: '{ version: 17.0.10 }'
  ...

```

To point to the major version of the SapMachine JDK 17, specify it the following way:

```

---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "{ version: 17.+ }"

```

## SapMachine 21

Use environment variable JBP\_CONFIG\_SAP\_MACHINE\_JDK in analogical way. For example:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: '{ version: 21.0.2 }'
  ...
```

To point to the major version of the SapMachine JDK 21, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "{ version: 21.+ }"
```

#### ⚠ Restriction

As the SapMachine JDK is not bundled into the SAP Java Buildpack, if you want to use SapMachine JDK 11, 17 or 21, you have to download them from the [GitHub project](#) as an online component.

## Related Information

<https://sap.github.io/SapMachine/>

### 4.1.3.5.1.3.6 Memory Calculator

The memory calculator provides a mechanism to fine-tune the Java Virtual Machine (JVM) memory for an application. Its goal is to ensure that applications perform well while not exceeding a container's memory limit.

Below you can find which memory calculators are used in the relevant Java buildpacks.

## SAP Java Buildpack 1

This buildpack supports two memory calculator versions:

- [Memory Calculator V2 \[page 273\]](#) – activated by default.

- [Memory Calculator V1 \(SAP JVM Memory Calculator\) \[page 277\]](#) – this is an optional memory calculator. You can activate it by adding the following environment variable:

```
---
applications:
- name: <app-name>
  ...
  env:
    MEMORY_CALCULATOR_V1: true
  ...
```

## SAP Java Buildpack 2

This buildpack supports only [Memory Calculator V2 \[page 273\]](#), which is the same as the one provided by the community Java Buildpack. See: [\(GitHub\) Java Buildpack Memory Calculator](#) 🐱

### 📄 Note

Memory Calculator V1 is deprecated (not available) for SAP Java Buildpack 2. If you try to activate it by setting the MEMORY\_CALCULATOR\_V1 environment variable, an error message will be thrown.

## Community Java Buildpack

This buildpack uses its default and only memory calculator: [\(GitHub\) Java Buildpack Memory Calculator](#) 🐱

## Related Information

[Buildpacks \[page 243\]](#)

### 4.1.3.5.1.3.6.1 Memory Calculator V2

#### Manual Memory Customization

Customize the memory options by using the JBP\_CONFIG\_JAVA\_OPTS environment variable:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_JAVA_OPTS: "[java_opts: '-Xms144M -Xss3M -Xmx444444K
-XX:MetaspaceSize=66666K -XX:MaxMetaspaceSize=88888K']"
```

## Automatic Memory Customization

The `memory_calculator_v2` section in the `config/sapjvm.yml` [page 278] configuration file has three sizing options:

- `stack_threads` – an estimate of the number of threads that will be used by the application
- `class_count` – an estimate of the number of classes that will be loaded
- `headroom` – percentage of total memory available that is unallocated to cover JVM overhead. Maximum recommended value for headroom is **10**. Default value (if not specified) is **0**.

Depending on which Java version you use (8 or 11), you can customize these three memory options by using the relevant environment variables:

- `JBP_CONFIG_SAPJVM`
- `JBP_CONFIG_SAP_MACHINE_JRE`
- `JBP_CONFIG_SAP_MACHINE_JDK`

## Java 8

### Note

Only relevant for SAP Java Buildpack 1

If you need JRE with Java 8, you have to use SAP JVM. Customize your memory options as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_SAPJVM: "[memory_calculator_v2: {stack_threads: 266, class_count:
1001, headroom: 5}]"
```

## Java 11

### Note

Only relevant for SAP Java Buildpack 1

If you need JRE with Java 11, you have to use SapMachine 11. Customize your memory options as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
```

```
JBP_CONFIG_SAP_MACHINE_JRE: "[version: 11.+, memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

If you want to point to the SapMachine JDK component, you need to provide a specific version as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 11.0.22, memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

You can also point to the major version of the SapMachine JDK, in order to always get the latest patch versions. In this case, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 11.+, memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

## Java 17

### Note

Relevant for all Java buildpacks

If you need JRE with Java 17, you use SapMachine 17. Customize your memory options as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: "[version: 17.+, memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

If you want to point to the SapMachine JDK component, you need to provide a specific version as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 17.0.10, memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

You can also point to the major version of the SapMachine JDK, in order to always get the latest patch versions. In this case, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 17.+ , memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

## Java 21

### 📌 Note

Only relevant for SAP Java Buildpack 2

If you need JRE with Java 21, you use SapMachine 21. Customize your memory options as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
    JBP_CONFIG_SAP_MACHINE_JRE: "[version: 21.+ , memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

If you want to point to the SapMachine JDK component, you need to provide a specific version as follows:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 21.0.2 , memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

You can also point to the major version of the SapMachine JDK, in order to always get the latest patch versions. In this case, specify it the following way:

```
---
applications:
- name: <app-name>
  ...
  env:
    JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jdk.SAPMachineJDK']"
    JBP_CONFIG_SAP_MACHINE_JDK: "[ version: 21.+ , memory_calculator_v2:
{stack_threads: 266, class_count: 1001, headroom: 5}]"
```

### 4.1.3.5.1.3.6.2 Memory Calculator V1 (SAP JVM Memory Calculator)

This memory calculator is optional, and you can activate it by adding the following environment variable:

```
---
applications:
- name: <app-name>
  ...
  env:
    MEMORY_CALCULATOR_V1: true
  ...
```

#### ⚠ Restriction

Memory Calculator V1 is only available for [SAP Java Buildpack 1 \[page 244\]](#).

If you try to activate it for [SAP Java Buildpack 2 \[page 248\]](#), an error will be thrown.

## General Information

When pushing applications to Cloud Foundry, application developers could specify the memory limit of the application.

The main goal of the SAP JVM Memory Calculator is to provide mechanism to fine tune the Java Virtual Machine (JVM) in terms of restricting the JVM's memory to grow below this memory limit.

There are three memory types, which can be sized - **heap**, **metaspace** and **stack**. For each memory type there is a command-line option, which must be passed to the JVM:

- The initial and maximum size of the *heap* memory is controlled by the `-Xms` and `-Xmx` options, respectively.
- The initial and maximum size of the *metaspace* memory is controlled by the `-XX:MetaspaceSize` and `-XX:MaxMetaspaceSize` options, respectively.
- The size of the *stack* is controlled by the `-Xss` option.

## Default Settings

The SAP Java Buildpack is delivered with a default built-in configuration of the memory sizing options in YAML format - `config/sapjvm.yml` (path related to the buildpack archive). That configuration file is parsed during

application staging, and the memory configuration specified in it is used for calculating the memory sizes of the *heap*, *metaspace* and *stack*.

The default structure of the `config/sapjvm.yml` configuration file is the following:

### Sample Code

`config/sapjvm.yml`

```
---
repository_root: "{default.repository.root}/sapjvm/{platform}/{architecture}"
version: +
default_keystore_pass: changeit
memory_calculator:
  version: 1.+
  repository_root: "{default.repository.root}/memory-calculator/{platform}/
  {architecture}"
memory_sizes:
  heap:
  metaspace: 64m..
  stack:
  native:
memory_heuristics:
  heap: 75
  metaspace: 10
  stack: 5
  native: 10
memory_initials:
  heap: 100%
  metaspace: 100%
memory_settings:
  codecache:
  directmemory:
memory_calculator_v2:
  version: 1.+
  repository_root: "{default.repository.root}/memory-calculator-v2/{platform}/
  {architecture}"
  class_count:
  stack_threads: 250
```

The **memory\_calculator** section encloses the input data for the memory calculation techniques utilized in determining the JVM memory sizing options.

- *heap* – configure sizing options for the Java heap. Affects JVM options `-Xms` and `-Xmx`
- *metaspace* – configure sizing options for the metaspace. Affects JVM options `-XX:MetaspaceSize` and `-XX:MaxMetaspaceSize`
- *stack* – configure sizing options for the stack. Affects JVM option `-Xss`
- *native* – serves to represent the rest of the memory (different from *heap*, *stack*, *metaspace*) in the calculations performed by the SAP JVM Memory Calculator. No JVM options are affected by this setting.
- *memory\_heuristics* – this section defines the proportions between the memory regions addressed by the memory calculator. The ratios above will result in a *heap* space that is about 7.5 times larger than the *metaspace* and *native*; *stack* will be about half of the *metaspace* size.
- *memory\_sizes* – this section defines sizes of the corresponding memory regions. The size of the memory region could be specified in kilobytes (by using the K symbol), megabytes (by using the M symbol) and gigabytes (by using the G symbol).

Syntax	Range	Value that satisfies the Range
120M	120M	120M
120M..	[120M)	>=120M
120M..150M	[120M, 150M]	>=120M & <=150M

- [memory\\_initials](#) - this section defines initial and maximum values for *heap* and *metaspace*. By default, the initial values for *heap* and *metaspace* are set to 100%. That means, the memory calculation will result in **-Xms=-Xmx** and **-XX:MetaspaceSize=-XX:MaxMetaspaceSize**. If those values are set to 50%, then **-Xmx = 2\*-Xms** and **-XX:MaxMetaspaceSize=2\*-XX:MetaspaceSize**.
- [memory\\_settings](#) - for details, see [Java Out Of Memory Behavior \[page 267\]](#)
- [memory\\_calculator\\_v2](#) - for details, see [Memory Calculator V2 \[page 273\]](#)

## Customizing the Default Settings

There are two ways to customize the default settings - during application staging and during application runtime.

### Customizing the defaults during application staging

- Customize the memory options by using the `JBP_CONFIG_SAPJVM` environment variable

```
---
applications:
- name: <app-name>
  memory: 512M
  ...
  env:
    JBP_CONFIG_SAPJVM: "[memory_calculator: {memory_heuristics: {heap: 85,
stack: 10}}]"
```

- Customize the memory options by using the `JBP_CONFIG_SAPJVM_MEMORY_*` environment variables

```
---
applications:
- name: <app-name>
  memory: 512M
  ...
  env:
    JBP_CONFIG_SAPJVM_MEMORY_SIZES:
'heap:30m..400m,stack:2m..,metaspace:10m..12m'
    JBP_CONFIG_SAPJVM_MEMORY_WEIGHTS: 'heap:5,stack:1,metaspace:3,native:1'
    JBP_CONFIG_SAPJVM_MEMORY_INITIALS: "heap:50%,metaspace:50%"
```

### Customizing the defaults during application runtime

There are several ways to customize the SAP JVM Memory Calculator's settings during the application runtime. All of them include executing the `set -env` command – either on XSA or on Cloud Foundry. Below are some examples:

- By using the JBP\_CONFIG\_SAPJVM environment variable

```
cf set-env sapjbp-memcalc-sample JBP_CONFIG_SAPJVM "[memory_calculator:
{memory_heuristics: {heap: 85, stack: 10}}]"
```

- Customize the memory sizes by using the JBP\_CONFIG\_SAPJVM\_MEMORY\_SIZES environment variable

```
cf set-env myapp JBP_CONFIG_SAPJVM_MEMORY_SIZES
'heap:30m..400m,stack:2m..,metaspace:10m..12m'
```

- Customize the memory weights by using the JBP\_CONFIG\_SAPJVM\_MEMORY\_WEIGHTS environment variable

```
cf set-env myapp JBP_CONFIG_SAPJVM_MEMORY_WEIGHTS
'heap:5,stack:1,metaspace:3,native:1'
```

- Customize the memory initials by using the JBP\_CONFIG\_SAPJVM\_MEMORY\_INITIALS environment variable

```
cf set-env myapp JBP_CONFIG_SAPJVM_MEMORY_INITIALS "heap:50%,metaspace:50%"
```

## Algorithm

When given certain memory limit, the memory calculator will try to calculate memory sizes for *heap*, *metaspace*, *stack* and *native* in a way that satisfies the proportions configured with the *memory\_heuristics*. Then the calculator will validate and adjust those sizes against the configured *memory\_sizes*.

Let's say that the calculated value for *heap*, according to the *memory\_heuristics*, is 120M. Let's assume that the *memory\_sizes* configuration for heap is 10M..100M. Even though 120M goes beyond the configured range, according to *memory\_heuristics*, 120M could be allocated for heap and the chosen value for *heap* size would be 100M. The calculation goes on until sizes (*heap*, *metaspace*, *stack*, and *native*) are calculated for all of the regions. Finally, the *memory\_initials* will be respected. This would affect the values of `-Xms`, `-Xms`, `-XX:MetaspaceSize`, and `-XX:MaxMetaspaceSize`.

### Example 1 (memory limit of 1G with default settings of the memory calculator)

Memory limit	Memory calculator settings
1G	default

First, the algorithm will try to estimate the number of threads for the given *memory\_limit* and *memory\_heuristics* given 1M per thread. This way, we'll have  $\text{estimated\_number\_of\_threads} = ((5/100) * 1024M) = 51.2M$  space for *stack*. Considering 1M per thread (which by default is the `-xss` size of the SAP JVM), we'll get  $\text{estimated\_number\_of\_threads} = 51.2$

1. Apply the configured *memory\_heuristics*:
  - *heap*:  $(75/100) * 1024M = 768M$
  - *metaspace*:  $(10/100) * 1024M = 104857K$
  - *stack*:  $(5/100) * 1024M = 51.2M$
  - *native*:  $(10/100) * 1024M = 104858K$
2. Apply the configured *memory\_sizes*:  
There is a memory range defined for *metaspace*, which is 64.

The value 104857K calculated in step1 for *metaspace* satisfies the range.

3. Apply the *memory\_initials*:

- *-Xms*:  $100\% * 768M = 768M$
- *-Xmx*: 768M
- *-XX:MetaspaceSize*:  $100\% * 104857K = 104857K$
- *-XX:MaxMetaspaceSize*: 104857K
- *-Xss: stack* / *estimated\_number\_of\_threads* =  $51.2M / 51.2 = 1M$

## Example 2 (memory limit of 1G with customized settings of the memory calculator)

Memory limit	Memory calculator settings
1G	<pre>memory_sizes:   • metaspace: 64m..70m  memory_heuristics:   • heap: 75   • metaspace: 10,   • stack: 5   • native: 10  memory_initials:   • heap: 100%   • metaspace: 50%</pre>

First, the algorithm will try to estimate the number of threads for the given *memory\_limit* and *memory\_heuristics* given 1M per thread. This way, we'll have  $estimated\_number\_of\_threads = ((5/100) * 1024M) = 51.2M$  space for *stack*. Considering 1M per thread (which by default is the *-xss* size of the SAP JVM), we'll get  $estimated\_number\_of\_threads = 51.2$ .

### Round 1:

1. Apply the configured *memory\_heuristics*:

- *heap* =  $(75/100) * 1024M = 768M$
- *metaspace* =  $(10/100) * 1024M = 104857K$
- *stack* =  $(5/100) * 1024M = 51.2M$
- *native*:  $(10/100) * 1024M = 104857K$

2. Apply the configured *memory\_sizes*:

The *metaspace* should be between 60m and 70m. Since the value calculated in step 1 goes beyond this range, the chosen value for *metaspace* becomes 70M. This leads to a second round of calculation since there are  $(104857K - 70M) = 33177K$ , which are available to be distributed among the other regions - heap, stack, native.

### Round 2:

The *metaspace* is already calculated, so its size is subtracted from the memory limit leading to memory available for distribution, which is  $(1G - 70M) = 954M$ .

The same calculation takes place, this time the *metaspace* is not considered because it's already calculated.

1. Apply the `memory_heuristics`:
  - `heap` =  $(75/90) * 954M = 795M$
  - `stack` =  $(5/90) * 954M = 53$
  - `native` =  $(10/90) * 954M = 106M$
2. Apply the `memory_sizes`:  
No settings for `heap`, `stack` or `native`, thus no changes are needed in the calculations from step 1.
3. Apply the `memory_initials`:
  - `-Xms`:  $100\% * 795M = 795M$
  - `-Xmx`:  $795M$
  - `-XX:MetaspaceSize`:  $50\% * 70M = 35M$
  - `-XX:MaxMetaspaceSize`:  $70M$
  - `-Xss`:  $stack / estimated\_number\_of\_threads = 53 / 51.2 = 1060K$

## Related Information

### 4.1.3.5.1.4 Overriding Resources in Droplet

Applications can override resources in the droplet by placing files in `META-INF/sap_java_buildpack/resources/`. These files override files inside the droplet that have the same relative path to the droplet root.

The following example shows how application could override the default Tomcat's `server.xml`. Having the following structure in the application files:

```
META-INF/
- sap_java_buildpack/
  - resources/
    - tomcat/
      - conf/
        - server.xml/
WEB-INF/
```

will result in the following file structure in the droplet:

```
META-INF/
- .sap_java_buildpack/
  - tomcat
    - conf/
      - server.xml
WEB-INF/
```

Meaning that when the Tomcat container is started the `server.xml` file used will be the one coming from the application.

This mechanism also allows of adding new resources inside of the droplet on their respective places based on where the files are located under `META-INF/sap_java_buildpack/resources/`.

## 4.1.3.5.1.5 Resource Configuration

Both application containers [Tomcat 9 \[page 256\]](#) and [TomEE 7 \[page 253\]](#) are configured through text configuration files. For example – `conf/server.xml`, `conf/tomee7.xml` Or `conf/logging.properties` (see [Apache Tomcat 9 Configuration Reference](#) ).

Resource configuration feature of SAP Java Buildpack provides means for changing parameterized values in all text files (part of the application container or part of the application files) during staging.

Files can contain multiple key value pairs containing placeholders – marked as `${propname}`. To prevent undesired modifications, all files that can be changed must be explicitly listed by the application in a corresponding `resource_configuration.yml` file, along with the default values for all placeholders.

**Example** for `resource_configuration.yml`:

```
---
filepath:
  key1: value1
  key2: value2
filepath2:
  key1: value1
```

The `filepath` must start with either **tomcat** or **tomee7** to match the used application container, and then contain a subpath to a resource.

- When changing parametrized values inside application files, the file path should look like this:  
`<application_container>/webapps/ROOT/  
<path_to_file_relative_to_the_application_root>`
- When changing parametrized values inside the configuration of an application container, the file path should look like this:  
`<application_container>/conf/<path_to_config_file>`

### Example 1

```
tomcat/webapps/ROOT/WEB-INF/mytextfile.txt:
  placeholder: "defaultValue"
tomcat/conf/server.xml
  connector.maxThreads: 800
```

### Example 2

Given an application with the following application files:

```
src/
  main/
    java/
    resources/
    webapp/
      META-INF/
        sap_java_buildpack/
          config/
            resource_configuration.yml
      WEB-INF/
        mytextfile.txt
```

where the content of `mytextfile.txt` is:

```
My hometown is ${hometown}.
```

The `resource_configuration.yml` looks like:

```
---
tomcat/webapps/ROOT/WEB-INF/mytextfile.txt:
  hometown: "London"
```

After the application is staged, the content of `mytextfile.txt` will be:

```
My hometown is London.
```

### Example 3

The follow example demonstrates how to provide values for placeholders during staging.

Given the example above, add the following environment variable in the `manifest.yml` file of the application:

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/webapps/ROOT/WEB-INF/
  mytextfile.txt': { 'hometown': 'Paris' } ]"
```

This gives the possibility to provide values for placeholders that differ from the default ones provided in the example above. Staging the application with this environment variable will modify the content of `mytextfile.txt` to:

```
My hometown is Paris.
```

## 4.1.3.5.1.6 Context Root Redirect

The SAP Java Buildpack provides a context root redirect functionality.

When you call a Web application without adding its runtime ([Tomcat 9 \[page 256\]](#) or [TomEE 7 \[page 253\]](#)) context path to the URL, it will be automatically appended.

### Example:

If you have configured `/test_context_path` as a context path, and the Web application is available on `/test_app`, when you call:

```
<HOST>:<PORT>/test_app
```

you'll be redirected to:

```
<HOST>:<PORT>/test_context_path/test_app
```

The default context path value for Tomcat and TomEE 7 is "" (Empty String).

For more information on how to change this default value, see: [Tomcat 9 \[page 256\]](#) and [TomEE 7 \[page 253\]](#).

## 4.1.3.5.1.7 Multitenant Java Applications

In the Cloud Foundry environment, you can develop and run multitenant Java applications, and share them with multiple consumers simultaneously on SAP BTP.

### What is Multitenancy?

SAP BTP provides a multitenant functionality that allows application providers to own, deploy, and operate tenant-aware applications for multiple consumers, with reduced costs. For example, the application provider can upgrade the application for all your consumers instead of performing each update individually, or can share resources across multiple consumers. The application consumers launch the applications using consumer-specific URLs, and can configure certain application features.

To learn more, see: [Developing Multitenant Applications in the Cloud Foundry Environment \[page 327\]](#)

### Multitenancy in the SAP Java Buildpack

SAP Java Buildpack provides the possibility for multitenant applications running on Cloud Foundry to consume tenant-aware data sources out of the box. This is achieved by integrating the SAP Service Manager capabilities in the buildpack. The SAP Java buildpack provides out of the box tenant-aware data sources for:

- All tenants that have already been onboarded to an SAP Service Manager service instance.
- Newly onboarded tenants at runtime. No restart of the Java application is needed.

### Configure the Application Multitenancy

To achieve multitenant support in your application deployed with the SAP Java buildpack, your application should meet the following requirements:

1. Multitenancy support for Cloud Foundry is set up in advance. See: [Developing Multitenant Applications in the Cloud Foundry Environment \[page 327\]](#)
2. The application should be bound to a managed database service. Your application should also use one of the following datasources that the SAP Java buildpack provides:
  - `com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory`
  - `com.sap.xs.jdbc.datasource.tomee7.TomEE7DataSourceFactory`See section: [Configure Tenant-Aware Data Source \[page 286\]](#)
3. The security concept that the application uses should be XSUAA. See section: [Configure XSUAA Authentication Method \[page 286\]](#)

Once these requirements are fulfilled, the application takes care of the onboarding of tenants in the SAP Service Manager service they use. For each request that comes from the application, the SAP Java buildpack will acquire (obtain) the tenant ID from the request through the JWT token provided by the XSUAA service. The buildpack will provide different database instance object for each tenant.

## Configure Tenant-Aware Data Source

Once a multitenant application is bound to a managed database service instance, provisioning of the tenant-aware data source comes out of the box.

In the following example of `context.xml`, the `jpa-db-managed` service instance is used to configure the data source. Provided that the `jpa-db-managed` service instance is of type `managed-hana` or `service-manager`, it will make the `jdbc/DatasourceOne` tenant aware.

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DatasourceOne"
    auth="Container"
    type="javax.sql.DataSource"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="jpa-db-managed"
    personalize="true"/>
</Context>
```

If a custom tenant provider is used, define the class in the `Resource` configuration as a `tenantProvider`. For example:

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DatasourceOne"
    auth="Container"
    type="javax.sql.DataSource"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="jpa-db-managed"
    personalize="true"/>
    tenantProvider="com.sap.test.custom.provider.UserDefinedTenantProvider"/>
</Context>
```

**Tip:** If you want a non-JPA application to consume `jdbc/Outsource`, use the following:

```
public class TestServlet extends HttpServlet {
    private static final long serialVersionUID = 1L;
    @Resource(name = "jdbc/DatasourceOne")
    private DataSource tenantAwareDataSource;
    ...
}
```

## Configure XSUAA Authentication Method

The configuration is done in the `login-config` section of the `web.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://
java.sun.com/xml/ns/javaee" xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd" version="3.0">
  <display-name>sample</display-name>
  <login-config>
    <auth-method>XSUAA</auth-method>
  </login-config>
</web-app>
```

## Control Determination of the Current Tenant for Tenant-Aware Data Source

As described above, by default the tenant-aware data source determines which tenant to be used for a specific request by getting the current log user from the JWT token provided by the XSUAA service.

For specific scenarios, the application can get control over the tenant determination with the following steps:

1. Implement and bundle a class which will handle the tenant provisioning. For example:

```
package com.sap.test.custom.provider;
public class UserDefinedTenantProvider implements Supplier<String> {
    private static ThreadLocal<String> currentTenant = new
    InheritableThreadLocal<>();
    public static ThreadLocal<String> getCurrentTenant() {
        currentTenant.set("tenant1");
        return currentTenant;
    }
    @Override
    public String get() {
        return getCurrentTenant().get();
    }
}
```

### Note

The class is **required** in order to implement the `Supplier` interface.

2. Define the application class as a `tenantProvider`. For example:

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DatasourceOne"
    auth="Container"
    type="javax.sql.DataSource"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="jpa-db-managed"
    personalize="true"/>
    tenantProvider="com.sap.test.custom.provider.UserDefinedTenantProvider"/>
</Context>
```

## Related Information

[Providing Multitenant Applications to Consumers in the Cloud Foundry Environment \[page 344\]](#)

### 4.1.3.5.1.8 Logging and Tracing

#### Context

SAP Java Buildpack integrates the [Cloud Foundry Java Logging Support](#) libraries, allowing applications to produce logs in the JSON format that can be parsed by the SAP Application Logging Service for SAP BTP.

## Procedure

1. Bind the application to the SAP Application Logging service. In this way, you can produce application logs and forward them to a central application logging stack.
2. If you want to generate request metrics for applications using the Tomcat/TomEE 7 application containers, add **com.sap.hcp.cf.logging.servlet.filter.RequestLoggingFilter** to the `web.xml` file.

```
<filter-name>request-logging</filter-name>
  <filter-class>com.sap.hcp.cf.logging.servlet.filter.RequestLoggingFilter</
filter-class>
</filter>
<filter-mapping>
  <filter-name>request-logging</filter-name>
  <url-pattern>/*</url-pattern>
</filter-mapping>
```

### Note

The default logging level of `com.sap.hcp.cf.logging.servlet.filter.RequestLoggingFilter` is set to INFO.

3. Check the logs of the application.

If the binding of your application to the SAP Application Logging service is successful, the application logs can be found on `https://logs.cf.<LANDSCAPE>`. To request the logs of your application, execute:

```
cf logs <app_name> --recent
```

4. Change the logging level of a logging location.

You can change the logging level of a specific location by setting the `SET_LOGGING_LEVEL` environment variable in the application's `manifest.yml` file.

```
env:
  SET_LOGGING_LEVEL: '{com.sap.sample.java.LogInfo: INFO,
com.sap.sample.java.LogWarn: WARN}'
```

## Related Information

[Configure a Java Application for Logs and Traces \[page 289\]](#)

[SAP Application Logging Service for Cloud Foundry](#)

## 4.1.3.5.1.8.1 Configure a Java Application for Logs and Traces

Configure the collection of log and trace messages generated by a Java application in the Cloud Foundry Environment.

### Prerequisites

- You have bound an application to the SAP Application Logging service. See: [Logging and Tracing \[page 287\]](#)
- You have installed and configured Maven.
- You use SAP JVM 8 and your <JAVA\_HOME> environment variable points to this location.
- You do not have any SLF4J and logback JAR files in the application.

#### ⚠ Caution

The JARs for the *SLF4J* and *logback* are included as part of the Tomcat and TomEE 7 runtimes provided by SAP Java Buildpack. Packing them in the application could cause problems during class loading.

### Context

The recommended framework for logging is Simple Logging Facade for Java (SLF4J). To use this framework, you can create an instance of the *org.slf4j.Logger* and *org.slf4j.LoggerFactory* classes. You can use SLF4J to configure your Java application to generate logs and traces, and if appropriate – set the logging and tracing levels.

#### 📘 Note

It is the application's responsibility to ensure that *logback* is configured in a secure way in the case when the application overrides the default logback configuration included in the SAP Java buildpack. See step 2 below.

### Procedure

1. Instruct Maven that the application should not package the SLF4J dependency, since it's already provided by the runtime.

To do that, go to the `pom.xml` file and set scope **provided** for the following dependency:

```
<dependency>
  <groupId>org.slf4j</groupId>
  <artifactId>slf4j-api</artifactId>
  <version>1.7.12</version>
  <scope>provided</scope>
```

```
</dependency>
```

2. (Optional) Configure the logback in case the application overrides the default logback configuration. To do that, you need to do the following two steps:
  1. Create a custom `logback.xml` file. For example:

#### ❁ Example

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration debug="false" scan="false">
  <contextListener
class="ch.qos.logback.classic.jul.LevelChangePropagator"/>
  <appender name="STDOUT" class="ch.qos.logback.core.ConsoleAppender">
    <encoder class="${encoder}">
      ${pattern}
    </encoder>
  </appender>
  <root level="INFO">
    <appender-ref ref="STDOUT"/>
  </root>
</configuration>
```

2. Add the following property in your `manifest.yml` file. For example (using Tomcat):

#### ❁ Example

```
---
applications:
- name: <APP_NAME>
  ...
  env:
    JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/webapps/ROOT/META-
INF/.sap_java_buildpack/tomcat/conf/logback.xml': { 'encoder':
'com.sap.hcp.cf.logback.encoder.JsonEncoder', 'pattern': '' } ]"
```

## Related Information

[Configure the Access Logs of an Application \[page 290\]](#)

### 4.1.3.5.1.8.2 Configure the Access Logs of an Application

The SAP Java Buildpack uses the *logback-access* module to provide HTTP-access log functionality.

## Prerequisites

- [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
- [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)

## Context

The access logs differ slightly from the other logs and traces. There are many standard tools available that read access logs from any server, display them, calculate statistics and so on. That's why the format of the access log produced by Tomcat and TomEE 7 is not SAP-specific. The default pattern defined in the configuration file is "%date "%r" %s %b".

To find the access log files of your application, you have to connect via SSH to the Cloud Foundry container and go to the `logs` directory.

## Procedure

1. Modify the default configuration.

SAP Java buildpack uses LogbackValve to configure access logs in Tomcat and TomEE 7. The following environment variables are used in the configuration file and can be overwritten:

- `<ACCESS_LOG_FILE>`
- `<ACCESS_LOG_FILE_COUNT>`
- `<ACCESS_LOG_FILE_MAX_SIZE>`
- `<logback.access.log.xs.pattern>`

2. (Optional) Change the name of the access log files.

By default access logs are placed in the application container in the `logs/access.log` file. You can configure the directory containing this file and the name of the files – with the environment variable `ACCESS_LOG_FILE`. To do that, define the full path to the desired directory and the file name. For example:

```
env:
  ACCESS_LOG_FILE: "/home/vcap/logs/access-log/access.log"
```

3. (Optional) Change the number of access log files.

You can change the number of stored files with the environment variable `ACCESS_LOG_FILE_COUNT`. The default value is **3**. For example:

```
env:
  ACCESS_LOG_FILE_COUNT: 5
```

4. (Optional) Change the size of the access log files.

You can modify the size of every access log file with the environment variable `ACCESS_LOG_FILE_MAX_SIZE`. The default value is **8 MB**. For example:

```
env:
  ACCESS_LOG_FILE_MAX_SIZE: 10
```

5. (Optional) Change the format of the HTTP access log

You can change the default format and have your access logs written differently. The SAP Java buildpack uses the [Resource configuration](#) functionality to allow this. Changing the `pattern` attribute in the configuration file of Tomcat and TomEE 7 is supported. The application has to provide the new value via the `JBP_CONFIG` mechanism:

- Changing the format of the access log for Tomcat:

```
env:
```

```
JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/conf/logback-access-localhost.xml': { 'logback.access.log.xs.pattern' : 'combined' } ]"
```

- Changing the format of the access log for TomEE 7:

```
env:  
JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomee7/conf/logback-access-localhost.xml': { 'logback.access.log.xs.pattern' : 'combined' } ]"
```

## 4.1.3.5.1.9 Debugging Java Applications

Debugging an application helps you detect and diagnose errors in your code. You can control the execution of your program by setting breakpoints, suspending threads, stepping through the code, and examining the contents of the variables.

- [Debug an Application Running on SAP JVM \[page 292\]](#)
- [Debug an Application Running on SapMachine \[page 293\]](#)
- [Debug a Community Java Buildpack Application \[page 295\]](#)

### 4.1.3.5.1.9.1 Debug an Application Running on SAP JVM

You can debug an application running on a Cloud Foundry container that uses SAP JVM.

#### Prerequisites

- [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
- [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)
- Deploy your application using SAP Java Buildpack. To do that, from the cf CLI execute:

```
cf push <app name> -p <war file> -b sap_java_buildpack
```

- Ensure that SSH is enabled for the application. See [Accessing Apps with SSH](#) ➔

#### Note

SAP JVM is included in SAP Java Buildpack 1. With SAP JVM, you can enable debugging on-demand without the need to set any debugging parameters, hence without having to restart the application or SAP JVM.

#### Context

After enabling the debugging port, you need to open an SSH tunnel that connects to this port.

## Procedure

1. To enable debugging or to check the debugging state of your JVM, run `jvmmmon` in your Cloud Foundry container by executing:

```
cf ssh <app name> -c "app/META-INF/.sap_java_buildpack/sapjvm/bin/jvmmmon"
```

2. From the `jvmmmon` command line window, execute:

```
start debugging
```

3. (Optional) To confirm that debugging is enabled and see which port is open, execute:

```
print debugging information
```

The following is an example of the information displayed by `jvmmmon`:

```
State: Debugging back is waiting for debugger to connect
Port: 8000
Client:
Globally accessible
```

The default port is 8000.

4. To exit `jvmmmon`, execute: `q`
5. To open the SSH tunnel, execute:

```
cf ssh <app name> -N -T -L 8000:127.0.0.1:8000
```

Your local port 8000 is connected to the debugging port 8000 of the JVM running in the Cloud Foundry container. Also, 8000 is the default port.

### Note

The connection is active until you close the SSH tunnel. When you finish debugging, close the SSH tunnel by pressing `Ctrl` + `C`.

6. Connect a Java debugger to your application. For example, use the standard Java debugger provided by Eclipse IDE and connect to `localhost:8000`

## 4.1.3.5.1.9.2 Debug an Application Running on SapMachine

Debug a Java web application running on a Cloud Foundry container that uses SapMachine.

### Prerequisites

- [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
- [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)

## Context

To debug an application using [SapMachine](#), you need to open a debugging port on your Cloud Foundry container, and then open an SSH tunnel to connect to that port.

## Procedure

1. To open the debugging port, you need to configure the `JAVA_OPTS` parameter in your JVM. By default, the *agentlib* (which enables the debugging) is pre-configured. It could be turned off by setting the following property in the environment:

```
env
...
JBP_CONFIG_SAP_MACHINE_JDK: "[default_debug_agent_active: false]"
```

You could also disable the default configuration by specifying it manually. Set the following option in the application manifest file:

```
JBP_CONFIG_JAVA_OPTS: "[java_opts: '-agentlib:jdwp=transport=dt_socket,address=8000,server=y,suspend=n]'"
```

You can change the default port 8000 in the command.

2. To enable SSH tunneling in your application, execute:

```
cf enable-ssh
```

3. To open the SSH tunnel, execute:

```
cf ssh <app name> -N -T -L 8000:127.0.0.1:8000
```

Your local port 8000 is connected to the debugging port 8000 of the JVM, which is running in the Cloud Foundry container.

### Note

The connection is active until you close the SSH tunnel. When you finish debugging, close the SSH tunnel by pressing `Ctrl` + `C`.

4. Connect a Java debugger to your application. For example, use the standard Java debugger provided by Eclipse IDE and connect to `localhost:8000`.

## 4.1.3.5.1.9.3 Debug a Community Java Buildpack Application

You can debug an application running on a Cloud Foundry container that uses the community Java buildpack.

### Prerequisites

- [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
- [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)

### Context

To debug an application using the [community Java buildpack](#), you need to open a debugging port on your Cloud Foundry container and open an SSH tunnel that will connect to that port.

### Procedure

1. To open the debugging port, you need to configure the `JAVA_OPTS` parameter in your JVM. From the cf CLI, execute:

```
cf set-env <app name> JAVA_OPTS '-Xrunjdwp:transport=dt_socket,server=y,suspend=n,address=8000'
```

2. To enable SSH tunneling for your application, execute:

```
cf enable-ssh <app name>
```

3. To activate the previous changes, restart the application by executing:

```
cf restart <app name>
```

4. To open the SSH tunnel, execute:

```
cf ssh <app name> -N -T -L 8000:127.0.0.1:8000
```

Your local port 8000 is connected to the debugging port 8000 of the JVM running in the Cloud Foundry container. Also, 8000 is the default port.

#### Note

The connection is active until you close the SSH tunnel. When you finish debugging, close the SSH tunnel by pressing `Ctrl` + `C`.

5. Connect a Java debugger to your application. For example, use the standard Java debugger provided by Eclipse IDE and connect to `localhost:8000`.

## 4.1.3.5.1.10 Dynatrace Integration

### Context

Dynatrace OneAgent is a Java agent that sends all captured monitoring data to your Dynatrace monitoring environment for analysis. Dynatrace supports full-stack monitoring for Cloud Foundry, from the application down to the infrastructure layer. See: [Cloud Foundry monitoring](#)

### Procedure

1. Obtain an environment ID and an IP token. To do that, follow the steps described on page: [Deploy OneAgent on SAP BTP Cloud Foundry Runtime](#)
2. Create a user-provided service.

The service name should contain the string "dynatrace" (for example, **dynatracesevice**). The `environmentid` and `apitoken` parameters have been generated in the previous step. You also need to set up the API URL, which depends on the Dynatrace type you want to integrate:

- **SaaS Dynatrace**

```
"apiurl": "https://<environmentid>.live.dynatrace.com/api"
```

- **Managed Dynatrace**

```
"apiurl": "https://<your_domain>/e/<environmentid>/api"
```

Then, in cf CLI, execute:

```
cf cups dynatracesevice -p "environmentid, apitoken, apiurl"
```

For more information, see:

- Dynatrace Docs: [Create a user-provided service in your SAP BTP, Cloud Foundry Environment](#)
  - Cloud Foundry Docs: [User-Provided Service Instances](#)
3. Bind the application to the service instance created in the previous step, by using the *manifest.yml* file.

#### Sample Code

```
---
applications:
- name: myapp
  memory: 1G
  instances: 1
  buildpack: sap_java_buildpack
  services:
  - dynatracesevice
```

4. Deploy the application to Cloud Foundry with the updated *manifest.yml* file. Execute:

```
cf push myapp
```

Once the application receives web traffic, monitoring data will show up in Dynatrace.

## 4.1.3.5.1.11 Multiple Buildpack Framework

The Multiple Buildpack Framework enables the SAP Java Buildpack to act as the final buildpack in a multiple buildpack deployment. It reads the contributions of other, earlier buildpacks and incorporates them into its standard staging.

### Note

If you try to use the SAP Java Buildpack as a non-final buildpack, an error will be thrown.

When the Java Buildpack acts as the final buildpack in a multiple buildpack deployment it honors the following core contract integration points with non-final buildpacks.

Integration Point	Buildpack Usage
<code>/bin</code>	An existing <code>/bin</code> directory contributed by a non-final buildpack will be added to the <code>&lt;\${PATH}&gt;</code> of the application as it executes.
<code>/lib</code>	An existing <code>/lib</code> directory contributed by a non-final buildpack will be added to the <code>&lt;\${LD_LIBRARY_PATH}&gt;</code> of the application as it executes.

## 4.1.3.5.1.12 Configuring a Database Connection

You can configure your application to use a database connection so that the application can persist its data. This configuration is applicable for the [Tomcat 9 \[page 256\]](#) and [TomEE 7 \[page 253\]](#) application containers.

- [Configure a Database Connection for the Tomcat Application Container \[page 300\]](#)
- [Configure a Database Connection for the TomEE 7 Application Container \[page 298\]](#)
- [Database Connection Configuration Details \[page 301\]](#)
- [SAP HANA HDI Data Source Usage \[page 303\]](#)

### 4.1.3.5.1.12.1 Configure a Database Connection for the TomEE Application Container (Deprecated)

#### Context

### Caution

Effective **May 5, 2022**, Apache TomEE 1.7 is no longer supported by the SAP Java buildpack for the SAP BTP, Cloud Foundry environment. TomEE was removed from the buildpack with version 1.53.0.

## Procedure

1. Create a `resources.xml` file.

The `resources.xml` file must be inside the application's `WEB-INF/` folder and must contain information about the data source to be used.

```
<?xml version='1.0' encoding='utf-8'?>
<resources>
<Resource id="jdbc/DefaultDB" provider="xs.openejb:XS Default JDBC Database"
type="javax.sql.DataSource" >
  service=${service_name_for_DefaultDB}
</Resource>
</resources>
```

2. Add the default keys and their values.

The data source information must be included in the `META-INF/sap_java_buildpack/config/resource_configuration.yml` file.

```
---
tomee/webapps/ROOT/WEB-INF/resources.xml:
  service_name_for_DefaultDB: di-core-hdi
```

3. Add the key values to be updated.

Include the data source information to be updated in the `manifest.yml` file.

```
env:
  TARGET_RUNTIME: tomee
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomee/webapps/ROOT/WEB-INF/
resources.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-core-
hdi' } ]"
```

## 4.1.3.5.1.12.2 Configure a Database Connection for the TomEE 7 Application Container

### Procedure

1. Create a `resources.xml` file.

#### Note

If the data source is to be used from a Web application, you have to create the file inside the `WEB-INF/` directory.

If the data source is to be used from Enterprise JavaBeans (EJBs), you have to create the file inside the `META-INF/` directory.

The `resources.xml` file has to be inside the application's WAR file and has to contain information about the data source to be used.

```
<?xml version='1.0' encoding='utf-8'?>
<resources>
  <Resource id="jdbc/DefaultDB" provider="xs.openejb:XS Default JDBC Database"
type=" javax.sql.DataSource" >
    service=${service_name_for_DefaultDB}
  </Resource>
</resources>
```

2. Add the default keys and their values.

You need to include the data source information in `META-INF/sap_java_buildpack/config/resource_configuration.yml` of the WAR file.

#### Sample Code

Defining a default service in `resource_configuration.yml` for a Web application

```
---
tomee7/webapps/ROOT/WEB-INF/resources.xml :
  service_name_for_DefaultDB: di-core-hdi
```

#### Sample Code

Defining a default service in `resource_configuration.yml` for an EJB

```
---
tomee7/webapps/ROOT/META-INF/resources.xml :
  service_name_for_DefaultDB: di-core-hdi
```

3. Add the key values to be updated.

Include the data source information to be updated in the `manifest.yml` file.

#### Sample Code

Defining a new service for the look-up of the data source in a Web application

```
env:
  TARGET_RUNTIME: tomee7
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomee7/webapps/ROOT/WEB-INF/
resources.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-core-
hdi' } ]"
```

#### Sample Code

Defining a new service for the look-up of the data source in an EJB

```
env:
  TARGET_RUNTIME: tomee7
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomee7/webapps/ROOT/META-INF/
resources.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-core-
hdi' } ]"
```

## Results

As a result of this configuration, when the application starts, the `com.sap.xs.jdbc.datasource.TomEEDataSourceFactory` factory takes the parameters bound to the `my-local-special-di-core-hdi` service from the environment, creates a data source, and binds it under `jdbc/DefaultDB`. The application then uses the Java Naming and Directory Interface (JNDI) to look up how to connect with the database.

## Related Information

[SAP HANA HDI Data Source Usage \[page 303\]](#)

[Database Connection Configuration Details \[page 301\]](#)

[Configuring a Database Connection \[page 297\]](#)

### 4.1.3.5.1.12.3 Configure a Database Connection for the Tomcat Application Container

#### Procedure

1. Create a `context.xml` file.

The `context.xml` file has to be inside the `META-INF/` folder of the application WAR file and has to contain information about the data source to be used.

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DefaultDB"
    auth="Container"
    type="javax.sql.DataSource"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="{service_name_for_DefaultDB}"/>
</Context>
```

2. Add the default keys and their values.

You need to include the data source information in `META-INF/sap_java_buildpack/config/resource_configuration.yml` of the WAR file.

```
---
tomcat/webapps/ROOT/META-INF/context.xml:
  service_name_for_DefaultDB: di-core-hdi
```

3. Add the key values to be updated.

You include the data source information to be updated in `manifest.yml`.

```
env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/webapps/ROOT/META-INF/
context.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-core-
hdi' } ]"
```

## Results

When the application starts, the factory named `com.sap.xs.jdbc.datasource.TomcatDataSourceFactory` takes the parameters bound for service `my-local-special-di-core-hdi` from the environment, creates a data source, and binds it under `jdbc/DefaultDB`. The application then uses the Java Naming and Directory Interface (JNDI) to look up how to connect with the database.

### 4.1.3.5.1.12.4 Database Connection Configuration Details

Define details of the database connection used by your Java Web Application running on SAP BTP, Cloud Foundry with SAP Java Buildpack.

## Configuration Files

To configure your application to establish a connection to the SAP HANA database, you must specify details of the connection in a configuration file. For example, you must define the data source that the application will use to discover and look up data. The application then uses a Java Naming and Directory Interface (JNDI) to look up the specified data in the file.

The easiest way to define the required data source is to declare the keys for the data source in a resource file.

For the Tomcat application container, you can create a `context.xml` file in the `META-INF/` directory with the following content:

#### Sample Code

context.xml

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DefaultDB"
    auth="Container"
    type="javax.sql.DataSource"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="di-core-hdi" />
</Context>
```

For the TomEE 7 application container, you can create a `resources.xml` file in the `WEB-INF/` directory with the following content:

#### Sample Code

resources.xml

```
<?xml version='1.0' encoding='utf-8'?>
<resources>
  <Resource id="jdbc/DefaultDB" provider="xs.openejb:XS Default JDBC Database"
    type="javax.sql.DataSource" >
    service=di-core-hdi
```

```
</Resource>
</resources>
```

The problem with this simple approach is that your WAR file cannot be signed, and any modifications can only be made in the WAR file. For this reason, it is recommended that you do not use the method in a production environment but rather take advantage of the [Resource Configuration \[page 283\]](#) feature of the SAP Java Buildpack. Use modification settings in `resource_configuration.yml` and `manifest.yml` as illustrated in the following examples.

Defining a default service in `resource_configuration.yml`.

### Sample Code

`resource_configuration.yml`

```
---
tomcat/webapps/ROOT/META-INF/context.xml:
  service_name_for_DefaultDB: di-core-hdi
```

Specifying a default name for a service is useful (for example, for automation purposes) only if you are sure there can be no conflict with other names. For this reason, it is recommended that you include a helpful and descriptive error message instead of a default value. That way the error message will be part of an exception triggered when the data source is initialized, which helps troubleshooting.

Sample `resource_configuration.yml`.

### Sample Code

```
---
tomcat/webapps/ROOT/META-INF/context.xml:
  service_name_for_DefaultDB: Specify the service name for Default DB in
manifest.yml via "JBP_CONFIG_RESOURCE_CONFIGURATION" ..
```

## Placeholders

The generic mechanism `JBP_CONFIG_RESOURCE_CONFIGURATION` basically replaces the key values in the specified files. For this reason, if you use placeholders in the configuration files, it is important to ensure that you use unique names for the placeholders, see [Resource Configuration \[page 283\]](#).

Sample `context.xml`.

### Sample Code

`context.xml`

```
<?xml version='1.0' encoding='utf-8'?>
<Context>
  <Resource name="jdbc/DefaultDB"
    auth="Container"
    type="javax.sql.DataSource"
    description="Datasource for general functionality"
    factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
    service="${service_name_for_DefaultDB}"
    maxActive="${max_Active_Connections_For_DefaultDB}" />
```

```

<Resource name="jdbc/DefaultXADB"
  auth="Container"
  type="javax.sql.XADataSource"
  description="Datasource for functionality requiring more than one
  transactional resource"
  factory="com.sap.xs.jdbc.datasource.tomcat.TomcatDataSourceFactory"
  service="${service_name_for_DefaultXADB}"
  maxActive="${max_Active_Connections_For_DefaultXADB}" />
</Context>

```

The names of the defined placeholders are also used in the other resource files.

Sample `resource_configuration.yml`.

### Sample Code

`resource_configuration.yml`

```

---
tomcat/webapps/ROOT/META-INF/context.xml:
  service_name_for_DefaultDB: di-core-hdi
  max_Active_Connections_For_DefaultDB: 100
  service_name_for_DefaultXADB: di-core-hdi-xa
  max_Active_Connections_For_DefaultXADB: 100

env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/webapps/ROOT/META-INF/
context.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-
core-hdi' , 'max_Active_Connections_For_DefaultDB' : '30',
'service_name_for_DefaultXADB' : 'my-local-special-xa-di-core-hdi' ,
'max_Active_Connections_For_DefaultXADB' : '20' } ]"

```

Sample `manifest.yml`.

### Sample Code

`manifest.yml`

```

env:
  JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomcat/webapps/ROOT/META-INF/
context.xml': { 'service_name_for_DefaultDB' : 'my-local-special-di-
core-hdi' , 'max_Active_Connections_For_DefaultDB' : '30',
'service_name_for_DefaultXADB' : 'my-local-special-xa-di-core-hdi' ,
'max_Active_Connections_For_DefaultXADB' : '20' } ]"

```

## 4.1.3.5.1.12.5 SAP HANA HDI Data Source Usage

### Procedure

1. Create a service instance for the HDI container, using the `cf create-service` command.

```
cf create-service hana hdi-shared my-hdi-container
```

2. Bind the service instance to a Java application.

Specify the service instance in the Java application's deployment manifest file.

### Sample Code

manifest.yml

```
services:  
- my-hdi-container
```

3. Add the resource reference to the `web.xml` file, which must have the name of the service instance.

### Sample Code

web.xml

```
<resource-ref>  
  <res-ref-name>jdbc/my-hdi-container</res-ref-name>  
  <res-type>javax.sql.DataSource</res-type>  
</resource-ref>
```

4. Look up the data source in your code.

You can find the reference to the data source in the following ways:

- Annotations

```
@Resource(name = "jdbc/my-hdi-container")  
private DataSource ds;
```

- Java Naming and Directory Interface (JNDI) look-up

```
Context ctx = new InitialContext();  
return (DataSource) ctx.lookup("java:comp/env/jdbc/my-hdi-container");
```

## 4.1.3.5.113 SAP Java Connector

You can use the SAP Java Connector through the SAP Java buildpacks.

### Activation

SAP Java Buildpack (1 and 2) provide an option to use [SAP Java Connector \(SAP JCo\)](#).

To activate SAP JCo in the buildpack, set the environment variable `USE_JCO` to `true`.

### Sample Code

manifest.yml

```
---  
applications:  
- name: <app_name>  
  ...  
  env:  
    USE_JCO: true
```

The previous method of activating the SAP JCo feature, by defining a service instance for both the connectivity and destination services in the `manifest.yml` file, has been deprecated and stops working at the end of a transition phase.

The activation of SAP JCo provides all relevant libraries in the application container, so that [SAP JCo API](#) can be used. To use SAP JCo during runtime, a destination and an SAP Authorization and Trust Management (XSUAA) service instance are mandatory. Additionally, if you want to set up on-premise connectivity, a connectivity service instance is required.

## Limitations

SAP JCo is only available for the Tomcat-based application containers that are included in the SAP Java buildpacks. Spring Boot applications only work with SAP JCo if you're using WAR deployment.

### 4.1.3.5.14 Profiling an Application Running on SAP JVM

The SAP JVM Profiler is a tool that helps you analyze the resource consumption of a Java application running on SAP Java Virtual Machine (JVM). You can use it to profile simple standalone Java programs or complex enterprise applications.

## Prerequisites

- Install the SAP JVM Tools for Eclipse. For more information, see [Install the SAP JVM Tools in Eclipse \[page 306\]](#).
- Open a debugging connection using an SSH tunnel. For more information, see [Debug an Application Running on SAP JVM \[page 292\]](#)

## Context

To measure resource consumption, the SAP JVM Profiler enables you to run different profiling analyses. Each profiling analysis creates profiling events that focus on different aspects of resource consumption. For more information about the available analyses, see the SAP JVM Profiler documentation in Eclipse. Go to [Help](#) [Help Contents](#) [SAP JVM Profiler](#).

## Procedure

1. In Eclipse, open the *Profiling* perspective.
2. From the *VM Explorer* view, choose  (*Connect Host Via Debugging Port*).
3. Enter your host name and port number, and choose *Next*.

### Note

Your port number is your local SSH tunnel endpoint.

4. Choose the analysis you want to run and specify your profiling parameters.

### Note

To use the thread annotation filters, complete the fields under the *Analysis Options* section. By default, all filters are set to \*, which means that all annotations pass the filter.

## 4.1.3.5.1.14.1 Install the SAP JVM Tools in Eclipse

*SAP JVM Profiler* is included in the SAP JVM Tools.

## Prerequisites

You have downloaded and installed **Eclipse IDE for Java Developers**. See: [Eclipse Packages](#) 

## Procedure

1. Open the Eclipse IDE and navigate to  *Help*  *Install New Software* .
2. In the *Work with* combo box, enter <https://tools.hana.ondemand.com/oxygen> and choose *Add*.
3. Select  *SAP BTP Tools*  *SAP JVM Tools*  and choose *Next*.
4. Select *SAP JVM Tools*, accept the terms and conditions, and choose *Finish*.
5. Restart the Eclipse IDE to apply the new changes.

## Results

After the restart, a new *SAP JVM Profiler* section is displayed in the *Overview* page.

## 4.1.3.5.14.2 (Optional) Add your SAP JVM to the VM Explorer

You can add your SAP JVM to the *VM Explorer* view of the **SAP JVM Profiler**.

### Prerequisites

- [Install the SAP JVM Tools in Eclipse \[page 306\]](#).
- [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#)
- [Log On to the Cloud Foundry Environment Using the Cloud Foundry Command Line Interface \[page 2260\]](#)

### Context

From the *VM Explorer*, you can debug, monitor or profile your SAP JVM. For more information about the *VM Explorer*, see the *SAP JVM Profiler* documentation in the Eclipse Help.

#### Note

You need to use the **jvmmond** tool, which is included in the SAP Java Buildpack.

### Procedure

1. From the cf CLI, execute:

```
cf ssh app name -c "app/META-INF/.sap_java_buildpack/sapjvm/bin/
jvmmond -port 50003 -J-Dcom.sap.jvm.tools.portRange=50004-50005 -J-
Djava.rmi.server.hostname=127.0.0.1"
```

This starts the **jvmmond** service on your Cloud Foundry container. It is listening to port **50003**. This command also specifies a port range of 50004-50005 in case additional ports need to be opened.

2. To enable an SSH tunnel for these ports, execute:

```
cf ssh <app name> -N -T -L 50003:127.0.0.1:50003 -L 50004:127.0.0.1:50004 -L
50005:127.0.0.1:50005
```

3. In your Eclipse IDE, open the *Profiling* perspective, and from the *VM Explorer* view choose *Manage Hosts*.
4. Choose *Add* and enter the following host name and port number: **localhost:50003**

### Results

Your application is added to the VM Explorer.

## 4.1.3.5.1.15 Profiling an Application Running on SapMachine

You can use Java Flight Recorder (JFR [↗](#)) to profile your Java application on SapMachine, and Java Mission Control (JMC [↗](#)) to do remote profiling and analysis.

### Prerequisites

- You have downloaded and installed a JDK Mission Control console. To do that, go to [SapMachine](#) [↗](#) → [Download](#) → [JMC 8](#), select your operating system, and then choose [Download](#).
- You have installed the Cloud Foundry command line interface. See: [Download and Install the cf CLI](#)
- You are logged on to a SAP BTP, Cloud Foundry space. See: [Log On to the Cloud Foundry Environment Using cf CLI](#)
- You have a Java application that is up and running on SAP BTP, Cloud Foundry.
- You have enabled SSH for your application. See: [Configuring SSH access at the app level](#) [↗](#)

### Context

To profile with JMC, you need to start the Management Agent on a RMI port and then open an SSH tunnel to connect to that port. To do that, follow the steps below.

#### Note

In the steps below, we use **myapp** and **5555** as *exemplary* application name and port. Replace them with your actual app name and a free port number on your localhost.

### Procedure

1. Set the RMI server to localhost. To do that, set the following JBP\_CONFIG\_JAVA\_OPTS option in the `manifest.yml` file of your application:

```
---
applications:
- name: myapp
  buildpack: sap_java_buildpack
...
env:
  TARGET_RUNTIME: tomcat
  JBP_CONFIG_COMPONENTS: "jres:
['com.sap.xs.java.buildpack.jre.SAPMachineJRE']"
  JBP_CONFIG_SAP_MACHINE_JRE: '{version: 11.+}'
  JBP_CONFIG_JAVA_OPTS: "[java_opts: '-
Djava.rmi.server.hostname=127.0.0.1']"
```

2. Start the Management Agent by running `jcmd` in your Cloud Foundry container. Execute:

```
cf ssh myapp -c "app/META-INF/.sap_java_buildpack/sap_machine_jre/bin/jcmd $(pgrep java) ManagementAgent.start jmxremote.authenticate=false jmxremote.ssl=false jmxremote.port=5555 jmxremote.rmi.port=5555"
```

Depending on what your SapMachine is using (JRE or JDK), specify the path accordingly (`sap_machine_jre` or `sap_machine_jdk`). To learn more, see: [SapMachine \[page 268\]](#)

**Result:**

```
7:
Command executed successfully
```

Management Agent is started and is listening to port **5555**.

3. (Optional) You can check the status of the Management Agent. Execute:

```
cf ssh myapp -c "app/META-INF/.sap_java_buildpack/sap_machine_jre/bin/jcmd $(pgrep java) ManagementAgent.status"
```

4. Enable an SSH tunnel for this port. Execute:

```
cf ssh myapp -N -T -L 5555:127.0.0.1:5555
```

Your *local* port 5555 is connected to the *remote* port 5555 of the JVM, which is running in the Cloud Foundry container.

**Note**

The connection is active until you close the SSH tunnel. When you finish profiling, close the SSH tunnel by pressing `Ctrl` + `C`.

5. Connect with JMC to `localhost:5555`. To do that:
  1. Open your JDK Mission Control (JMC) console.
  2. From the *JVM Browser* tab, choose icon *Create a new custom JVM connection*.
  3. For *Port*, enter **5555** (or your actual port number), and then choose *Finish*.
6. In the left-side menu, a new node `localhost:5555` appears.
7. Double-click on *MBean Server*.
8. To start profiling, go to *Flight Recorder* and from its context menu, choose *Start Flight Recording*.
9. Set up the event settings. From the drop-down menu, choose one of the following options (templates):
  - *Continuous* – Low overhead configuration, safe for continuous use in production environments
  - *Profiling* – Low overhead configuration for profiling
  - *gc* – GC related events. Generates a small recording size.
  - *gc\_details* – GC related events. Gets heap statistic and generates a large recording size.
  - Create your own configuration. To do that, choose *Template Manager*, then select a predefined template and choose *Duplicate*. Rename the new template and edit its configuration parameters according to your needs and preferences.
10. After profiling is done, go to `localhost:5555` and from its context menu, choose *Disconnect*.
11. Then go back to your command line and close the SSH tunnel by pressing `Ctrl` + `C`.

12. Stop the Management Agent. Execute:

```
cf ssh myapp -c "app/META-INF/.sap_java_buildpack/sap_machine_jre/bin/jcmd $(pgrep java) ManagementAgent.stop"
```

## Related Information

[Debug an Application Running on SapMachine \[page 293\]](#)

### 4.1.3.5.1.16 Bill of Materials (BOM)

For Maven projects, the versions of the SAP Java Buildpack dependencies and the APIs provided by supported runtime containers can be consumed through a Bill of Materials (BOM).

The BOM contains the dependencies you can rely on in a runtime environment provided by SAP Java Buildpack. It can also be used to control the versions of a project's dependencies without the need to manually maintain the version of each single artifact.

The BOMs of SAP Java Buildpack are provided through [Maven Central](#) .

## Usage

There are two runtimes for which a BOM is provided: Tomcat and TomEE 7. The version of the BOM must match the version of the `sap_java_buildpack` you're using. For example, if your application uses `sap_java_buildpack` version 1.75.0, the BOM must be in version 1.75.0 as well.

If you want to use version control, add the desired BOM artifact to your project's `pom.xml` file in the section *dependencyManagement*. The following code is an example.

- For Tomcat:

```
...
<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.sap.cloud.sjb.cf</groupId>
      <artifactId>cf-tomcat-bom</artifactId>
      <version>1.75.0</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
...
```

- For TomEE 7:

```
...
<dependencyManagement>
  <dependencies>
```

```

    <dependency>
      <groupId>com.sap.cloud.sjb.cf</groupId>
      <artifactId>cf-tomee7-bom</artifactId>
      <version>1.75.0</version>
      <type>pom</type>
      <scope>import</scope>
    </dependency>
  </dependencies>
</dependencyManagement>
...

```

To add the dependencies that you want, use *groupId* and *artifactId*:

```

...
<dependency>
  <groupId>com.sap.cloud.sjb</groupId>
  <artifactId>xs-env</artifactId>
</dependency>
<dependency>
  <groupId>com.sap.cloud.sjb</groupId>
  <artifactId>xs-user-holder</artifactId>
</dependency>
<dependency>
  <groupId>com.fasterxml.jackson.core</groupId>
  <artifactId>jackson-annotations</artifactId>
</dependency>
<dependency>
  <groupId>org.slf4j</groupId>
  <artifactId>jul-to-slf4j</artifactId>
</dependency>
<dependency>
  <groupId>ch.qos.logback</groupId>
  <artifactId>logback-access</artifactId>
</dependency>
...

```

If you simply want to have all dependencies in your project, you can also add the BOM to your project's section. By doing so, you don't need to enumerate single dependency artifacts.

## Related Information

[Maven Repository: SAP Java Buildpack BOM](#) 

### 4.1.3.5.2 Developing Node.js in the Cloud Foundry Environment

This section offers selected information for Node.js development on SAP BTP, Cloud Foundry and references to more detailed sources.

You'll get information about the buildpack supported by SAP, the Node.js packages, and how to consume them in your application.

There is also a tutorial with an introduction to securing your application, and some tips and tricks for developing and running Node.js applications on SAP BTP, Cloud Foundry.

## Node.js Community Buildpack

SAP BTP uses the standard [Node.js buildpack](#) provided by the Cloud Foundry community to deploy Node.js applications.

To get familiar with the buildpack and how to deploy applications with it, take a look at the [Cloud Foundry Node.js Buildpack documentation](#).

## SAP Node.js Packages

You can download and consume SAP developed Node.js packages via the SAP NPM Registry. There is an overview of Node.js packages developed by SAP, what they are meant for, and where they are included in the SAP HANA Developer Guide for XS Advanced Model. See:

- [Download and Consume SAP Node.js Packages](#)
- [Standard Node.js Packages](#)
- [The SAP NPM Registry](#)

## Buildpack Versioning

The SAP BTP, Cloud Foundry environment provides one recent version of `nodejs_buildpack` as part of its system buildpacks. To check this version, proceed as follows:

1. Log in to a particular SAP BTP region and subaccount. For example, if your region is **eu10**, run:

```
cf api https://api.cf.eu10.hana.ondemand.com
```

2. Then run:

```
cf buildpacks
```

To learn about changes in Node.js versions and features, regularly check the latest [buildpack releases](#) in the GitHub community page.

## Supported Versions

The `nodejs_buildpack` running on SAP BTP, Cloud Foundry environment supports the following versions:

- Node.js 18
- Node.js 20

### Node.js 14 and 16 – end of life

Node.js 14 reached end of life on **April 30, 2023** and was removed from the Cloud Foundry community in [version 1.8.10](#).

Node.js 16 reached end of life on **September 11, 2023** and was removed from the Cloud Foundry community in [version 1.8.15](#) .

This means that deployment and redeployment of applications with Node.js 14 and 16 will **fail**. For more information, see:

- [Node.js Roadmap](#)
- [Bringing forward the End-of-Life Date for Node.js 16](#)

We recommend that you migrate your applications to Node.js **18** or **20** as soon as possible.

#### Note

Applications using XSJS are strongly impacted as the [@sap/fibers](#) library (on which [@sap/xsjs](#) depends) is **not supported** on Node.js 16 and later versions. To learn more, see: [Migrating Applications from XSJS to Async-XSJS \[page 314\]](#)

In exceptional cases (if you haven't completed the migration to Node.js 18), to avoid application failures during redeployment, you may pin the last buildpack version that contains Node.js 14 or 16, as provided by the [nodejs-buildpack](#) community. To learn how, see: [Specify a buildpack version in manifest.yml \[page 321\]](#)

#### → Remember

SAP does **not** recommend use of deprecated Node.js versions, as support and security fixes are no longer provided for them.

## What's New

To see the latest news and updates about the Node.js system buildpack, regularly check the release notes on the [What's New portal](#).

#### Note

In May 2023, SAP migrated the root file system used in the Cloud Foundry environment in SAP BTP from the deprecated `cflinuxfs3` stack to **cflinuxfs4**. If you are running Node.js applications on SAP BTP, Cloud Foundry using the Node.js buildpack, we recommend that you update and migrate your applications, as well as the Node.js buildpack. For more information about migration timelines, risks, and consequences, see:

- [Deprecation of Cloud Foundry Stack cflinuxfs3 and Migration to cflinuxfs4](#)
- [What's New for SAP BTP, Cloud Foundry Runtime \(cflinuxfs\)](#)

## Troubleshooting

If you encounter an issue while using the Node.js buildpack, you can:

- Search for your problem in our Guided Answers: [Node.js Buildpack](#)

- Create an incident for your specific problem, using support component **BC-CP-CF-BLDP**. To provide the necessary details, use the following template: [Initial Problem-Related Data](#)

## Node.js Tutorial

The following tutorial will guide you through creating a Node.js application in Cloud Foundry Command Line Interface (cf CLI), consuming a Cloud Foundry service, and setting up authentication and authorization checks. See: [Create an Application with Cloud Foundry Node.js Buildpack](#)

## Tips and Tricks

For selected tips and tricks for your Node.js development, see [Tips and Tricks for Node.js Applications \[page 319\]](#).

### 4.1.3.5.2.1 Migrating Applications from XSJS to Async-XSJS

This page explains how to migrate XSJS to Async-XSJS to benefit from latest Node.js versions (16 and later).

## Context

SAP HANA XSJS applications are based on *synchronous* API. On the other hand, Node.js is an *asynchronous* runtime. Thus, for XSJS applications that run on Node.js there is a certain code incompatibility. Up until Node.js 14, this incompatibility has been handled by an NPM package called [@sap/fibers](#) (forked from [laverdet/node-fibers](#)). Unfortunately, [@sap/fibers](#) is not compatible with Node.js version 16 and higher.

Also, Node.js supports two kinds of scripts:

- CommonJS - it's synchronous and does not support top-level await. In XSJS, all files are loaded as common Java scripts.
- ECMAScript - it's fully asynchronous and supports top-level await

The only possible way for your XSJS applications to be up and running on latest Node.js versions is to modify their codes – by migrating them to a new XSJS layer with asynchronous API. See the migration process below to learn what you need to do.

#### 📌 Note

In exceptional cases (if you haven't completed the migration to Async-XSJS), to avoid application failures during redeployment, you may pin the last buildpack version that contains Node.js14, as provided by the [nodejs-buildpack](#) community. You can do this in your **manifest.yml** file, and then redeploy your app. To learn how, see: [Specify a buildpack version in manifest.yml \[page 321\]](#)

Please be advised, that SAP does **not** recommended usage of Node.js 14, as no support and security fixes are provided for this version anymore.

## Migration Process

1. To switch from XSJS to Async-XSJS, open your `package.json` file, and in the **dependencies** section, add the `@sap/async-xsjs` package. For example:

```
{
  "name": "myapp",
  "engines": {
    "node": "16.x.x"
  },
  ...
  "dependencies": {
    "express": "^4.18.1",
    "@sap/xssec": "^3.2.15",
    "@sap/async-xsjs": "^1.0.0"
  }
  ...
}
```

2. Enable the ECMAScript virtual-machine interface on application startup. With `@sap/async-xsjs`, your asynchronous JavaScript code is loaded by default as ECMAScript (ES). To make use of the support that Node.js provides for ES modules, you need to start your application using the option `--experimental-vm-modules`.

```
{
  "name": "myapp",
  "engines": {
    "node": "16.x.x"
  },
  ...
  "dependencies": {
    "express": "^4.18.1",
    "@sap/xssec": "^3.2.15",
    "@sap/async-xsjs": "^1.0.0"
  }
  "scripts": {
    "start": "node --experimental-vm-modules index.js"
    ...
  },
  ...
}
```

3. In all your `.xsjs` and `.xsjslib` files, for every asynchronous function call, add an **await** statement.
4. Every function that uses an **await** statement must be declared as **async**.
5. XSJS files should be loaded as ECMAScript. To do this, in the end of every function in an `.xsjslib` file, add an **export** statement.

### Note

You can do this for `.xsjs` files too, but that would be only necessary if a function needs to be exported for some reason (like job execution or job handling).

6. If you're using the [@sap/audit-logging](#) package in your XSJS application, the code must be migrated. For example, if you have a code snippet like this:

```
auditLog
  .securityMessage('Content of the message')
  .by($.session.getUsername())
  .sync.log();
```

it should be converted to:

```
await auditLog
  .securityMessage('Content of the message')
  .by($.session.getUsername())
  .log();
```

To do these steps, refer to the API of the new [@sap/async-xsjs](#) package. See: [SAP HANA 2 - ASYNC XS JavaScript API Reference](#)

You can find this API reference if you go to the [SAP HANA Platform](#) product page, and then choose *View All* → [SAP HANA Asynchronous XS JavaScript API Reference](#).

### Note

For huge application codes, you can optimize your work by using a migration tool. See: [@sap/async-migrator](#)

Bear in mind that this is an open-source product and a fully-covered migration of your XSJS code is not guaranteed.

## Examples

The following exemplary code snippet from an `.xsjslib` file:

### Example

Original Code

```
...
$.import('lib', 'converters');
function select(tableName){
  let conn;
  try {
    conn = $.hdb.getConnection();
    let resultSet = conn.executeQuery('SELECT * FROM "' + tableName + '"');
    return $.lib.converters.resultSet_to_Entities(resultSet, ["id", "name"]);
  } finally {
    if (conn) {
      conn.commit();
      conn.close();
    }
  }
}
```

should be converted to:

### ❖ Example

Modified Code

```
...
await $.import('lib', 'converters');
async function select(tableName){
  let conn;
  try {
    conn = await $.hdb.getConnection();
    let resultSet = await conn.executeQuery('SELECT * FROM ' + tableName +
    '');
    return $.lib.converters.resultSet_to_Entities(resultSet, ["id", "name"]);
  } finally {
    if (conn) {
      await conn.commit();
      conn.close();
    }
  }
}
export default {select};
```

## Side Effects

### .sync Statements

Since the [@sap/fibrous](#) package is not supported anymore, the **.sync** statements will no longer work. To fix a code that uses the `sync` property, see **step 4** from the procedure above.

### this Pointer

Since all `.xsjs` and `.xsjslib` files are based on ECMAScript module, **this** pointer behaves differently from when used with CommonJS. For example, when ECMAScript is loaded, the value of **this** is *undefined*.

In the context of a module function execution, the value of pointer **this** is the **export <object>** module.

The following sample code will throw an error due to `this=undefined` during loading.

### ❖ Example

```
=== my.xsjslib ===XSJS ===
```

```
this.funcA = function(){}
(function(self){
  self.funcB = function(){};
})(this);
this.x = 5;
```

Adapt the code to Async-XSJS:

### ❖ Example

```
=== my.xsjslib ===Async-XSJS ===
```

```
function funcA(){}
```

```
function funcB(){
  var x = 5;
  export default {funcA, funcB, x};
}
```

This example just illustrates the problem and gives a possible solution. Depending on the software design of your application, there could be various solutions.

To learn more about the differences between these two kinds of Node.js scripts, see:

- [ECMAScript documentation](#)
- [Differences between ES modules and CommonJS](#)

`Array.forEach` **and** `Array.map`

In the Async-XSJS layer, the **Array.forEach** and **Array.map** functions change their behavior when the argument function is asynchronous.

For example, the SQL statements are read and executed sequentially, one after the other, and then written to the database in the same order.

### ❁ Example

=== my.xsjslib ===XSJS ===

```
var sqls = ['create table "PRODUCT"("ID" integer, "NAME": varchar(200))',
           'insert into "PRODUCT" values (1, \'iphone\')'
           ];
function runSql(sql){
  var conn = $.hdb.getConnection();
  conn.execute(sql);
}
sqls.forEach(runSql);
...
<additional code>
```

The following example shows how the same code looks when adapted to Async-XSJS:

### ❁ Example

=== my.xsjslib ===Async-XSJS ===

```
var sqls = ['create table "PRODUCT"("ID" integer, "NAME": varchar(200))',
           'insert into "PRODUCT" values (1, \'iphone\')'
           ];
async function runSql(sql){
  var conn = await $.hdb.getConnection();
  await conn.execute(sql);
}
sqls.forEach(runSql);
...
<some additional code>
```

In the previous example, the SQL statements are only scheduled for execution; they are not executed immediately. When it is time to record them in the database, the order of operation might be different to the order in which the tables were initially read.

### ⚠ Caution

If you have additional code after the `sqs.forEach` function, it will be executed before any of the SQL statements.

To avoid unwanted side effects and ensure that the SQL statements are created in the database in the correct order, you can replace `sqs.forEach(runSql);` with one of the following examples:

- **Example**

#### *Sequential execution*

```
for (int i=0; i<sqs.length; i++){
    await runSql(sqs[i]);
}
<some additional code>
//SQL statements are executed in the correct order, then the additional
code is executed
```

- **Example**

#### *Parallel execution*

```
await Promise.all(sqs.map(runSql));
<some additional code>
//SQL statements are executed in a random order, then the additional code
is executed
```

The same configuration steps can be applied for `Array.map` in analogical way – just replace `sqs.forEach` with `sqs.map`.

Another function that can be asynchronous is `Array.reduce`.

## 4.1.3.5.2.2 Tips and Tricks for Node.js Applications

Get to know the Node.js buildpack for the SAP BTP, Cloud Foundry environment.

Check the following Cloud Foundry documentation:

- [Node.js Buildpack](#) ↗
- [Tips for Node.js Developers](#) ↗

### NPM Version

When deploying an application in the SAP BTP, Cloud Foundry environment without specifying the `npm` version in the `package.json` file, it will install the default `npm` version (depending on the Node.js version) during the build step. A version mismatch can cause the build step to fail.

To check your Node.js version, run:

```
node --version
```

To check your npm version, run:

```
npm --version
```

### → Tip

We recommend that you use the same *npm* version as the one on the SAP BTP, Cloud Foundry environment.

Alternatively, you can specify the *npm* version in the **package.json** file. For example, if you use Node.js 20, you can set:

```
"engines": {  
  "npm": "^8.4.1"  
},
```

### ⓘ Note

Bear in mind that **Node.js** and **npm** are different products, with their own independent versions. To check the version mapping between them, see [NodeJS: Previous Releases](#) ↗.

## Vendor Application Dependencies

Sometimes, productive Cloud Foundry applications might need to be deployed as self-contained. That means, they need to carry all of their dependencies so that the staging process does not require any network calls. For more information, see: [Vendoring App Dependencies](#) ↗

Depending on the region where the application is deployed:

- Running on the China (Shanghai) region: it is **mandatory** for the application to be deployed as self-contained.
- Running on the AWS, Azure, or GCP regions: it is only **recommended** but not mandatory for the application to be deployed as self-contained.

There are various reasons to use vendoring. For example, productive applications usually rely on security scans and because *npm* doesn't provide reliable dependency fetch, it's possible that your Node.js application ends up with different dependencies in case such are installed during deployment. Additionally, *npm* downloads any missing dependencies from its registry, so if this registry isn't accessible for some reason, the deployment can fail.

### ⓘ Note

Bear in mind when using dependencies containing native code that you need to reinstall in the same environment as the Cloud Foundry container, or make sure that the package has built-in support for it.

To ensure that prepackaged dependencies are pushed to the SAP BTP, Cloud Foundry environment and on-premise runtime, make sure that the `node_modules` directory isn't listed in the `.cfignore` file. It's also preferable that development dependencies are not deployed for productive deployments. To ensure that, run:

```
npm prune --production
```

## Out of Memory at Runtime

For performance reasons, Node.js (powered by V8 engine) has lazy garbage collection. Even if there are no memory leaks in your application, this can cause occasional restarts, as explained in the official Cloud Foundry documentation – [Tips for Node.js Applications](#) .

Enforce the garbage collector to run before the memory is consumed by limiting the V8 application's heap size at about ~75% of the available memory. To do that, you can either use the `OPTIMIZE_MEMORY` environment variable supported by the Node.js buildpack, or specify the V8 heap size directly in your application `start` command (recommended).

Example for an application started with 256M of RAM:

### Sample Code

```
node --max_old_space_size=192 server.js
```

You can optimize V8 behavior using additional options. To list these options, run:

```
node --v8-options
```

## Specify a buildpack version in `manifest.yml`

At some point, you might need (or decide) to deploy your application with a particular buildpack version from the community [nodejs-buildpack](#) repository. For example, if this buildpack contains a Node.js version that is no longer supported by the SAP BTP, Cloud Foundry environment.

Let's say, you want to pin version [1.8.9](#) . To do that, proceed as follows:

1. Open the **manifest.yml** file of your Node.js application.
2. For the `buildpack` attribute, add the URL to version 1.8.9, like this:

```
---
applications:
- name: myapp
  random-route: true
  buildpack: https://github.com/cloudfoundry/nodejs-buildpack.git#v1.8.9
  memory: 128M
```

3. Redeploy your application. Run:

```
cf push myapp
```

### Alternative way:

If you don't want to make changes in your **manifest.yml** file, you can include the buildpack version in the `cf push` command.

- To deploy just a **single** application with this particular buildpack version, run:

```
cf push myapp -b https://github.com/cloudfoundry/nodejs-buildpack.git#v1.8.9
```

- To pin this buildpack version for **all** applications running in your SAP BTP, Cloud Foundry environment subaccount, run:

```
cf push -b https://github.com/cloudfoundry/nodejs-buildpack.git#v1.8.9
```

## Specify application memory in `manifest.yml`

When deploying an application in the Cloud Foundry environment without specifying the application memory requirements, the Cloud Foundry controller assigns the default (1G of RAM currently) for your application. Many Node.js applications require less memory and assigning the default is a waste of resources.

To save memory from your quota, specify the memory size in the deployment descriptor of your Cloud Foundry application – `manifest.yml`. For example:

```
---
applications:
- name: myapp
  memory: 128M
  buildpack: nodejs_buildpack
...
```

### 4.1.3.5.3 Developing Python in the Cloud Foundry Environment

This section offers selected information for Python development on the SAP BTP, Cloud Foundry environment and references to more detailed sources.

You'll get information about the buildpack supported by SAP, about the Python packages, and how to consume them in your application.

There is also a tutorial with an introduction to securing your application, and some tips and tricks for developing and running Python applications on the SAP BTP, Cloud Foundry environment.

## Python Community Buildpack

SAP BTP uses the standard [Python buildpack](#)  provided by the Cloud Foundry community to deploy Python applications.

To get familiar with the buildpack and how to deploy applications with it, take a look at the [Cloud Foundry Python Buildpack documentation](#) .

## SAP Python Packages

SAP includes a selection of Python packages, which are available for download and use for customers and partners who have the appropriate access authorization. To download them, log on to [SAP Software Download Center](#) and search for software component **XS\_PYTHON**, which is an archive that contains the SAP packages.

The following table lists the SAP Python packages that are currently available. For more details about the contents of each Python package, as well as any configuration tips, see the README file in the corresponding package.

Package	Description
<code>sap_instance_manager</code>	Python package for creating and deleting service instances per tenant within an application at runtime.
<code>sap_audit_logging</code>	Provides audit logging functionalities for Python applications.
<code>sap_xssec</code>	SAP XS Advanced Container Security API for Python.
<code>sap_cf_logging</code>	This is a collection of support libraries for Python applications running on Cloud Foundry that: <ul style="list-style-type: none"><li>• provide means to emit structured application log messages</li><li>• instrument web applications of your application stack to collect request metrics</li></ul>
<a href="#">hdbcli</a>	The SAP HANA Database Client provides means for database connectivity.

## Buildpack Versioning

The SAP BTP, Cloud Foundry environment provides one recent version of `python_buildpack` as part of its system buildpacks. To check this version, proceed as follows:

1. Log in to a particular SAP BTP region and subaccount. For example, if your region is **eu10**, run:

```
cf api https://api.cf.eu10.hana.ondemand.com
```

2. Then run:

```
cf buildpacks
```

To learn about changes in Python versions and features, regularly check the latest [buildpack releases](#) in the GitHub community page.

## Supported Versions

The `python_buildpack` supports the following versions:

- Python **3.8**
- Python **3.9**
- Python **3.10**
- Python **3.11**

### Note

Version **3.7** is out of maintenance, as per [Python release roadmap](#). We strongly recommend that you switch to version 3.8 or higher.

You can also decide to deploy your application with a particular buildpack version from the community [python-buildpack](#) repository. To learn how, see: [Specify a buildpack version in manifest.yml \[page 325\]](#)

### Remember

SAP does **not** recommend use of deprecated Python versions, as support and security fixes are no longer provided for them.

## What's New

To see the latest news and updates about the Python buildpack, regularly check the release notes on the [buildpack releases](#) in the GitHub community page.

### Note

In May 2023, SAP migrated the root file system used in the Cloud Foundry environment in SAP BTP from the deprecated `cflinuxfs3` stack to **`cflinuxfs4`**. If you are running Python applications on SAP BTP, Cloud Foundry using the Python buildpack, we recommend that you update and migrate your applications, as well as the Python buildpack. For more information about migration timelines, risks, and consequences, see:

- [Deprecation of Cloud Foundry Stack cflinuxfs3 and Migration to cflinuxfs4](#)
- [What's New for SAP BTP, Cloud Foundry Runtime \(cflinuxfs\)](#)

## Troubleshooting

If you encounter an issue while using the Python buildpack, you can:

- Search for your problem in our Guided Answers: [Python Buildpack](#)
- Create an incident for your specific problem, using support component **BC-CP-CF-BLDP**. To provide the necessary details, use the following template: [Initial Problem-Related Data](#)

## Python Tutorial

The following tutorial will guide you through creating a Python application in Cloud Foundry Command Line Interface (cf CLI), consuming Cloud Foundry services, and setting up authentication and authorization checks. See: [Create an Application with Cloud Foundry Python Buildpack](#) 📄

## Tips and Tricks

Selected tips and tricks for your Python development. See [Tips and Tricks for Python Applications](#) [page 325].

### 4.1.3.5.3.1 Tips and Tricks for Python Applications

Get to know the Python buildpack for the SAP BTP, Cloud Foundry environment.

Check the following Cloud Foundry documentation: [Python Buildpack](#) 📄

## Vendor Application Dependencies

Sometimes, productive Cloud Foundry applications might need to be deployed as self-contained. That means, they need to carry all of their dependencies so that the staging process does not require any network calls. For more information, see: [Vendor App Dependencies](#) 📄

Depending on the region where the application is deployed:

- Running on the China (Shanghai) region: it is **mandatory** for the application to be deployed as self-contained
- Running on the AWS, Azure, or GCP regions: it is only **recommended** but not mandatory for the application to be deployed as self-contained.

## Specify a buildpack version in `manifest.yml`

At some point, you might need (or decide) to deploy your application with a particular buildpack version from the community [python-buildpack](#) 📄 repository. For example, if this buildpack contains a Python version that is no longer supported by the SAP BTP, Cloud Foundry environment.

Let's say, you want to pin version [1.8.4](#) 📄 . To do that, proceed as follows:

1. Open the **manifest.yml** file of your Python application.
2. For the `buildpack` attribute, add the URL to version 1.8.4, like this:

```
---
applications:
```

```
- name: myapp
  random-route: true
  buildpack: https://github.com/cloudfoundry/python-buildpack.git#v1.8.4
  memory: 128M
```

3. Redeploy your application. Run:

```
cf push myapp
```

#### Alternative way:

If you don't want to make changes in your **manifest.yml** file, you can include the buildpack version in the `cf push` command.

- To deploy just a single application with this particular buildpack version, run:

```
cf push myapp -b https://github.com/cloudfoundry/python-buildpack.git#v1.8.4
```

- To pin this buildpack version for all applications running in your SAP BTP, Cloud Foundry environment subaccount, run:

```
cf push -b https://github.com/cloudfoundry/python-buildpack.git#v1.8.4
```

## Specify application memory in `manifest.yml`

When deploying an application in the SAP BTP, Cloud Foundry environment without specifying the application memory requirements, the Cloud Foundry controller assigns the default (1G of RAM currently) for your application. Many Python applications require less memory and assigning the default is a waste of resources.

To save memory from your quota, specify the memory size in the deployment descriptor of your Cloud Foundry application – `manifest.yml`. For example:

```
---
applications:
- name: myapp
  memory: 128M
  buildpack: python_buildpack
...
```

## Additional Tips

- The `cfenv` package provides access to the Cloud Foundry application environment settings by parsing all the relevant environment variables. The settings are returned as a class instance. See: <https://github.com/jmcarp/py-cfenv> 🐘
- When developing Python applications, it's a good practice to use virtual environments. The most popular Python package providing such a functionality is `virtualenv`. See: <https://virtualenv.pypa.io/en/stable/> 🐘
- The [PEP 8 Style Guide for Python](#) 🐘 will help you improve your applications.

## 4.1.3.6 Developing Multitenant Applications in the Cloud Foundry Environment

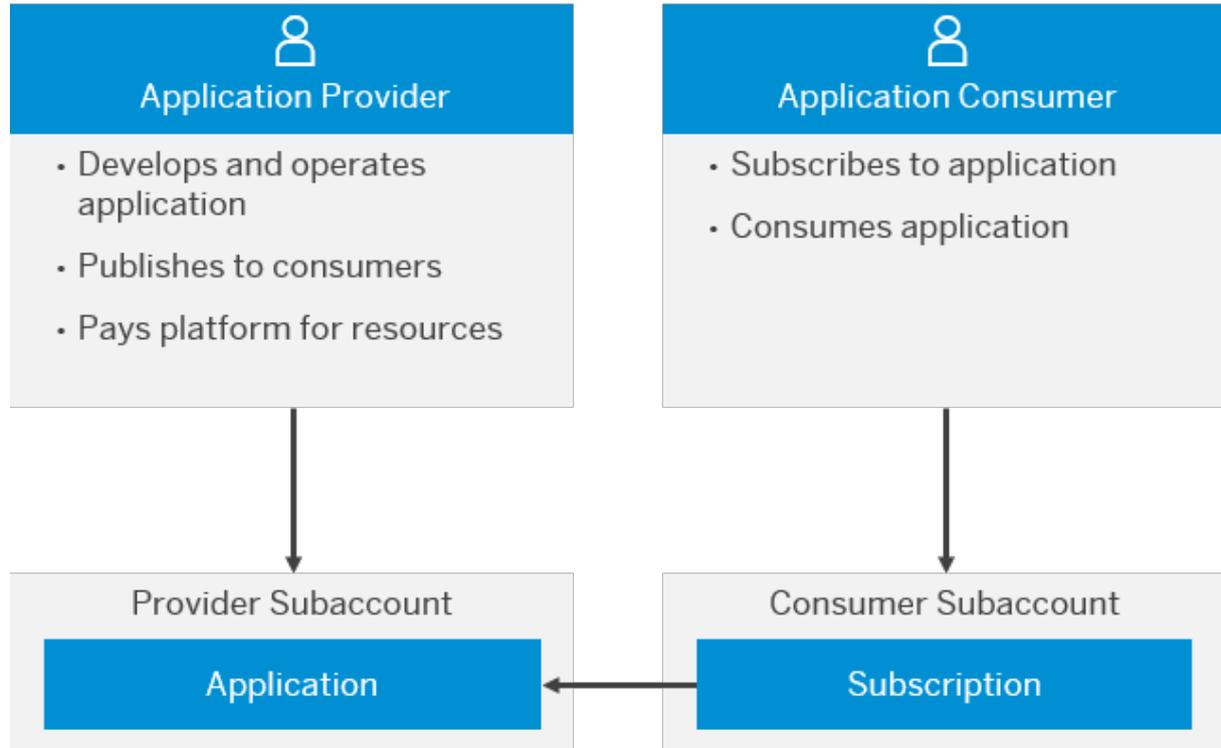

In the Cloud Foundry environment, you can develop and run multitenant applications, and share them with multiple consumers simultaneously on SAP BTP.

### What is Multitenancy?

SAP BTP provides a multitenant functionality that allows application providers to own, deploy, and operate tenant-aware applications for multiple consumers, with reduced costs. For example, the application provider can upgrade the application for all your consumers instead of performing each update individually, or can share resources across multiple consumers. The application consumers launch the applications using consumer-specific URLs, and can configure certain application features.

With tenant-aware applications, you can:

- Separate data securely for each tenant
- Save resources by sharing them among tenants
- Update applications efficiently, in a single step

Consumers cannot see the data of other consumers; the multitenant application maintains data separation between tenants, and SAP Customer Identity and Access Management (SAP CIAM) is kept isolated. Each consumer accesses the multitenant application through a dedicated URL.

## Multitenancy Roles

The multitenancy concept involves two main user roles:

Application provider	An SAP global account owner that uses SAP BTP to own, build, run, and offer custom-developed applications to its consumers.
Application consumer	A consumer of the application provider, such as a department or organizational unit, whose users use the multitenant application.

## How Does Multitenancy Work for the Application Consumer?

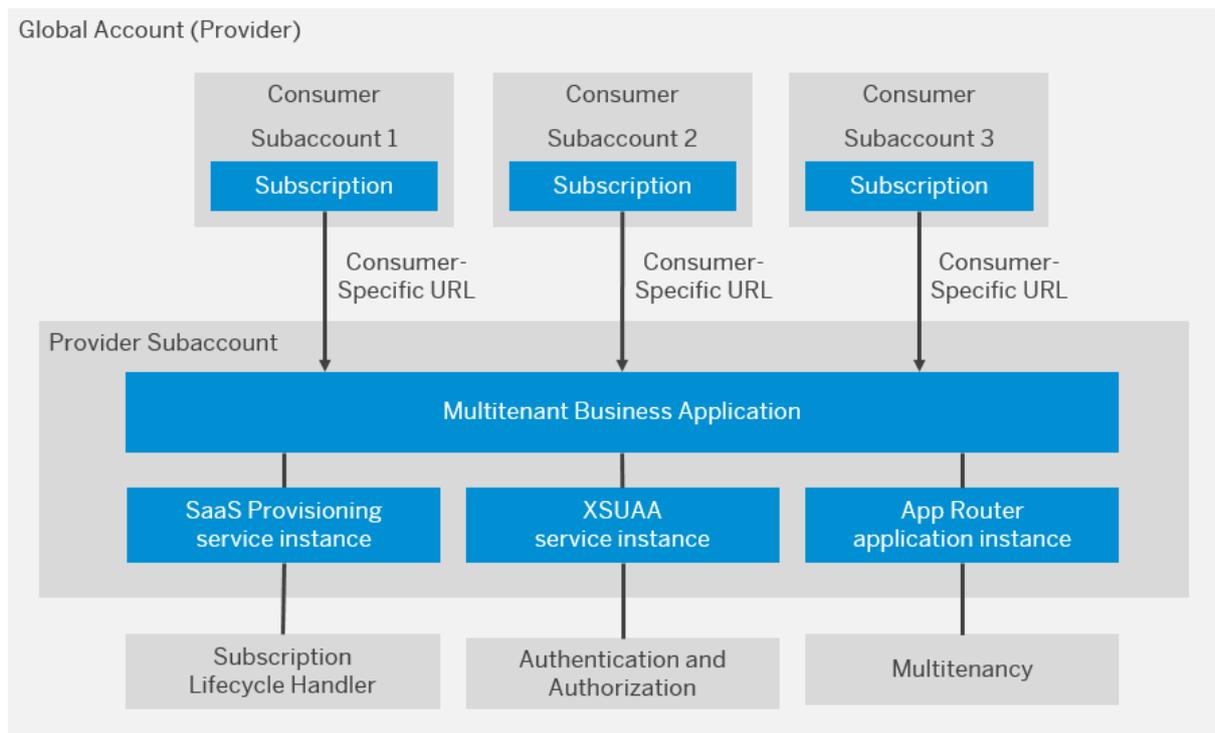

For a consumer to use a tenant-aware application on SAP BTP, the application owner must ensure that each consumer:

1. Has a dedicated subaccount in the application provider's global account.
2. Subscribes to the application using either the SAP BTP cockpit, SAP BTP command-line interface, or a dedicated REST API.  
A subscription means that there is a direct relationship between an application provider and the consumer's tenant. The application provider authorizes the consumer tenant to use the application.
3. Receives a dedicated URL so that its business users can access the application  
As with any application running in SAP BTP, these multitenant applications consume platform resources, such as compute units, structured and unstructured storage, and outgoing bandwidth. The costs for these consumed resources, and those of the application consumer, are billed to the provider of the multitenant application.

For more information about these consumer-related steps, see [Providing Multitenant Applications to Consumers in the Cloud Foundry Environment \[page 344\]](#) and [Subscribe to Multitenant Applications Using the Cockpit \[page 2008\]](#).

When a consumer accesses the application, the application environment identifies them by their unique tenant ID. The application distinguishes between requests from different consumer tenants based on the tenant ID, thus ensuring data isolation.

The following figure illustrates the relationship between the application provider's subaccount and consumer subaccounts (tenants) in the provider's global account. You deploy the multitenant application to the provider subaccount, and subsequently the consumer subaccounts subscribe to the deployed application. The application uses the tenant-aware `approuter` application and `xsuaa` service (with the `application` plan) to authenticate business users of the application at runtime. The application is then registered with the SAP Software-as-a-Service Provisioning service (technical name: `saas-registry`) with the `application` plan, which makes the application available for subscription to consumers.

## Workflow

This is the workflow and requirements for developing and deploying a multitenant application in the Cloud Foundry environment:

1. [Develop the Multitenant Application \[page 330\]](#)  
In the Cloud Foundry environment of SAP BTP, you can develop and run multitenant applications that can be accessed by multiple consumers (tenants) through a dedicated URL.
2. [Deploy the Multitenant Application to the Provider Subaccount \[page 333\]](#)  
After you have developed your multitenant application and authorizations, you need to deploy the application in a Cloud Foundry space in the provider's subaccount.
3. [Configure the approuter Application \[page 334\]](#)  
To authenticate business users of the application at runtime, use the tenant-aware approuter application and `xsuaa` service in SAP BTP.
4. [Bind the Multitenant Application and Application Router to the xsuaa Service Instance \[page 336\]](#)  
Bind your multitenant application and the approuter application to the `xsuaa` service instance, which acts as an OAuth 2.0 client to your application.
5. [Register the Multitenant Application to the SAP SaaS Provisioning Service \[page 337\]](#)  
To make a multitenant application available for subscription to SaaS consumer tenants, you (the application provider) must register the application in the Cloud Foundry environment via the SAP Software-as-a-Service Provisioning service (`saas-registry`).
6. [Providing Multitenant Applications to Consumers in the Cloud Foundry Environment \[page 344\]](#)  
Create a subaccount in your global account for each application consumer, subscribe each consumer subaccount to the hosted application deployed in the provider account, and then set up application roles and assign users.

## Related Information

[Using SAP SaaS Provisioning Service APIs to Manage Multitenant Applications \[page 346\]](#)

[Data Protection and Privacy \[page 2838\]](#)

[Using the Subscription Management Dashboard \[page 351\]](#)

### 4.1.3.6.1 Develop the Multitenant Application

In the Cloud Foundry environment of SAP BTP, you can develop and run multitenant applications that can be accessed by multiple consumers (tenants) through a dedicated URL.

#### Context

When developing tenant-aware applications in the Cloud Foundry environment, keep in mind the following general programming guidelines:

- Shared in-memory data such as Java static fields will be available to all tenants.
- Avoid any possibility that an application user can execute custom code in the application JVM, as this may give them access to other tenants' data.
- Avoid any possibility that an application user can access a file system, as this may give them access to other tenants' data.
- To perform internal tenant onboarding activities, such as creating a database schema for tenants, you must implement the `subscription` callbacks of the SAP Software-as-a-Service Provisioning service (`saas-registry`) and use the information provided in the subscription event. You can also implement the `getDependencies` callback to obtain the dependencies of any SAP reuse services by your application. See details in the procedure below.

#### Procedure

1. Develop the application as for any other Java and Node.js application on the SAP BTP.

For more information, see [Developing Java in the Cloud Foundry Environment \[page 242\]](#).

2. In your application, you must implement a REST API that will be called by the SAP SaaS Provisioning service (`saas-registry`) on a subscription event. Optionally, you can implement the `getDependencies` REST API to obtain the dependencies of any SAP reuse services consumed by your application.

When a consumer tenant creates or revokes a subscription to your multitenant application via the cockpit, the SAP SaaS Provisioning service calls the application with two `subscription` callbacks. The first callback gets the dependencies of any reuse services used by your application. The second callback informs the application about the subscription event (`PUT` for subscribe and `DELETE` for unsubscribe) and provides details about the subscriber (the consumer tenant).

- To inform the application that a new consumer tenant wants to subscribe to the application, implement the callback service with the `PUT` method. The callback must return a 200 response code and a string in the body, which is the access URL of the tenant to the application subscription (the URL contains the subdomain). This URL is generated by the multitenant application based on the approuter configuration (see [Configure the approuter Application \[page 334\]](#))

### Sample Code

Callback response (`PUT`).

```
https://subscriber_subdomain-
approuter_saas_app.cfapps.eu10.hana.ondemand.com
```

The URL must be in the format: `https://<SUBSCRIBER_TENANT_SUBDOMAIN >-<APPROUTER_APPLICATION_HOST>.<CF_DOMAIN>`

- To inform the application that a tenant has revoked its subscription to the multitenant application and is no longer allowed to use it, implement the same callback with the `DELETE` method.

### Sample Code

Payload of subscription `PUT` and `DELETE` methods:

```
{
  "subscriptionAppId": "<value>",           # The
  application ID of the main subscribed application.
  "subscriptionAppName": "<value>"         # Generated by
  Authorization and Trust Management service(xsuaa)-based on the
  xsappname.
  "subscribedTenantId": "<value>"         # The
  application name of the main subscribed application.
  "subscribedSubdomain": "<value>"        # ID of the
  subscription tenant
  "globalAccountGUID": "<value>"         # The subdomain
  of the subscription tenant (hostname for
  identityzone).
  "subscribedLicenseType": "<value>"      # the
  global account
  "subscribedLicenseType": "<value>"      # ID of the
  type of the subscription tenant
}
```

- If your application consumes any reuse services provided by SAP, you must implement the `getDependencies` callback to return the service dependencies of the application. The callback must return a 200 response code and a JSON file with the dependent services `appName` and `appId`, or just the `xsappname`.

### Note

The JSON response of the callback must be encoded as either UTF8, UTF16, or UTF32, otherwise an error is returned.

### Sample Code

Sample dependency response:

```
[
  {
```

```

    "xsappname" : "<value>" # The xsappname of the reuse service
which the application consumes. # Can be found in the environment
variables of the application: #
VCAP_SERVICES.<service>.credentials.xsappname
}
]

```

For more information about the subscription callbacks and dependencies, see [Register the Multitenant Application to the SAP SaaS Provisioning Service \[page 337\]](#).

3. Configure the application's authentication and authorization for the SAP HANA XS advanced Java run time.

For general instructions, see [SAP Authorization and Trust Management Service \[page 2778\]](#).

4. Create a security descriptor file in JSON format that specifies the functional authorization scopes for the application:
  - Define the application provider tenant as a shared tenant:

```
"tenant-mode": "shared"
```

- Provide access to the SAP SaaS Provisioning service SAP Authorization and Trust Management service (technical name: `saas-registry`) for calling callbacks and getting the dependencies API by granting scopes:

```
"grant-as-authority-to-apps" : [ "$XSAPPNAME(application,sap-
provisioning,tenant-onboarding)" ]
```

### Sample Code

Security descriptor file in JSON format:

```

{
  "xsappname": "saas-app",
  "tenant-mode": "shared",
  "scopes": [
    {
      "name": "$XSAPPNAME.Callback",
      "description": "With this scope set, the callbacks for subscribe,
unsubscribe and getDependencies can be called.",
      "grant-as-authority-to-apps": [
        "$XSAPPNAME(application,sap-provisioning,tenant-onboarding)"
      ]
    }
    ....
  ],
  ....
}

```

5. In the Cloud Foundry space in the provider's subaccount where your application is going to be deployed (see [Deploy the Multitenant Application to the Provider Subaccount \[page 333\]](#)), create an `xsuaa` service instance with the security configurations, which you defined in the security descriptor file in the previous step, by executing this command in the Cloud Foundry command line interface (cf CLI):

```
cf create-service xsuaa application <XSUAA_INSTANCE_NAME> -c
<XS_SECURITY_JSON>
```

Specify the following parameters:

Parameter	Description
XSUAA_INSTANCE_NAME	The new name for the xsuaa service instance. Use only alphanumeric characters, hyphens, and underscores.
<XS_SECURITY_DESCRIPTOR_NAME>	Name of the security descriptor file from the previous step.

#### Sample Code

```
cf create-service xsuaa application xsuaa-application -c xs-security.json
```

#### Tip

You can also create the service instance directly in the cockpit.

For general instructions, see [Create Spaces Using the Cloud Foundry Command Line Interface \[page 2289\]](#).

## 4.1.3.6.2 Deploy the Multitenant Application to the Provider Subaccount

After you have developed your multitenant application and authorizations, you need to deploy the application in a Cloud Foundry space in the provider's subaccount.

### Context

To make the application available to subaccounts in multiple regions, you need to deploy the application to a provider subaccount in each of the regions.

### Procedure

1. Create a subaccount in the Cloud Foundry environment in the global account of the application provider. This subaccount will host the multitenant application for the provider tenant.

For general instructions, see [Create a Subaccount \[page 1977\]](#).

2. In the subaccount, create a space in a Cloud Foundry organization.

For general instructions, see [Create Spaces \[page 2251\]](#).

3. Assign the appropriate quota for the application runtime memory to the provider's subaccount.

For general instructions, see [Configure Entitlements and Quotas for Subaccounts \[page 2003\]](#).

4. Deploy the application to the Cloud Foundry space and start it by executing the `push` command in the command line interface (cf CLI).

For more information, see [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#).

### 4.1.3.6.3 Configure the approuter Application

To authenticate business users of the application at runtime, use the tenant-aware `approuter` application and SAP Authorization and Trust Management service (technical name: `xsuaa`) in SAP BTP.

#### Context

You deploy the `approuter` application as a Cloud Foundry application and as a logical part of the multitenant application. Then you configure `approuter` application as an external access point of the application. You need to deploy a separate application router for each multitenant application.

#### How does the application router and multitenancy work?

When a consumer accesses the application, their consumer tenant calls the multitenant application via the application router with their tenant-specific URL (cf route).

- **During a development phase** of your multitenant application, the following URL structure applies:

`<SUBSCRIBER_TENANT_SUBDOMAIN>-<APPROUTER_APPLICATION_HOST>.<SAP-PROVIDED_STANDARD_DOMAIN>`

In each development landscape, SAP provides a different standard domain you can use to create URLs. Using that domain, and following the specified URL structure, a created URL would be:

`tenant1-myapprouter.cfapps.sap.hana.ondemand.com`

Where: `tenant1-myapprouter` is the hostname, and `cfapps.sap.hana.ondemand.com` is the SAP-provided standard domain for this development landscape.

In this format, create a new URL for each new tenant.

- **During a production phase** of your multitenant application, apply for a custom domain via the custom domain service, then create a URL using the following structure:

`*.<YOUR_CUSTOM_DOMAIN>.`

Where: `*` is the wildcard hostname.

In this format, since the wildcard is replaced by an actual tenant during runtime, there is no need to create a new URL for each new tenant.

For more information, see [Using Custom Domains \[page 2302\]](#)

In both cases, the application router then derives the tenant from the URL and calls the tenant-aware `xsuaa` (containing the user account and authentication service), which is responsible for the authentication of the business user. The `xsuaa` reads the tenant and gets the customer-specific identity provider (IdP) from the tenant-specific identity zone. Then, the `xsuaa` delegates the authentication to the configured IdP, and creates a JSON Web Token (JWT) that contains the tenant, the current user, and the authorization scopes of the user. The JWT is then sent back to the application router, and from there to the application.

To read and store tenant-specific data, the multitenant application needs to know the tenant ID. To read the tenant ID, use the Container Security API to enable the multitenant application to read the tenant, user,

and scopes from the given JWT. The API also validates whether the JWT is valid. The tenant information is contained in the `identityZone` user attribute.

### Sample Code

Java code for retrieving the identity zone

```
UserInfo userInfo = SecurityContext.getUserInfo();
String identityZone = userInfo.getIdentityZone();
```

For more information, see:

- [Web Access Control \[page 2789\]](#)
- [What Is the SAP Authorization and Trust Management Service? \[page 2785\]](#)

## Procedure

1. Create the application structure of the application router and configure it accordingly.

For general instructions, see [Application Router \[page 377\]](#).

2. Configure the application router with the destination of your multitenant application.

If you are defining the destination as an environment variable for the `approuter` application, set the router information in the `env: destinations` section of the `manifest.yml`.

- `url`: Specify the URL of the multitenant application.
- `forwardAuthToken`: Set to `true`

### Sample Code

`manifest.yml` for a development phase:

```
---
applications:
- name: approuter-saas-app
  host: approuter_saas_app
  path: approuter
  buildpack: nodejs_buildpack
  memory: 256M
  env:
    TENANT_HOST_PATTERN: "^(.*)-cfapps.eu10.hana.ondemand.com"
  destinations: >
  [
    {"name": "saas-application",
     "url": "https://backend-saas-app.cfapps.sap.hana.ondemand.com",
     "forwardAuthToken": true}
  ]
```

### Sample Code

`manifest.yml` for a production phase:

```
---
applications:
- name: approuter-saas-app
  host: approuter_saas_app
```

```

path: approuter
buildpack: nodejs_buildpack
memory: 256M
env:
  TENANT_HOST_PATTERN: "^(.*).mydomain.com"
  destinations: >
  [
    {"name": "saas-application",
     "url": "https:// backend-saas-app.mydomain.com",
     "forwardAuthToken": true}
  ]

```

For more information, see [Application Routes and Destinations \[page 416\]](#).

3. Configure the routes in the application router security descriptor file (`xs-app.json`) so that application requests are forwarded to the multitenant application destination.

#### Sample Code

`xs-app.json`:

```

{
  "routes": [{
    "source": "/",
    "target": "/",
    "destination": "saas-application"
  }]
}

```

For more information, see [Routing Configuration File \[page 387\]](#).

4. Use the `push` command in the `cf` CLI to deploy the `approuter` application to the Cloud Foundry space where your multitenant is deployed.

## 4.1.3.6.4 Bind the Multitenant Application and Application Router to the xsuaa Service Instance

Bind your multitenant application and the `approuter` application to the SAP Authorization and Trust Management service (technical name: `xsuaa`) instance, which acts as an OAuth 2.0 client to your application.

### Procedure

Execute the following commands in the Cloud Foundry command line interface to bind both your multitenant application and the `approuter` application to the `xsuaa` service instance.

```
cf bind-service <APP_NAME> <XSUAA_INSTANCE_NAME>
```

```
cf bind-service <APPROUTER_APP_NAME> <XSUAA_INSTANCE_NAME>
```

Specify the following parameters:

Parameter	Description
APP_NAME	The name of the deployed multitenant application.
XSUAA_INSTANCE_NAME	The name of the <code>xsuaa</code> service instance you created in <a href="#">Develop the Multitenant Application [page 330]</a> .
APPROUTER_APP_NAME	The name of the <code>xsuaa</code> application you deployed in <a href="#">Configure the approuter Application [page 334]</a> .

#### Sample Code

```
cf bind-service saas-app xsuaa-application
cf bind-service approuter-saas-app xsuaa-application
```

#### Tip

You can also bind the application to the `xsuaa` service instances directly in the SAP BTP cockpit.

## 4.1.3.6.5 Register the Multitenant Application to the SAP SaaS Provisioning Service

To make a multitenant application available for subscription to SaaS consumer tenants, you (the application provider) must register the application in the Cloud Foundry environment via the SaaS Provisioning Service (technical name: `saas-registry`).

### Context

The SaaS Provisioning Service allows application providers to register multitenant applications and services in the Cloud Foundry environment in SAP BTP. This activity is a one-time procedure per multitenant application.

### Procedure

1. Create a service instance of the SaaS Provisioning Service with a configuration JSON file in the Cloud Foundry space where the multitenant application is deployed.

#### Tip

You can create the SaaS Provisioning Service instance directly in the SAP BTP cockpit.

For general instructions, see [Creating Service Instances](#).

- a. The configuration JSON file must follow the following format and set these properties (note that instead of `xsappname` you can use `appId`):

```
{
  "xsappname" : "<xsappname>",
  "appUrls": {
    "getDependencies" : "<getDependenciesUrl>",
    "onSubscription" : "<onSubscriptionUrl>/{tenantId}"
  },
  "appPlans": [
    {
      "name": "...",
      "description": "..."
    }, {
      ...
    }
  ],
  "displayName" : "<displayName>",
  "description" : "<description>",
  "category" : "<category>",
  "onSubscriptionAsync": true/false,
  "callbackTimeoutMillis": <int>
  "allowContextUpdates": true/false,
}
```

Specify the following parameters:

Parameters	Description
<code>xsappname</code>	The <code>xsappname</code> configured in the security descriptor file used to create the <code>xsuaa</code> instance (see <a href="#">Develop the Multitenant Application [page 330]</a> ).

Parameters	Description
getDependencies	<p>(Optional) Implement a callback API that is executed by the SaaS Provisioning Service to retrieve your application's dependencies.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>Implement only if your application has dependencies.</p> </div> <p><b>API Structure</b></p> <ul style="list-style-type: none"> <li>Request: <ul style="list-style-type: none"> <li>GET</li> <li>URL: Define the endpoint to which SaaS Provisioning Service executes the request. For example: <code>https://&lt;app url&gt;/callback/v1.0/dependencies</code></li> </ul> </li> <li>Response: <ul style="list-style-type: none"> <li>HTTP Status Code: 200 (Ok)</li> <li>Header: <code>content-type: application/json</code></li> <li>Response Body: Specify the <code>xsappname</code> of each of your dependencies.</li> </ul> </li> </ul> <pre style="background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> {   "xsappname": "...", # The   xsappname of the reusable service instance   that the application consumes.   Find it   in the following environment variable of   your application:   &lt;VCAP_SERVICES.&lt;service&gt;.credentials.xsappn   ame   &gt;   },   .... </pre> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>The JSON response of the callback must be encoded as either UTF8, UTF16, or UTF32, otherwise an error is returned.</p> </div>
onSubscription	<p>Any URL that the application exposes via PUT and DELETE subscription. It must end with <code>/ {tenantId}</code>. The tenant for the subscription is passed to this callback as a path parameter. You must keep <code>{tenantId}</code> as a parameter in the URL so that it's replaced at real time with the tenant calling the subscription. This callback URL is called when a subscription between a multitenant application and a consumer tenant is created (PUT) and when the subscription is removed (DELETE).</p>
appPlans	<p>(Optional) Specify the plan for your application. Name it and provide a short description. With the help of plans, you can try out your application in different modes or variations. For example, an app for staging or development purposes. Note that the plans are only visible in the subaccounts that belong to the provider global account.</p>

Parameters	Description
displayName	(Optional) The display name of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's technical name.
description	(Optional) The description of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's display name.
category	(Optional) The category to which the application is grouped in the <a href="#">Subscriptions</a> page in the cockpit. If left empty, gets assigned to the default category.
onSubscriptionAsync	Whether the subscription callback is asynchronous.  If set to true, <code>callbackTimeoutMillis</code> is mandatory.
callbackTimeoutMillis	The number of milliseconds the SaaS Provisioning Service waits for the application's subscription asynchronous callback to execute, before it changes the subscription status to <code>FAILED</code> .
allowContextUpdates	Whether to send updates about the changes in contextual data for the service instance.  For example, when a subaccount with which the instance is associated is moved to a different global account.  Default value is false.

### Sample Code

Configuration JSON file (example: config.json):

```
{
  "xsappname": "saas-app",
  "appUrls": {
    "getDependencies": "https://saas-app.cfapps.eu10.hana.ondemand.com/callback/v1.0/dependencies",
    "onSubscription": "https://saas-app.cfapps.eu10.hana.ondemand.com/callback/v1.0/tenants/{tenantId}"
  },
  "displayName": "Hello World",
  "description": "My multitenant biz app",
  "category": "Test"
}
```

- b. Execute the following cf CLI command to create the service instance with the JSON configuration file:

```
cf create-service saas-registry application
<SAAS_REGISTRY_SERVICE_INSTANCE> -c <JSON_CONFIG_FILE>
```

Specify the following parameters:

Parameters	Description
SAAS_REGISTRY_SERVICE_INSTANCE	The new name for your service instance. Use only alphanumeric characters, hyphens, and underscores.

Parameters	Description
JSON_CONFIG_FILE	The file name of the service-specific configuration parameters, in a valid JSON object (described above).

### Sample Code

```
cf create-service saas-registry application saas-registry-application
-c config.json
```

- To ensure that the application trusts the JWT issued for another identity zone (`sap-provisioning`), add the environment variable: `SAP_JWT_TRUST_ACL`

```
SAP_JWT_TRUST_ACL: '[{"clientid":"*", "identityzone":"sap-provisioning"}]'
```

### Note

The client libraries (java-security, spring-xsuaa, container security api for node.js >= 3.0.6, approuter >= 8.x, and sap\_xssec for Python >= 2.1.0) have been updated. When using these libraries, setting the parameter `SAP_JWT_TRUST_ACL` has become obsolete.

Instead, the `xsuaa` service adds audiences to the issued JSON Web Token audience field (`aud`). Client libraries provide an audience validator to check whether the token is issued for your service or application. Technically, this information is implicitly derived from the audience field (`aud`) or from the scopes.

Therefore, this update comes with a change regarding scopes. For a business application A that wants to call an application B, it's now mandatory that application B grants at least one scope to the calling business application A. Furthermore, business application A has to accept these granted scopes or authorities as part of the application security descriptor. You can grant scopes with the `xs-security.json` file.

For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

- Bind the SaaS Provisioning Service instance that you created to the multitenant application that you deployed in your Cloud Foundry space using the following cf CLI command:

```
cf bind-service <APP_NAME> <SAAS_REGISTRY_SERVICE_INSTANCE>
```

Specify the following parameters:

Parameters	Description
APP_NAME	The ID of your deployed multitenant application.
SAAS_REGISTRY_SERVICE_INSTANCE	The name of the SaaS Provisioning Service instance you created in step 1 above.

### Sample Code

```
cf bind-service saas-app saas-registry-application
```

### → Tip

You can bind your application to the SaaS Provisioning Service instance directly in the SAP BTP cockpit.

For general instructions, see [Binding Service Instances to Applications \[page 234\]](#).

4. To ensure that the environment variables in the application take effect, execute the following cf CLI command:

```
cf restage <APP_NAME>
```

Specify the following parameter:

Parameters	Description
APP_NAME	The ID of your deployed multitenant application.

### ↗ Sample Code

```
cf restage saas-app
```

## Next Steps

1. In your global account, create a subaccount for each consumer tenant.
2. Subscribe your consumer tenants to the multitenant applications using the cockpit.
3. Test your multitenant application from consumer tenants to ensure availability, subscription lifecycle, and optional application configurations.
4. Supply your customers or users of the multitenant application with their consumer-specific URL to access the application.

For more information, see [Providing Multitenant Applications to Consumers in the Cloud Foundry Environment \[page 344\]](#).

## 4.1.3.6.5.1 Unregister a Multitenant Application from the SAP SaaS Provisioning Service

Unbind and delete the service instance you have created during the registration of your multitenant application to complete the unregistration process.

### Prerequisites

Make sure that no tenant is subscribed to your application before you initiate the deletion of the service instance.

#### → Tip

Use the `Get Application Subscriptions` API to get the application subscriptions.

In case there are subscribed tenants, unsubscribe them first by calling the `Unsubscribe the tenant from an application` API.

For more information, see [Using SAP SaaS Provisioning Service APIs to Manage Multitenant Applications \[page 346\]](#).

### Context

The procedure described in this section uses the cf CLI.

#### → Tip

You can delete a service instance directly in the SAP BTP cockpit, in the [Service Instances](#) page.

### Procedure

1. Use cf CLI to remove any existing service keys and app bindings:
  - a. Run the following command to delete the service key:

```
cf delete-service-key SERVICE-INSTANCE-NAME KEY-NAME
```

#### 📌 Note

Service key is an optional parameter.

In case you haven't created a service key during the registration process, skip to substep b.

- b. Run the following command to unbind your application from the service instance:

```
cf unbind-service APP-NAME SERVICE-INSTANCE-NAME
```

- c. Run the following command to delete the service instance:

```
cf delete-service SERVICE-INSTANCE-NAME
```

2. The deletion process is asynchronous. Run `cf services` to view the current status of the process.

### 4.1.3.6 Providing Multitenant Applications to Consumers in the Cloud Foundry Environment

Once you have built a multitenant application in the Cloud Foundry environment using SAP BTP, you can then share the application with multiple consumers, such as business units in your organization.

#### Consumer Subaccounts and Subaccount Members

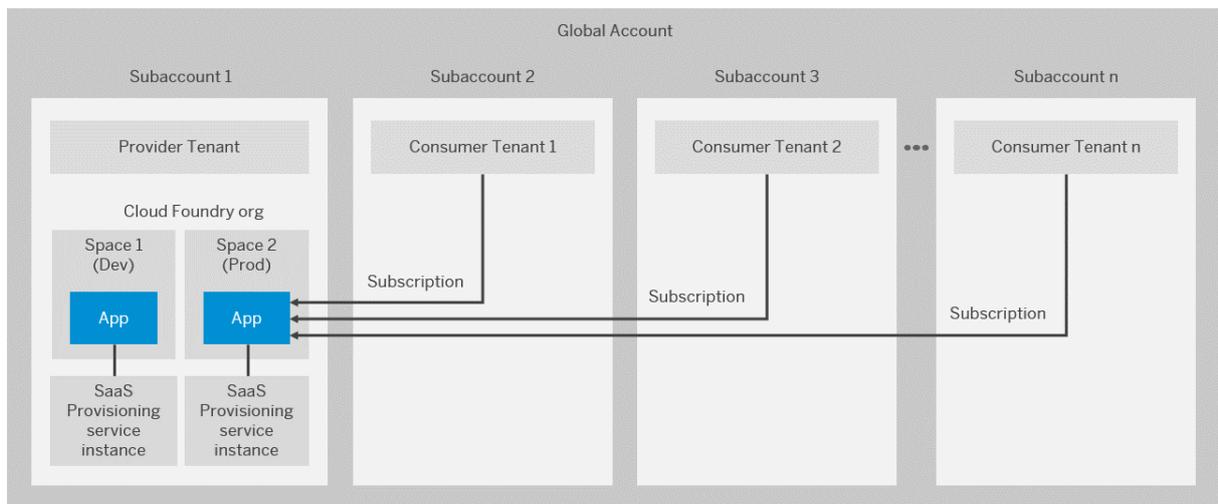

To use multitenancy in the Cloud Foundry environment in SAP BTP, the application provider must create a subaccount for each consumer in the same global account where the multitenant application is deployed.

The multitenant application is deployed to one subaccount only, which is the hosting subaccount of the application provider. Consumers simply subscribe to the provider application from their subaccount through the SAP BTP cockpit, the SAP BTP command line interface, or dedicated REST APIs.

The application provider is responsible for:

- Creating and managing the tenant subaccounts.
- Setting up the necessary role access authorizations.
- Subscribing each tenant to the application.

Typically, consumers of multitenant applications provided by a non-SAP application owner, such as an IT department of an organization, do not own or have access to their tenant subaccount.

Account setup for an application owner provisioning a multitenant application to its consumers.

Subaccount members are users who are registered via the SAP ID service. Subaccount members may have different privileges regarding the operations that are possible for a subaccount (for example, subaccount administration, deploy, start, and stop applications).

The subaccount-specific configuration allows application providers to adapt the consumer subaccounts to their specific needs.

## What Do You Need to Do, and How?

Once you have developed, deployed, configured, and registered your multitenant application, your account administrator is ready to do the following.

1. Create a subaccount in your global account for each application consumer.  
See [Create a Subaccount \[page 1977\]](#).
2. Subscribe each consumer subaccount to the hosted application deployed in the provider account.  
See:
  - [Subscribe to Multitenant Applications Using the Cockpit \[page 2008\]](#)
  - [Working with Multitenant Applications Using the `btp` CLI \[page 2173\]](#)
  - Subscribe the tenant to an application using the REST API. For more information, see [Using SAP SaaS Provisioning Service APIs to Manage Multitenant Applications \[page 346\]](#)
3. Set up application roles and assign users.  
See [Configure Application Roles and Assign Roles to Users \[page 2011\]](#).

## Viewing and Managing of Your Multitenant Application's Subscriptions

Once you've provided your multitenant application to consumers to subscribe to it, you can view and manage all the subscriptions by using a dedicated interface called SAP BTP subscription management dashboard.

For more information, see [Using the Subscription Management Dashboard \[page 351\]](#).

## 4.1.3.6.7 Using SAP SaaS Provisioning Service APIs to Manage Multitenant Applications

Use the SaaS Provisioning Service (technical name: `saas-registry`) APIs to work with multitenant applications.

### Background

Most of the SaaS Provisioning Service APIs are concentrated into two main groups:

1. APIs for Application Providers
2. APIs for Application Consumers

Application providers can use both groups to either manage their application subscriptions from the global account in which they deployed their multitenant application when using the first group, or mimic their consumers in working with the application from a different global account than the one in which their application is deployed, when using the second group.

Consumers can use the second group to work with the multitenant applications.

All SaaS Provisioning Service APIs adhere to the rate limiting rules as described in [Rate Limiting \[page 2221\]](#).

### APIs for Application Providers

#### → Tip

Instead of APIs, can use a dedicated user interface with the same capabilities to manage your multitenant application's subscriptions.

For more information, see [Using the Subscription Management Dashboard \[page 351\]](#).

### Prerequisites

- You have a global account and have deployed a multitenant application in it.
- You've registered your multitenant application to the SaaS Provisioning Service. For more information, see [Register the Multitenant Application to the SAP SaaS Provisioning Service](#).

### Preparation

1. For an existing instance of `saas-registry` service with the `application` plan, create a service key or service binding if you don't already have one. For more information, see [Service Bindings](#).
2. From the created key or service binding, extract the values of the following fields:
  - `url`
  - `clientid`
  - `clientsecret`
  - `saas_registry_url`

You need the first three values to authenticate your SaaS Provisioning Service API requests and the last one as base URL in each API call.

## Authentication

To authenticate, obtain an OAuth token by calling a POST API with the acquired parameters in any REST API tool or directly in your code. For example:

```
curl -XPOST '<url>/oauth/token?grant_type=client_credentials&client_id=<clientid>' -H 'Content-Type: application/x-www-form-urlencoded' -H 'Authorization: Basic <encodedString>'
```

where:

`<encodedString>` is the result of base64 encoding `<clientid>:<clientsecret>`.

## Available APIs

Go to [SAP Business Accelerator Hub](#) and select the **Application Operations for App Providers** section to get information about all the available APIs and their details.

You can also try out the APIs in the SAP Business Accelerator Hub.

For more information, see [Trying Out APIs](#).

### Note

To authenticate to try out the APIs in SAP Business Accelerator Hub, configure an environment.

During the environment configuration, select the *OAuth 2.0 Application Flow* option from the dropdown menu. You must do so for the Application Provider API group because these specific APIs only support the Client Credentials authentication type.

For more information about configuring an environment in general, see [Trying Out APIs in a Configured Environment](#).

## APIs for Application Consumers

### Prerequisites

- You've created an instance of Cloud Management (technical name: `cis`) service with `local` plan.

### Authentication

To learn how to authenticate, see [Getting an Access Token for SAP Cloud Management Service APIs](#).

### Available APIs

Go to [SAP Business Accelerator Hub](#) and select the **Subscription Operations for App Consumers** section to get information about all the available APIs and their details.

You can also try out the APIs in the SAP Business Accelerator Hub. For more information, see [Trying Out APIs](#).

To authenticate to try out the APIs in SAP Business Accelerator Hub, configure an environment.

For more information about configuring an environment in general, see [Trying Out APIs in a Configured Environment](#).

### 4.1.3.6.7.1 Getting an Application Access Token

Use this API to get the application access token from the SAP Software-as-a-Service Provisioning service instance.

#### Prerequisites

You've registered your multitenant application to the SAP SaaS Provisioning service.

For more information, see [Register the Multitenant Application to the SAP SaaS Provisioning Service \[page 337\]](#).

#### Obtaining API Request Parameters

To get the token, you call the API with the parameters obtained from the service binding object you created during the registration of your multitenant application to the SAP SaaS Provisioning service.

Use the following cf CLI command to get the service binding object:

```
cf env <APP_NAME>
```

See the step 3 in the [Register the Multitenant Application to the SAP SaaS Provisioning Service \[page 337\]](#) to find the `<APP_NAME>`.

The example of the binding object you get after executing the cf CLI command, with the needed values for the API (`clientId`, `clientsecret`, and `url`) marked in bold:

#### Sample Code

```
"saas-registry": [
  {
    "credentials": {
      "apiurl": "https://api.authenticat*****avlab.ondemand.com",
      "appName": "sample-saas-ap*****-45",
      "appUrls": "{ \"getDependencies\": \"http*****.cf.stag**\":0 }",
      "clientId": "sb-sample-saas-*****-broker!b4",
      "clientsecret": "riH*****0=",
      "description": "Sample multitenant application",
      "display_name": "Sample multitenant application",
      "identityzone": "cfs*****44",
      "saas_registry_url": "https://saa*****ab.ondemand.com",
      "sbsuburl": "https://internal-xsu*****ndemand.com",
      "subaccountid": "3358efc9-*****10b456",
      "tenantid": "34584*****711",
      "url": "https://cfs-3035-7*****avlab.ondemand.com",
      "xsappname": "sample-saa*****istry-broker!b4",
```

```

"zoneid": "34584*****f499711"
},
"instance_name": "saas-app-saas-registry",
"label": "saas-registry",
"name": "saas-app-saas-registry",
"plan": "application",
}
]

```

The token you get after executing the API is a JSON Web Token (JWT).

For more information, see [JSON Web Token \(JWT\)](#).

You use this token to manage the SAP SaaS Provisioning service APIs.

## Request

**URI:** <THE URL OBTAINED FROM THE BINDING OBJECT "URL" FIELD>/oauth/token

**HTTP Method:** *POST*

### Request Headers

Header	Required	Values
Content-Type	Yes	<application/x-www-form-urlencoded>
Authorization	Yes	Basic <encodedString> where <encodedString> is the result of base64 encoding the OAuth client's values as <code>clientId:clientSecret</code> that you obtained from the binding object as described in the previous section.  For more information about the base64 encoding, see <a href="#">Base64</a> .

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
grant_type	Yes	String	The type of the authorization that is supported by the authorization server.  Set it to <code>client_credentials</code> .	Authorization protocol
client_id	No	String	The ID of the client associated with the	Relative URL path or JavaScript source code

Parameter	Required	Data Type	Description	Parameter Type
			SaaS Provisioning service instance.	
			Obtained from the service binding object. See the section Obtaining API Request Parameters of this document for details.	

### Request Example (curl for Mac OS)

#### Sample Code

```
curl --location --request POST '<url>/oauth/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'Authorization: Basic <base64.encoded(client_id:client_secret)>' \
--data-urlencode 'client_id=<client_id>' \
--data-urlencode 'grant_type=client_credentials'
```

### Request Example (curl for Windows OS)

#### Sample Code

```
curl --location --request POST "<url>/oauth/token" ^
--header "Content-Type: application/x-www-form-urlencoded" ^
--header "Authorization: Basic <base64.encoded(client_id:client_secret)>" ^
--data-urlencode "client_id=<client_id>" ^
--data-urlencode "grant_type=client_credentials"
```

## Response

Generates the access token for a multitenant application.

**Content Type:** *JSON*

### Response Headers

Header	Values
Content-Type	<application/json;charset=UTF-8>

### Response Status and Error Codes

Code	Description
200	Access token created successfully.

## Response Properties

Property Name	Property Type	Description
access_token	JWT	Access token for the multitenant application.  This is the value for which you call the API
token_type	String	The type of access token issued.
expires_in	Number	The number of seconds until the access token expires.
scope	String	A space-delimited list of scopes that you authorized for the client.
jti	String	A globally unique identifier for JWT.

## Response Example

### Sample Code

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
{
  "access_token": "eyJ**mh0d...",
  "token_type": "bearer",
  "expires_in": 43199,
  "scope": "uaa.re***.subscription.read",
  "jti": "df6cb84439a541fab33d5b7c298debe1"
}
```

## Related Information

[Using SAP SaaS Provisioning Service APIs to Manage Multitenant Applications \[page 346\]](#)

## 4.1.3.6.8 Using the Subscription Management Dashboard

Learn how to use the SAP BTP subscription management dashboard to manage your multitenant applications through a user interface.

## Context

SaaS and IAS application providers can now use the new subscription management dashboard to manage their multitenant application's subscriptions.

The tool is based on the SaaS Provisioning service APIs that you can now work with using a user interface to simplify your operation and maintenance work.

## Main Capabilities

You can do the following in the subscription management dashboard:

- View all subscriptions to your application and the information about them, such as their state and tenant ID.
- View each subscription's dependencies and status.
- Perform operations on subscriptions, for example update the list of dependencies.
- Control access to the dashboard using dedicated roles.

The dashboard also displays detailed information about any errors that arise during the subscription process. This gives you means to identify the source of issues and fix them.

## Accessing the Dashboard in the SAP BTP Cockpit

### Assign Roles

To access the subscription management dashboard, you must be assigned to one of these roles:

- **Subscription Management Dashboard Administrator** - Provides access to the dashboard with full read and write capabilities.
- **Subscription Management Dashboard Viewer** - Provides read-only access to the dashboard.

Add the relevant role to a role collection and assign yourself or another user to it.

#### Note

You assign roles per tenants. To assign roles in a global account or subaccount tenant, you must be a global account or subaccount admin respectively.

For more information about roles, see [Configure Application Roles and Assign Roles to Users](#).

#### Note

If you don't see the roles, you need to update the instance of the SaaS Provisioning service (technical name: `saas-registry`) associated with your application (`application plan`). This enables the new roles.

### Open the Dashboard

1. In the left-hand navigation bar of the SAP BTP cockpit, select **Services** > **Instances and Subscriptions**.

#### Note

Only users who are assigned to one of the roles specified in the previous section can see the link to the dashboard and open it.

- In the *Instances* section, find the instance of the SaaS Provisioning service (technical name: *saas-registry*) with the application plan and click on it. Details about the instance open to the right.
- In the top-right corner, select **•••** and from the dropdown menu, choose *View Dashboard*. A new tab with the subscription management dashboard opens.

## Using the Dashboard

The main screen shows a table with details about all of your application's subscriptions.

You can apply various search and filtering criteria such as plan, subscription status, and time periods to get a more specific list of subscriptions.

### → Tip

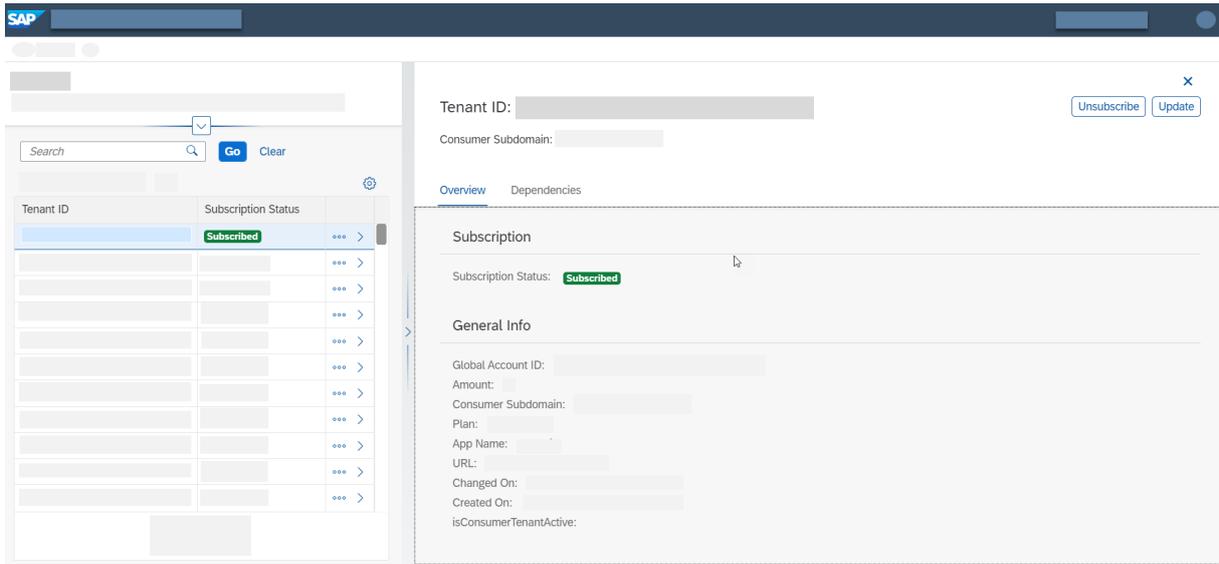

Select the *Show provider subaccounts only* checkbox to see only the subaccounts that are in the global account in which your application is deployed. This can be useful because you can only create new subscriptions for these subaccounts.

The screenshot shows the SAP Subscription Management Dashboard interface. At the top, there is a search bar and several filter dropdowns: 'All Plans', 'All Subscription Statuses', and 'All Time Periods'. A checkbox labeled 'Show provider subaccounts only' is also present, along with 'Go' and 'Clear' buttons. Below the filters is a table with the following columns: Tenant ID, Consumer Subdomain, Subaccount ID, Plan, Amount, Subscription Status, and Changed On. Each row in the table has a three-dot menu icon on the right side, indicating that more actions can be performed on each subscription.

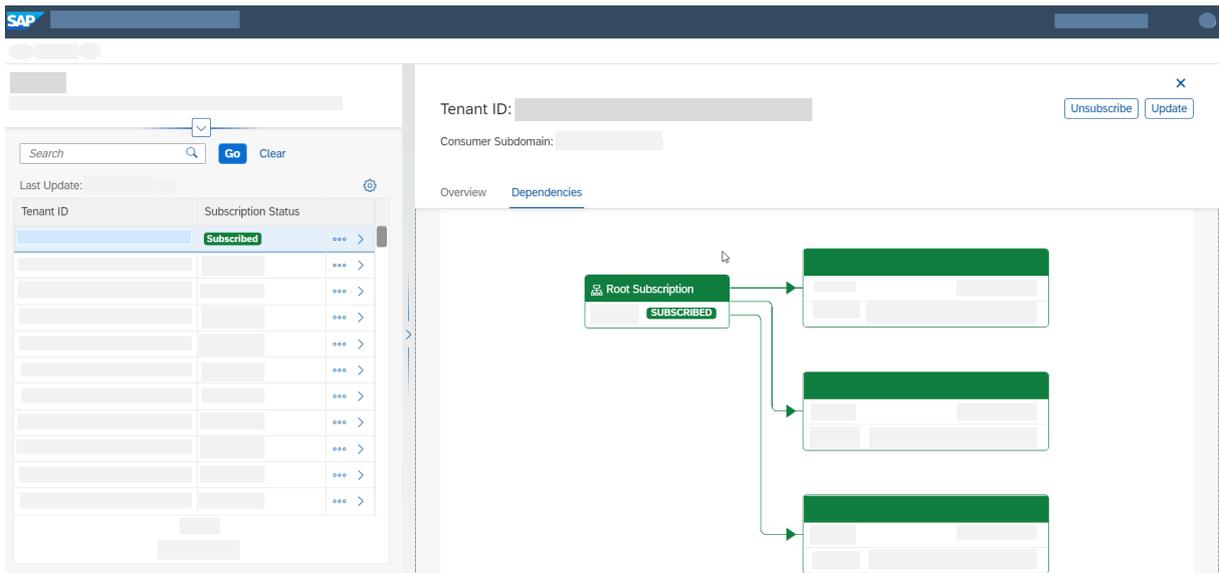

Clicking on a subscription row opens details about the subscription to the right where you can find more information about the subscription and analyze errors if the subscription status is *Failed*.

You can also perform additional operations, such as update subscription dependencies, if you're assigned to the *Subscription Management Dashboard Administrator* role.

This operation updates the subscription with the latest list of dependencies (if an app provider has added or removed dependencies of a particular subscription, for example.)

You can choose to see your subscription dependencies in a tree or table view. See the following image for the tree view representation:

#### → Tip

If you've more than one multitenant application, you can switch between them in the dashboard. Click on the dropdown menu in the upper-left corner and select the application for which you want to view or manage subscriptions.

## 4.1.4 Developing User Interface

Get information on user interface development in the SAP BTP, Cloud Foundry environment.

The key to a modern user interface is pairing great performance with a consistent and recognizable design across applications, platforms, and devices. To keep the user experience homogenous, you can establish a

flexible implementation paradigm based on reusable components. Doing so enables extensibility and easier maintainability.

We know that it can be difficult to decide this up front. You can find information about UI development options in the SAP BTP, Cloud Foundry environment in the following sections.

## Fiori Design Guidelines

The [SAP Fiori Design Guidelines](#) define design solutions that are easy to use, robust, scalable, and of enterprise-grade quality. The guidelines are independent of the implementation technology.

The modular design approach focuses on user tasks and workflows. It enables seamless transitions between applications and offers clear guidance for extension and integration design. To ensure a consistent user experience, we recommend following the Fiori Design Guidelines independent of the UI technology you plan on using.

## SAPUI5

SAPUI5 is a JavaScript framework for building cross-platform, enterprise-grade web apps with modern, responsive, and rich user interfaces. For more information, see [Developing SAPUI5 \[page 355\]](#).

## HTML5

On SAP BTP, you can access and run HTML5 applications in a cloud environment without the need to maintain your own runtime infrastructure. For more information, see [Developing HTML5 Applications in the Cloud Foundry Environment \[page 358\]](#).

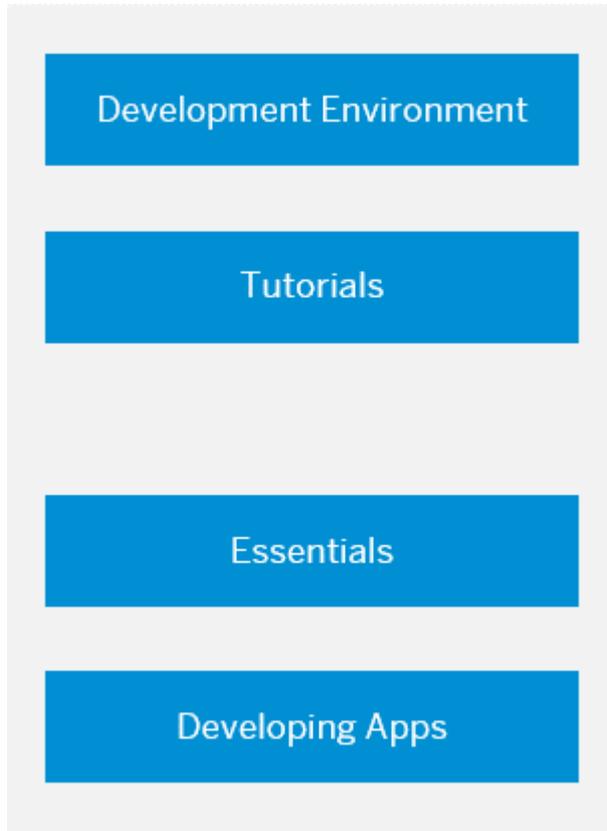

### 4.1.4.1 Developing SAPUI5

Get to know certain aspects of SAPUI5 development, to get up and running quickly.

If you are about to decide which UI technology to use, read everything you need to know about supported library combinations, the supported browsers and platforms, and so on, at the [Read Me First](#) section that contains the following topics and more:

- [Supported Library Combinations](#)
- [Supported Combinations of Themes and Libraries](#)
- [Browser and Platform Support](#)

## Quick Start

- [#unique\\_146/unique\\_146\\_Connect\\_42\\_subsection-im1](#) [page 356]
- [#unique\\_146/unique\\_146\\_Connect\\_42\\_subsection-im2](#) [page 357]
- [#unique\\_146/unique\\_146\\_Connect\\_42\\_subsection-im3](#) [page 357]
- [#unique\\_146/unique\\_146\\_Connect\\_42\\_subsection-im4](#) [page 357]

Select the tiles to discover SAPUI5 Development. The references guide you to the documentation of the SAPUI5 Demo Kit. Besides the entry points we provide here on each tile, start exploring the demo kit on your own whenever you feel comfortable enough.

### SAP Business Application Studio

Use the SAP Business Application Studio to develop on Cloud Foundry. You just need to create a dev space, which is a preconfigured development environment with the tools, capabilities, and resources needed for developing your application.

1. Register for an SAP BTP trial account at <https://account.hanatrial.ondemand.com/> and log on afterwards.
2. [Set Up SAP Business Application Studio in a trial account.](#)
3. [Create a SAP Fiori dev space.](#)

4. [Create a Project](#) - either using the wizard or the terminal.

Learn how you can use SAP Business Application Studio together with UI5 Tooling to develop state-of-the-art UI5 apps.

## Tutorials

Depending on the project template you're using you have a project that is more advanced than what you see in the following tutorials. Those tutorials show you the basics and you can start a new and empty project to follow along those SAPUI5 tutorials from the demo kit.

Have a look at the [Get Started: Setup and Tutorials](#) section that contains the following topics and more:

- ["Hello World!"](#)
- [Data Binding](#)
- [Navigation and Routing](#)
- [Mock Server](#)
- [Worklist App](#)
- [Ice Cream Machine](#)

## Essentials

This is reference information that describes the development concepts of SAPUI5, such as the Model View Controller, data binding, and components.

The following topics are excerpts from the [Essentials](#) section:

- [Bootstrapping: Loading and Initializing](#)
- [Structuring: Components and Descriptor](#)
- [Model View Controller \(MVC\)](#)
- [Data Binding](#)
- [Reusing UI Parts: Fragments](#)

## Developing Apps

Create apps with rich user interfaces for modern Web business applications, responsive across browsers and devices, based on HTML5.

The following topics are excerpts from the [Developing Apps](#) section:

- [App Templates: Kick Start Your App Development](#)
- [App Overview: The Basic Files of Your App](#)
- [App Initialization: What Happens When an App Is Started?](#)
- [Folder Structure: Where to Put Your Files](#)
- [Coding Issues to Avoid](#)
- [Securing Apps](#)

## 4.1.4.2 Developing HTML5 Applications in the Cloud Foundry Environment

SAP BTP enables you to access and run HTML5 applications in a cloud environment without the need to maintain your own runtime infrastructure.

HTML5 applications consist of static content that runs on a browser. Then you develop your applications - either in SAP Business Application Studio, or in your own IDE (integrated development environment) - and deploy them to the [HTML5 application repository \[page 359\]](#).

Depending on your backed application setup, you either configure the destinations during development, or define them after deploying the application. Finally, to consume the applications, you can create a site using SAP Cloud Portal service or SAP Launchpad service, build the URL, and define custom domains.

On the Cloud Foundry environment of SAP BTP you can run an application that was uploaded to HTML5 application repository using one of the following options:

- Use the application router that is managed by SAP.  
For more information, see [Managed Application Router \[page 453\]](#).
- Set up and maintain your own application router in your own space.  
For more information, see [Application Router \[page 377\]](#).

Both options allow you to serve static content from HTML5 application repository, authenticate users, rewrite URLs, and forward or proxy requests to other micro services while propagating user information. However, the [managed application router \[page 453\]](#) brings many benefits, such as:

- Simplify and speed up your development and deployment experience
- Save resources by running a serverless HTML5 application, which doesn't require any application runtime
- Lower maintenance efforts by leveraging the most up-to-date routing capabilities
- Meet the changing demand for HTML5 applications by automatically adjusting the service to maintain consistent and predictable performance
- Monitor and run your HTML5 applications from the [HTML5 Applications](#) UI in the SAP BTP cockpit

Therefore, we recommend running your own [application router \[page 377\]](#) only in advanced cases, for example when application router extensibility is required.

### Note

When using the [managed application router \[page 453\]](#), you can monitor and run your HTML5 applications from the [HTML5 Applications](#) UI for your subaccount in the SAP BTP cockpit.

For monitoring and running HTML5 applications served by a standalone [application router \[page 377\]](#), you can use the [CF HTML5 applications repository CLI plugin](#) .

## Related Information

[HTML5 Application Repository \[page 359\]](#)

[Application Router \[page 377\]](#)

[Managed Application Router \[page 453\]](#)

## 4.1.4.2.1 HTML5 Application Repository

HTML5 application repository enables central storage of HTML5 applications' static content on the SAP BTP, Cloud Foundry environment. This service can be consumed from the SAP BTP, Cloud Foundry runtime, the SAP BTP, Kyma runtime, Kubernetes, or by creating a service instance on the subaccount level regardless of an environment.

HTML5 applications consist of static content such as HTML, CSS, JavaScript, and other files, that run on a browser. For more information, see [Basic Template](#) and [openui5-basic-template-app](#) .

HTML5 application repository allows application developers to manage the lifecycle of their HTML5 applications. In runtime, the repository enables the consuming application, typically the application router, to access HTML5 application static content in a secure and efficient manner. For more information, see [Configure Application Router](#).

### Features

#### Zero Down-Time Enablement

- The HTML5 applications are decoupled from the consuming application router. This enables updating the static content of the HTML5 applications without restarting the application router.

#### Versioning and Authorization

- Exploration of HTML5 application content by version.
- Access control that is based on private or public authorization.  
When the HTML5 application is public, the service enables sharing this content with consuming application routers from different spaces.

#### Availability and Performance

- During runtime, the HTML5 application content is cached and optimized to provide high performance with minimal network load.
- The service provides several instances for a runtime to serve a high load of application requests.

### Environment

This service is available in the following environments:

- Cloud Foundry environment
- Kyma environment

### Multitenancy Support

This service supports multitenancy. It can be used by tenant-aware applications.

## Technical Constraints

- The size of an application deployed to the repository is limited to 100 MB per service instance of the *app-host* service plan.
- Since the applications stored in HTML5 application repository can be shared, it is advised not to add personal data to them.
- You can perform up to 50 deployments per minute at design time per SAP BTP subaccount. If you exceed this rate limit, the HTTP error code 429 is returned.
- You can make up to 300 requests per second at runtime per SAP BTP subaccount. If you exceed this rate limit, the HTTP error code 429 is returned.

## See Also

If you want to learn more about services in the SAP BTP, Cloud Foundry environment, see [Using Services in the Cloud Foundry Environment \[page 229\]](#).

### 4.1.4.2.1.1 Deploying Content

Learn how to deploy your content using the preferred Generic Application Content Deployer or `deploy`, `redeploy`, and `undeploy` content from the HTML5 Application Repository.

#### Note

The HTML5 Application Repository service does not provide the technical capabilities to support the collection, processing, and storage of personal data. The file names used for deploying the HTML5 applications are not intended for personal data.

You use a service instance of the *app-host* service plan to deploy your applications to the HTML5 Application Repository.

#### Note

If you delete an *app-host* service instance, the apps that are deployed with this *app-host* service instance are deleted from the HTML5 Application Repository.

#### Restriction

Delta deployments are not supported.

If you deploy new application content using an existing *app-host* service instance, the new application content will completely replace the old application content that had been previously deployed with this service instance in the HTML5 Application Repository.

For example, if you have already deployed the applications a, b, and c with the instance 123 and now want to deploy the new applications d and e, you can do one of the following to avoid overwriting the applications a, b, and c:

- Redeploy instance 123 with applications a, b, c, d, and e (with the new and the old applications).
- Create a new instance 456 and use this instance to deploy the applications d and e.

## Related Information

[Deploy Content Using the Generic Application Content Deployer \[page 361\]](#)

[Deploy Content Using HTML5 Application Deployer \[page 363\]](#)

[Redeploy Content \[page 368\]](#)

[Undeploy Content \[page 369\]](#)

### 4.1.4.2.1.1.1 Deploy Content Using the Generic Application Content Deployer

Deploy content from the HTML5 Application Repository using the Generic Application Content Deployer (GACD).

## Prerequisites

- `cf` CLI is installed locally, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- The multitarget application (MTA) plug-in for the Cloud Foundry command-line interface to deploy MTAs is installed locally. For more information, see [Install the MultiApps CLI Plugin in the Cloud Foundry Environment \[page 2262\]](#).
- The Cloud MTA Build Tool (MBT) is installed, see [Cloud MTA Build Tool: Download](#) 

## Context

You can deploy your content to the HTML5 Application Repository using the GACD (Generic Application Content Deployer) module. The GACD module has the module type `com.sap.application.content`. This module type enables the deploy plug-in generic application content deploy support. It means that when a module is processed in the `cf` deploy flow, the deploy service locates the service resource that is required as a target for the deploy and deploys the corresponding `content.zip` file.

## Procedure

1. Create a nested `content.zip` file that contains a zip file for each HTML5 application.

Example of a nested `content.zip` file

### Sample Code

```
content.zip
  appl.zip
    manifest.json
    xs-app.json
    ...
  app2.zip
  ...
```

2. Create an MTA development descriptor (`mta.yaml` file).

See [Defining Multitarget Application Development Descriptors \[page 541\]](#).

3. In the MTA development descriptor (`mta.yaml` file), define the deployer module:

### Sample Code

```
ID: testdeployer
_schema-version: '3.1'
modules:
  - name: ui_deployer
    type: com.sap.application.content
    path: deployer/
    requires:
      - name: uideployer_html5_repo_host
        parameters:
          content-target: true
resources:
  - name: uideployer_html5_repo_host
    parameters:
      service-plan: app-host
      service: html5-apps-repo
      type: org.cloudfoundry.managed-service
    version: 0.0.1
```

4. To create an MTA archive (mtar file), build your content with the [MTA Build Tool \(MBT\)](#) .

Run the following command:

### Sample Code

```
mbt build
```

For more information on MBT build options, see: [How to build an MTA archive from the project sources](#) .

5. Deploy the MTA archive (mtar file) using the CLI command `cf deploy`.

Run the following command:

### Sample Code

```
cf deploy <path-to-mtar-file>
```

For example, from the directory where your mtar file is located, run `cf deploy myapp_0.0.1.mtar`.

## Related Information

[Deploying Content with Generic Application Content Deployment \[page 627\]](#)

### 4.1.4.2.1.1.2 Deploy Content Using HTML5 Application Deployer

Use the HTML5 application deployer module to deploy the content of the HTML5 applications to the HTML5 Application Repository.

## Prerequisites

- `cf` CLI is installed locally, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- The multi-target application (MTA) plug-in for the Cloud Foundry command line interface to deploy MTAs is installed locally. For more information, see [Install the MultiApps CLI Plugin in the Cloud Foundry Environment \[page 2262\]](#).

#### Note

It is not recommended to use the HTML5 application deployer to deploy application content that is larger than 10 MB.

For larger application content, please use the [Generic Application Content Deployer \(GACD\) \[page 361\]](#) or configure the [asynchronous content upload \[page 366\]](#).

## Context

The HTML5 application deployer is available on npmjs.com (NPM), see [@sap/html5-app-deployer](#) .

You can deploy your content to the HTML5 Application Repository using the HTML5 application deployer npm module.

## Procedure

1. Add the `html5-app-deployer` module as a dependency to your `package.json` file. To do so, navigate to your `package.json` file and execute `npm install` to download the `html5-app-deployer` module from the SAP npm registry.

The basic `package.json` file should look similar to the following example:

### Sample Code

```
{
  "name": "myAppDeployer",
  "engines": {
    "node": ">=6.0.0"
  },
  "dependencies": {
    "@sap/html5-app-deployer": "2.0.1"
  },
  "scripts": {
    "start": "node node_modules/@sap/html5-app-deployer/index.js"
  }
}
```

The `start` script is mandatory as it is executed after the deployment of the application.

2. In the `html5-app-deployer` structure, create a `resources` folder and add the static content that you want to deploy. In the `resources` folder, add one folder for each application you want to deploy. For each application you want to deploy, provide a `manifest.json` and `xs-app.json` file at root level.

If you want to deploy more than one application to the same app host instance, you can add multiple zip archives to the `resources` folder.

### Sample Code

```
myAppsDeployer
+ node_modules
- resources
  - appl
    index.html
    manifest.json
    xs-app.json
  - app2
  ...
package.json
manifest.yaml
```

- a. The `manifest.json` file contains `sap.app.id` and `sap.app.applicationVersion.version`, which are used in the HTML5 Application Repository as `applicationName` and `applicationVersion`.

### Note

The format of the application version is `xx.xx.xx`.

### Sample Code

```
manifest.json
```

```

{
  "_version": "1.7.0",
  "sap.app": {
    "id": "app1",
    "type": "application",
    "il8n": "il8n/il8n.properties",
    "applicationVersion": {
      "version": "1.0.0"
    }
  }
}

```

- b. The `xs-app.json` file is used to support application routing.

### Sample Code

```

xs-app.json
{
  "welcomeFile": "index.html",
  "authenticationMethod": "route",
  "routes": [
    {
      "source": "^/be$",
      "destination": "simpleui_be",
      "authenticationType": "xsuaa"
    },
    {
      "source": "^/ui(/.*)",
      "target": "$1",
      "service": "html5-apps-repo-rt",
      "authenticationType": "xsuaa"
    }
  ]
}

```

3. Create an `mta.yaml` (MTA development descriptor) file:
- Under `resources`, add a resource definition to create an `html5-apps-repo` service instance of the `app-host` service plan.
  - Under `modules`, add your app.
  - Add a dependency to the `html5-apps-repo` service and the `app-host` service plan instance using the `requires` statement.

### Sample Code

```

ID: html5.repo.deployer.myHTML5App
_schema-version: '2.0'
version: 0.0.3
modules:
- name: myHTML5App_app-deployer
  type: com.sap.html5.application-content
  path: deployer/
  requires:
  - name: myHTML5App_app-host

resources:
- name: myHTML5App_app-host //Resource name
  type: org.cloudfoundry.managed-service
  parameters:
    service: html5-apps-repo //Service name
    service-plan: app-host //Service plan
    service-name: myHTML5App_app-host //Service instance name

```

For a general description of MTA descriptors, see [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#).

4. Build and deploy the `mta.yaml` (MTA development descriptor).

For more information about the build and deployment of MTA descriptors, see [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#).

The deployment starts the following:

- Create an HTML5 Application Repository service instance of the `app-host` service plan.
- Create an HTML5 application deployer application, which uses the HTML5 application deployer npm module.
- Bind the `app-host` service instance to the HTML5 application deployer application.
- Start the HTML5 application deployer application:
  - Create a zip archive for each application in resources folder.
  - Create a client credential token from the `app-host` service instance credentials.
  - Deploy the content to the HTML5 application repository: passing on the zip archives and the client credential token.
- Stop the HTML5 application deployer application.

#### **4.1.4.2.1.1.2.1 Asynchronous Upload Using the HTML5 Application Deployer**

You can specify that the upload of content is performed asynchronously by adding the environment variable `ASYNC_UPLOAD` to the `manifest.yaml` or `mta.yaml` files.

The asynchronous upload is especially useful, if you want to trigger the upload of service instances with a large content (more than 10 MB). A synchronous upload of service instances with a large content can result in health check errors or a connection timeout during the upload. You can avoid this by using the asynchronous upload.

During an asynchronous upload, the html5 applications content is handled synchronously to the HTML5 Application Repository, while the internal file validation and processing is performed asynchronously. To verify that the upload has completed successfully, you have to check the HTML5 Application Deployer logs.

#### **4.1.4.2.1.1.2.2 Automatic Creation of Destination Configurations**

If you use the HTML5 application deployer together with an application router managed by SAP for the Kyma runtime, you can enable that the required destination configurations pointing to the service instances are created automatically.

To enable the automatic creation of destination configurations, add the environment variable `SAP_CLOUD_SERVICE` in the `deployment.yaml` or Helm chart of the Kyma project and provide the value of the `sap.cloud.service` property from the `manifest.json` file of the HTML5 application that you want to deploy. The destination configurations can point to instances of the following services:

- An HTML5 Application Repository service instance of the app-host service plan (mandatory)
- An SAP Authorization and Trust Management (XSUAA) service instance (optional)  
To create a destination that points to an SAP Authorization and Trust Management (XSUAA) service instance, the SAP Authorization and Trust Management (XSUAA) service instance and a destination service instance must be bound to the HTML5 application deployer.
- A business service instance (optional)
- One or more backend destinations that point to cloud or on-premise backend applications.  
In addition to the SAP\_CLOUD\_SERVICE environment variable, also add the environment variable BACKEND\_DESTINATIONS to create backend destinations.

### Note

To enable app-to-app navigation, you also have to add the environment variable IAS\_DEPENDENCY\_NAME and provide the name of the dependency that has been configured for the Identity Authentication token exchange that is required for app-to-app navigation. For more information about how to configure the dependency for app-to-app navigation, see [Consume an API from Another Application](#).

You would typically use the automatic creation of destination configurations in Kubernetes if the HTML5 application deployer application has been previously uploaded as a docker image to Artifactory or Docker Hub. See, for example, this Kubernetes deployment:

### Sample Code

```
--
apiVersion: apps/v1
kind: Deployment
metadata:
  name: html5appdeployer
  namespace: default
  labels:
    app: html5appdeployer
spec:
  replicas: 1
  selector:
    matchLabels:
      app: html5appdeployer
  template:
    metadata:
      labels:
        app: html5appdeployer
    spec:
      containers:
        - image: html5-apps-repo.docker.repositories.sap.ondemand.com/myapp-
html5-app-deployer:1.0
          name: html5appdeployer
          volumeMounts:
            - name: html5-repo-app-host-volume
              mountPath: "/etc/secrets/sapcp/html5-apps-repo/myapp-app-host-
instance"
              readOnly: true
            - name: xsuaa-volume
              mountPath: "/etc/secrets/sapcp/xsuaa/myapp-xsuaa-instance"
              readOnly: true
            - name: destination-volume
              mountPath: "/etc/secrets/sapcp/destination/myapp-destination-
instance"
              readOnly: true
          env:
            - name: PORT
              value: "5000"
```

```

```

## Related Information

### 4.1.4.2.1.1.3 Redeploy Content

You can redeploy changed content to the existing app-host service instance.

After making changes to the static content files of HTML5 applications, you can redeploy the new content to the already existing app-host service instance of the HTML5 application repository. All content referenced by the app-host service instance ID is replaced by the new content. If you want to keep more than one version of your HTML5 application on the repository, you deploy all versions, the new versions and the old versions that you want to keep, to the same app-host service instance ID.

### Example: Deploying two Versions to the Repository

- Application **app1** with version 1.0.0 has been deployed to the repository. This app matches a back-end application with version 3.0.0
- For the app, a new back-end version 4.0.0 is available. Therefore, the application with version 2.0.0 is developed that matches the new back-end version.
- As customers may still have a backend with version 3.0.0, **app1** with version 1.0.0 cannot be dropped. On the repository, both versions shall be available so the customer can decide which one to use depending on their back-end version.

### Sample Code

```
myAppsDeployer
+ node_modules
- resources
- appl
  index.html
  manifest.json
  xs-app.json
- app2
  ...
package.json
manifest.yaml
```

## 4.1.4.2.1.1.4 Undeploy Content

To undeploy content you need to delete the content from the repository and delete the `app-host` service plan instance.

### Procedure

1. Open the Cloud Foundry command line interface (CLI).
2. Undeploy the \*.mtar file using the CLI command: `cf undeploy` and add the `--delete-services` `--delete-service-keys` option.

Example: `cf undeploy html5.repo.deployer.myHTML5App --delete-services --delete-service-keys`

- Use the `-delete-services` option, to delete the `app-host` service plan instance and the application content from HTML5 application repository.
- For the `cf undeploy` command, you need the `mta id`. To get the `mta id`, do one of the following:
  - Call `cf mtas`.
  - Check the `mtad.yaml ID`.

### Note

If you do not want to use the `-delete-services` option, you can delete the `app-host` service plan instance manually using the CLI command: `cf delete-service SERVICE-NAME`.

## 4.1.4.2.1.2 Service Plans

The HTML5 Application Repository service comprises the following service plans:

- `app-host`

Use this service plan to deploy HTML5 applications to the repository. For more information, see [Deploying Content \[page 360\]](#).

- *app-runtime*

Use this service plan to consume HTML5 applications stored in the repository. For more information, see [Consuming Content \[page 370\]](#).

### 4.1.4.2.1.3 Consuming Content

Use the `app-runtime` service plan to consume HTML5 applications from the HTML5 Application Repository.

#### Context

Application router can consume content from the HTML5 Application Repository by binding an HTML5 Application Repository service instance with `app-runtime` plan to the application router. In addition, the routing to the HTML5 Application Repository service is configured in the `xs-app.json` file.

#### Procedure

1. Create a service instance of `app-runtime` service plan.

```
Example: cf create-service html5-apps-repo app-runtime  
MyHtml5AppsRepoRuntimeInstance
```

2. Bind the HTML5 Application Repository runtime instance to the application router in the `manifest.yaml` file.

#### Sample Code

```
applications:  
- name: myCRMApp  
  memory: 256M  
  services:  
    - MyHtml5AppsRepoRuntimeInstance
```

3. Push the application with the following command: `cf push`
4. To redirect requests to the HTML5 Application Repository runtime, configure the routing to the HTML5 Application Repository service in your `xs-app.json` file.

#### Sample Code

```
{  
  
  "source": "^(/.*)",  
  
  "target": "$1",  
  
  "service": "html5-apps-repo-rt",
```

```
"authenticationType": "xsuaa"  
}
```

5. HTML5 application content can be consumed from the application router using an URL in the following format: `https://<host>.<domain>/<appName>-<appVersion>/<resourcePath>`

#### Note

`appName` - the `manifest.json` `app.id` **without the dots**

`appVersion` - the `manifest.json` `applicationVersion.version`. The `appVersion` is optional. If not provided, the latest version will be used.

## 4.1.4.2.1.4 Security and Data Privacy Configuration

This section provides information about security and data privacy.

- Identity Provider and Identity Management  
You can use the User Account and Authentication (UAA) server for user authentication. In Cloud Foundry, a service is created for this configuration. By using the standard service binding mechanism, the content of this configuration is available in the `VCAP_SERVICES` environment variable.  
As an alternative to the User Account and Authentication (UAA) service, you can also use the Identity Authentication service of the SAP Cloud Identity Services for authentication.
- Authorization Configuration  
To obtain the access token to authorize API requests, the client credentials authorization flow is used.
- Data Protection and Data Privacy  
The HTML5 application repository service applies the legally required data protection and privacy measures to data that is stored on behalf of customers. These measures include, for example, the need to know principle during support processes, or data isolation between spaces.  
The HTML5 application repository runtime is a microservice responsible for providing read access to HTML5 applications during runtime. When the HTML5 application is public, the service enables sharing this content with consuming application routers from different spaces.

#### Note

The HTML5 application repository service does not provide the technical capabilities to support the collection, processing, and storage of personal data. The file names used for deploying the HTML5 applications are not intended for personal data.

## 4.1.4.2.1.4.1 Configure the Credential Type for HTML5 Application Repository Service Instances

When you create an HTML5 application repository service instance key or bind a service instance to an application, values for `client_id` and `client_secret` are generated. The `client_secret` is the equivalent to a password.

As of January 28, 2021, the credential type `binding_secret` is automatically used for the `client_secret` value of new HTML5 application repository service instance keys. This increases the security because the credential type `binding_secret` creates a new `client_secret` for each binding and service key.

If you have older HTML5 application repository service instances, the `client_secret` value is the same for all bindings and service keys because the HTML5 application repository still uses the credentials type `instance_secret` for older HTML5 application repository service instances. To configure the more secure credential type `binding_secret` for your older HTML5 application repository service instances, please follow the instructions in [Configure the Credential Type `binding\_secret` for HTML5 Application Repository Service Instances](#) [page 372].

As an alternative to the credential type `binding_secret`, you can also use the credential type `x.509` to authenticate your apps with X.509 certificates. For more information, see [Credential Type `x509` for HTML5 Application Repository Service Instances](#) [page 373].

### Configure the Credential Type `binding_secret` for HTML5 Application Repository Service Instances

1. Extract the UUID part of the `xsappname` from the of the existing instance. For example:

1.  Sample Code

```
cf create-service-key <serviceInstanceName> <serviceInstanceKeyName>
```

2.  Sample Code

```
cf service-key <serviceInstanceName> <serviceInstanceKeyName>
.....
"clientsecret": "HksDYy9RxYFUQeOHIzprqBam3vQ=", //Old instance secret
...
"xsappname": "fec39a25-a570-46b0-8ac9-1691f8d663cc!b6711|html5-apps-
repo-uaa!b6711",
.....
```

3. Copy the UUID. In this example: `fec39a25-a570-46b0-8ac9-1691f8d663cc`
2. Create a file `instance-xs-security.json`, such as the following:

 Sample Code

```
{
  "xs-security": {
    "xsappname": "fec39a25-a570-46b0-8ac9-1691f8d663cc",
    "oauth2-configuration": {
      "credential-types": ["binding-secret"]
    }
  }
}
```

```
}  
}
```

3. Update the service instance:

#### Sample Code

```
cf update-service <serviceInstanceName> -c instance-xs-security.json
```

4. Check that the instance now creates binding secrets as follows:

#### 1. Sample Code

```
cf create-service-key <serviceInstanceName>  
<serviceInstanceKeyNameNew>
```

#### 2. Sample Code

```
cf service-key <serviceInstanceName> <serviceInstanceKeyNameNew>  
.....  
"clientId": "sb-fec39a25-a570-46b0-8ac9-1691f8d663cc!b6711|html5-apps-  
repo-uaa!b6711",  
"clientsecret":  
"8c902673-00d4-471f-9ebb-4463d4073fda$7NIo5batSFZCF1RNGcpNkRfo4mDj6vq-  
cE1DFIcvcwg=", //New binding secret (long)  
"identityzone": ....,  
"identityzoneid": ....,  
.....
```

## Credential Type x509 for HTML5 Application Repository Service Instances

To use the HTML5 application repository service and authenticate with X.509 certificate, you need to acquire the required key, certificate, and base URLs. These are provided when you create an instance of the HTML5 application repository service and a binding or a service key for the instance.

When you bind an HTML5 applications repository service instance to an application, you have to explicitly provide the required configuration parameters for the authentication with x.509:

```
cf bind-service <application> <service-instance> -c parameters.json
```

The same applies if you create service keys:

```
cf create-service-key <service-instance> <key-name> -c parameters.json
```

The configuration for the credential type x509 must be wrapped with xsuaa. You have to use exactly the following format for the configuration:

```
{  
  "xsuaa": {  
    "credential-type": "x509",  
    "x509": {  
      "key-length": 2048, // specifies the byte length of the generated private  
key,  
// defaults to 2048  
      "validity": 7, // specifies the number of time units in validity-type,  
.....
```

```

// defaults to 7, thus the complete validity defaults to 7
days
  "validity-type": "DAYS" // specifies the validity time unit,
                        // only DAYS, MONTHS and YEARS are supported,
                        // defaults to DAYS
    }
  }
}

```

### Note

The following applies to existing HTML5 application repository service instances:

Before you create a binding to a service instance or a service key as described above, you have to update of the service instance of your existing HTML5 application repository service instance. Use parameters to provide the configuration during the update of the existing service instance:

```
cf update-service <service-instance> -c update-instance-xs-security.json
```

To configure the credential type x509 for existing HTML5 application repository service instances, please follow the instructions below:

## Configuring Credential Type x509 for Existing HTML5 Application Repository Service Instances

To configure the credential type x509 for your existing HTML5 application repository service instances, perform the following steps:

1. Extract the UUID part of the xsappname from the service key or the binding for the service instance. For example:

### 1. Sample Code

```

cf service-key <serviceInstanceName> <existingServiceInstanceKeyName>
.....
"clientsecret": "HksDYy9RxYFUQeOHIzprqBam3vQ=", //Old instance secret
...
"xsappname": "fec39a25-a570-46b0-8ac9-1691f8d663cc!b6711|html5-apps-
repo-uaa!b6711",
.....

```

2. Copy the UUID. In this example: **fec39a25-a570-46b0-8ac9-1691f8d663cc**
2. Create a file `update-instance-xs-security.json` with the following format:

### Sample Code

```

{
  "xs-security": {
    "xsappname": "fec39a25-a570-46b0-8ac9-1691f8d663cc", //The UUID that
was extracted before
    "oauth2-configuration": {
      "credential-types": ["x509"]
    }
  }
}

```

3. Update the service instance:

```
cf update-service <serviceInstanceName> -c update-instance-xs-security.json
```

4. Create a file `parameters.json`, such as the following: :

```

{ } Sample Code

{
  "xsuaa": {
    "credential-type": "x509",
    "x509": {
      "key-length": 2048,
      "validity": 7,
      "validity-type": "DAYS"
    }
  }
}

```

(Note that the values of the "x509" properties used here are just examples.)

5. Create a binding or a service key with the credential type x509 configuration (`parameters.json` file). For example:

```
cf create-service-key <serviceName> <serviceNameNew> -c parameters.json
```

6. Check that the instance now creates a certificate and that the credential-type is "x509", as follows:

```
cf service-key <serviceName> <serviceNameNew>
```

The following binding is generated as a result:

```

{
  .....
  "certificate": "-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----\n-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----\n-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----\n",
  "clientid": ".....",
  "credential-type": "x509",
  .....
}

```

## 4.1.4.2.1.4.2 Auditing and Logging Information

Here you can find a list of the security events that are logged by the HTML5 application repository.

Events written in audit logs

Event grouping	What events are logged	How to identify related log events	Additional information
Authentication failure	Authentication failed because of an invalid token	Message: <i>Authentication failure status: 401</i>	
	Authentication failed because the token has expired	Message: <i>Authentication failure status: 403</i>	

Event grouping	What events are logged	How to identify related log events	Additional information
Attempt to access an application with an invalid app-host ID	Attempt to access an application with an invalid app-host ID	Message: <i>Invalid App Host ID</i>  If there was an attempt to get an application that was deployed by a developer in another space.	
Attempt to access a private application from another space	Attempt to access a private application from another space	Message: <i>Attempt to access private application.</i> <i>application name : ' +</i> <i>appKey + ' ,</i> <i>app-host : ' +</i> <i>dtServiceInstanceId</i>	
Deletion of an application (Deletion of an app-host service instance from the HTML5 application repository)	Deletion of data started	Message: <i>Deletion of data started for SPACE &lt;space&gt; in ORG &lt;org&gt;</i>	
	Deletion of data completed	Message: <i>Deletion of data completed for SPACE &lt;space&gt; in ORG &lt;org&gt;</i>	
	Deletion of data failed	Message: <i>Deletion of data failed for SPACE &lt;space&gt; in ORG &lt;org&gt;</i>	

The following information is described in the table columns:

- [Event grouping](#) - Events that are logged with a similar format or are related to the same entities.
- [What events are logged](#) - Description of the security or data protection and privacy related event that is logged.
- [How to identify related log events](#) - Search criteria or key words, that are specific for a log event that is created along with the logged event.
- [Additional information](#) - Any related information that can be helpful.

## 4.1.4.2.2 Application Router

The application router is the single point-of-entry for an application running in the Cloud Foundry environment on SAP BTP. The application router is used to serve static content, authenticate users, rewrite URLs, and forward or proxy requests to other micro services while propagating user information.

You can set up and run your own application router or you can use the application router that is managed by SAP (for more information see [Managed Application Router \[page 453\]](#)).

We recommend running your own application router only in advanced cases, for example when application router extensibility is required. The application router is available on the following sites:

- As a library on npmjs.com (NPM), see [@sap/approuter](#) 
- As a container image on Docker Hub, see <https://hub.docker.com/r/sapse/approuter> 

### Related Information

[Extending the Application Router \[page 448\]](#)

[Extension API of the Application Router \[page 451\]](#)

### 4.1.4.2.2.1 Setting Up Your Own Application Router

This section describes how you can set up your own application router.

#### Prerequisites

- cf CLI is installed locally, see [Download and Install the Cloud Foundry Command Line Interface \[page 2259\]](#).
- [Node.js](#)  is installed and configured locally, see [npm documentation](#) .
- The SAP npm registry, which contains the Node.js package for the application router, is configured:  

```
npm config set @sap:registry https://registry.npmjs.org
```

## Context

The application router is configured in the `xs-app.json` file. The `package.json` file contains the start command for the application router, a list of the package dependencies, and the supported Node.js versions.

## Procedure

1. Create the application resource-file structure.

For example, `/path/<myAppName>/`

2. Create a subfolder for the static Web resources module.

The subfolder for the Web-resources module must be located in the application root folder, for example, `/path/<myAppName>/web`.

### → Tip

The Web-resource module uses `@sap/approuter` as a dependency; the Web-resources module also contains the configuration and static resources for the application.

3. Create the subfolder for the application's static resources.

Static resources can, for example, include the following file and components: `index.html`, style sheets (`.css` files), images and icons. Typically, static resources for a Web application are placed in a subfolder of the Web module, for example, `/path/<myAppName>/web/resources`.

4. Create the application-router configuration file.

The application router configuration file `xs-app.json` must be located in the application's Web-resources folder, for example, `/path/<MyAppName>/web`.

### 📄 Sample Code

```
<myAppName>
|- web/                               # Application descriptors
|  |- xs-app.json                     # Application routes configuration
|  |- package.json                   # Application router details/dependencies
|  \- resources/
```

5. Define details of the application's routes, destinations, and security scopes.

The contents of the `xs-app.json` file must use the required JSON syntax. For more information, see [Routing Configuration File \[page 387\]](#).

- a. Create the required destinations configuration.

### 📄 Sample Code

```
/path/<myAppName>/web/xs-app.json.

{
  "welcomeFile": "index.html",
  "routes": [
    {
      "source": "/sap/ui5/1(.*)",
```

```

        "target": "$1",
        "localDir": "sapui5"
      },
      {
        "source": "/rest/addressbook/testdataDestructor",
        "destination": "backend",
        "scope": "node-hello-world.Delete"
      },
      {
        "source": "/rest/*",
        "destination": "backend"
      },
      {
        "source": "^/(.*)",
        "localDir": "resources"
      }
    ]
  }
}

```

- b. Add the routes (destinations) for the specific application (for example, `node-hello-world`) to the `env` section of the application's deployment manifest (`manifest.yml`).

Every route configuration that forwards requests to a micro service has property `destination`. The destination is a name that refers to the same name in the destinations configuration. The destinations configuration is specified in an environment variable passed to the approuter application.

#### Sample Code

```

<myAppName>/manifest.yml

- name: node-hello-world
  routes:
  - route: myHost-node-hello-world.xsapps.acme.ondemand.com
    memory: 100M
    path: web
    env:
      destinations: >
      [
        {
          "name": "backend",
          "url": "http://myHost-node-hello-world-
backend.xsapps.acme.ondemand.com",
          "forwardAuthToken": true
        }
      ]

```

6. Add a package descriptor (`package.json`) for the application router to the root folder of your application's Web resources module (`web/`) and execute `npm install` to download the approuter npm module from the SAP npm registry.

The package descriptor describes the prerequisites and dependencies that apply to the application router and starts the application router, too.

#### Sample Code

```

<myAppName>
|- web/                               # Application descriptors
|  |- xs-app.json                       # Application routes configuration
|  |- package.json                      # Application router details/dependencies
|  \- resources/

```

The basic `package.json` file for your Web-resources module (`web/`) should look similar to the following example:

#### Sample Code

```
{
  "name": "node-hello-world-approuter",
  "dependencies": {
    "@sap/approuter": "5.1.0"
  },
  "scripts": {
    "start": "node node_modules/@sap/approuter/approuter.js"
  }
}
```

#### → Tip

The start script (for example, `approuter.js`) is mandatory; the start script is executed after application deployment.

## Related Information

[Managed Application Router \[page 453\]](#)

### 4.1.4.2.2.2 Resource Files

The routing configuration for an application is defined in one or more destinations.

The application router is used to serve static content, authenticate users, rewrite URLs, and forward or proxy requests to other micro services while propagating user information. The following table lists the resource files used to define routes for multi-target applications:

Application-Router Resource Files Overview

File	Description	Mandatory
<code>package.json</code>	The package descriptor is used by the Node.js package manager ( <code>npm</code> ) to start the application router; in the <code>"dependencies": {}</code> section	Yes
<code>xs-app.json</code>	The application descriptor contains the configuration used by the application router (for example, destinations for request forwarding)	Yes

File	Description	Mandatory
<code>resources/</code>	A folder that contains all static resources which should be served by the application router. If no <code>resources/</code> folder is present, the application router will not serve any static content. However, it still forwards requests to the configured destinations.  <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px; margin-top: 10px;"> <p>→ Tip</p> <p>If you have a static resources folder name in the <code>xs-app.json</code> file, we recommend that you use <code>localDir</code> as default.</p> </div>	No
<code>local-destinations.json</code>	Provides the required destinations information for local development	No
<code>default-services.json</code>	Defines the configuration for one or more special User Account and Authentication (UAA) services for local development	-

#### 🔗 Sample Code

`xs-app.json`

```
{
  "source": "^/web-pages/(.*)$",
  "localDir": "my-static-resources"
}
```

### 4.1.4.2.2.3 Application Router Configuration

A file that contains the configuration information used by the application router.

The application router configuration file is named `xs-app.json` and its content is formatted according to JavaScript Object Notation (JSON) rules.

When a business application consists of several different apps (microservices), the application router is used to provide a single entry point to that business application. The application router is responsible for the following tasks:

- Dispatch requests to back-end microservices (reverse proxy)
- Authenticate users
- Serve static content
- In multitenancy scenarios, derive the tenant information from the URL and forward the information to the XS UAA service so that the authentication request is redirected to the appropriate tenant-specific Identity Provider (IdP), for example, using SAML "Bearer Assertions".

### → Tip

The different applications (microservices) are the destinations to which the incoming requests are forwarded. The rules that determine which request should be forwarded to which destination are called routes. For every destination there can be more than one route.

## User Authentication Services

For the user authentication, you can use User Account and Authentication (UAA) service or the Identity Authentication service.

### User Account and Authentication (UAA)

User authentication is performed by the User Account and Authentication (UAA) server. In the run-time environment (on-premise and in the Cloud Foundry environment), a service is created for the UAA configuration; by using the standard service-binding mechanism, the content of this configuration is available in the `<VCAP_SERVICES>` environment variable, which the application router can access to read the configuration details.

#### Note

The UAA service should have `xsuaa` in its tags or the environment variable `<UAA_SERVICE_NAME>` should be defined, for example, to specify the **exact** name of the UAA service to use.

A calling component accesses a target service by means of the application router only if there is no JSON Web Token (JWT) available, for example, if a user invokes the application from a Web browser. If a JWT token is already available, for example, because the user has already been authenticated, or the calling component uses a JWT token for its own OAuth client, the calling component calls the target service directly; it does not need to use the application router.

#### Note

The application router does not “hide” the back-end microservices in any way; they remain directly accessible when bypassing the application router. So the back-end microservices must protect all their end points by validating the JWT token and implementing proper authorization scope checks.

The application router supports the use of the `XSAPPNAME` placeholder, which you can use in your route configuration, for example, in the `scope` property for the specified route. The value of `XSAPPNAME` is taken from the UAA configuration (for example, the `xsappname` property). For more information, see [Routing Configuration File \[page 387\]](#).

### Identity Authentication Service

As an alternative to the User Account and Authentication service (UAA), you can also use Identity Authentication. This service provides authentication and single sign-on for users in the cloud. For more information, see the product page for [SAP Cloud Identity Services - Identity Authentication](#) on the SAP Help Portal.

## Headers

If back end nodes respond to client requests with URLs, these URLs need to be accessible for the client. For this reason, the application router passes the following `x-forwarding-*` headers to the client:

- `x-forwarded-host`  
Contains the **host** header that was sent by the client to the application router
- `x-forwarded-proto`  
Contains the **protocol** that was used by the client to connect to the application router
- `x-forwarded-for`  
Contains the **address** of the client which connects to the application router
- `x-forwarded-path`  
Contains the original **path** which was requested by the client from the approuter

### ⚠ Caution

If the application router forwards a request to a destination, it blocks the header `host`.

“Hop-by-hop” headers are meaningful only for a single transport-level connection; these headers are not forwarded by the application router. The following headers are classified as “Hop-By-Hop” headers:

- Connection
- Keep-Alive
- Public
- Proxy-Authenticate
- Transfer-Encoding
- Upgrade

You can configure the application router to send additional HTTP headers, for example, either by setting it in the `httpHeaders` environment variable or in a `local-http.headers.json` file.

### 🔗 Sample Code

`local-http.headers.json`

```
[
  {
    "X-Frame-Options": "ALLOW-FROM http://localhost"
  },
  {
    "Test-Additional-Header": "1"
  }
]
```

### ⚠ Caution

For security reasons, the following headers must not be configured:

- Authorization
- Set-Cookie
- Cookie

## Sessions

The application router establishes a session with the client (browser) using a session cookie. The application router intercepts all session cookies sent by back-end services and stores them in its own session. To prevent collisions between the various session cookies, back-end session cookies are not sent to the client. On request, the application router sends the cookies back to the respective back-end services so the services can establish their own sessions.

### Note

Non-session cookies from back-end services **are** forwarded to the client, which might cause collisions between cookies. Applications should be able to handle cookie collisions.

### Restriction

You must not use multiple destinations with the same URL in an application router user session!

The application router stores the session cookies from the backend services in a user session according to the destination URLs for the backend services. If there are multiple destinations with the same URL, the application router cannot correctly send the cookies back to the backend services.

To avoid conflicts, the destination URLs must have different domains.

If there is no session in the application router, either because there has been a session timeout or because no session has been created yet, and if the incoming request matches a non-public route, the application router triggers a redirect to the authentication service (UAA or IAS).

After a successful login, a redirect back to application router takes place using the login callback endpoint, which triggers the creation of a new session. If the incoming request is an AJAX request (has the request header `X-Requested-With: XMLHttpRequest`) or if the HTTP verb is not `GET` and no session exists (there is no session cookie and the request doesn't have an `x-approuter-authorization` header), the application router returns the response code `401 - Unauthorized`. This enables the client application to handle the `401` response before it navigates to the authentication service. For example, the application can store data entered by the user and prevent data loss. When the handling of the `401` response is completed, the client application should send a request without an `xmlhttprequest` object to trigger the application router authentication flow.

## Session Contents

A session established by the application router typically contains the following elements:

- Redirect location  
The location to redirect to after logon; if the request is redirected to a UAA logon form, the original request URL is stored in the session so that, after successful authentication, the user is redirected back to it.
- CSRF token  
The CSRF token value if it was requested by the clients. For more information about protection against Cross Site Request Forgery see [CSRF Protection \[page 386\]](#) below.
- OAuth token  
The JSON Web Token (JWT) fetched from the User Account and Authentication service (UAA) and forwarded to back-end services in the `Authorization` header. The client never receives this token. The application router refreshes the JWT automatically before it expires (if the session is still valid). By default, this routine is triggered 5 minutes before the expiration of the JWT, but it can also be configured with the

<JWT\_REFRESH> environment variable (the value is set in minutes). If <JWT\_REFRESH> is set to 0, the refresh action is disabled.

- OAuth scopes  
The scopes owned by the current user, which are used to check if the user has the authorizations required for each request.
- Back-end session cookies  
All session cookies sent by back-end services.

## Scaling

The application router keeps all established sessions in local memory, and if multiple instances of the application router are running, there is no synchronization between the sessions. To scale the application router for multiple instances, session stickiness is used so that each HTTP session is handled by the same application router instance.

## Sizing and Memory Configuration

The application-router process should run with at least 256MB memory. The amount of memory actually required depends on the application the router is serving. The following aspects have an influence on the application's memory usage:

- Concurrent connections
- Active sessions
- Size of the Java Web Token
- Back-end session cookies

You can use the start-up parameter `max-old-space-size` to restrict the amount of memory used by the JavaScript heap. The default value for `max-old-space-size` is less than 2GB. To enable the application to use all available resources, the value of `max-old-space-size` should be set to a number equal to the memory limit for the whole application. For example, if the application memory is limited to 2GB, set the heap limit as follows, in the application's `package.json` file:

### Sample Code

```
"scripts": {  
  "start": "node --max-old-space-size=2048 node_modules/@sap/approuter/  
  approuter.js"  
}
```

If the application router is running in an environment with limited memory, set the heap limit to about 75% of available memory. For example, if the application router memory is limited to 256MB, add the following command to your `package.json`:

### Sample Code

```
"scripts": {
```

```
"start": "node --max-old-space-size=192 node_modules/@sap/approuter/  
approuter.js"  
}
```

### Note

For detailed information about memory consumption in different scenarios, see the Sizing Guide for the Application Router located in `approuter/approuter.js/doc/sizingGuide.md`.

## CSRF Protection

The application router enables CSRF protection for any HTTP method that is not `GET` or `HEAD` and the route is not public. A path is considered public, if it does not require authentication. This is the case for routes with `authenticationType: none` or if authentication is disabled completely via the top level property `authenticationMethod: none`.

To obtain a CSRF token one must send a `GET` or `HEAD` request with a `x-csrf-token: fetch` header to the application router. The application router will return the created token in a `x-csrf-token: <token>` header, where `<token>` will be the value of the CSRF token.

If a CSRF protected route is requested with any of the above mentioned methods, `x-csrf-token: <token>` header should be present in the request with the previously obtained token. This request must use the same session as the fetch token request. If the `x-csrf-token` header is not present or is invalid, the application router will return status code "403 - Forbidden".

## Cloud Connectivity

The application router supports integration with SAP Connectivity service. The connectivity service enables you to manage proxy access to Cloud Connector, which you can use to create tunnels for connections to systems located in private networks, for example, on-premise. To use the connectivity feature, you must create an instance of the connectivity service and bind it to the `Approuter` application.

In addition, the relevant destination configurations in the `<destinations>` environment variable must have the proxy type `"onPremise"`, for example, `"proxyType": "onPremise"`. You must also ensure that you obtain a valid XSUAA logon token for the XS advanced User Account and Authentication service.

## Troubleshooting

The application router uses the `@sap/logging` package, which means that all of the typical logging features are available to control application logging. For example, to set all logging and tracing to the most detailed level, set the `<XS_APP_LOG_LEVEL>` environment variable to `"debug"`.

### Note

Enabling debug log level could lead to a very large amount of data being written to the application logs and trace files. The asterisk wild card (\*) enables options that trace sensitive data that is then written to the logs and traces.

### → Tip

Logging levels are application-specific and case-sensitive; they can be defined with lower-case characters (for example, "debug") or upper-case characters (for example, "DEBUG"). An error occurs if you set a logging level incorrectly, for example, using lower-case characters "debug" where the application defines the logging level as "DEBUG".

You can enable additional traces of the incoming and outgoing requests by setting the environment variable `<REQUEST_TRACE>` to true. When enabled basic information will be logged for every incoming and outgoing request of the application router.

The `@sap/logging` package sets the header `x-request-id` in the application router's responses. This is useful if you want to search the application router's logs and traces for entries that belong to a particular request execution. Note that the application router does not change the headers received from the back end and forwarded to the client. If the back end is a `Node.js` application which uses the `@sap/logging` package (and also sets the `x-request-id` header), then the value of the header that the client receives is the one coming from the back end and not the one from the application router itself.

### 4.1.4.2.2.4 Routing Configuration File

The routing configuration defined in the `xs-app.json` file contains the properties used by the application router.

The following example of an `xs-app.json` application descriptor shows the JSON-compliant syntax required and the properties that either must be set or can be specified as an additional option.

#### Code Syntax

```
{
  "welcomeFile": "index.html",
  "authenticationMethod": "route",
  "sessionTimeout": 10,
  "pluginMetadataEndpoint": "/metadata",
  "routes": [
    {
      "source": "^/sap/ui5/1(.*)$",
      "target": "$1",
```

```

    "destination": "ui5",
    "csrfProtection": false
  },
  {
    "source": "/employeeData/(.*)",
    "target": "/services/employeeService/$1",
    "destination": "employeeServices",
    "authenticationType": "xsuaa",
    "scope": ["$XSAPPNAME.viewer", "$XSAPPNAME.writer"],
    "csrfProtection": true
  },
  {
    "source": "^/(.*)$",
    "target": "/web/$1",
    "localDir": "static-content",
    "replace": {
      "pathSuffixes": ["/abc/index.html"],
      "vars": ["NAME"]
    }
  },
  {
    "source": "^/user-api(.*)",
    "target": "$1",
    "service": "sap-approuter-userapi"
  }
],
"login": {
  "callbackEndpoint": "/custom/login/callback"
},
"logout": {
  "logoutEndpoint": "/my/logout",
  "logoutPage": "/logout-page.html"
},
"destinations": {
  "employeeServices": {
    "logoutPath": "/services/employeeService/logout",
    "logoutMethod": "GET"
  }
},
"responseHeaders" : [
  {"name": "Content-Security-Policy", "value": "default-src 'self'"}
],
"compression": {
  "minSize": 2048
},
"whitelistService": {
  "endpoint": "/whitelist/service"
},
"websockets": {
  "enabled": true
},
"errorPage": [
  {"status": [400,401,402], "file": "/custom-err-4xx.html"},
  {"status": 501, "file": "/custom-err-501.html"}
]
}

```

The following table lists the properties that either must be set or can be specified as an additional option. Click on the links for information for each property:

Property	Type	Description
<a href="#">welcomeFile [page 390]</a>	String	The Web page served by default if the HTTP request does not include a specific path, for example, index.html.
<a href="#">authenticationMethod [page 391]</a>	String	The method used to authenticate user requests, for example: "route" or "none" (no authentication).
<a href="#">sessionTimeout [page 391]</a>	Number	Define the amount of time (in minutes) for which a session can remain inactive before it closes automatically (times out); the default time out is 15 minutes.
<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>We recommend using the environment variable <a href="#">SESSION_TIMEOUT [page 435]</a> to configure the session timeout.</p> <p>If the environment variable <a href="#">SESSION_TIMEOUT [page 435]</a> is set this property will be overwritten.</p> </div>		
<a href="#">routes [page 392]</a>	Array	Defines all route objects, for example: <code>source</code> , <code>target</code> , and <code>destination</code> .
<a href="#">login [page 404]</a>	Object	A redirect to the application router at a specific endpoint takes place during OAuth2 authentication with the User Account and Authentication service (UAA).
<a href="#">logout [page 404]</a>	Object	You can define any options that apply if you want your application to have central log out end point.
<a href="#">destinations [page 408]</a>	Object	Specify any additional options for your destinations.
<a href="#">services [page 409]</a>	Object	Specify options for a service in your application.
<a href="#">responseHeaders [page 409]</a>	Array	Add custom response headers to your application.
<a href="#">compression [page 410]</a>	Object	The <code>compression</code> keyword enables you to define if the application router compresses text resources before sending them.

Property	Type	Description
<a href="#">pluginMetadataEndpoint [page 411]</a>	String	Adds an endpoint that serves a JSON string representing all configured plugins.
<a href="#">whitelistService [page 412]</a>	Object	Enable the allowlist service to help preventing click-jacking attacks.
<a href="#">websockets [page 413]</a>	Object	The application router can forward web-socket communication. Web-socket communication must be enabled in the application router configuration.
<a href="#">errorPage [page 414]</a>	Array	Errors originating in the application router show the HTTP status code of the error. It is possible to display a custom error page using the <code>errorPage</code> property.

## Related Information

[Application Router \[page 377\]](#)

[Application Router Configuration \[page 381\]](#)

### 4.1.4.2.2.4.1 welcomeFile

The Web page served by default if the HTTP request does not include a specific path, for example, `index.html`.

XS Advanced Application-Router Parameters

Property	Type	Mandatory	Values
<code>welcomeFile</code>	String	No	HTML page, for example, <code>index.html</code>

#### Code Syntax

```
"welcomeFile": "index.html"
```

## 4.1.4.2.2.4.2 authenticationMethod

The method used to authenticate user requests, for example: "route" or "none" (no authentication).

### Code Syntax

```
"authenticationMethod" : "route"
```

Property	Type	Mandatory	Values
authenticationMethod	String	No	<ul style="list-style-type: none"><li>route (default) Authentication type is defined in the routes configuration</li><li>none Disables authentication for all routes</li></ul>

### Caution

If `authenticationMethod` is set to "none", logon with User Account and Authentication (UAA) is disabled.

## 4.1.4.2.2.4.3 sessionTimeout

Define the amount of time (in minutes) for which a session can remain inactive before it closes automatically (times out); the default time out is 15 minutes.

### Note

We recommend using the environment variable `SESSION_TIMEOUT` [page 435] to configure the session timeout.

If the environment variable `SESSION_TIMEOUT` [page 435] is set this property will be overwritten.

### Sample Code

```
{  
  "sessionTimeout": 40  
}
```

With the configuration in the example above, a session timeout will be triggered after 40 minutes and involves central log out.

A session timeout triggers a central log out with the following consequences:

- Deletes the user session
- Requests the log out paths for all your back-end services (if you provided these paths in the `destinations` and `service` properties).

## 4.1.4.2.2.4.4 routes

Defines all route objects, for example: source, target, and, destination.

- [Routes Properties \[page 392\]](#)
- [Route Configuration Examples \[page 398\]](#)

Application Router: Routes Properties

Property	Type	Mandatory	Description
source	RegExp	Yes	<p>Describes a regular expression that matches the incoming request URL.</p> <p>A request matches a particular route when its path contains the given pattern. To ensure the RegExp matches the complete path, use the following form: <code>^\$`</code>.</p> <div data-bbox="863 891 1394 1032"><p><b>Note</b></p><p>Be aware that RegExp is applied to the full URL, including query parameters.</p></div>
<a href="#">httpMethods [page 395]</a>	Array of upper-case HTTP methods	No	<p>HTTP methods that are served by this route; the supported methods are: DELETE, GET, HEAD, OPTIONS, POST, PUT, TRACE, and PATCH.</p> <div data-bbox="863 1189 1394 1330"><p><b>→ Tip</b></p><p>If this option isn't specified, the route serves any HTTP method.</p></div>
target	String	No	<p>Defines how the incoming request path is rewritten for the corresponding destination or static resource.</p>
destination	String	No	<p>The name of the destination to which the incoming request is forwarded. The destination name can be a static string or a regular expression that defines how to dynamically fetch the destination name from the source property or from the host.</p> <p>For more information about additional destination properties, see <a href="#">Application Routes and Destinations [page 416]</a>.</p>
service	String	No	<p>The name of the service to which the incoming request is forwarded.</p>
endpoint	String	No	<p>The name of the endpoint within the service to which the incoming request is forwarded. It must only be used in a route containing a service attribute.</p>

Property	Type	Mandatory	Description
<a href="#">localDir</a> [page 396]	String	No	The directory from which application router serves static content (for example, from the application's web/ module).
<code>preferLocal</code>	Boolean	No	Defines from which subaccount the destination is retrieved. If <code>preferLocal</code> is true, the destination is retrieved from the provider subaccount. If <code>preferLocal</code> is false or undefined, the destination is retrieved from the subscriber subaccount.
<a href="#">replace</a> [page 397]	Object	No	An object that contains the configuration for replacing placeholders with values from the environment.
			<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>Note</b></p> <p>It is only relevant for static content.</p> </div>
<code>authenticationType</code>	String	No	<p>The value can be <code>ias</code>, <code>xsuaa</code>, <code>basic</code>, or <code>none</code>.</p> <p>The default <code>authenticationType</code> depends on the authentication service binding: If the application router is bound to the Identity Authentication service, the default <code>authenticationType</code> is <code>ias</code>. Otherwise, the default value is <code>xsuaa</code>.</p> <p>If you use the value <code>xsuaa</code> or <code>ias</code>, the specified authentication server (Identity Authentication or User Account and Authentication) handles the authentication and the user is redirected to the login form of Identity Authentication or User Account and Authentication.</p> <p>The <code>basic</code> <code>authenticationType</code> works with SAP S/4 HANA users, SAP ID service, and Identity Authentication service. For more information, see the SAP Note 3015211 - BASIC authentication options for SAP BTP Cloud Foundry applications.</p> <p>If the value <code>none</code> is used, no authentication is required for this route.</p>
<code>csrfProtection</code>	Boolean	No	Toggle whether this route needs CSRF token protection. The default value is "true". The application router enforces CSRF protection for any HTTP request that changes state on the server side, for example: PUT, POST, or DELETE.

Property	Type	Mandatory	Description
scope	Array/String/Object	No	The authorization scope required to access the target path. The scope itself is defined in the application's security descriptor ( <code>xs-security.json</code> ), for example, " <code>XSAPPNAME.Display</code> " or " <code>XSAPPNAME.Create</code> ".
cacheControl	String	No	<p>A string representing the value of the Cache-Control header, which is set on the response when serving static resources. By default the Cache-Control header isn't set.</p> <p>The cacheControl property is only effective when one of the following settings is performed:</p> <ul style="list-style-type: none"> <li>localDir property is set</li> <li>Service pointing to HTML5 Application Repository ("service": "html5-apps-repo-rt") is set</li> </ul>
identityProvider	String	No	<p>The name of the identity provider you use if it's provided in the definition of the route. If it isn't provided, the route is authenticated with the default identity provider.</p> <div data-bbox="863 1111 1396 1305" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>If authenticationType is set to <i>Basic Authentication</i> or <i>None</i>, don't define the identityProvider property.</p> </div>
dynamicIdentityProvider	Boolean	No	<p>Enables dynamic identity provider provisioning.</p> <p>If dynamicIdentityProvider is true, the end user can set the identity provider (IDP) for the application's login process by filling the request query parameter <code>sap_idp</code> with the IDP origin key. If the IdentityProvider property is defined in the route, its value is overwritten by the <code>sap_idp</code> query parameter value. The default value for dynamicIdentityProvider is false.</p>

### Note

Route order is important. The first matching route will be used. Therefore, it is recommended to sort the routes from the most specific source to the more generic one. For example:

#### Sample Code

```
"routes": [
  {
```

```

    "source": "^/sap/backend/employees(.*?)$",
    "target": "$1",
    "destination": "sfsf"
  } ,
  {
    "source": "^/sap/backend/(.*?)$",
    "target": "$1",
    "destination": "erp",
  }
]

```

### Code Syntax

```

"routes": [
  {
    "source": "^/sap/ui5/1(.*?)$",
    "target": "$1",
    "destination": "ui5",
    "scope": "$XSAPPNAME.viewer",
    "authenticationType": "xsuaa",
    "csrfProtection": true
  }
]

```

### Note

The properties `service`, `destination`, and `localDir` are optional. However, at least one of them **must** be defined.

### httpMethods

The `httpMethods` option allows you to split the same path across different targets depending on the HTTP method. For example:

### Sample Code

```

"routes": [
  {
    "source": "^/app1/(.*?)$",
    "target": "/before/$1/after",
    "httpMethods": ["GET", "POST"]
  }
]

```

This route only serves GET and POST requests. Any other method (including extension ones) gets a 405 Method Not Allowed response. The same endpoint can be split across multiple destinations depending on the HTTP method of the requests:

### Sample Code

```

"routes": [
  {

```

```

    "source": "^/appl/(.*)$",
    "destination" : "dest-1",
    "httpMethods": ["GET"]
  },
  {
    "source": "^/appl/(.*)$",
    "destination" : "dest-2",
    "httpMethods": ["DELETE", "POST", "PUT"]
  }
]

```

This sample code routes GET requests to the target `dest-1`, DELETE, POST and PUT to `dest-2`, and any other method receives a 405 Method Not Allowed response. It's also possible to specify `catchAll` routes, namely routes that don't specify `httpMethods` restrictions:

### Sample Code

```

"routes": [
  {
    "source": "^/appl/(.*)$",
    "destination" : "dest-1",
    "httpMethods": ["GET"]
  },
  {
    "source": "^/appl/(.*)$",
    "destination" : "dest-2"
  }
]

```

In this sample code, GET requests are routed to `dest-1`, and all of the rest are routed to `dest-2`.

`localDir`

If there's no route defined for serving static content via `localDir`, a default route is created for "resources" directory as follows:

### Sample Code

```

{
  "routes": [
    {
      "source": "^/(.*)$",
      "localDir": "resources"
    }
  ]
}

```

### Note

If there is at least one route using `localDir`, the default route isn't added.

replace

The `replace` object configures the placeholder replacement in static text resources.

### Sample Code

```
{
  "replace": {
    "pathSuffixes": ["index.html"],
    "vars": ["escaped_text", "NOT_ESCAPED"]
  }
}
```

The `replace` keyword requires the following properties:

Replacement Properties for Static Resource URLs

Property	Type	Description
<code>pathSuffixes</code>	Array	An array defining the path suffixes that are relative to <code>localDir</code> . Only files with a path ending with any of these suffixes are processed.
<code>vars</code>	Array	A whitelist with the environment variables that are replaced in the files matching the suffix specified in <code>pathSuffixes</code> .

The supported tags for replacing environment variables are: `{{ENV_VAR}}` and `{{{ENV_VAR}}}`. If such an environment variable is defined, it's replaced; otherwise, it's just an empty string.

### Note

Any variable that is replaced using two-brackets syntax `{{ENV_VAR}}` is HTML-escaped; the triple brackets syntax `{{{ENV_VAR}}}` is used when the replaced values don't need to be escaped and all values remain unchanged. For example, if the value of the environment variable is `ab"cd` the result is `ab&quot;cd`.

If your application descriptor `xs-app.json` contains a route like the one illustrated in the following example,

```
{
  "source": "^/get/home(.*)",
  "target": "$1",
  "localDir": "resources",
  "replace": {
    "pathSuffixes": ["index.html"],
    "vars": ["escaped_text", "NOT_ESCAPED"]
  }
}
```

And your application uses the following `index.html` start file:

### Sample Code

```
<html>
  <head>
    <title>{{escaped_text}}</title>
    <script src="{{{NOT_ESCAPED}}}/index.js"/>
  </head>
```

```
</html
```

Then, in the `index.html`, `{{escaped_text}}` and `{{{NOT_ESCAPED}}}` are replaced with the value defined in the environment variables `<escaped_text>` and `<NOT_ESCAPED>`.

### Note

All `index.html` files are processed; if you want to apply the replacement only to specific files, you must set the path relative to `localDir`. In addition, all files must comply with the UTF-8 encoding rules.

The content type returned by a request is based on the file extension specified in the route. The application router supports the following file types:

- `.json` (`application/json`)
- `.txt` (`text/plain`)
- `.html` (`text/html`) **default**
- `.js` (`application/javascript`)
- `.css` (`text/css`)

The following table illustrates some examples of the `pathSuffixes` properties:

Examples of the `pathSuffixes` Property

Example	Result
<pre>{ "pathSuffixes":   [ ".html" ] }</pre>	All files with the extension <code>.html</code> under <code>localDir</code> and its subfolders are processed.
<pre>{ "pathSuffixes": [ "/abc/ main.html", "some.html" ] }</pre>	For the suffix <code>/abc/main.html</code> , all files named <code>main.html</code> that are inside a folder named <code>abc</code> are processed.  For the suffix <code>some.html</code> , all files with a name that ends with <code>"some.html"</code> are processed. For example: <code>some.html</code> , <code>awesome.html</code> .
<pre>{ "pathSuffixes":   [ ".html" ] }</pre>	All files with the name <code>"some.html"</code> are processed. For example: <code>some.html</code> , <code>/abc/some.html</code> .

## Route Configuration Examples

### Route with a `destination` and no `target`

#### Sample Code

```
{  
  "source": "^/app1/(.*)$",  
  "destination": "app-1"  
}
```

Since there is no `target` property for that route, no path rewriting will take place. If `/app1/a/b` is received as a path, then a request to `http://localhost:3001/app1/a/b` is sent. The source path is appended to the destination URL.

## Route with case-insensitive matching

### Sample Code

```
{
  "source": {
    "path": "^/app1/(.*)$",
    "matchCase": false
  },
  "destination": "app-1"
}
```

### Note

The property `matchCase` must be boolean. It is optional and has a default value of `true`.

## Route with a destination and a target

### Sample Code

```
{
  "source": "^/app1/(.*)$",
  "target": "/before/$1/after",
  "destination": "app-1"
}
```

## Route with a service, a target and an endpoint

### Sample Code

```
{
  "source": "^/odata/v2/(.*)$",
  "target": "$1",
  "service": "com.sap.appbasic.country",
  "endpoint": "countryservice"
}
```

When a request with path `/app1/a/b` is received, the path rewriting is done according to the rules in the `target` property. The request will be forwarded to `http://localhost:3001/before/a/b/after`.

### Note

In regular expressions there is the term capturing group. If a part of a regular expression is surrounded with parenthesis, then what has been matched can be accessed using `$` + the number of the group (starting from 1). In code sample, `$1` is mapped to the `(.*)` part of the regular expression in the source property.

## Route with dynamic destination and target

### Sample Code

```
{
  "source": "^/destination/([^/]+)/(.*)$",
  "target": "$2",
  "destination": "$1",
  "authenticationType": "xsuaa"
}
```

```
}
```

If you have another destination configured, use this:

#### Sample Code

```
[
  {
    "name" : "myDestination",
    "url" : "http://localhost:3002"
  }
]
```

When a request with the path `/destination/myDestination/myTarget` is received, the destination will be replaced with the URL from "myDestination", the target will get "myTarget" and the request will be redirected to `http://localhost:3002/myTarget`.

#### Note

You can use a dynamic value (regex) or a static string for `destination` and `target` values.

The Application Router first looks for the destination name in the `manifest.yaml` file, and if it is not found, it looks for it in the destination service.

## Destination in Host

For legacy applications that do not support relative URL paths, you need to define your URL in the following way to enable the destination to be extracted from the host:

```
https://<tenant>-<destination>.<customdomain>/<pathofile>
```

To enable the application router to determine the destination of the URL host, a `DESTINATION_HOST_PATTERN` attribute must be provided as an environment variable. For example, When a request with the path `https://myDestination.some-approuter.someDomain.com/app1/myTarget` is received, the following route is used:

#### Sample Code

```
{
  "source": "^/app1/([^/]+)/",
  "target": "$1",
  "destination": "*",
  "authenticationType": "xsuaa"
}
```

In this example, the target will be extracted from the source and the `'$1'` value is replaced with "myTarget". The destination value is extracted from the host and the `"*"` value is replaced with "myDestination".

## Route with a localDir and no target

#### Sample Code

```
{
  "source": "^/web-pages/(.*)$",
  "target": "$1",
  "localDir": "my-static-resources"
}
```

```
}
```

If we receive a request with a path `/web-pages/welcome-page.html`, the local file at `my-static-resources/welcome-page.html` under the working directory will be served.

#### Note

The capturing group used in the `target` property.

### Route with `localDir` and `cacheControl`

#### Sample Code

```
{
  "source": "^/web-pages/",
  "localDir": "my-static-resources",
  "cacheControl": "public, max-age=1000, must-revalidate"
}
```

### Route with service `"html5-apps-repo-rt"` and `cacheControl`

#### Sample Code

```
{
  "source": "^/index.html$",
  "service": "html5-apps-repo-rt",
  "authenticationType": "xsuaa",
  "cacheControl": "public, max-age=1000, must-revalidate"
}
```

### Route with `httpMethods` restrictions

This option allows you to split the same path across different targets depending on the HTTP method. For example:

#### Sample Code

```
{
  "source": "^/app1/(.*)$",
  "target": "/before/$1/after",
  "httpMethods": ["GET", "POST"]
}
```

This route only supports `GET` and `POST` requests. Any other method (including extensions) will receive a [405 Method Not Allowed](#) response. The same endpoint can be split across multiple destinations depending on the HTTP method of the requests:

#### Sample Code

```
{
  "source": "^/app1/(.*)$",
  "destination": "dest-1",
  "httpMethods": ["GET"]
},
{
```

```

"source": "^/app1/(.*)$",
"destination": "dest-2",
"httpMethods": ["DELETE", "POST", "PUT"]
}

```

In the setup above, GET requests will be routed to "dest-1", and all the rest to "dest-2".

### Note

localDir and httpMethods are not compatible.

## Route with a scope

An application specific scope uses the following format:

```
<application-name>.<scope-name>
```

It is possible to configure what scope the user needs to possess in order to access a specific resource. Those configurations are per route. The user should have at least one of the scopes in order to access the corresponding resource.

### Sample Code

```

{
  "source": "^/web-pages/(.*)$",
  "target": "$1",
  "scope": ["$XSAPPNAME.viewer", "$XSAPPNAME.reader", "$XSAPPNAME.writer"]
}

```

For convenience if your route only requires one scope, the scope property can be a string instead of an array. The following configuration is also valid:

### Sample Code

```

{
  "source": "^/web-pages/(.*)$",
  "target": "$1",
  "scope": "$XSAPPNAME.viewer"
}

```

You can configure scopes for different HTTP methods, such as GET, POST, PUT, HEAD, DELETE, CONNECT, TRACE, PATCH, and OPTIONS. If some of the HTTP methods are not explicitly set, the behaviour for them is defined by the default property. In case there is no default property specified and the HTTP method is also not specified, the request is rejected by default.

### Sample Code

```

{
  "source": "^/web-pages/(.*)$",
  "target": "$1",
  "scope": {
    "GET": "$XSAPPNAME.viewer",
    "POST": ["$XSAPPNAME.reader", "$XSAPPNAME.writer"],
    "default": "$XSAPPNAME.guest"
  }
}

```

The application router supports the `$XSAPPNAME` placeholder. Its value is taken (and then substituted in the routes) from the UAA configuration.

#### Note

The substitution is case sensitive.

You can use the name of the business application directly instead of using the `$XSAPPNAME` placeholder:

#### Sample Code

```
{
  "source": "^/backend/(.*)$",
  "scope": "my-business-application.viewer"
}
```

### Routes with an `identityProvider`

You can define several identity providers for different types of users. In this code example, there are two categories: hospital patients and hospital personnel:

- `patientsIDP` – use for authenticating patients.
- `hospitalIDP` – use for authenticating all hospital personnel (doctors, nurses etc..).

#### Sample Code

```
[
  {
    "source": "^/patients/sap/opu/odata/(.*)",
    "target": "/sap/opu/odata$1",
    "destination": "backend",
    "authenticationType": "xsuaa",
    "identityProvider": "patientsIDP"
  },
  {
    "source": "^/hospital/sap/opu/odata/(.*)",
    "target": "/sap/opu/odata$1",
    "destination": "backend", "authenticationType": "xsuaa",
    "identityProvider": "hospitalIDP"
  }
]
```

A patient who tries to log into the system will be authenticated by `patientIDP`, and a doctor who tries to log in will be authenticated by `hospitalIDP`.

#### Note

If a user logs in as one identity and then wants to perform tasks for another identity type, the user must log out and log back in to the system.

Dynamic provisioning of the subscriber account identity provider is not supported.

Identity provider configuration is only supported in the client side logon redirect flow.

## Route with a `dynamicIdentityProvider`

This is an example of a route where the value of `identityProvider` is `patientsIDP` and where dynamic identity provider provisioning is enabled by setting `dynamicIdentityProvider` to `true`:

### Sample Code

```
[
  {
    "source": "^/patients/index.html",
    "target": "/patients-index.html",
    "service": "html5-apps-repo-rt",
    "identityProvider": "patientsIDP",
    "dynamicIdentityProvider": true
  }
]
```

In this example, the `patientsIDP` value for the `identityProvider` is replaced by `hospitalIDP` if a request with `sap_idp=hospitalIDP` is executed, for example, if the request is `https://shiva.health-center-approuter.cfapps.hana.ondemand.com/healthreport/patients/index.html?sap_idp=hospitalIDP`.

## 4.1.4.2.2.4.5 login

A redirect to the application router at a specific endpoint takes place during OAuth2 authentication with the service that you are using for the authentication (User Account and Authentication service (UAA) or Identity Authentication service).

This endpoint can be configured in order to avoid possible collisions, as illustrated in the following example:

### Sample Code

Application Router "login" Property

```
"login": {
  "callbackEndpoint": "/custom/login/callback"
}
```

### → Tip

The default endpoint is `/login/callback`.

## 4.1.4.2.2.4.6 logout

You can define any options that apply if you want your application to have a central logout end point.

In this object you can define an application's central logout end point by using the `logoutEndpoint` property. The value of `logout` property should be an object with the following properties:

Property	Type	Mandatory	Description
<code>logoutPath</code>	String	Yes	The path to be used when logging out from the application router
<code>logoutPage</code>	String	No	The URL path of the logout page
<code>logoutMethod</code>	String	No	Can be POST or GET. The default value is GET.
<code>csrfProtection</code>	Boolean	No	Can only be defined if the <code>logoutMethod</code> is POST.  If the <code>logoutMethod</code> is POST and this property is not defined, the default value is <code>true</code> . You can set it to <code>false</code> – for example if <code>csrfProtection</code> is implemented in back-end application

#### Note

For security reasons, it is recommended to use the POST method and to enable CSRF protection.

This is an example:

#### Sample Code

```
"logout" {
  "logoutEndpoint": "/my/logout"
}
```

Making a GET or POST request to `/my/logout` triggers a client-initiated central logout with the following consequences:

- Deletes the user session
- Requests the logout paths for all your back-end services (if you provided these paths in the `destinations` and `service` properties).
- Redirects to the authentication service (UAA or Identity Authentication - depending on which service you are using for the authentication), if such a service is provided, and logs out from there.

You can use the `logoutPage` property to specify the Web page in one of the following ways:

- URL path

The authentication service (UAA or Identity Authentication - depending on which service you are using for the authentication) redirects the user back to the application router, and the path is interpreted according to the configured routes.

The `logoutEndpoint` can be called with query parameters. For example:

#### Sample Code

```
window.location.replace('/my/logout?siteId=3');
```

These parameters will be appended as is to the redirect URL set by the `logoutPage` property. For example, if the logout section is:

#### Sample Code

```
"logout": {
  "logoutEndpoint": "/logout",
  "logoutPage": "/logoff.html"
},
```

The redirect URL will end with:

#### Sample Code

```
/logoff.html?siteId=3
```

#### Note

The resource that matches the URL path specified in the property `logoutPage` should not require authentication; for this route, the property `authenticationType` must be set to `none`.

In the following example, `my-static-resources` is a folder in the working directory of the application router; the folder contains the file `logout-page.html` along with other static resources.

#### Sample Code

```
{
  "authenticationMethod": "route",
  "logout": {
    "logoutEndpoint": "/my/logout",
    "logoutPage": "/logout-page.html"
  },
  "routes": [
    {
      "source": "^/logout-page.html$",
      "localDir": "my-static-resources",
      "authenticationType": "none"
    }
  ]
}
```

- Absolute HTTP(S) path

The authentication service (UAA or Identity Authentication - depending on which service you are using for the authentication) redirects the user to a page (or application) different from the application router.

### Sample Code

```
"logout": {
  "logoutEndpoint": "/my/logout",
  "logoutPage": "http://acme.com/employees.portal"
}
```

## Using the POST Method for Logout

For security reasons, it is recommended to use *POST* method for logout and to enable CSRF protection.

The `logoutMethod` and `csrfProtection` properties are included in the `logout` property:

### Sample Code

```
"logout": {
  "logoutEndpoint": "/my/logout",
  "logoutPage": "/logout-page.html",
  "logoutMethod": "POST",
  "csrfProtection": true
}
```

### Note

For backward compatibility reasons, the default value of `logoutMethod` is `GET`. The `csrfProtection` property can only be set if the `logoutMethod` is `POST`. If the `logoutMethod` is `POST` and the `csrfProtection` property is not set, the `csrfProtection` is enabled by default.

In this example, the `POST` request is an AJAX request and includes a CSRF token:

### Sample Code

```
async function getToken() {
  return new Promise((resolve) => {
    jQuery.ajax({
      type: "GET",
      url: 'my/logout',
      headers: {
        "X-CSRF-Token": 'fetch',
        contentType: "application/json",
      },
      success: function(data, textStatus, request){
        resolve(request.getResponseHeader('X-CSRF-Token'));
      },
    });
  });
};
```

This is an example for the `POST` request:

### Sample Code

```
const token = await getToken();
jQuery.ajax({
```

```

type: "POST",
url: "my/logout",
headers: {
  "X-CSRF-Token": token,
  contentType: "application/json",
},
success: function (data) {
  window.location.href = data;
}
});

```

### Note

Make sure that the `url` field matches the `logoutEndpoint`.

## 4.1.4.2.2.4.7 destinations

Specify any additional options for your destinations.

The destinations section in `xs-app.json` extends the destination configuration in the deployment manifest (`manifest.yml`), for example, with some static properties such as a logout path.

### Sample Code

```

{
  "destinations": {
    "node-backend": {
      "logoutPath": "/ui5logout",
      "logoutMethod": "GET"
    }
  }
}

```

The following syntax rules apply:

Application Router: Destination Properties

Property	Type	Mandatory	Description
<code>logoutPath</code>	String	No	The log out end point for your destination. The <code>logoutPath</code> will be called when central log out is triggered or a session is deleted due to a time out. The request to <code>logoutPath</code> contains additional headers, including the JWT token.
<code>logoutMethod</code>	String	No	The <code>logoutMethod</code> property specifies the HTTP method with which the <code>logoutPath</code> will be requested, for example, POST, PUT, GET; the default value is POST

## 4.1.4.2.2.4.8 services

Specify options for a service in your application.

The services section in `xs-app.json` extends the services configuration in the deployment manifest (`manifest.yml`), for example, with some static properties such as an endpoint.

### Sample Code

```
{
  "services": {
    "com.sap.appbasic.country": {
      "endpoint": "countryservice",
      "logoutPath": "/countrieslogout",
      "logoutMethod": "GET"
    }
  }
}
```

The following syntax rules apply:

Application Router: Services Properties

Property	Type	Mandatory	Description
<code>endpoint</code>	String	No	The name of the attribute in the <code>VCAP_SERVICES</code> that contains the URL of the service.
<code>logoutPath</code>	String	No	The log out end point for your destination. The <code>logoutPath</code> will be called when central log out is triggered or a session is deleted due to a time out. The request to <code>logoutPath</code> contains additional headers, including the JWT token.
<code>logoutMethod</code>	String	No	The <code>logoutMethod</code> property specifies the HTTP method with which the <code>logoutPath</code> will be requested, for example, POST, PUT, GET; the default value is POST

## Related Information

[Integration with Business Services \[page 425\]](#)

## 4.1.4.2.2.4.9 responseHeaders

You can add headers that the application router returns to the client in its responses.

You can add response headers to your application, for example, to comply with security standards.

The `responseHeaders` property is an array of objects, each object having the following properties:

Property	Type	Description
name	string	response header name
value	string	response header value

```
{ "responseHeaders" : [
  { "name": "header1", "value": "value1" },
  { "name": "header2", "value": "value2" }
]
```

Example:

#### Sample Code

```
{ "responseHeaders" : [
  { "name": "Content-Security-Policy", "value": "default-src 'self'" }
]
```

#### Note

The response headers are added to the list of additional http headers that you have configured in the [<httpHeaders> environment variable \[page 429\]](#). If the name of a response header configured in the routing configuration is identical with name of an additional http header in the list, the value of the response header overrides the value of the additional http header.

## Related Information

[Environment Variables \[page 429\]](#)

### 4.1.4.2.2.4.10 compression

The `compression` keyword enables you to define if the application router compresses text resources before sending them.

By default, resources larger than 1KB are compressed. If you need to change the compression size threshold, for example, to "2048 bytes", you can add the optional property `"minSize": <size_in_KB>`, as illustrated in the following example.

#### Sample Code

```
{
  "compression": {
    "minSize": 2048
  }
}
```

You can disable compression in the following ways:

- Global  
Within the compression section add "enabled": false
- Front end  
The client sends a header "Accept-Encoding" which does not include "gzip".
- Back end  
The application sends a header "Cache-Control" with the "no-transform" directive.

Application Router: Compression Properties

Property	Type	Mandatory	Description
minSize	Number	No	Text resources larger than this size will be compressed.
enabled	Boolean	No	Globally disables or enables compression. The default value is true.
compressResponseMixedTypeContent	Boolean	No	Determines whether response content of the multipart / mixed content type should be compressed. The default value is false.

#### Note

If the `<COMPRESSION>` environment variable is set it will overwrite any existing values.

### 4.1.4.2.2.4.11 pluginMetadataEndpoint

Adds an endpoint that serves a JSON string representing all configured plugins.

#### Sample Code

```
{
  "pluginMetadataEndpoint": "/metadata"
}
```

#### Note

If you request the relative path `/metadata` of your application, a JSON string is returned with the configured plug-ins.

## 4.1.4.2.2.4.12 whitelistService

Enable the allowlist service to help prevent against click-jacking attacks.

Enabling the allowlist service (which is called `whitelistService` in the code) opens an endpoint accepting GET requests at the relative path configured in the `endpoint` property, as illustrated in the following example:

### Sample Code

```
{
  "whitelistService": {
    "endpoint": "/whitelist/service"
  }
}
```

If the allowlist service is enabled in the application router, each time an HTML page needs to be rendered in a frame, the allowlist service is used check if the parent frame is allowed to render the content in a frame.

### Host Names and Domain Names

The allowlist service reads a list of allowed host names and domains defined in the environment variable `<CJ_PROTECT_WHITELIST>`; the content is a JSON list of objects with the following properties:

Allowlist of Host and Domain Names

Property	Type	Mandatory	Description
<code>protocol</code>	String	No	URI scheme, for example "HTTP".
<code>host</code>	String	Yes	A valid host name, for example, <code>acme.com.hostname</code> , or a domain name defined with an asterisk (*) <code>*.acme.com</code> .
<code>port</code>	String/Number	No	Port string or number containing a valid port.

The following snippet shows an example of the resulting JSON array:

### Sample Code

```
[
  {
    "protocol": "http",
    "host": "*.acme.com",
    "port": 12345
  },
  {
    "host": "hostname.acme.com"
  }
]
```

### Note

Matching is done against the properties provided. For example, if only host name is provided, the allowlist service returns `"framing: true"` for all, and matching will be for all schemata and protocols.

## Return Value

The allowlist service accepts only GET requests, and returns a JSON object as the response. The allowlist service call uses the parent origin as URI parameter (URL encoded) as follows:

### Sample Code

```
GET url/to/whitelist/service?parentOrigin=https://parent.domain.acme.com
```

The response is a JSON object with the following properties; property "active" has the value `false` only if `<CJ_PROTECT_WHITELIST>` is not provided:

### Sample Code

```
{
  "version" : "1.0",
  "active" : true | false,
  "origin" : "<same as passed to service>",
  "framing" : true | false
}
```

The "active" property enables framing control; the "framing" property specifies if framing should be allowed. By default, the application router (`approuter.js`) sends the `X-Frame-Options` header with value the `SAMEORIGIN`.

### Tip

If the allowlist service is enabled, the header value probably needs to be changed, see the *X-Frame-Options* header section for details about how to change it.

## 4.1.4.2.2.4.13 websockets

The application router can forward web-socket communication. Web-socket communication must be enabled in the application router configuration.

If the back-end service requires authentication, the upgrade request should contain a valid session cookie. The application router supports the destination schemata "ws", "wss", "http", and "https".

### Sample Code

```
{
  "websockets": {
    "enabled": true
  }
}
```

To use web-sockets when the application router is integrated with the HTML5 Application Repository, the `websockets` property should be added to the `xs-app.json` of the deployed HTML5 application. When an incoming request for an application in the repository goes through the application router, it retrieves the application's configuration from the repository. If this flag is set, the application router creates a web-socket connection to the back end (the target url of the request) and acts as a proxy which delivers messages on top of the `ws` protocol from the back end to the user, and vice versa.

### ⚠ Restriction

A web-socket ping is not forwarded to the back-end service.

## 4.1.4.2.2.4.14 errorPage

Errors originating in the application router show the HTTP status code of the error. It is possible to display a custom error page using the `errorPage` property.

The property is an array of objects, each object can have the following properties:

Application Router: `errorPage` Properties

Property	Type	Mandatory	Description
<code>status</code>	Number/Array	Yes	HTTP status code.
<code>file</code>	String	Yes	File path relative to the working directory of the application router.

In the following code example, errors with status code "400", "401" and "402" will show the content of `./custom-err-4xx.html`; errors with the status code "501" will display the content of `./http_resources/custom-err-501.html`.

### ↗ Sample Code

```
{ "errorPage" : [
  { "status": [400,401,402], "file": "./custom-err-40x.html" },
  { "status": 501, "file": "./http_resources/custom-err-501.html" }
]
```

### 📌 Note

The contents of the `errorPage` configuration section have no effect on errors that are not generated by the application router.

## 4.1.4.2.2.5 Headers

### Forwarding Header

The application router sends the following `x-forwarding-` headers to the route targets:

Header Name	Description
<code>x-forwarded-host</code>	Contains the host header that is sent from the client to the application router.
<code>x-forwarded-proto</code>	Contains the protocol that is used by the client to connect to the application router.
<code>x-forwarded-for</code>	Contains the address of the client that connects to the application router.
<code>x-forwarded-path</code>	Contains the original path that the client requested.

If a client performs a path rewriting, it sends the `x-forwarded-proto`, `x-forwarded-host`, and the `x-forwarded-path` headers to the application router. The values of these headers are forwarded to the route targets without modifications instead of being generated from the application router request URL. The `x-forwarded-path` header of a request does not impact the source pattern of routes in the `xs-app.json`.

### Hop-by-Hop Headers

Hop-by-hop headers are only for a single transport-level connection and are not forwarded by the application router. The headers are:

- `Connection`
- `Keep-Alive`
- `Public`
- `Proxy-Authenticate`
- `Transfer-Encoding`
- `Upgrade`

### Custom Header

`x-custom-host` is used to support the application router behind an external reverse proxy. The `x-custom-host` header must contain the internal reverse proxy host.

#### ⓘ Note

`EXTERNAL_REVERSE_PROXY` environment variable is set to true.

In a multi-tenancy landscape, application router can be called from multiple tenants. During the authentication flow, application router uses the tenant ID to fetch the authentication token from XSUAA. Application router extracts the tenant ID from the corresponding host using the tenant host pattern configuration.

In an external reverse proxy flow, the application router uses the `x-custom-host` to extract the tenant ID using the tenant host pattern configuration.

If the `x-custom-host` is not provided, the application router uses the host header to extract the tenant ID.

## Authorization Header for Service to Application Router

The `x-approuter-authorization` header contains the JWT token or Open ID Connect (OIDC) access token to support the service-to-application-router scenario.

The application router can receive a JWT token created by the SAP Authorization and Trust Management service (XSUAA) service or an OIDC access token created by Identity Authentication and use it to access the UI and the data. The JWT token is passed to the application router in the `x-approuter-authorization` header of a request.

### Note

The JWT token or the OIDC token are generated with the same SAP Authorization and Trust Management service (XSUAA) service instance or the same Identity Authentication service instance that is bound to the application router.

## 4.1.4.2.2.6 Application Routes and Destinations

The application router is the single point of entry for an application.

The application router is used to serve static content, propagates user information, and acts as a proxy to forward requests to other microservices. The routing configuration for an application is defined in one or more destinations. The application router configuration is responsible for the following tasks:

- Act as the main user-entry point to application service
- Serve static content
- Serve routes and destinations
- Rewrite URLs
- Forward requests to other services
- Propagate user information
- Handle authentication
- Manage HTML5 application/browser sessions

### Note

The application router doesn't manage server caching. The server cache must be set (with e-tags) in the server itself. The cache must contain not only static content, but container resources too. For example, relating to OData metadata.

## Destinations

A destination defines the back-end connectivity. In its simplest form, a destination is a URL to which requests are forwarded. There has to be a destination for every single app (microservice) that is a part of the business application.

### Note

You must not use multiple destinations with the same URL in an application router user session!

The application router stores the session cookies from the backend services in a user session according to the destination URLs for the backend services. If there are multiple destinations with the same URL, the application router cannot correctly send back the cookies to the backend services. Note that to avoid conflicts, the destination URLs must have different domains. For more information, see [Sessions \[page 384\]](#).

The destinations configuration can be provided by the destinations environment variable or by the destination service.

## Destinations Environment Variable

Destinations can be defined in an environment variable for the `approuter` application. The destinations are typically specified in the application manifest file (`manifest.yml`). The router information is added to the `env: destinations` section of the `manifest.yml` file, as illustrated in the following example:

### Sample Code

Destinations Defined in the Application Manifest (`manifest.yml`)

```
---
applications:
- name: node-hello-world
  port: <approuter-port> #the port used for the approuter
  memory: 100M
  path: web
  env:
    destinations: >
      [
        {
          "name": "backend",
          "url": "http://<hostname>:<node-port>",
          "forwardAuthToken": true
        }
      ]
  services:
    - node-uaa
```

### Note

The "name" and "url" properties are mandatory.

The value of the destination "name" : "backend" must match the value of the `destinations` property configured for a route in the corresponding application-router configuration file (`xs-app.json`). It's also possible to define a logout path and method for the `destinations` property in the `xs-app.json` file.

## Destination Service

Destination configuration can be provided by `destination` service. The destination service can be consumed by the application router after binding a destination service instance to it.

The following guidelines apply to the configuration of the mandatory properties of a destination:

### Mandatory Properties of a Destination

Property	Description
Type	Only HTTP is supported.
Authentication	All authentication types are supported. <div data-bbox="750 705 1394 1048"><p><b>Note</b></p><ul style="list-style-type: none"><li>When using <code>basic</code> authentication, <code>User</code> and <code>Password</code> are mandatory.</li><li>When using <code>principal</code> propagation, the proxy type is <code>on-premise</code>.</li><li>When using <code>OAuth2SAMLBearerAssertion</code>, the <code>uaa.user</code> scope in the <code>xs-security.json</code> file is required.</li></ul></div>
ProxyType	Supported types: <ul style="list-style-type: none"><li><code>on-premise</code> If set, binding to SAP Connectivity service is required.</li><li><code>internet</code></li><li><code>private-link</code> To check the availability of the <code>private-link</code> proxy type, see <a href="#">SAP Private Link Service</a> in the SAP Discovery Center.</li></ul>

The following guidelines apply to the configuration of the additional properties of a destination:

### Additional Properties of a Destination

Property	Description
HTML5.ForwardAuthToken	If <code>true</code> , the OAuth token is sent to the destination. The default value is <code>false</code> . This token contains the user identity, scopes, and other attributes. It's signed by the UAA so it can be used for user authentication and authorization with back-end services. <div data-bbox="590 1736 1394 1982"><p><b>Note</b></p><p>If the <code>ProxyType</code> is set to <code>on-premise</code>, don't set the <code>ForwardAuthToken</code> property to <code>true</code>.</p><p>If the <code>Authentication</code> is other than <code>NoAuthentication</code>, don't set the <code>ForwardAuthToken</code> property to <code>true</code>.</p></div>

Property	Description
HTML5.Timeout	<p>Positive integer representing the maximum time to wait for a response (in milliseconds) from the destination. The default value is 30000 ms.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>The timeout value specified also applies to the destination's log out path (if defined), which belongs to the <code>destination</code> property.</p> </div>
HTML5.PreserveHostHeader	<p>If <code>true</code>, the application router preserves the host header in the back-end request.</p> <p>This is expected by some back-end systems like AS ABAP, which don't process <code>x-forwarded-*</code> headers.</p>
HTML5.DynamicDestination	<p>If <code>true</code>, the application router allows this destination to be used dynamically on the host or path level.</p>
HTML5.SetXForwardedHeaders	<p>If <code>true</code>, the application router adds X-Forwarded-(Host, Path, Proto) headers to the back-end request. The default value is <code>true</code>.</p>
sap-client	<p>If <code>true</code>, the application router propagates the <code>sap-client</code> and its value as a header in the back-end request.</p> <p>This is expected by ABAP back-end systems.</p>
HTML5.IASDependencyName	<p>Configures the name of the Identity Authentication dependency that is used to exchange the Identity Authentication token used for the user authentication at login. If configured, the exchanged token is then also forwarded to the backend application.</p>
HTML5.ForwardAuthCertificates	<p>If <code>true</code>, the certificates and key of the authentication service are added to the HTTP connection to the destination. The default value is <code>false</code>. For more information see: <a href="#">Mutual TLS Authentication (mTLS) and Certificates Handling [page 443]</a>.</p>

- If a destination with the same name is defined both in the environment destination and the destination service, the destination configuration loads the settings from the environment.
- If the configuration of a destination is updated in runtime, the changes are reflected automatically to the AppRouter. There's no need to restart the AppRouter.
- The destination service is only available in the Cloud Foundry environment.
- You can define destinations at the service instance level. This destination type has a higher priority than the same destination defined on the subaccount level. This enables exposing a specific destination to a specific application instead of to the entire subaccount.

## Connectivity

Application Router supports integration with the SAP Connectivity service. The Connectivity service handles proxy access to the Cloud Connector, which tunnels connections to private network systems. In order to use

connectivity, a connectivity service instance must be created and bound to the Application Router application. In addition, the relevant destination configurations must contain `proxyType=OnPremise` and a valid XSUAA login token must be obtained from the login flow.

## Configure the `IASDependencyName` Property to Enable App-to-App Navigation

You can enable an application to consume the APIs of another application. For more information, see: [Configure Integration Between Applications](#) and [Consume APIs from Other Applications](#)

To enable the technical communication between the applications, the application router must exchange the Identity Authentication token that was used for the user authentication at login to the application with the Identity Authentication token used for the other application. The exchanged token is then forwarded by the application router to the backend applications.

For this, you must configure either a new destination with an `HTML5.IASDependencyName` property that points to the backend application or a destination environment variable with the `IASDependencyName` property (see [Environment Variables \[page 429\]](#)). When the application router has to send a request to the backend destination, the application router uses the `IASDependencyName` property to trigger the exchange of the token and the exchanged token is then forwarded to the backend application in the `Authorization` header.

[Consuming the Destination Service](#)

[Consuming the Connectivity Service](#)

### 4.1.4.2.2.7 User API Service

The application router exposes a user API that returns the details of the users who are logged in to the application.

You implement the user API by modelling an `xs-app.json` route [\[page 392\]](#).

The user API supports two endpoints:

- `/currentUser` returns all details of logged in users.
- `/attributes` returns the main user properties.

The `/currentUser` endpoint response has the following format:

## Sample Code

```
...
{
  "firstname": "John",
  "lastname": "Doe",
  "email": "john.doe@sap.com",
  "name": "john.doe@sap.com",
  "displayName": "John Doe (john.doe@sap.com)" (The user ID in the identity provider),
  "scopes": ["openid", "user_attributes", "uaa.user"] (Only if the authentication type is "xsuaa")
}
...
```

The `/attributes` endpoint response has the following format:

## Sample Code

```
...
{
  "firstname": "John",
  "lastname": "Doe",
  "email": "john.doe@sap.com",
  "name": "john.doe@sap.com" (The user ID in the identity provider),
  "scopes": ["openid", "user_attributes", "uaa.user"] (Only if the the authentication type is "xsuaa"),
  < user attributes including custom attributes > (Only if the the authentication type is "xsuaa")
}
...
```

## Note

The "name" property is the user ID in the identity provider, which in many cases is also the email address.

## Note

If you specify "xsuaa" as the authentication type for the route, the following applies:

- User scopes from the xsuaa access token are added to the response of both endpoints (`/currentUser` and `/attributes`).
- User attributes from the identity provider (IdP) chosen for the authentication are added to the response of the `/attributes` endpoint. If a custom IdP is configured for SAP Cloud Identity Services – Identity Authentication, the custom user attributes are also added to the response of the `/attributes` endpoint. For more information about the definition of user attributes in Identity Authentication, see [User Attributes](#).
- To get the user attributes from the custom IdP, add the following property to `xs-security.json` file of the application router: `"foreign-scope-references": ["user_attributes"]`

## Configuring the User API Service in the Routing Configuration File

You implement the user API by modelling an `xs-app.json` route [page 392] using the `sap-approuter-userapi` service.

The following example handles both endpoints:

### Sample Code

```
{
  "source": "^/user-api(.*)",
  "target": "$1",
  "service": "sap-approuter-userapi"
}
```

The following example uses only the `/currentUser` endpoint:

### Sample Code

```
{
  "source": "^/user-api/currentUser$",
  "target": "/currentUser",
  "service": "sap-approuter-userapi"
}
```

## Related Information

[routes \[page 392\]](#)

### 4.1.4.2.2.8 Integration with HTML5 Application Repository

The application router is integrated with the HTML5 Application Repository service, to retrieve all the static content and routes (`xs-app.json`) of the HTML5 applications stored in the repository.

To integrate HTML5 Application Repository with an application router, create an instance of the `html5-apps-repo` service of the `app-runtime` plan, and bind it to the application router.

Model the `xs-app.json` routes that are used to retrieve static content from HTML5 Application Repository in the following way:

### Sample Code

```
{
  "source": "^(/.*)",
  "target": "$1",
  "service": "html5-apps-repo-rt",
  "authenticationType": "xsuaa"
}
```

In case the application router needs to serve HTML5 applications not stored in HTML5 Application Repository, it is possible to model that in the `xs-app.json` file of the application router.

When the application router is bound to HTML5 Application Repository, the following restrictions apply:

- It is not possible to implement the "first" middleware slot to provide routes dynamically.
- Only the `workingDir` option can be provided in the start of the application router.
- A mixed scenario of modeling part of the static content in a local resources folder and also retrieving static content from HTML5 Application Repository is not supported.

## Related Information

### 4.1.4.2.2.8.1 Processing a Request at Runtime

At runtime, the application router tries to fetch the `xs-app.json` file from the HTML5 application in the HTML5 Application Repository, and to use it for routing the request.

A valid request to an application router that uses the HTML5 Application Repository must have the following format:

#### Sample Code

```
https://<tenantId>.<appRouterHost>.<domain>/<bsPrefix>.<appName-appVersion>/<resourcePath>
```

For example:

#### Sample Code

```
https://tenant1.myapprouter.cf.sap.hana.com/comsapappcountry.countrylist/index.html
```

Placeholder	Mandatory	Description
<code>bsPrefix</code>	No	Used when the application is provided by a business service bound to this approuter.
<code>appName</code>	Yes	Used to uniquely identify the application in HTML5 Application Repository.

#### Note

Must not contain dots or special characters.

Placeholder	Mandatory	Description
appVersion	No	Used to uniquely identify a specific application version in HTML5 Application Repository. If no version is provided, the default application version will be used.
resourcePath	Yes	The path to the file as it was stored in HTML5 Application Repository.

When processing a request at runtime, the following algorithm is applied:

- If no HTML5 application is found in HTML5 Application Repository for the current request, the central application router `xs-app.json` will be used for routing.
- If the HTML5 application exists in HTML5 Application Repository but no `xs-app.json` file is returned, an error message will be issued and the request processing will be stopped.

## 4.1.4.2.2.8.2 Multitenancy of HTML5 Application Repository

The HTML5 Application Repository is a multitenant service. Non-public HTML5 Applications are visible only to the application providers (with provider subaccounts) and the consumers subscribed to the applications (with consumer subaccounts).

When a multitenant application router is subscribed to a subaccount, the HTML5 Application Repository app-runtime instance that is bound to the application router is returned as a dependency, which triggers the subscription to the app-runtime instance. You can also bind HTML5 Application Repository app-host service instances to the application router to enable the subscription of the corresponding HTML5 applications. During runtime, the application router creates an HTML5 Application Repository app-runtime `client_credentials` token using the tenant URL that the application router determines from the `<TENANT_HOST_PATTERN>` environment variable.

### Note

The creation of the token can fail if the app-runtime instance is not subscribed to the subaccount, which happens if, for example, the application router was subscribed to the subaccount before the HTML5 Application Repository became a multitenant service. In this case the application router will create the token using the provider subaccount.

You can trigger the subscription to the HTML5 Application Repository app-runtime instance by using the SAAS Provisioning API: <https://api.sap.com/api/APISaasManagerService/resource>.

```
PATCH /saas-manager/v1/application/tenants/{tenantId}/subscriptions
```

### Note

If you have an old application router version, the HTML5 Application Repository app-runtime `client_credentials` token is created by using HTML5 application provider subaccount.

## Related Information

[Developing Multitenant Applications in the Cloud Foundry Environment \[page 327\]](#)

### 4.1.4.2.2.9 Integration with Business Services

Application router supports integration with Business Services, which are a flavor of reuse-services.

An SAP Business Service exposes in its binding information in a set of attributes in the VCAP\_SERVICES credentials block that enable application router to serve Business Service UI and/or data.

To access business services, the following applies:

- The Business Service UI must be stored in HTML5 Application Repository to be accessible from an application router.
- The Business Service UI must be defined as "public" to be accessible from an application router in a different space than the one from which the UI was uploaded.
- The Business Service data can be served using two grant types:

Grant Type	Description
<code>user_token</code>	The application router performs a token exchange between the login JWT token and the Business Service token, and uses it to trigger a request to the Business Service endpoint.
<code>client_credentials</code>	The application router generates a <code>client_credentials</code> token and uses it to trigger a request to the Business Service endpoint.

To bind a Business Service instance to the application router, provide the following information in the VCAP\_SERVICES credentials:

Information	Mandatory	Description
<code>sap.cloud.service</code>	Yes	Service name as referenced from <code>xs-app.json</code> route and business service prefix, if provided by the Business Service UI.
<code>sap.cloud.service.alias</code>	No	Short service name alias for user friendly URL business service prefix. Make sure the alias is unique in the context of the application router.
<code>endpoints</code>	No	One or more endpoints that can be used to access Business Service data.
<code>html5-apps-repo</code>	No	The <code>html5-apps-repo.app_host_id</code> contains one or more <code>html5-apps-repo</code> service instance GUIDs that can be used to retrieve Business Service UIs.
<code>saasregistryenabled</code>	No	Indicates that this Business Service supports SaaS Registry subscription. If provided, the application router returns this Business Service <code>xsappname</code> in the SaaS Registry <code>getDependencies</code> callback.

Information	Mandatory	Description
<code>grant_type</code>	No	The grant type that should be used to trigger requests to the Business Service. Allowed values: <code>user_token</code> (default) or <code>client_credentials</code> .
<code>forwardiaastoken</code>	No	This flag that indicates if, in addition to the exchanged JWT token created by the SAP Authorization and Trust Management Service (xsuaa), the OIDC access token created by Identity Authentication should be forwarded as well. The Identity Authentication token is forwarded in the request header <code>x-ias-token</code> .
<code>forwardiasauthentication</code>	No	This flag indicates that if the login was performed using Identity Authentication, the application router will not exchange the JWT token created by the SAP Authorization and Trust Management Service (XSUAA). Instead, the OIDC access token created by Identity Authentication will be forwarded in the authorization header.
<code>URL.headers.&lt;header-name&gt;:header-value</code>	No	If you provide this information, the application router propagates this attribute as the header to the business service backend. Existing request headers will not be overwritten.

The value of the `endpoints` is an object containing the following properties:

Property	Type	Optional	Default	Description
<code>url</code>	String			URL to access the Business Service data.
<code>timeout</code>	Number	X	30000ms	Positive integer representing the maximum wait time for a response (in milliseconds) from the Business Service.

The following example shows how to provide the required information. This information should be provided via the `onBind` hook in the service-broker implementation:

#### Sample Code

```
"country": [
  {
    ...
    "credentials": {
      "sap.cloud.service": "com.sap.appbasic.country",
      "sap.cloud.service.alias": "country",
      "endpoints": {
        "countryservice": { "url": "https://icf-countriesapp-test-
service.cfapps.sap.hana.ondemand.com/odata/v2/countryservice" },
        "countryconfig": {
          "url": "https://icf-countriesapp-test-
service.cfapps.sap.hana.ondemand.com/rest/v1/countryconfig",
          "timeout": 120000
        }
      }
    }
  }
]
```

```

    },
    "html5-apps-repo": {
      "app_host_id": "1bd7c044-6cf4-4c5a-b904-2d3f44cd5569,
1cd7c044-6cf4-4c5a-b904-2d3f44cd54445"
    },
    "saasregistryenabled": true,
    "grant_type": "user_token"
    ....

```

## Related Information

[Accessing Business Service Data \[page 427\]](#)

[Accessing Business Service UI \[page 428\]](#)

[services \[page 409\]](#)

### 4.1.4.2.2.9.1 Accessing Business Service Data

This section describes how the application router accesses the Business Service data.

To access Business Service data, the `xs-app.json` file should have a route referencing a specific `sap.cloud.service` or `sap.cloud.service.alias` via the `service` attribute. If an `endpoint` attribute is also modeled, it will be used to get the service URL; otherwise the fallback URL or URI attribute will be used.

#### Sample Code

```

"routes": [
  {
    "source": "^/odata/v2/(.*)$",
    "target": "$1",
    "service": "com.sap.appbasic.country",
    "endpoint": "countryservice"
  },

```

In order to support JWT token exchange, the login JWT token should contain the `uaa.user` scope. This requires that the `xs-security` configuration file contain a role template that references the `uaa.user` scope.

#### Sample Code

```

{
  "xsappname" : "simple-approuter",
  "tenant-mode" : "shared",
  "scopes": [
    {
      "name": "uaa.user",
      "description": "UAA"
    },
    {
      "name": "$XSAPPNAME.simple-approuter.admin",
      "description": "Simple approuter administrator"
    }
  ],
  "role-templates": [

```

```

    {
      "name": "Token_Exchange",
      "description": "UAA",
      "scope-references": [
        "uaa.user"
      ]
    },
    {
      "name": "simple-approuter-admin",
      "description": "Simple approuter administrator",
      "scope-references": [
        "$XSAPPNAME.simple-approuter.admin"
      ]
    }
  ]
}

```

## Related Information

[Integration with Business Services \[page 425\]](#)

[Accessing Business Service UI \[page 428\]](#)

### 4.1.4.2.2.9.2 Accessing Business Service UI

This section provides information about accessing Business Services UIs that are stored in HTML5 Application Repository.

Business Service UI's must be stored in HTML5 Application Repository and defined in their `manifest.json` files as `public: true` in order to be accessible from an application router application that is typically running in a different space than the Business Service space. In addition, `dataSource` URIs must be relative to the base URL, which means there is no need for a slash as the first character.

The following is an example `manifest.json` file of a Business Service:

#### Sample Code

```

{
  "sap.app": {
    "id": "com.sap.appbasic.country.list",
    "applicationVersion": {
      "version": "1.0.0"
    }
  },
  "dataSources": {
    "mainService": {
      "uri": "odata/v2/countryservice",
      "type": "OData"
    }
  },
  "sap.cloud": {
    "public": true,
    "service": "com.sap.appbasic.country"
  }
}

```

A Business Service that exposes UI, must provide one or more `app-host` GUIDs in an `html5-apps-repo` block in `VCAP_SERVICES` credentials.

To access the Business Service UI, the URL request to the application router must contain a business service prefix, as in the following example of a request URL:

#### Sample Code

```
https://tenant1.approuter-repo-examples.cfapps.sap.hana.ondemand.com/  
comsapappbasiccountry.comsapappbasiccountrylist/test/flpSandbox.html
```

In this example, `comsapappbasiccountry` is the business service prefix which matches the `sap.cloud.service` attribute in the country service `VCAP_SERVICES` credentials (without dots). The `comsapappbasiccountrylist` is the name of the HTML5 application as defined in the `app.id` attribute in the `manifest.json` file (without dots).

### 4.1.4.2.2.10 Environment Variables

A list of environment variables that can be used to configure the application router.

The following table lists the environment variables that you can use to configure the application router. The table also provides a short description of each variable and, where appropriate, an example of the configuration data.

Application Router Configuration Variables

Variable	Description
<code>httpHeaders</code>	Configures the application router to return additional HTTP headers in its responses to client requests
<code>destinations</code>	Provides information about the available application (microservice) destinations.

Variable	Description
<a href="#">cookies [page 434]</a>	<p>The application router generates the following third-party cookies and sends them to the client:</p> <ul style="list-style-type: none"> <li>• <code>locationafterLogin</code></li> <li>• <code>fragmentAfterLogin</code></li> <li>• <code>signature</code></li> <li>• <code>JSESSION ID</code></li> </ul> <p>To control the behavior and usage of the third-party cookies, you can configure the attributes <code>SameSite</code> and <code>Partitioned</code>.</p> <p>For more information about third-party cookies, please see the KBA <a href="#">3409306</a>.</p>
<a href="#">SESSION_TIMEOUT</a>	Sets the time to trigger an automatic central log out from the User Account and Authentication (UAA) server.
<a href="#">SEND_XFRAMEOPTIONS</a>	Sets or changes the <code>X-Frame-Options</code> header
<a href="#">CJ_PROTECT_WHITELIST</a>	A list of allowed server or domain origins to use when checking for click-jacking attacks.
<a href="#">WS_ALLOWED_ORIGINS</a>	A list of the allowed server (or domain) origins that the application router uses to verify requests.
<a href="#">JWT_REFRESH</a>	Configures the automatic refresh of the JSON Web Token (JWT) provided by the User Account and Authentication (UAA) service to prevent expiry (default is 5 minutes).
<a href="#">UAA_SERVICE_NAME</a>	Specifies the <b>exact</b> name of the UAA service to bind to an application.
<a href="#">INCOMING_CONNECTION_TIMEOUT</a>	Specifies the maximum time (in milliseconds) for a client connection. If the specified time is exceeded, the connection is closed.
<a href="#">TENANT_HOST_PATTERN</a>	Defines a regular expression to use when resolving tenant host names in the request's host name.
<a href="#">COMPRESSION</a>	Configures the compression of resources before a response to the client.
<a href="#">SECURE_SESSION_COOKIE</a>	Configures the enforcement of the <code>Secure</code> flag of the application router's session cookie.
<a href="#">REQUEST_TRACE</a>	Enables additional traces of the incoming and outgoing requests.
<a href="#">EXTERNAL_REVERSE_PROXY</a>	Indicates the use of the application router behind an external reverse proxy outside of the Cloud Foundry domain. For more information, see <b>Customer Header</b> under <a href="#">Headers [page 415]</a> .
<a href="#">CORS</a>	Provides support for cross-origin requests, for example, by allowing the modification of the request header.

Variable	Description
<a href="#">DIRECT_ROUTING_URI_PATTERNS</a>	Defines a list of URIs that are directed to the routing configuration file (xs-app.json file) of the application router instead of to a specific application's xs-app.json file that is stored in the HTML5 Application Repository. This configuration improves the application loading time and monitoring options.
EXT_SESSION_MGT	You can configure external session management. See <a href="#">External Session Management [page 444]</a> .
CF_NODEJS_LOGGING_LEVEL	Sets the minimal logging level of the <code>cf-nodejs-logging-support</code> library of the application router.
STATE_PARAMETER_SECRET	Enables the use of state parameters to prevent CRFS attacks.  If this environment variable is set, the application router creates a state parameter for each initial authorization request. By validating that the authentication server returns the same state parameter in its response, the application server can verify that the response did not originate from a third party.
HTTP2_SUPPORT	Enables the application router to start as an HTTP/2 server.  <div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>Note</b></p> <p>To configure HTTP/2 support, you must use Cloud Foundry routes with an HTTP/2 destination protocol. See <a href="#">Configuring HTTP/2 Support</a> in the Cloud Foundry Documentation.</p> <p>As connection-specific header fields aren't supported by the HTTP/2 protocol (see <a href="https://datatracker.ietf.org/doc/html/rfc9113">https://datatracker.ietf.org/doc/html/rfc9113</a>), the application router removes such headers automatically when they are returned from a backend to prevent a failure of the HTTP/2 response.</p> </div>
FULL_CERTIFICATE_CHAIN	Enables the application router to send the entire chain of certificates provided in the binding of the authentication service (XSUAA or Identity Authentication) to the backend applications. The certificates are required for mutual TLS authentication (mTLS handshake). See <a href="#">Mutual TLS Authentication (mTLS) and Certificates Handling [page 443]</a> .

## httpHeaders

If configured, the application router sends additional HTTP headers in its responses to a client request. You can set the additional HTTP headers in the `<httpHeaders>` environment variable. The following example configuration shows how to configure the application router to send two additional headers in the responses to the client requests from the application `<myApp>`:

```
cf set-env <myApp> httpHeaders "[ { \"X-Frame-Options\": \"ALLOW-FROM http://acme.com\" }, { \"Test-Additional-Header\": \"1\" } ]"
```

or

```
cf set-env <myApp> httpHeaders ' [{ "X-Frame-Options": "ALLOW-FROM http://
acme.com" }, { "Test-Additional-Header": "1" } ]'
```

→ Tip

To ensure better security of your application set the `Content-Security-Policy` header. This is a response header which informs browsers (capable of interpreting it) about the trusted sources from which an application expects to load resources. This mechanism allows the client to detect and block malicious scripts injected into the application. A value can be set via the `<httpHeaders>` environment variable in the additional headers configuration. The value represents a security policy which contains directive-value pairs. The value of a directive is an allowlist of trusted sources.

Usage of the `Content-Security-Policy` header is considered second line of defense. An application should always provide proper input validation and output encoding.

## destinations

The destinations configuration is an array of objects that is defined in the `destinations` environment variable. A destination is required for every application (microservice) that is part of the business application. The following table lists the properties that can be used to describe the destination:

Destination Environment Variable Properties

Property	Type	Mandatory	Description
<code>name</code>	String	Yes	A unique identifier for the destination
<code>url</code>	String	Yes	The Unique Resource Locator for the application (microservice)
<code>proxyHost</code>	String	No	The host of the proxy server used in case the request should go through a proxy to reach the destination.
			<p>→ Tip</p> <p>Mandatory if <code>proxyPort</code> is defined.</p>
<code>proxyPort</code>	String	No	The port of the proxy server used in case the request should go through a proxy to reach the destination.
			<p>→ Tip</p> <p>Mandatory if <code>proxyHost</code> is defined.</p>

Property	Type	Mandatory	Description
<code>forwardAuthToken</code>	Boolean	No	<p>If true, the OAuth token will be sent to the destination. The default value is "false". This token contains the user identity, scopes, and some other attributes. The token is signed by the User Account and Authorization (UAA) service so that the token can be used for user-authentication and authorization purposed by back-end services.</p>
<code>strictSSL</code>	Boolean	No	<p>Configures whether the application router should reject untrusted certificates. The default value is "true".</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>For testing purposes only. Do <b>not</b> use this property in production environments!</p> </div>
<code>timeout</code>	Number	No	<p>A positive integer representing the maximum amount of time to wait for a response (in milliseconds) from the specified destination. The default is 30000ms.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>→ Tip</b></p> <p>The timeout specified here also applies to the logout path, <code>logoutPath</code>, if the logout path is defined, for example, in the application's descriptor file <code>xs-app.json</code>.</p> </div>
<code>proxyType</code>	String	No	<p>Indicates if the destination is used to access applications in private networks (for example, on-premise) or publicly available on the Internet. Possible value: <code>onPremise</code>. If <code>proxyType</code> is not specified, the default (Internet access) is assumed.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>→ Tip</b></p> <p>In Cloud environments, if you set the application's destination <code>proxyType</code> to <code>onPremise</code>, a binding to the SAP BTP connectivity service is required, and the <code>forwardAuthToken</code> property must not be set.</p> </div>

Property	Type	Mandatory	Description
IASDependencyName	String	No	Configures the name of the Identity Authentication dependency that is used to exchange the Identity Authentication token used for the user authentication at login. If configured, the exchanged token is then also forwarded to the backend applications.
forwardAuthCertificates	Boolean	No	If <code>true</code> , the certificates and key of the authentication service are added to the HTTP connection to the destination. The default value is <code>false</code> . For more information see: <a href="#">Mutual TLS Authentication (mTLS) and Certificates Handling [page 443]</a>

If `true`, the certificates and key of the authentication service are added to the HTTP connection to the destination. The default value is `false`. For more information see: [Mutual TLS Authentication \(mTLS\) and Certificates Handling \[page 443\]](#)

The following example shows a simple configuration for the `<destinations>` environment variable:

#### Sample Code

```
[
  {
    "name" : "ui5",
    "url" : "https://sapui5.acme.com",
    "proxyHost" : "proxy",
    "proxyPort" : "8080",
    "forwardAuthToken" : false,
    "timeout" : 1200
  }
]
```

It is also possible to include the destinations in the `manifest.yml` file, as illustrated in the following example:

#### Sample Code

```
- name: node-hello-world
  memory: 100M
  path: web
  env: destinations: >
    [
      { "name": "ui5", "url": "https://sapui5.acme.com" }
    ]
```

## Additional Cookie Attributes

If configured, the application router sends additional cookie attributes in its responses to the client. Additional cookies attributes can be set in the `<COOKIES>` environment variable.

Example of configuration for cookies in the `manifest.yml`:

### Sample Code

```
env:
  COOKIES: >
    {
      "SameSite": "None",
      "Partitioned":
        {
          "supportedPartitionAgents": "^Mozilla.*(Chrome|Chromium|)/"
          ((109)|([1-9][0-9])|([2-9][0-9][0-9]))",
          "unsupportedPartitionAgents": "PostmanRuntime/7.29.2"
        }
    }
```

In this example, the application router sets the `SameSite` attribute of the cookie to `None` and specifies a `Partitioned` attribute that is sent in the responses to the client.

### Note

Currently, only the values `None` and `Lax` are supported for the `SameSite` attribute. The value `Strict` is not supported.

The `Partitioned` attribute contains two required regular expressions:

- `supportedPartitionAgents` for supported agents
- `unsupportedPartitionAgents` for unsupported agents

You can use a wildcard `'(*)'` in `supportedPartitionAgents` to allow all agents to use the `Partitioned` attribute.

### Note

`unsupportedPartitionAgents` overwrites the configurations in `supportedPartitionAgents`. If an agent is allowed in `supportedPartitionAgents` but disallowed in `unsupportedPartitionAgents`, the `Partitioned` attribute will not be returned.

## SESSION\_TIMEOUT

You can configure the triggering of an automatic central log-out from the User Account and Authentication (UAA) service if an application session is inactive for a specified time. A session is considered to be inactive if no requests are sent to the application router. The following command shows how to set the environment variable `<SESSION_TIMEOUT>` to 40 (forty) minutes for the application `<myApp1>`:

```
cf set-env <myApp1> SESSION_TIMEOUT 40
```

### Note

You can also set the session timeout value in the application's `manifest.yml` file, as illustrated in the following example:

### Sample Code

```
- name: myApp1
  memory: 100M
  path: web
  env:
    SESSION_TIMEOUT: 40
```

### → Tip

If the authentication type for a route is set to "xsuaa" (for example, "authenticationType": "xsuaa"), the application router depends on the UAA server for user authentication, and the UAA server might have its own session timeout defined. To avoid problems caused by unexpected timeouts, it is recommended that the session timeout values configured for the application router and the UAA are identical."

## SEND\_XFRAMEOPTIONS

By default, the application router sends the `X-Frame-Options` header with the value "SAMEORIGIN". You can change this behavior either by disabling the sending of the default header value (for example, by setting `SEND_XFRAMEOPTIONS` environment variable to false) or by overriding the value, for example, by configuring additional headers (with the `<httpHeaders>` environment variable).

The following example shows how to disable the sending of the `X-Frame-Options` for a specific application, `myApp1`:

```
cf set-env <myApp1> SEND_XFRAMEOPTIONS false
```

## CJ\_PROTECT\_WHITELIST

The `<CJ_PROTECT_WHITELIST>` specifies a list of origins (for example, host or domain names) that do not need to be protected against click-jacking attacks. This list of allowed host names and domains are used by the application router's allowlist service to protect XS advanced applications against click-jacking attacks. When an HTML page needs to be rendered in a frame, a check is done by calling the allowlist service to validate if the parent frame is allowed to render the requested content in a frame. The check itself is provided by the allowlist service

The following example shows how to add a host name to the click-jacking protection allowlist for the application, `myApp1`:

```
cf set-env <myApp1> CJ_PROTECT_WHITELIST {<protocol>, <hostname>, <portNr>}
```

The content is a JSON list of objects with the properties listed in the following table:

Allowlist of Host and Domain Names

Property	Type	Mandatory	Description
protocol	String	No	URI scheme, for example "HTTP".
host	String	Yes	A valid host name, for example, <code>acme.com.hostname</code> , or a domain name defined with an asterisk (*) <code>*.acme.com</code> .
port	String/Number	No	Port string or number containing a valid port.

#### Note

Matching is done against the properties provided. For example, if only the host name is provided, the allowlist service matches all schemata and protocols.

```
xs set-env <myApp1> CJ_PROTECT_WHITELIST {<*.acme.com>}
```

## WS\_ALLOWED\_ORIGINS

When the application router receives an upgrade request, it verifies that the `origin` header includes the URL of the application router. If this is not the case, then an HTTP response with status 403 is returned to the client. This origin verification can be further configured with the environment variable `<WS_ALLOWED_ORIGINS>`, which defines a list of the allowed origins the application router uses in the verification process.

#### Note

The structure of the `<WS_ALLOWED_ORIGINS>` variable is the same as the variable `<CJ_PROTECT_WHITELIST>`.

```
cf set-env <myApp1> WS_ALLOWED_ORIGINS {<*.acme.com>}
```

## JWT\_REFRESH

The `JWT_REFRESH` environment variable is used to configure the application router to refresh a JSON Web Token (JWT) for an application, by default, 5 minutes before the JWT expires, if the session is active.

```
cf set-env <myApp1> JWT_REFRESH 1
```

If the JWT is close to expiration and the session is still active, a JWT refresh will be triggered `<JWT_REFRESH>` minutes before expiration. The default value is 5 minutes. To disable the automatic refresh, set the value of `<JWT_REFRESH>` to 0 (zero).

## UAA\_SERVICE\_NAME

The `UAA_SERVICE_NAME` environment variable enables you to configure an instance of the User Account and Authorization service for a specific application, as illustrated in the following example:

```
cf set-env <myApp1> UAA_SERVICE_NAME <myUAAServiceName>
```

### Note

The details of the service configuration are defined in the `<VCAP_SERVICES>` environment variable, which is not configured by the user.

## INCOMING\_CONNECTION\_TIMEOUT

The `INCOMING_CONNECTION_TIMEOUT` environment variable enables you to set the maximum time (in milliseconds) allowed for a client connection, as illustrated in the following example:

```
cf set-env <myApp1> INCOMING_CONNECTION_TIMEOUT 60000
```

If the specified time is exceeded, the connection is closed. If `INCOMING_CONNECTION_TIMEOUT` is set to zero (0), the connection-timeout feature is disabled. The default value for `INCOMING_CONNECTION_TIMEOUT` is 120000 ms (2 min).

## TENANT\_HOST\_PATTERN

The `TENANT_HOST_PATTERN` environment variable enables you to specify a string containing a regular expression with a capturing group. The requested host is matched against this regular expression. The value of the first capturing group is used as the tenant id, as illustrated in the following example:

```
cf set-env <myApp1> TENANT_HOST_PATTERN
```

## COMPRESSION

The `COMPRESSION` environment variable enables you to configure the compression of resources before a response to the client, as illustrated in the following example:

```
cf set-env <myApp1> COMPRESSION
```

Here is a complete example of the compression environment variable:

### Sample Code

```
env:  
  COMPRESSION: >  
    {  
      "enabled": true,
```

```
"minSize": 2048,  
"compressResponseMixedTypeContent": true  
}
```

## SECURE\_SESSION\_COOKIE

The `SECURE_SESSION_COOKIE` can be set to `true` or `false`. By default, the `secure` flag of the session cookie is set depending on the environment the application router runs in. For example, when the application router is running behind a router that is configured to serve HTTPS traffic, then this flag will be present. During local development the flag is not set.

### Note

If the `secure` flag is enforced, the application router will reject requests sent over unencrypted connections.

The following example illustrates how to set the `SECURE_SESSION_COOKIE` environment variable:

```
cf set-env <myApp1> SECURE_SESSION_COOKIE true
```

## REQUEST\_TRACE

You can enable additional traces of the incoming and outgoing requests by setting the environment variable `<REQUEST_TRACE>` to `true`. If enabled, basic information is logged for every incoming and outgoing request to the application router.

The following example illustrates how to set the `REQUEST_TRACE` environment variable:

```
cf set-env <myApp1> REQUEST_TRACE true
```

### → Tip

This is in addition to the information generated by the Node.js package `@sap/logging` that is used by the XS advanced application router.

## CORS

The `CORS` environment variable enables you to provide support for cross-origin requests, for example, by allowing the modification of the request header. Cross-origin resource sharing (CORS) permits Web pages from other domains to make HTTP requests to your application domain, where normally such requests would automatically be refused by the Web browser's security policy.

Cross-origin resource sharing (CORS) is a mechanism that allows restricted resources on a Web page to be requested from another domain (protocol and port) outside the domain (protocol and port) from which the first resource was served. The CORS configuration enables you to define details to control access to your

application resource from other Web browsers. For example, you can specify where requests can originate from or what is allowed in the request and response headers. The following example illustrates a basic CORS configuration:

```
[
  {
    "uriPattern": "^\\route1$",
    "allowedMethods": [
      "GET"
    ],
    "allowedOrigin": [
      {
        "host": "host.acme.com",
        "protocol": "https",
        "port": 345
      }
    ],
    "maxAge": 3600,
    "allowedHeaders": [
      "Authorization",
      "Content-Type"
    ],
    "exposeHeaders": [
      "customHeader1",
      "customHeader2"
    ],
    "allowedCredentials": true
  }
]
```

The CORS configuration includes an array of objects with the following properties, some of which are mandatory:

Available Settings for CORS Options

CORS Property	Type	Mandatory	Description
uriPattern	String	Yes	A regular expression (RegExp) representing the source routes to which the CORS configuration applies. To ensure that the RegExp matches the complete path, surround it with ^ and \$, for example, "uriPattern": "^\\route1\$". Defaults: none
allowedOrigin	Array	Yes	A comma-separated list of objects each of which contains a host name, port and protocol that are allowed by the server, for example: [ { "host": "www.acme.com" } ] or [ { "host": ".acme.com" } ].

#### Note

Matching is case-sensitive. In addition, if no port or protocol is specified, the default is "\*" .

The default configuration is: [ { "host": "\*" } ], which means that the server allows **any** origin to access the resource.

CORS Property	Type	Mandatory	Description
allowedMethods	Array	No	<p>A comma-separated list of HTTP methods that are allowed by the server, for example, "GET", "POST". If allowedMethods is defined but no method is specified, the default "GET", "POST", "HEAD", "OPTIONS" (all) applies.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p>→ Tip</p> <p>The specified methods must be upper-case, for example, GET. Matching of the method type is case-sensitive.</p> </div>
allowedHeaders	Array	No	<p>A comma-separated list of request headers that are allowed by the server. the default values are as follows: ["Origin", "Accept", "X-Requested-With", "Content-Type", "Access-Control-Request-Method", "Access-Control-Request-Headers"].</p>
maxAge	String	No	<p>A single value specifying the length of time (in seconds) a preflight request should be cached for. A negative value that prevents CORS filter from adding this response header to the pre-flight response. If maxAge is defined but no value is specified, the default time of "1800" seconds applies.</p>
exposeHeaders	Array	No	<p>A comma-separated list of <b>response</b> headers that are allowed to be exposed. If exposeHeaders is defined but no response header is specified for exposure, no default value is supplied.</p>
allowedCredentials	Boolean	No	<p>A Boolean flag that indicates whether the specified resource supports user credentials. The default setting is "true".</p>

It is also possible to include the CORS configuration in either the `manifest.yml` or the `manifest-op.yml` file. The code in the following example enables the CORS configuration for any route with a source URI pattern that matches the RegExp `“^\\route1$”`:

### Sample Code

CORS Configuration in the `manifest.yml` File

```

- name: node-hello-world
  memory: 100M
  path: web
  env:
    CORS: >
      [
        {
          "allowedOrigin": [
            {
              "host": "my_host",
              "protocol": "https"
            }
          ]
        }
      ]

```

```
    ],  
    "uriPattern": "^/route1$"br/>  }  
}
```

## DIRECT\_ROUTING\_URI\_PATTERNS

With the direct routing URI patterns configuration, you can define a list of URIs that are directed to the routing configuration file (xs-app.json file) of the application router instead of to a specific application's xs-app.json file that is stored in the HTML5 Application Repository. This configuration improves the application loading time and monitoring options because it prevents unnecessary calls to the HTML5 Application Repository.

The configuration is an array of strings or regular expressions. You have to provide only the first segment in the URL, after the approuter host. For example, for the URL `https://<approuter-host>/route1/index.html`, you enter `route1` in the direct routing URI patterns array.

### Sample Code

```
env:  
  DIRECT_ROUTING_URI_PATTERNS: >  
    ["route1", "^route2$", "route3"]
```

## CF\_NODEJS\_LOGGING\_LEVEL

With the `CF_NODEJS_LOGGING_LEVEL` variable, you can set the minimal logging level of the `cf-nodejs-logging-support` library of the application router. The following levels are available:

- `off`
- `error`
- `warn`
- `info`
- `verbose`
- `debug`
- `silly`

The default value is `error`.

Here is a sample content for the `CF_NODEJS_LOGGING_LEVEL` environment variable:

### Sample Code

```
env:  
  CF_NODEJS_LOGGING_LEVEL: "debug"
```

## Note

The application router also uses the `@sap/logging` library. To configure the log level for this library, you use the `XS_APP_LOG_LEVEL` environment variable.

## Related Information

[Application Router \[page 377\]](#)

[Routing Configuration File \[page 387\]](#)

### 4.1.4.2.2.10.1 Performance Statistics

The application router provides performance statistics in an HTTP response header if the HTTP request contains an HTTP query parameter (URL parameter) `sap-statistics=true` or if the HTTP request contains an HTTP header field `sap-statistics:true`.

If an HTTP request that contains a header field or query parameter with `sap-statistics=true` reaches the application router, the application router forwards an `sap-statistics` header to the corresponding backend. If SAP statistics is implemented for the backend, the backend returns to the application router a response header containing the statistics information from the backend.

The application router returns the following statistics information in an `sap-statistics` response header:

- `total`: The time that has passed between the moment when the request entered into the application router and the moment when the application router started writing the response
- `ext` (in case of destination forwarding): The time spent in the backend

Each backend sub-component can add its own response header with duration measurements when it receives the HTTP header `sap-statistics:true`.

### 4.1.4.2.2.10.2 Mutual TLS Authentication (mTLS) and Certificates Handling

Mutual TLS (mTLS) is a mutual authentication mechanism. The application router supports the use of certificates for the creation of tokens and an mTLS handshake in backend connections.

To enable the mTLS authentication for backend connections, the following prerequisites must be met:

- The authentication service instance that is bound to the application router, Authorization and Trust Management service (XSUAA) or Identity Authentication (IAS), must provide a certificate chain and a private key in its credentials.  
If the private key isn't provided in the credentials, you can also configure the environment variables `XSUAA_PRIVATE_KEY` (Authorization and Trust Management) and `IAS_PRIVATE_KEY` (Identity Authentication) in the application router to provide the private key.

- The destinations for the backend applications must contain either the `HTML5.ForwardAuthCertificates` property in the configuration provided by the destination service (see [Application Routes and Destinations \[page 416\]](#)) or the `forwardAuthCertificates` property in the destinations environment variable (see [Environment Variables \[page 429\]](#)).
- In Cloud Foundry, the client certificate is propagated using the `x-forwarded-client-cert` header. To enable this, the backend URL must contain a `.cert` segment in its domain.

The application router gets the XSUAA or IAS tokens that provide the certificates chain and private key. The application router uses the certificates chain and private key from the credentials of the authentication service instance for the following:

- The application router creates the HTTP connection to backend using the private key and a chain of intermediate and client certificates to enable the mTLS handshake. If the `FULL_CERTIFICATE_CHAIN` environment variable is enabled, the application router sends the entire chain of certificates provided in the binding of the authentication service (XSUAA or IAS) to the backend applications. If this environment variable is not enabled, the application router sends only the root and intermediate certificates from the chain.
- When forwarding a request to business services, the application router uses these certificates also to create a `client_credentials` token or to exchange the login token.

#### 4.1.4.2.2.11 External Session Management

The application router supports the backup of user sessions in an external session store. This enables a session recovery if the application router instance that stores a session crashes and another application router instance needs to continue handling the running user session.

To enable this capability the you must bind a service instance of a service that supports a fast persistence store such as Redis. When such a service is bound, the application router backs up the in memory session information into the external persistency store. If, in subsequent requests, the session information is not found in the in memory session store, the application router tries to rebuild the in memory session store session information from external persistency store.

The sessions are stored encrypted and compressed. For capacity planning, you can assume 50 Kb per session storage in fast persistence store.

### Configuration of External Session Management

To use external session management, you have to the `EXT_SESSION_MGT` environment variable. The variable value is defined in JSON format, providing the following properties:

- `instanceName` (mandatory): the name of the service instance of the storage service
- `storageType` (mandatory): the type of the storage, for example - "redis".  
Note that if no custom storage driver is used, only `redis` is allowed.
- `sessionSecret` (mandatory): Since the application router stores encrypted sessions in a persistence store, a shared secret shall be provided. Please generate a unique string with at least 64 characters.

For example:

### Sample Code

```
{
  "instanceName": "approuter-redis",
  "storageType": "redis",
  "sessionSecret": "someuniquesessionsecret"
}
```

### Note

Currently, the application router supports only a Redis store.

## Configuration of a Custom Storage Driver

You can use your own driver. In order to do that, the user injects its own implementation of a store.

The class has to implement the following interface:

### Sample Code

```
interface UserCustomStore {
  // delete all sessions
  clear(): Promise<void>;
  // remove <sessionId> session
  destroy(sessionId : string): Promise<void>;
  // retrieve <sessionId> session
  get(sessionId : string): Promise<object | null>;
  // number of sessions
  length(): Promise<number>;
  // get <sessionId> expiration
  ttl(sessionId : string): Promise<number>;
  // set <sessionId> data to <session> with <timeout> expiration
  set(sessionId: string, session: object, timeout: number): Promise<void>;
  // check if session <sessionId> exists
  exists(sessionId: string): boolean;
  // update existing session <sessionId> expiration to <timeout>
  resetTimer(sessionId: string, timeout: number);
}
```

In addition, the file must include a method to get an instance of the store, for example:

### Sample Code

```
let store;
module.exports.getStore = () => {
  if (!store) {
    store = new UserCustomStore();
  }
  return store;
};
```

In order for application router to use it, user has to set the `externalStoreFilePath` property in the `EXT_SESSION_MGT` environment variable with the path to the storage. The application router uses this path to require your storage. For example:

## Sample Code

```
{
  "instanceName": "approuter-redis",
  "storageType": "redis",
  "sessionSecret": "someuniquesessionsecret",
  "externalStoreFilePath": "./src/storage/my-special-storage"
}
```

## Related Information

[Environment Variables \[page 429\]](#)

### 4.1.4.2.2.12 Multitenancy

Each multitenant application has to deploy its own application router, and the application router handles requests of all tenants to the application. The application router is able to determine the tenant identifier out of the URL and then forwards the authentication request to the tenant User Account and Authentication (UAA) service and the related identity zone.

To use a multitenant application router, you must have a shared UAA service and the version of the application router has to be greater than 2.3.1.

The application router must determine the tenant-specific subdomain for the UAA that in turn determines the identity zone, used for authentication. This determination is done by using a regular expression defined in the environment variable `TENANT_HOST_PATTERN`.

`TENANT_HOST_PATTERN` is a string containing a regular expression with a capturing group. The request host is matched against this regular expression. The value of the first capturing group is used as the tenant subdomain.

If you have multiple routes to the same application, for example:

```
tenant1.<application domain> and tenant2.<application domain>
```

The `TENANT_HOST_PATTERN` could be:

```
TENANT_HOST_PATTERN: "^(.*)<application domain>"
```

With this configuration, the application router extracts the tenant subdomain, which is used for authentication against a multitenant UAA.

## Register an Application (SaaS Registry Configuration)

Create a service instance of the SaaS Provisioning service with a configuration JSON file in the Cloud Foundry sub-account space where the multitenant business application is deployed.

The configuration JSON file must use the following format and set these properties:

```
{
  "xsappname" : "<xsappname>",
  "appUrls": {
    "getDependencies" : "<approuter-host>/<getDependenciesPath>/<tenantId>",
    "onSubscription" : "<approuter-host>/<onSubscriptionPath>/<tenantId>"
  },
  "displayName" : "<displayName>",
  "description" : "<description>",
  "category" : "<category>"
}
```

Specify the following parameters:

Parameters	Description
xsappname	The xsappname configured in the security descriptor file used to create the XSUAA instance (see <a href="#">Develop the Multitenant Application [page 330]</a> ).
getDependenciesPath	(Optional) Any URL that the application exposes for GET dependencies. If the application doesn't have dependencies and the callback isn't implemented, it mustn't be declared.
onSubscriptionPath	This parameter must end with / {tenantId}. The tenant for the subscription is passed to this callback as a path parameter. You must keep {tenantId} as a parameter in the URL so that it's replaced at runtime with the tenant calling the subscription. This callback URL is called when a subscription between a multitenant application and a consumer tenant is created (PUT) and when the subscription is removed (DELETE).
displayName	(Optional) The display name of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's technical name.
description	(Optional) The description of the application when viewed in the cockpit. For example, in the application's tile. If left empty, takes the application's display name.
category	(Optional) The category to which the application is grouped in the <a href="#">Subscriptions</a> page in the cockpit. If this parameter is left empty, it's assigned to the default category.

#### Note

For information about how to model the security settings for activating the `saas-registry` callbacks, see [Develop the Multitenant Application \[page 330\]](#).

## 4.1.4.2.2.13 Extending the Application Router

Configure application-specific extensions for the application router.

Instead of starting the application router directly, you can configure your XS advanced application to use its own start script. You can also use the application router as a regular Node.js package.

### Sample Code

```
var approuter = require('@sap/approuter');
var ar = approuter();
ar.start();
```

## Custom Middleware Injection

The application router uses the connect framework, for more information, see *Connect framework* in the *Related Links* below. You can reuse all injected “connect” middleware within the application router, for example, directly in the application start script:

### Sample Code

```
var approuter = require('@sap/approuter');
var ar = approuter();
ar.beforeRequestHandler.use('/my-ext', function myMiddleware(req, res, next) {
  res.end('Request handled by my extension!');
});
ar.start();
```

### → Tip

To facilitate troubleshooting, always provide a name for your custom middleware.

The `path` argument is optional. You can also chain `use` calls.

### Sample Code

```
var approuter = require('@sap/approuter');
var morgan = require('morgan');
var ar = approuter();
ar.beforeRequestHandler
  .use(morgan('combined'))
  .use('/my-ext', function myMiddleware(req, res, next) {
    res.end('Request handled by my extension!');
  });
ar.start();
```

The application router defines the following slots where you can insert custom middleware:

- `first` - right after the connect application is created, and before any application router middleware. At this point security checks are not performed yet.

→ Tip

This is good place for infrastructure logic, for example, logging and monitoring.

- `beforeRequestHandler` - before standard application router request handling, that is static resource serving or forwarding to destinations.

→ Tip

This is a good place to handle custom REST API requests.

- `beforeErrorHandler` - before standard application router error handling.

→ Tip

This is a good place to capture or customize error handling.

If your middleware does not complete the request processing, call `next` to return control to the application router middleware, as illustrated in the following example:

↗ Sample Code

```
ar.beforeRequestHandler.use('/my-ext', function myMiddleware(req, res, next) {
  res.setHeader('x-my-ext', 'passed');
  next();
});
```

## Application Router Extensions

An extension is defined by an object with the following properties:

- `insertMiddleware` - describes the middleware provided by this extension
  - `first`, `beforeRequestHandler`, and `beforeErrorHandler`  
An array of middleware, where each one can be either of the following elements:
    - A middleware function (invoked on all requests)
    - An object with the following properties:
      - `path`  
Handle requests only for this path
      - `handler`  
The middleware function to invoke

↗ Sample Code

Example Approuter Extension Configuration (`my-ext.js`)

```
module.exports = {
  insertMiddleware: {
    first: [
      function logRequest(req, res, next) {
        console.log('Got request %s %s', req.method, req.url);
      }
    ],
  },
};
```

```

    beforeRequestHandler: [
      {
        path: '/my-ext',
        handler: function myMiddleware(req, res, next) {
          res.end('Request handled by my extension!');
        }
      }
    ]
  }
};

```

The extension configuration can be referenced in the corresponding application's start script, as illustrated in the following example:

#### Sample Code

```

var approuter = require('@sap/approuter');
var ar = approuter();
ar.start({
  extensions: [
    require('./my-ext.js')
  ]
});

```

## Customize Command Line

By default the application router handles its command-line parameters, but that can be customized as well.

An `<approuter>` instance provides the property `cmdParser` that is a commander instance. It is configured with the standard application router command line options. You can add custom options like this:

#### Sample Code

```

var approuter = require('@sap/approuter');
var ar = approuter();
var params = ar.cmdParser
  // add here custom command line options if needed
  .option('-d, --dummy', 'A dummy option')
  .parse(process.argv);
console.log('Dummy option:', params.dummy);

```

To disable the handling of command-line options in the application router, reset the `ar.cmdParser` property to "false", as illustrated in the following example:

```

ar.cmdParser = false;

```

[Middleware Connect Framework](#)

[Extension API of the Application Router \[page 451\]](#)

## 4.1.4.2.2.14 Extension API of the Application Router

A detailed list of the features and functions provided by the application router extension API.

The application router extension API enables you to create new instances of the application router, manage the approuter instance, and insert middleware using the Node.js “connect” framework. This section contains detailed information about the following areas:

- Approuter Extension API Reference
- Middleware Slot

### Approuter Extension API Reference

The application router uses the “Connect” framework for the insertion of middleware components. You can reuse all connect middleware within the application router directly.

Approuter Extension API Functions

<code>approuter ( )</code>	Creates a new instance of the application router
<code>first</code>	Defines a “middleware slot” (a slot for the insertion of middleware) immediately after the <code>connect</code> application is created, and before any application router middleware  <b>→ Tip</b> This is a good place to insert infrastructure logic, for example, logging and monitoring.
<code>beforeRequestHandler</code>	Defines a “middleware slot” before the standard application router request handling, that is; static resource serving or forwarding to destinations.  <b>→ Tip</b> This is a good place to handle custom REST API requests.
<code>beforeErrorHandler</code>	Defines a “middleware slot” before the standard application router error handling  <b>→ Tip</b> This is a good place to capture or customize error handling.

`start(options, callback)`

Starts the application router with the given options.

- `options` this argument is optional. If provided, it should be an object which can have any of the following properties:
  - `port` - a TCP port the application router will listen to (string, optional)
  - `workingDir` - the working directory for the application router, should contain the `xs-app.json` file (string, optional)
  - `extensions` - an array of extensions, each one is an object as defined in Application Router Extensions (optional)
  - `xsappConfig` - An object representing the content which is usually put in `xs-app.json` file. If this property is present it will take precedence over the content of `xs-app.json`.
- `callback` - optional function with signature `callback(err)`. It is invoked when the application router has started or an error has occurred. If not provided and an error occurs (for example the port is busy), the application will abort.

---

`close(callback)`

Stops the application router.

- `callback` - optional function with signature `callback(err)`. It is invoked when the application router has stopped or an error has occurred.

---

## Middleware Slot

Manage the insertion of middleware slots with the application router.

`use(path, handler)`

Inserts a request handling middleware in the current slot.

- `path` - handle only requests starting with this path (string, optional)
- `handler` - a middleware function to invoke (function, mandatory)

Returns `this` for chaining.

---

[Middleware Connect Framework](#) ➔

### 4.1.4.2.3 Managed Application Router

The managed application router enables you to access and run HTML5 applications in a cloud environment without the need to maintain your own runtime infrastructure.

The managed application router is the HTML5 applications runtime capability that is provided by the following products:

- SAP Build Work Zone, standard edition
- SAP Build Work Zone, advanced edition
- SAP Cloud Portal

To use the managed application router, you must be subscribed to one of these services.

For information how to develop HTML5 applications and run them using the managed application router, see the following product-specific guides:

- [Developing HTML5 Applications](#) for **SAP Build Work Zone, standard edition**
- [Developing HTML5 Applications](#) for **SAP Build Work Zone, advanced edition**
- [Developing HTML5 Applications](#) for **SAP Cloud Portal**

### 4.1.4.2.4 Sizing Guide

This guide explains how much application runtime you must purchase to run HTML5 applications.

To develop and run HTML5 Applications using a standalone application router on Cloud Foundry, customers must purchase the Cloud Foundry application runtime.

The memory consumption for an idle application router is around 50 MB. An application router process should run with at least 256MB memory. It may require more memory depending on the application. These aspects influence the memory usage:

- Number of concurrent users. The number of users that log on to the applications at the same time has the greatest impact on the required runtime.
- Number of active sessions
- JWT token size
- Backend session cookies

Using the following table, estimate how much application runtime allocation you need, based on t-shirt sizes and the expected number of concurrent users.

T-Shirt Size	Concurrent Users	Required Application Runtime (in GB)
S	1000	1

T-Shirt Size	Concurrent Users	Required Application Runtime (in GB)
M	10000	4
L	30000	8
XL	80000	16

## Testing the Required Memory

The following tests provide measurements for different application router scenarios. You can use the measurements to approximately calculate the amount of memory that will be required by the application router. The tables contain the exact results from the measurements with Node.js v6.9.1. We recommend assuming higher numbers for productive use.

All measurements were done with authentication. If you have additional session content and want to count the session memory consumption, take a look at what is stored in the session (see "Sessions" in [Application Router Configuration \[page 381\]](#)). You must add the calculated session size taking into account the number of different users and the session timeout. In our tests, the JWT token alone required approximately 4 KB.

## Testing the HTTP Traffic

We tested two different test scenarios

- Scenario 1: A 'Hello World' static resource is served.
- Scenario 2:
  - A 'Hello World' static resource is served.
  - A static resource of 84.78 KB (compressed by application router to 28.36 KB) is served.
  - A backend application which returns a payload of 80 kb (compressed by application router to 58 KB) is called.
  - Another backend which returns a payload of 160 KB (compressed by application router to 116 KB) is called.

Results for HTTP Traffic Tests

Memory Limit	Max. Number of Sessions - Scenario 1	Max. Number of Sessions - Scenario 2
256 MB	5300	800
512 MB	13300	2300
1 GB	30100	8400
2 GB	65500	19500
4 GB	134900	46400
8 GB	275500	102300

## Testing Web Socket Traffic

We tested two different test scenarios:

- Scenario 1:

- A 'Hello World' static resource is served.
- A single 'Hello' message is sent and then received through a web socket connection.
- Scenario 2:
  - A 'Hello World' static resource is served.
  - A static resource of 84.78 KB (compressed by the application router to 28.36 KB) is served.
  - A backend which returns a payload of 80 KB over a web socket is called.
  - Another backend which returns a payload of 160 KB over a web socket is called.

### Note

Web sockets require a certain number of file handles to be available for the process. This number is approximately two times the number of the sessions. In Cloud Foundry, the default value is 16384.

Results for Web Socket Traffic Tests

Memory Limit	Max. Number of Sessions - Scenario 1	Max. Number of Sessions - Scenario 1
256 MB	600	300
512 MB	1100	500
1 GB	3100	800
2 GB	6500	1400
4 GB	13300	2900
8 GB	20700	6100

### Note

`--max-old-space-size` restricts the amount of memory used in the JavaScript heap. Its default value is below 2 GB. To use the full resources that has been provided to the application, the value of this restriction should be set to a number equal to the memory limit of the whole application.

For example, if the application memory is limited to 2 GB, set the V8 heap limit in the `package.json` file as follows:

```
"scripts": {
  "start": "node --max-old-space-size=2048 node_modules/@sap/
  approuter/approuter.js"
}
```

## 4.1.4.2.5 Getting Support

If you have questions or encounter an issue while working with HTML5 Application Repository, there are various ways to address them.

Create an incident in the SAP Support Portal using one of the following components:

Service	Component
HTML5 Application Repository	BC-CP-CF-HTML5
Application Router	BC-XS-APR

Provide the following incident details:

## HTML5 Application Repository

Enter and attach the following to the incident;

- Subaccount HTML5 Application Repository/app-host entitlement
- Requested app-host size limit
- Upload your mtad.yaml file
- Upload your html5-app-deployer application logs (cf logs <html5-app-deployerAppName> --recent)

## Application Router

Enter and attach the following to the incident;

- Version
- Working with or without HTML5 Apps Repo
- Upload your Application Router xs-app.json file
- Upload your Application Router xs-security.json file or configuration
- Application Router environment (cf env <approuterApp> or from cockpit).

### Note

The credentials(clientid/clientsecret) should be removed.

- Upload your Application Router logs

## Related Information

[Troubleshooting \[page 457\]](#)

## 4.1.4.2.6 Troubleshooting

A troubleshooting guide for HTML5 application repository.

### Uploading Applications

#### 400: Application metadata already exists when uploading HTML5 applications

Term	Description
Issue	HTML5 Application Deployment fails with error "Application metadata for application xyz already exists."
Cause	There is already an app-host service instance that contains a manifest.json with app.id = xyz in this space it is not possible to have multiple app-hosts containing the same app.id.
Solution	Delete or do not deploy the old app-host instance or use another app.id in the resources folder for a new app-host.

#### 400: Failed to run the application router after subscription; route not found

Term	Description
Issue	After subscribing to the application router using the <subdomain>-<myapprouter>.<scp domain> format, the calling the application router fails with error "route not found".
Cause	<p>In order to support subscriptions out of the box, a route with format *.&lt;custom-domain&gt; should be created and mapped to the application router. The * host represents a wildcard that is replaced by the actual subscriber subdomain during runtime.</p> <p>Without a custom domain, this type of route (wildcard host) cannot be created; only a fixed host can be used. Without a custom domain, the route format is &lt;subdomain&gt;-&lt;myapprouter&gt;.&lt;scp domain&gt;. It means that you have to create a route with the expected subdomain for each new subscriber.</p>
Solution	In development setups, if you don't have a custom domain before subscription, then create a route with the expected subscriber subdomain.

#### 400: Uploading application content failed

Term	Description
Issue	When trying to upload content, it fails with error: "Upload failed".

Term	Description
Cause	<p>One or more of the input validations performed by HTML5 application repository failed. The possible validation failures are:</p> <ol style="list-style-type: none"> <li>1. Missing manifest.json file on the root level.</li> <li>2. manifest.json app.id has invalid characters (hyphens, @, %, &amp;, etc.).</li> <li>3. manifest.json app.version is not using the following format: <i>xx.xx.xx</i>, where x must be an integer (e.g.: -snapshot is not supported).</li> <li>4. app.id of one or more of the applications already exists in another html5-apps-repo/app-host service instance in the same space.</li> </ol>
Solution	<p>Check if one of the causes is your issue. For example, check the size of your html5-app-deployer resources folder, check manifest.json. If you are not sure if another service instance already uses your app.id, try making a small change to your app.id and deploy it again.</p>

### 403: App-host is being modified by another process

Term	Description
Issue	HTML5 application repository deployment fails with error "app-host is being modified by another process."
Cause	The HTML5 application repository deployer attempts to upload content while another deployer is also uploading content using the same app-host.
Solution	Try again after the first HTML5 application repository deployer has completed its upload.

### 409: App-host deploy or redeploy remains in progress

Term	Description
Issue	HTML5 application repository deployment fails with error "Deploy in progress" or "Redeploy in progress" and response type 409 for a long time or any other issue.
Cause	If something happens during the upload, it might cause some inconsistencies.
Solution	<p>Delete the content of one or more multiple app-hosts, and reset the state to initial without deleting the service instances. Use the following command line in the CF CLI HTML5 application repository plug-in:</p> <pre>cf html5-delete --content &lt;app-host-id&gt; [...]</pre>

## Failed to upload content; exceeded maximum file length

Term	Description
Issue	When trying to upload content, it fails with error: "Error while parsing request; Error: maximum file length exceeded".
Cause	The zipped application file length exceeds the size limit of the app-host service instance.
Solution	Increase the app-host size limit using the update service. For example: <code>cf update-service my-app-host -c '{"sizeLimit":100}'</code> .

## Timeout while uploading content

Term	Description
Issue	When trying to upload content using the <code>cf push</code> command, it fails with error: "Failed to make TCP connection to port 8080: connection refused. Timed out after 1m0s: health check never passed."
Cause	The <code>cf push</code> plugin checks if the start process is finished. If the process times out, then it tries to start it again.
Solution	Set <code>health-check-type</code> to <code>none</code> in the <code>manifest.yaml</code> of the HTML5 Application Deployer.

## Uploading application content failed; application size exceeds the maximum size limit of 100 MB

Term	Description
Issue	When trying to upload content, you receive the following error: "Uploading application content failed: application's size exceeds the maximum size limit of 100 MB".
Cause	The unzipped applications content exceeds the size limit (deprecated) of the app-host service instance.
Solution	Deploy an application that is less than 100 MB or remove some of your applications and move them to another app-host. .

## Running Applications

### 400: Failed to retrieve xs-app.json; invalid app-host ID

Term	Description
Issue	Serving content from the HTML5 application repository fails with error "Invalid App Host ID. Please check with business service provider if the requested App Host ID is valid".

Term	Description
Caution	HTML5 application repository belongs to a business service and the app host ID is invalid or incompatible.
Solution	Ask the business service owner to define <code>"public" : true</code> in the app manifest.json or wait until the HTML5 application repository is restarted.

#### 403: Failed to retrieve xs-app.json; unauthorized

Term	Description
Issue	Serving content from the application router fails with error "Unauthorized. Please check with the business service UI provider if the requested UI is defined as public".
Cause	HTML5 application repository belongs to a business service and it is not public.
Solution	Ask the business service owner to define <code>"public" : true</code> in the app manifest.json.

#### 404: Application does not exist

Term	Description
Issue	The HTML5 application repository fails to serve content. The application log states: "Application xyz does not exist" is printed to the console.
Cause	<p>The application name provided in URL is not correct or the request URL doesn't provide the application key:</p> <p>Application names are stored in HTML5 application repository without using full stops as separators in the URL. If <i>manifest.json app.id</i> equals <i>country.list</i>, then the application name is <i>countrylist</i> and the same application name should be used in URL.</p> <p>A request to the application router must provide the application key in the URL because the application router uses the application key to fetch the xs-app.json file of the HTML5 application from the HTML5 Application Repository. The application key can consist of the business service prefix, application name, and application version. (Only the application name is mandatory.).</p>

Term	Description
Solution	<p>First check the application name. For the request URL, use the application name without full stops as separators.</p> <p>If the application name is correct, check if the request URL to the application router contains the application key. If it doesn't contain the application key, check how you configured the backend application data retrieval in your HTML5 application:</p> <ul style="list-style-type: none"> <li>• If you use SAP Fiori tools such as BAS, in the <code>manifest.json</code> file of the application, check the <code>dataSources.uri</code> property. The value for <code>dataSources.uri</code> must not start with a slash("/"). For example, the value <code>northwind/V2/ Northwind.svc</code> this is correct, but <code>/northwind/V2/ Northwind.svc/</code> is wrong because it would create an absolute path from which the browser cannot concatenate the application key for the request. If there is a slash, remove it.</li> <li>• If you use a JQueryAjax call for the request, make sure that the URL that is provided to the JQueryAjax call is a relative path and does not start with a slash ("/").</li> </ul>

#### 404: Calls to service endpoints specified in an application's xs-app.json fails

Term	Description
Issue	You have defined routes in a UI app's local <code>xs-app.json</code> but calls do not get routed and instead return a 404 error.
Cause	The routes in the <code>xs-app.json</code> file are processed top to bottom. If a route maps the pattern, it is picked even if a route below it is a better match. The route for the HTML5 application repository typically is a "catch all" route, and if any routes are defined below it, then they are never reached.
Solution	Move the route leading to the <code>html5-apps-repo-rt</code> to be the last entry in the <code>xs-app.json</code> file.

#### 500: Failed to retrieve xs-app.json

Term	Description
Issue	Serving content fails with error "Error while retrieving xsApp configuration".
Cause	The HTML5 application repository is not available.
Solution	Wait until HTML5 application repository is restarted.

## 500: Failed to use dynamic destination

Term	Description
Issue	Serving content from the application router failed with an internal server error. In the application router application log, an error: "Destination <destinationName> is not defined as a dynamic destination in destination service, configure additional property HTML5.DynamicDestination true" appears.
Cause	The destination name provided on the host or path level is not defined as a dynamic destination in destination service.
Solution	In the additional properties section of the destination section of the SAP BTP cockpit, add the HTML5.DynamicDestination property and set the value to <i>true</i> .

## 500: Missing xs-app.json in HTML5 application repository when reading an HTML5 application file from the application router

Issue	Serving content from the application router fails with error "Application does not have xs-app.json".
Cause	xs-app.json file is missing in HTML5 Application.
Solution	Redeploy the HTML5 Application with xs-app.json file or ask the business service owner to add the xs-app.json.

## Bearer token invalid

Term	Description
Issue	The app-router token exchange with a business service token fails. XSUAA returns the following error: "Bearer token invalid, requesting client does not have grant_type=user_token or no scopes were granted."
Cause	The uaa.user scope in XSUAA instance configuration is missing or the target business service is not subscribed.

Term	Description
Solution	<ol style="list-style-type: none"> <li>1. If missing, add the following to the <code>xs-security.json</code> file:  <pre>"scopes": [ { "name": "uaa.user", "description": "UAA" } ], "role-templates": [ { "name": "Token_Exchange", "description": "UAA", "scope-references": ["uaa.user"] } ]</pre> </li> <li>2. Redeploy or update the XSUAA service instance.</li> <li>3. Make sure that the users have the new role_template, <a href="#">Token_Exchange</a> added to their role_collections in the SAP BTP cockpit ► <a href="#">Global Account</a> ► <a href="#">Subaccount</a> ► <a href="#">Security</a> ► <a href="#">Role Collections</a> and verify that the created role's <a href="#">Application Identifier</a> is the same as the <code>xsappname</code> from the <code>xs-security.json</code>.</li> <li>4. If the roles of the target business service does not appear on the subscriber tenant UI, it means that the target business service subscription failed or it was bound to the application router after the subscription took place. In this case, try to unsubscribe and subscribe again. Make sure that the target business service roles appear on subscriber tenant UI.</li> </ol>

## Caching issue in browser

Term	Description
Issue	Your application does not work properly after logging out and when you try to log back in, for example, click anywhere on the application screen, nothing happens.
Cause	The main page of your application, that appears after you log in, is cached by the browser. Clicking links does not reach the backend (application router) and the log in process does not work.
Solution	<p>Check that the main page is not configured to be cached by the browser in your <code>xs-app.json</code> file. The best practice is to model the <code>cacheControl</code> as follows:</p> <pre>{   "routes": [     {       "source": "^/ui/index.html",       "target": "index.html",       "service": "html5-apps-repo-rt",       "authenticationType": "xsuaa"     }   ] }</pre>

## Running application router after subscribing to it fails

Term	Description
Issue	After subscribing to the application router using <code>&lt;subdomain&gt;-&lt;myapprouter&gt;.&lt;scp domain&gt;</code> format, it fails and returns the following error, "route not found."
Cause	<p>In order to support subscriptions out-of-the-box, create a route using <code>*.&lt;custom-domain&gt;</code> format and map it to the application router. The <code>* host</code> represents a wildcard that during runtime should be replaced by the actual subscriber sub-domain.</p> <p>Without a custom domain, this type of route (wildcard host) cannot be created, only a fixed host can be used. Without a custom domain, the route format will be <code>&lt;subdomain&gt;-&lt;myapprouter&gt;.&lt;scp domain&gt;</code>. It means that for each new subscriber you need to create a new route with the expected sub-domain.</p>
Solution	If you do not have a custom domain before subscribing to the application router, create a route with the expected subscriber sub-domain.

## 4.1.5 Consuming APIs

Discover APIs available on SAP BTP.

SAP BTP supports APIs that your applications can consume to interact, communicate, and exchange information with other applications, websites, and devices.

### SAP Business Accelerator Hub

The central repository for APIs from SAP and selected partners is the SAP Business Accelerator Hub. It contains reference documentation for a variety of REST and ODATA API packages that enable you to leverage the capabilities of SAP BTP.

For an overview of all API offerings for SAP BTP, see [SAP BTP on SAP Business Accelerator Hub](#).

If you're looking for information on APIs for a specific service, you can also use the [service catalog](#) in the SAP Discovery Center. Click on a service tile to display the available information. If the service has APIs, you can find links to their documentation under [Resources](#). You can also check if a service is available in your region by opening the [Service Plan](#) tab.

### 4.1.6 Adding Authentication and Authorization

Developers create authorization information for business users in their environment and deploy this information in an application. They make this available to administrators, who complete the authorization setup and assign the authorizations to business users.

Developers store authorization information as design-time role templates in the `xs-security.json` security descriptor file. Using the cockpit, administrators of the environment assign the authorizations to business users.

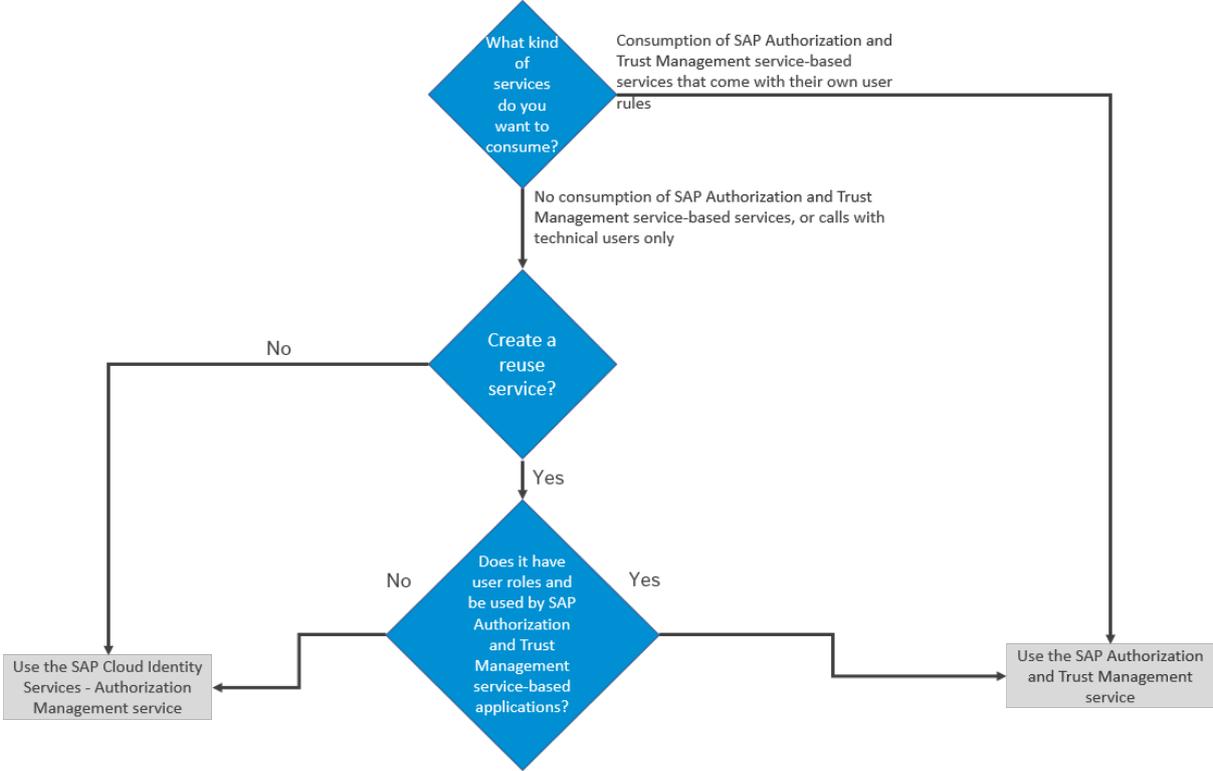

The following sections contain the process of adding authentication and authorization checks for protecting your applications, links to a number of associated tutorials, extended tasks for creating authorization artifacts, as well as reference information, including the syntax required to set the properties and values defined in the application security descriptor file.

### Using the SAP Authorization and Trust Management service or the SAP Cloud Identity Services - Authorization Management Service

SAP BTP is currently replacing the authorization management done by the SAP Authorization and Trust Management service, with an integrated solution with the SAP Cloud Identity Services - Authorization Management service. This service is integrated into the SAP Cloud Identity Services, which will offer authentication, authorization, user provisioning and management in one place.

Currently, there are still use cases where the usage of the old model with the SAP Authorization and Trust Management service is simpler when it comes to the technical setup, especially in the administration for business users.

For decision considerations on when to use the SAP Authorization and Trust Management service and when to use the SAP Cloud Identity Services - Authorization Management service as the authorization management system on SAP BTP, you can follow this decision tree that will be regularly updated:

For more information, see [Authorization and Access Control](#).

## Protecting Your Application

Application security is maintained in the application security descriptor file (`xs-security.json`). You can use this file to define application-based security artifacts, which are the building blocks for authorizations. In this section, you can learn how to create this file and use it to create a service instance of the SAP Authorization and Trust Management service. Following this single tenant scenario, move on in increasing complexity to procedures that depict how to propagate user information between applications or services, add multitenancy to your application, and set up instance-based authorizations.

## Tutorials for Authentication and Authorizations

Use tutorials to get familiar with the SAP Authorization and Trust Management service in the Cloud Foundry environment of SAP BTP.

For more information, see [Tutorials for the SAP Authorization and Trust Management Service \[page 493\]](#).

## Tasks On Demand

Here you can find information regarding accessing the UAA admin APIs for creating XSUAA artifacts, as well as the process of configuring redirect URLs.

In addition, as an application developer, you may want to create role collections for immediate use. For example, to deliver role collections that administrators can use in the SAP BTP cockpit and easily assign to users in an onboarding process.

For more information, see [Create Role Collections with Predefined Roles \[page 503\]](#).

## Reference Information

For the syntax required to set the properties and values defined in the application security descriptor file (`xs-security.json`), see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

## Related Information

[SAP Authorization and Trust Management Service \[page 2778\]](#)

### 4.1.6.1 Protecting Your Application

Developers create authorization information for business users in their environment; this information is deployed in an application and made available to administrators who complete the authorization setup and assign the authorizations to business users.

## Lifecycle of Security Artifacts for Developers and Administrators

Developers store authorization information as design-time role templates in the application security descriptor file (`xs-security.json`). Using the `xsuaa` service broker, they deploy the security information to the `xsuaa` service. The administrators view the authorization information in role templates, which they use as part of the run-time configuration. They use the role templates to build roles, which are aggregated in role collections. The role collections are then assigned, in turn, to business users.

The tasks required to set up authorization artifacts are performed by two distinct user roles: the application developer and the administrator of the Cloud Foundry environment. After the deployment of the authorization artifacts as role templates, the administrator of the application uses the role templates provided by the developers for building role collections and assigning them to business users.

## Note

To test authorization artifacts after deployment, developers can use the role templates to build role collections and assign authorization to business users in an authorization tool based on a REST API.

### Setting Up Authorization Artifacts (Developers)

Step	Task	User Role	Tool
1	Specify the application security descriptor file containing the functional authorization scopes for your application.	Application developer	Text editor
	(If applicable) If you want to create an OAuth 2.0 client in an application-related subaccount, you must use a separate security descriptor file where you specify the subaccount.	Application developer	CF command line interface
2	Create role templates for the application using the application security descriptor file.	Application developer	Text editor
3	Create a service instance from the <code>xsuaa</code> service using the service broker	Application developer	CF command line interface
4	Bind the service instance to the application by including it into the manifest file	Application developer	Text editor
5	Deploy the application	Application developer	CF command line interface or SAP BTP cockpit

## Note

For more information about the different steps in setting up authorization artifacts as an application developer, refer to the associated procedures in this section.

[Add Authentication and Functional Authorization Checks to Your Application \[page 470\]](#)

[Propagate User Information Between Applications or Services \[page 474\]](#)

[Application Security Descriptor Configuration Syntax \[page 511\]](#)

## 4.1.6.1.1 Add Authentication and Functional Authorization Checks to Your Application

Learn how to create a security application descriptor file and use it to create a service instance of the Authorization and Trust Management service.

### Context

You want to protect your application resources (functionality and data) so that only authenticated and authorized business users are able to access these resources.

You declare your application security descriptor with JSON syntax and store it in a flat file on the filesystem. The standard name for this file is `xs-security.json`.

### Procedure

1. Create your application security descriptor (`xs-security.json`) and set the `xsappname` element.

The element `xsappname` defines a prefix for the runtime name of the application. For each tenant (subaccount), which has subscribed to the application, the XSUAA service supplies a unique tenant index for the application subscription and internally concatenates the tenant index with `xsappname` at runtime (see also next step).

#### Sample Code

```
{
  "xsappname" : "hello-world",
  ...
}
```

```
}
```

2. Set the `scopes` element.

Scopes represent the API endpoints - or functions - for which access should be restricted. They're required if you want to define the functions a user is authorized to process. A scope has an arbitrary name and must be prefixed with the runtime application name to distinguish the user scopes between tenants (subaccounts) which have subscribed to the application and equally named scopes between different applications. The `XSAPPNAME` dummy value is a wildcard for the application runtime name and is used to prefix the arbitrary scope names. The XSUAA service substitutes the `XSAPPNAME` dummy value with the application runtime name for each of the subscribed tenants (see also step 1).

#### Sample Code

```
{
  ...
  "scopes" : [
    {
      "name" : "$XSAPPNAME.Display",
      "description" : "display" },
    {
      "name" : "$XSAPPNAME.Edit",
      "description" : "edit" },
    {
      "name" : "$XSAPPNAME.Delete",
      "description" : "delete" }
  ],
  ...
}
```

3. Set the `attributes` element.

Attributes represent the data entities for which access should be restricted. They're required if you want to define which data a user is authorized to process.

Attributes provide instance-based, fine-granular authorization checks. See [Setting Up Instance-Based Authorizations \[page 487\]](#).

#### Sample Code

```
{
  ...
  "attributes" : [
    {
      "name" : "Country",
      "description" : "Country",
      "valueType" : "string" },
    {
      "name" : "CostCenter",
      "description" : "CostCenter",
      "valueType" : "int" }
  ],
  ...
}
```

4. Set the `role-templates` element.

Role templates combine scopes with attributes and serve as templates from which roles are created later by the administrator.

### Sample Code

```
{
  ...
  "role-templates" : [
    {
      "name"           : "Viewer",
      "description"    : "View all books",
      "scope-references" : [ "$XSAPPNAME.Display" ],
      "attribute-references" : [ "Country" ] },
    {
      "name"           : "Editor",
      "description"    : "Edit, delete books",
      "scope-references" : [ "$XSAPPNAME.Edit", "$XSAPPNAME.Delete" ],
      "attribute-references" : [ "Country", "CostCenter" ] }
  ]
}
```

5. Deploy the application security descriptor (`xs-security.json`).

Example:

### Sample Code

```
cf create-service xsuaa application my_xsuaa_service_instance -c xs-
security.json
```

6. Check the scopes in the application.

### Sample Code

```
app.get('/books', checkReadScope, getBooks);
// Scope check
function checkReadScope(req, res, next) {
  if (req.authInfo.checkLocalScope('read')) {
    return next();
  } else {
    console.log('Missing the expected scope');
    res.status(403).end('Forbidden');
  }
}
```

The `checkReadScope` function ensures that only a user with the correct authorizations can look at the books.

See [Tutorials for the SAP Authorization and Trust Management Service \[page 493\]](#) for ways to check scopes in Java and other frameworks, like Spring.

7. In the manifest file, add the binding for the service instance to your application.

### Sample Code

```
...
services:
  - my_xsuaa_service_instance
```

8. Deploy the application.

## Sample Code

```
cf push
```

## Results

You've declared and deployed your application security descriptor (`xs-security.json`) with scopes (functional authorizations), attributes (data authorizations), and role templates (to combine scopes with attributes). The `xsappname` element is mandatory. The `scopes`, `attributes`, and `role-templates` elements are optional. You've also bound your service instance to your application, and then deployed it.

## Sample Code

```
{
  "xsappname" : "hello-world",
  "scopes" : [
    {
      "name" : "$XSAPPNAME.Display",
      "description" : "display" },
    {
      "name" : "$XSAPPNAME.Edit",
      "description" : "edit" },
    {
      "name" : "$XSAPPNAME.Delete",
      "description" : "delete" }
  ],
  "attributes" : [
    {
      "name" : "Country",
      "description" : "Country",
      "valueType" : "string" },
    {
      "name" : "CostCenter",
      "description" : "CostCenter",
      "valueType" : "int" }
  ],
  "role-templates" : [
    {
      "name" : "Viewer",
      "description" : "View all books",
      "scope-references" : [ "$XSAPPNAME.Display" ],
      "attribute-references" : [ "Country" ] },
    {
      "name" : "Editor",
      "description" : "Edit, delete books",
      "scope-references" : [ "$XSAPPNAME.Edit", "$XSAPPNAME.Delete" ],
      "attribute-references" : [ "Country", "CostCenter" ] }
  ]
}
```

## Next Steps

To implement web access using a browser or a browser-based user interface, you can use an application router to enable you to create a secure route to your application, or an open source UI framework, such as Spring (Boot). For more information, see the related links.

### 4.1.6.1.2 Propagate User Information Between Applications or Services

When a business application communicates with a service, you must decide whether you want to propagate the identity of the user that called the business application, or if a call from machine-to-machine is sufficient.

#### Principal Propagation Versus Technical Communication

If the business application triggers an action of the service that should be auditable or requires that the identity of the user be known, use principal propagation. Principal propagation enables the identity of the user to be propagated from the business application to the service.

If the business application triggers an action of the service for which the identity of the user is unimportant, such as a regular clean-up task or the checking of a queue, then you can use technical communication. In technical communication, the service performs the action for the business application without knowing the identity of the user.

#### Cross-Application API Calls from an External System to Applications in the Cloud Foundry Environment

If applications from an external system must make API calls to applications running in the Cloud Foundry environment, administrators must make sure that these applications can communicate with the relevant applications in the external system. In this case, the bearer assertion flow or client credentials identify the external application at the UAA, which can then issue a JSON web token. The external application can use this JSON web token when it makes the API calls to applications in the Cloud Foundry environment.

No browser is involved here. Users are propagated in the following ways:

- Using technical communication, for example, propagating scopes and authorities.
- Using a bearer assertion or client credentials (JSON web tokens) to propagate named users.

## Related Information

[Principal Propagation with Tightly Coupled Developments \[page 478\]](#)

[Technical Communication with Tightly Coupled Developments \[page 475\]](#)

[Principal Propagation \[page 2824\]](#)

### 4.1.6.1.2.1 Technical Communication with Tightly Coupled Developments

When a business application and a service are developed for the same subaccount, the two developments are tightly coupled together. The service is designed to be used with this particular application.

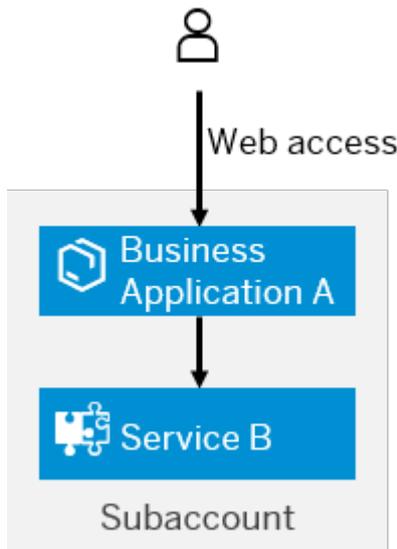

## Context

In this example, the call between the application and the service uses technical communication instead of the current user. The figure that follows illustrates this scenario.

#### Note

With service, we do not mean a development that has been registered as a service with the Cloud Controller, but rather the role one application takes in relationship to another. Both developments can be applications, but one application takes on the role of a business application enabling business users to perform tasks. The other application plays the role of a service, enabling the development of the business application.

We also assume that both applications have their own application router. Having separate application routers means that the applications can define their own authorization models.

Two Developments Tightly Coupled Using Technical Communication

Like a trust arrangement, you must configure service B to grant the authority to business application A to use the `XSAPPNAME.Create` scope. Likewise, you must configure business application A to accept such declarations of authority. This configuration is part of the `xs-security.json` of the UAA service instances of the two developments.

## Procedure

1. As the service developer, declare the grant of authority to business application A in the `scopes` section of the `xs-security.json` for service B.

### Sample Code

```
{
  "xsappname"      : "servb",
  "tenant-mode"    : "shared",
  "scopes"         : [
    {
      "name"                : "$XSAPPNAME.Create",
      "description"         : "create",
      "grant-as-authority-to-apps" :
    [ "$XSAPPNAME(application, appa) " ]
    }
  ]
}
```

Under `scopes`, the scope `XSAPPNAME.Create` grants authority to business application A to create data. Here the granted app is business application A and has been given the authorization to create data. When you create the UAA service instance for business application A, the system creates an OAuth client for business application A to call over to service B. When you bind the service, you make business application A aware of the client. In the security descriptor for the UAA service instance of business application A, accept this grant.

### Note

`XSAPPNAME` is replaced at runtime with the application name. The parameters that follow `XSAPPNAME` are the service plan for the XSUAA service and `xsappname` as defined in the `xs-security.json`. These parameters help uniquely identify other applications in the subaccount.

2. Create the UAA service instance for service B.

For example:

```
cf create-service xsuaa application servb-uaa -c /servb/security/xs-security.json
```

3. As the business application developer, accept the authority of other applications in the `authorities` section of the `xs-security.json` in business application A.

### Sample Code

```
{
  "xsappname"      : "appa",
  "tenant-mode"    : "shared",
  "authorities"    : [ "$ACCEPT_GRANTED_AUTHORITIES" ],
}
```

In this example, business application A accepts all authorities granted by any other application. You can explicitly define which authorities you want business application to accept. For example:

```
"authorities": [ "$XSAPPNAME(application,servb).Create]"
```

### Note

For the sake of this example, we've removed any scopes and role templates for application A. Naturally, we recommend that you protect application A with appropriate scopes and deliver role templates.

4. Create the UAA service instance for business application A.

For example:

```
cf create-service xsuaa application appa-uaa -c /appa/security/xs-security.json
```

5. Deploy the developments.
6. As an administrator, create a role from the role templates for business application A and assign the role to a user.

In the example, we created here, there are no role template to create roles from.

For more information, see [Administration: Managing Authentication and Authorization](#).

7. As an end user, access business application A.

When you access business application A, business application A accesses service B on your behalf. Because service B granted the `"XSAPPNAME.create` scope to business application A, business application A is allowed to access the resource.

## 4.1.6.1.2.2 Principal Propagation with Tightly Coupled Developments

A scenario is tightly coupled when a business application calls a service within the same subaccount in the Cloud Foundry environment. The business application calls the service with principal propagation, meaning information about the current user is carried over with the service call.

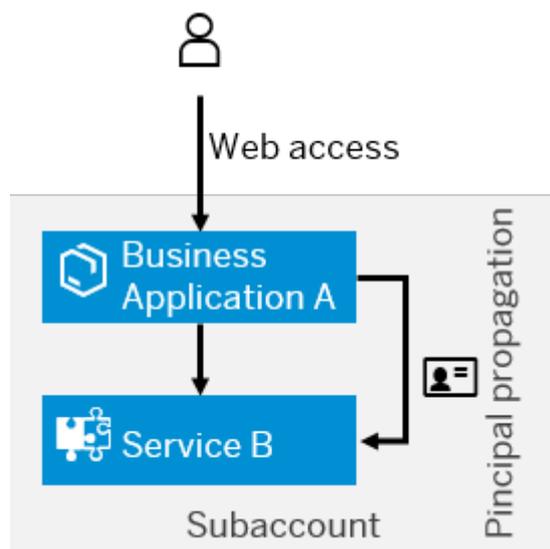

### Context

The figure that follows illustrates this scenario.

#### Note

With service, we do not mean a development that has been registered as a service with the Cloud Controller, but rather the role one application takes in relationship to another. Both developments can be applications, but one application takes on the role of a business application enabling business users to perform tasks. The other application plays the role of a service, enabling the development of the business application.

We also assume that both applications have their own application router. Having separate application routers means that the applications can define their own authorization models.

Two Applications, Tightly Coupled Using Principal Propagation

In this scenario, we enable the service to accept the JSON Web Token (JWT) of the business application. The JWT of the business application includes the scopes of both developments. When the service receives a JWT of the business application with the scopes of the service in it, the service implicitly accepts the JWT of the business application. This configuration is part of the `xs-security.json` of the UAA service instances of the two developments.

## Procedure

1. As the service developer, add the attribute `granted-apps` to scopes you want to share with other business applications in the `scopes` section of the `xs-security.json` for this service.

In this attribute, list the names of the applications (`xsappname`) you want to share the scope with.

### Sample Code

```
"scopes": [
  {
    "name"           : "$XSAPPNAME.Viewer",
    "description"   : "View log",
    "granted-apps"  : [ "$XSAPPNAME(application, appa)" ]
  },
  {
    "name"           : "$XSAPPNAME.Editor",
    "description"   : "view and write logs",
  }
]
```

In this example, we have defined two scopes, `viewer` and `editor`. Under `granted-apps`, we list the application names with which we want to share the `viewer` scope. All apps listed here can consume this scope in their role templates.

### Note

`$XSAPPNAME` is replaced at runtime with the application name. The parameters that follow `$XSAPPNAME` are the service plan for the XSUAA service and `xsappname` as defined in the `xs-security.json`. These parameters help uniquely identify other applications in the subaccount.

You might reserve the `editor` scope for a role template for the service. The `editor` role is only meant for administrators.

2. Create the UAA service instance for service B.

For example:

```
cf create-service xsuaa application servb-uaa -c /servb/security/xs-security.json
```

3. As the business application developer, add scope references to the scope of the service in the `role-templates` section of the `xs-security.json` in business application A.

### Sample Code

```
"role-templates": [
  {
    "name"           : "Viewer",
    "description"   : "View all data of the service",
    "scope-references" : [
      "$XSAPPNAME.Display",
      "$XSAPPNAME(application, servB).Viewer"
    ]
  }
]
```

Under `role-templates`, the `viewer` template includes a reference to the `viewer` scope of service B. This reference enables administrators to assign a single role to a user to grant authorizations for both applications.

4. Create the UAA service instance for application A.

For example:

```
cf create-service xsuaa application appa-uaa -c /appa/security/xs-security.json
```

5. Deploy the developments.
6. As an administrator, create a role from the role template from business application A and assign the role to a user.

Only assign the `viewer` template from business application A to your test user and no templates from service B.

For more information, see [Administration: Managing Authentication and Authorization](#).

7. As an end user, test access business application A.

Your test user can use the scopes delivered from the `viewer` template to access business application A or service B directly or indirectly.

## 4.1.6.1.2.2.1 Use Foreign Scope Option for Principal Propagation with Tightly Coupled Developments

With foreign scope reference, configure the business application to accept new scopes for the service without having to modify the business application.

### Procedure

1. As the service developer, add the attribute `granted-apps` to scopes you want to share with other business applications in the `scopes` section of the `xs-security.json` for this service.

In this attribute, list the names of the applications (`xsappname`) you want to share the scope with.

#### Sample Code

```
"scopes": [
  {
    "name"                : "$XSAPPNAME.Read",
    "description"         : "read",
    "granted-apps"       : [ "$XSAPPNAME(application, appa)" ]
  },
  {
    "name"                : "$XSAPPNAME.Approve",
    "description"         : "approval",
  }
]
```

In this example, we've defined two scopes, `Read` and `Approve`. Under `granted-apps`, we list the application names with which we want to share the `Read` scope. All apps listed here can consume this scope in their role templates.

### Note

`XSAPPNAME` is replaced at runtime with the application name. The parameters that follow `XSAPPNAME` are the service plan for the XSUAA service and `xsappname` as defined in the `xs-security.json`. These parameters help uniquely identify other applications in the subaccount.

You might reserve the `Approve` scope for a role template for the service. The approver role is only meant for administrators.

2. Create the UAA service instance for service B.

For example:

```
cf create-service xsuaa application servb-uaa -c /servb/security/xs-security.json
```

3. In the business application, accept all foreign scope references.

### Sample Code

```
{
  "xsappname": "appa",
  "tenant-mode": "shared",
  "description": "Application security descriptor for application A",
  "foreign-scope-references": [ "$ACCEPT_GRANTED_SCOPES" ],
  "scopes": [
    {
      "name": "$XSAPPNAME.View",
      "description": "View data"
    }
  ],
  "role-templates": [
    {
      "name": "View",
      "description": "View data",
      "scope-references": [
        "$XSAPPNAME.View"
      ]
    }
  ]
}
```

Under `foreign-scope-references`, the application security descriptor accepts any and all foreign scopes that were granted to it. You can limit the references to just those applications you want to accept. For example, `"$XSAPPNAME(application,servb).Read"`

4. Create the UAA service instance for application A.

For example:

```
cf create-service xsuaa application appa-uaa -c /appa/security/xs-security.json
```

5. Deploy the developments.
6. As an administrator, create a role from the role template from business application A and assign the role to a user.

Only assign the `viewer` template from business application A to your test user and no templates from service B.

For more information, see [Administration: Managing Authentication and Authorization](#).

7. As a business user, test business application A.

Your test user can use the scopes delivered from the `viewer` template to access business application A or service B directly or indirectly.

## Related Information

[Principal Propagation with Tightly Coupled Developments \[page 478\]](#)

### 4.1.6.1.3 Set Up Your Application for Multitenancy

Learn how to add multitenancy to your application and make it available for other subaccounts using the SaaS Provisioning service and the SAP Authorization and Trust Management service.

## Context

You've created an application in your subaccount that is secured by the SAP Authorization and Trust Management service. You now want to make that application available to other subaccounts (tenants). You'll use the SaaS Provisioning service to make your application available to a consumer subaccount within your global trial account.

You declare your application security descriptor with JSON syntax and store it in a flat file on the filesystem. The standard name for this file is `xs-security.json`.

## Procedure

1. Enable multitenancy in the application security descriptor file.
  - a. Go to the folder where the `xs-security.json` file is stored.
  - b. Change the value of the `tenant-mode` parameter to `shared`.
  - c. Under the `scopes` element, add access to the SaaS Provisioning service to call the product list callback API directly. You'll implement the callbacks in Step 3.

#### Sample Code

```
"scopes": [
  {
    "name": "$XSAPPNAME.read",
    "description": "With this scope, USER can read
products."
```

```

    },
    {
      "name": "$XSAPPNAME.Callback",
      "description": "With this scope set, the callbacks for
tenant onboarding, offboarding and getDependencies can be called.",
      "grant-as-authority-to-apps": [
        "$XSAPPNAME(application,sap-provisioning,tenant-
onboarding)"
      ]
    }
  ],
}

```

d. Save the file.

## 2. Update the manifest.

In this step, you need to complete the following tasks:

- Add a new routing pattern.
  - Add the service binding for the SaaS Provisioning service.
- a. Go to your application folder and open the `manifest.yml` file.
  - b. For the application router, add the `TENANT_HOST_PATTERN` parameter under the `env` parameter.

This parameter specifies a generic route for all tenants to call the application over the approuter.

### Sample Code

```

env:
  destinations: >
    [
      { "name": "hw-dest",
        "url": "https://product-list-ap25.cfapps.eu10.hana.ondemand.com",
        "forwardAuthToken": true }
    ]
  TENANT_HOST_PATTERN: "^(.*)-approuter-product-list-
ap25.cfapps.eu10.hana.ondemand.com"

```

### ⚠ Restriction

The value of the `TENANT_HOST_PATTERN` parameter must be in lowercase.

- c. Add the service binding for the SaaS Provisioning service to your application.

Adding the service binding of the SaaS Provisioning service in the `manifest.yml` file will automatically bind the service instance to your application, when deploying it.

### Sample Code

```

services:
  - xsuaa-service-tutorial
  - saas-registry-tutorial

```

## 3. Implement the subscribe/unsubscribe endpoints.

To enable other subaccounts to subscribe to your application, you need to implement an endpoint for the SaaS registration manager to subscribe/unsubscribe.

- a. Go to the `myapp` folder and open the `index.js` file.

- b. Add the following lines of code after the `checkReadScope` function. (Replace the `ap25` string with the string that you used when deploying your application security model. Adapt the region code if your trial isn't in the `eu10` region.)

#### Sample Code

```
app.put('/callback/v1.0/tenants/*', function (req, res) {
  var consumerSubdomain = req.body.subscribedSubdomain;
  var tenantAppURL = "https://\\" + consumerSubdomain + "-approuter-
product-list-ap25." + "cfapps.eu10.hana.ondemand.com/products";
  res.status(200).send(tenantAppURL);
});
app.delete('/callback/v1.0/tenants/*', function (req, res) {

  // Implement here any offboarding proces that's triggered when
user deletes a subscription to the application
  res.sendStatus(200);
});
```

Return the HTTP 200 OK success status response if the offboarding process was successful.

If the offboarding failed, return the relevant error code and an accompanying message.

#### Note

It's highly recommended to use a response object that contains both the error code and a user-friendly, customer-oriented error message and technical details about the error in the following format:

```
{
  "code":<The relevant response code, e.g., 500, 400>,
  "messageForCustomer":<A customer-facing message. Please write in a
user-friendly format, as clearly as possible>,
  "errorDetails":<Specify here additional technical details about the
error>
}
```

- c. To be able to read the body of those calls, add the body parser module at line 9 of the `index.js` file.

#### Sample Code

```
const bodyParser = require('body-parser')
app.use(bodyParser.json())
```

- d. Add the body parser module as a dependency to the `product list/myapp/package.json` file.

#### Sample Code

```
"dependencies": {
  "express": "^4.17.1",
  "@sap/xsenv": "^2.2.0",
  "@sap/xssec": "^3.0.0",
  "passport": "^0.4.1",
  "body-parser": "^1.19.0"
}
```

4. Create a SaaS configuration file.

To make your multitenant application endpoints available for subscription to consumer subaccounts, you need to register the application in the Cloud Foundry environment by using the SaaS Provisioning service.

To register your application, you need a configuration file called `config.json`. In this file, you specify the subscription URL, the name, and description of your application. The `xsappname` must be the same as the `xsappname` in the `xs-security.json` file.

- a. Go to your application folder and create the `config.json` file.
- b. Insert the following lines.

#### Sample Code

```
{
  "xsappname": "product-list",
  "appUrls": {
    "onSubscription" : "https://product-list-
ap25.cfapps.eu10.hana.ondemand.com/callback/v1.0/tenants/{tenantId}"
  },
  "displayName" : "Product List MTA",
  "description" : "Product list MTA sample application",
  "category" : "Custom SaaS Applications"
}
```

5. Delete the old service instance of the SAP Authorization and Trust Management service.

When you change the tenant mode from `dedicated` to `shared` like you did in step 1, it's not enough to update the service instance. You have to first unbind and delete the old service instance, to be able to later recreate it with the updated tenant mode settings.

- a. Unbind the existing service instance from your application.

```
cf unbind-service <APP_NAME> <SERVICE_INSTANCE>
```

#### Sample Code

```
cf unbind-service product-list xsuaa-service-tutorial
```

- b. Unbind the existing service instance from the application router.

```
cf unbind-service <APP_NAME> <SERVICE_INSTANCE>
```

#### Sample Code

```
cf unbind-service approuter xsuaa-service-tutorial
```

- c. Delete the existing service instance.

```
cf delete-service <SERVICE_INSTANCE>
```

#### Sample Code

```
cf delete-service xsuaa-service-tutorial
```

6. Create service instances and redeploy your application.

- a. Log in to your Cloud Foundry account with the Cloud Foundry CLI.

- b. Go to your application folder and create the service instance with the `xs-security.json` security descriptor file.

```
cf create-service <SERVICE> <PLAN> <SERVICE_INSTANCE> -c xs-security.json
```

#### Sample Code

```
cf create-service xsuaa application xsuaa-service-tutorial -c xs-security.json
```

- c. Create the SaaS Provisioning service instance with the `config.json` file.

#### Sample Code

```
cf create-service <SERVICE> <PLAN> <SERVICE_INSTANCE> -c config.json
```

```
cf create-service saas-registry application saas-registry-tutorial -c config.json
```

- d. Redeploy the application with the updated `manifest.yml` file.

#### Sample Code

```
cf push
```

7. Create a route for a consumer subaccount.

Make your application reachable for consumer subaccounts by adding a new route in the Cloud Foundry CLI. The route is composed of the subdomain of the subscribing subaccount and the `TENANT_HOST_PATTERN` of the application router that you defined in the `manifest.yml` file. You have to create a new route for every subaccount (tenant) that subscribes to the application.

- a. Log in to the Cloud Foundry account where the application is deployed with the Cloud Foundry CLI.
- b. Create a route for the consumer subaccount.

```
cf map-route <APP_NAME> <DOMAIN> --hostname <APPLICATION_HOSTNAME>
```

#### Note

The `APPLICATION_HOSTNAME` is the combined string of the subdomain ID of the consumer subaccount and the `TENANT_HOST_PATTERN` from the `manifest.yml` file.

#### Sample Code

```
cf map-route approuter cfapps.eu10.hana.ondemand.com --hostname consumer-tenant-ap25-approuter-product-list-ap25
```

8. Access the application with the consumer subaccount.

To access the application you need to subscribe to it. Follow these steps to subscribe to the SaaS application with the consumer subaccount and call the application URL.

- a. Open the SAP BTP trial.

- b. Navigate to your consumer subaccount.
- c. Choose *Subscriptions*.
- d. Choose *Product List MTA*.
- e. Choose *Subscribe*.
- f. Choose *Go to Application*.

You'll now see the application with the message `no data` because you have to assign the role collection to your user in the consumer subaccount.

#### 9. Assign the role collection.

Assign the `ProductListViewer` role collection to your user. This role collection contains the necessary role to view the products in your application.

- a. Open the SAP BTP cockpit.
- b. Navigate to your consumer subaccount.
- c. Choose **Security > Role Collections**.
- d. Choose the `ProductListViewer` role collection.
- e. Use the chevron at the right side to expand the role collection.
- f. Go to the *Users* section and choose *Edit*.
- g. Enter the e-mail address of the user that you want to assign to the role collection. Take care that your user's identity provider is SAP ID service.
- h. Save your changes.
- i. Clear your cache and reload the application URL.

#### Sample Code

```
https://consumer-tenant-ap25-aprouter-product-list-  
ap25.cfapps.eu10.hana.ondemand.com/products
```

The application will now show you the products.

### 4.1.6.1.4 Setting Up Instance-Based Authorizations

Instance-based authorizations are authorization checks based on the value of some authorization-relevant attribute defined by the application. Functional authorizations define whether you've permission to edit or view some function in the application, while instance-based authorizations define what data you can act upon.

As a developer, you develop your application as you did in our previous examples for functional authorization checks. In that example, we defined attributes in the application security descriptor (`xs-security.json`) even though we didn't use them. In that example, we defined *CostCenter* as an attribute. Let's look at an example.

Your application is used by a controller to view the expenses of their organization. So, your application shows the controller all invoices, which belong to the cost center of the controller. So, your application takes the dataset of invoices and shows the instance of that dataset where the cost center equals the cost center of the controller. Control access to this dataset by creating a role collection that includes the *CostCenter* attribute and the value required by the controller. Then assign that role collection to the user of the controller.

For more information about defining attributes in the application security descriptor, see [Add Authentication and Functional Authorization Checks to Your Application \[page 470\]](#).

For instance-based authorizations, you build checks against these attributes into your coding. To help you understand authorization checks against attributes, check out our sample bulletin board application on Github.

For more information, see <https://github.com/SAP-samples/cloud-application-security-sample/tree/master/spring-security-basis>.

Once you've built in your authorization checks, you've a few ways to populate the attributes with values, for your code to check.

## How Attribute Values Are Set

Once you've defined attributes in your role templates, how are attribute values filled? There are a couple different ways.

- Predefine the attribute values in role collections you deliver with your app.  
As a developer, you can define preconfigured role collections in your application security descriptor. When the role administrator assigns these role collections to users, the attribute values are hard-coded with the default values according to the role templates you define. These role collections enable a role administrator to get their users started quickly.
- The administrator builds static roles from your role templates.  
The administrator builds the roles they need, based on the role templates you deliver. The administrator builds each role, setting the values for the attributes you defined in the role templates. The administrator can't add or subtract any attributes. The administrator can only set the values. The administrator then bundles these roles into role collections and assigns them to users.
- The administrator builds dynamic roles from your role templates.  
The administrator builds the roles they need, based on the role templates you deliver. The administrator can decide to populate role values dynamically from the identity provider. When users log on, they receive a token with attributes defined by the identity provider. The manager of the identity provider controls the values a user has for given attributes, not the role administrator of the subaccount. This setup means that you as an application developer need to understand what kinds of attributes are available to the role administrator from the identity provider.

[Attributes \[page 2102\]](#)

## 4.1.6.1.5 Retrieving Access Tokens with Mutual Transport Layer Security (mTLS)

Mutual Transport Layer Security (mTLS) is considered more secure than the combination of client ID and client secret. Unlike retrieving the access token with client ID and client secret, no secret is shared between calling application and the service instance of SAP Authorization and Trust Management service (XSUAA).

This configuration enables your application to retrieve or exchange access tokens from an instance of the SAP Authorization and Trust Management service with mTLS. When using TLS, the client verifies the identity of the OAuth server during their handshake. By using mTLS, the OAuth server also verifies the identity of the client. Calls to other services and applications with the access token use the standard OAuth protocols.

You, as a developer, have the option to have the service provide the X.509 certificate for the binding or service key or if you already have your own public key infrastructure (PKI), you can provide your own.

### ⚠ Restriction

If you use your own PKI, your certificates must be issued by certificate authorities trusted by the service.

For more information, see [Binding Parameters of SAP Authorization and Trust Management Service \[page 2115\]](#).

## Related Information

[Enable mTLS Authentication to SAP Authorization and Trust Management Service for Your Application \[page 489\]](#)

[Implementing Custom Token Retrieval from SAP Authorization and Trust Management Service with mTLS \[page 492\]](#)

### 4.1.6.1.5.1 Enable mTLS Authentication to SAP Authorization and Trust Management Service for Your Application

Enabling your application to retrieve access tokens from SAP Authorization and Trust Management service(XSUAA) over mutual transport layer security (mTLS) requires you to enable mTLS token retrieval for the service instance. Then ensure the binding includes the X.509 credentials.

## Prerequisites

To handle tokens, use:

- Application router version 10.7.1 or later  
For more information, see <https://www.npmjs.com/package/@sap/approuter> .

- Our security libraries
  - For Java or Spring, see [XSUAA Token Client and Token Flow API](#) on *Github*.
  - For Python, see [SAP Python Security Library](#) on *Python Package Index*.
  - For Node.js, see [@sap/xssec](#) on *Node Package Manager (NPM)*.
- Your own integration  
For more information, see [Implementing Custom Token Retrieval from SAP Authorization and Trust Management Service with mTLS](#) [page 492].

### → Recommendation

Build automation into your deployment or CI/CD pipeline. Client certificates have a relatively short lifetime. The default lifetime for certificates managed by the service is 7 days. Only by automating the process, can you ensure that credentials are rotated and distributed in a timely manner. Otherwise, you risk authentication failures from expired certificates.

## Context

Use the same procedure as outlined in [Add Authentication and Functional Authorization Checks to Your Application](#) [page 470]. Modify this procedure with the following steps.

Be mindful of whether you're updating an existing application or starting with a brand new development.

- If you're adding mTLS to an existing application, add mTLS support to the credential types of the service instance. Then update all your bindings and service keys before removing the support for other credential types.

### → Tip

For an example of how to migrate from one secret type to another, see [Migrate from Instance Secrets to Binding Secrets](#) [page 2113].

- If you're starting from scratch, you can build in mTLS support from the beginning, without worrying about disrupting existing bindings or service keys.

## Procedure

1. Enable mTLS for the service instance.

Add the credential type x509 to the OAuth configuration of the service instance.

- The following is an example of the OAuth configuration from an application security descriptor (`xs-security.json`).

```
"oauth2-configuration": {
  "credential-types": [ "binding-secret", "x509" ]
}
```

In this example, binding secrets are the default credential type, but X.509 secrets are supported.

- The following is an example of the service as a resource in a multitarget application (MTA) descriptor (mta.yaml).

```
resources:
  - name: myXSUAA
    type: com.sap.xs.uaa
    parameters:
      service-plan: application
    config:
      xsappname: mAapp
      oauth2-configuration:
        credential-types:
          - x509
          - binding-secret
```

In this example, X.509 secrets are the default credential type. When deployed, any preconfigured bindings get service-managed client certificates. After deployment, you can create additional bindings with binding secrets.

2. Deploy the application or update the service instance.
3. Create bindings or service keys with the X.509 credentials.

You create the binding from the Cloud Foundry command-line interface (cf CLI),

- From the command-line interface, provide a `parameters.json` to configure the certificates managed by the service or to provide your own X.509 certificate.

The following is an example of a `parameters.json` with the certificates managed by the service.

```
{
  "credential-type": "x509",
  "x509": {
    "key-length": 2048,
    "validity": 8,
    "validity-type": "DAYS"
  }
}
```

The following is an example of a `parameters.json` with certificates you provide.

```
{
  "credential-type": "x509",
  "x509": {
    "certificate": "-----BEGIN CERTIFICATE-----...-----END
CERTIFICATE-----",
    "certificate-pinning": true
  }
}
```

Reference the `parameters.json` when you bind the service. For example:

```
cf bind-service myApp myXSUAA -c parameters.json
```

## Related Information

[Parameters for X.509 Certificates Managed by SAP Authorization and Trust Management Service \[page 2117\]](#)

[Parameters for Self-Managed X.509 Certificates \[page 2118\]](#)

[Rotate X.509 Secrets \[page 2112\]](#)

## 4.1.6.1.5.2 Implementing Custom Token Retrieval from SAP Authorization and Trust Management Service with mTLS

The application router and other token client libraries take care of getting tokens from the SAP Authorization and Trust Management service for you. If you build your own integration, you must handle token retrieval yourself.

### Note

The service doesn't check for certificate revocation. To stop the service from accepting a certificate that is still valid, delete the relevant bindings or service keys. As soon as the binding is deleted, the service stops accepting the certificate.

For bindings with self-managed certificates and the `certificate-pinning` parameter set to `false`, you can rotate the secrets without deleting bindings. Just use a new certificate with the same subject and issuer distinguished name (DN). The service saves the new validity date of the new certificate.

For more information, see [Parameters for Self-Managed X.509 Certificates \[page 2118\]](#).

### → Recommendation

Build automation into your deployment or CI/CD pipeline. Client certificates have a relatively short lifetime. The default lifetime for certificates managed by the service is 7 days. Only by automating the process, can you ensure that credentials are rotated and distributed in a timely manner. Otherwise, you risk authentication failures from expired certificates.

When called with mTLS, the token endpoint is a little different from the standard endpoint. The path includes `authentication.cert` instead of just `authentication`.

`https://<subdomain>.authentication.cert.<landscape>/oauth/token`

For example:

```
https://test-me.authentication.cert.eu20.hana.ondemand.com/oauth/token
```

Use the `/.well-known/openid-configuration` endpoint to find the endpoints for your subaccount. The endpoints appear under the `mtls_endpoint_aliases` parameter.

For example: `https://test-me.authentication.eu20.hana.ondemand.com/.well-known/openid-configuration`

The following is an example of part of the JSON returned by the endpoint.

```
{
  ...,
  "mtls_endpoint_aliases": {
    "token_endpoint": "https://test-
me.authentication.cert.eu20.hana.ondemand.com/oauth/token",
    "authorization_endpoint": "https://test-
me.authentication.cert.eu20.hana.ondemand.com/oauth/authorize"
  },
  ...
}
```

For X.509 authentication, the `grant_type` are as with client secret authentication:

- For UI user flows: Authorization code
- For API user flows: JWT bearer, refresh token, and password grant
- For technical flows: Client credentials

### Note

Leave out the `client_secret` parameter. The `client_id` is still required.

Finally, when building the call, include the client certificate (public key) and private key for signing in your request. The following syntax is for CURL:

```
curl --cert <Path_Client_Cert> --key <Path_Private_Key>
-XPOST https://<subdomain>.authentication.cert.<landscape>/oauth/token -d
'grant_type=<Grant_Type>&client_id=<Client_ID>'
```

The following is an example in CURL:

```
curl --cert x509certificate.pem --key x509privatekey.pem
-XPOST https://test-me.authentication.cert.eu20.hana.ondemand.com/oauth/
token -d 'grant_type=client_credentials&client_id=sb-na-
edb111d1-2c22-3eca-444-869fde307ac7!a5017'
```

## 4.1.6.3 Tasks On Demand

Here you can find information regarding the available extended tasks for creating authorization artifacts, as well as the process of configuring redirect URLs.

In addition, as an application developer, you may want to create role collections for immediate use. For example, to deliver role collections that administrators can use in the SAP BTP cockpit and easily assign to users in an onboarding process.

### [Update a Service Instance \[page 496\]](#)

You can update a service instance from the `xsuaa` service using the service broker.

### [Sharing and Unsharing Service Instances \[page 496\]](#)

You can share service instances of the SAP Authorization and Trust Management service across multiple spaces or environments. This has the advantage that you don't need to create separate service instances in multiple spaces or environments.

### [Compatible Changes in the Security Descriptor File \[page 497\]](#)

If you update a service instance, you can add, change, and/or delete scopes, attributes, and role templates. Whenever you change role templates, you adapt roles that are derived from the changed role template.

### [Retrieve Credentials for Remote Applications \[page 498\]](#)

You need to get the credentials of a service instance for an application that runs outside SAP BTP.

### [Configure Redirect URLs for Browser Logout \[page 501\]](#)

To avoid open redirect attacks, direct users to a safe and valid URL when they log out.

### [Create Role Collections with Predefined Roles \[page 503\]](#)

As an application developer, you want to create role collections for immediate use. You want to deliver role collections that administrators can use in the cockpit, and easily assign to users, for example in an onboarding process.

### [Validation and Revocation of Access Tokens \[page 505\]](#)

To confirm that access tokens were truly issued by the SAP Authorization and Trust Management service and are still valid, applications check the tokens for validity.

### [Include Tokens from Corporate Identity Providers or Identity Authentication in Tokens of the SAP Authorization and Trust Management Service \[page 506\]](#)

In scenarios where your SAP BTP application interacts with applications that don't support tokens issued by the SAP Authorization and Trust Management service, but require a token from a corporate identity provider or Identity Authentication, you can configure SAP Authorization and Trust Management service to include this token.

### [Best Practices When Handling Access Tokens \[page 508\]](#)

Calls to SAP Authorization and Trust Management service can fail for many reasons, including network latency, connection errors, service downtime, idle connections closed by routing components and so on. The following sections provide recommendations on when to retry connections and the caching of tokens.

### 4.1.6.3.1 Update a Service Instance

You can update a service instance from the `xsuaa` service using the service broker.

#### Context

You are running a service instance that grants user access to an application. It uses the security descriptor file `xs-security.json`. If you change properties, for example, you want to reflect the compatible changes you made in the `xs-security.json` file in an existing service instance.

#### ⚠ Restriction

If you define or update role templates and attributes in the `xs-security.json` file, observe the following configuration restrictions in [Relationship Between default-values of attribute-references and valueRequired](#).

#### Procedure

1. Edit the `xs-security.json` file and make your changes in the security descriptors.
2. Update the service instance. During the update, you use the security descriptors you changed in the `xs-security.json` file.

```
cf update-service <service_instance_name> -c xs-security.json
```

#### 🔗 Example

```
cf update-service authorizationtest-uaa -c xs-security.json
```

### 4.1.6.3.2 Sharing and Unsharing Service Instances

You can share service instances of the SAP Authorization and Trust Management service across multiple spaces or environments. This has the advantage that you don't need to create separate service instances in multiple spaces or environments.

- You must have the *Subaccount Service Administrator* role collection in the specified subaccount. Use the SAP BTP cockpit to assign this role collection (see [Assigning Role Collections to Users or User Groups \[page 2091\]](#).)

Using the SAP BTP command line interface (btp CLI), you can share service instances across spaces or environments (for example, Cloud Foundry and Kubernetes). Shared service instances don't have the same credential. The client ID can be the same or different. Sharing service instances is possible with service instances of the `application` and `broker` plan.

#### 📘 Note

It depends on the specific service whether sharing and unsharing service instances is available.

#### ⚠️ Restriction

You can only share service instances in the same subaccount.

For more information, see [btp share services/instance](#) and [btp unshare services/instance](#).

### 4.1.6.3.3 Compatible Changes in the Security Descriptor File

If you update a service instance, you can add, change, and/or delete scopes, attributes, and role templates. Whenever you change role templates, you adapt roles that are derived from the changed role template.

Compatible Changes in xs-security.json

Security Artifacts in the xs-security.json File	Action
Scope	<ul style="list-style-type: none"><li>• Add</li><li>• Delete</li><li>• Change<ul style="list-style-type: none"><li>• description</li><li>• granted-apps</li></ul></li></ul>
Attribute	<ul style="list-style-type: none"><li>• Add</li><li>• Delete</li><li>• Change<ul style="list-style-type: none"><li>• description</li></ul></li></ul>

#### 📘 Note

Do not change the valueType of the attribute.

## Security Artifacts in the xs-security.json File

### Action

- | Security Artifacts in the xs-security.json File | Action   |
|---|--|
| Role template                                   | <ul style="list-style-type: none"><li>• Add</li><li>• Delete</li><li>• Change<ul style="list-style-type: none"><li>• description</li><li>• scope-references</li><li>• attribute-references (can be deleted only)</li></ul></li></ul> |

#### ⚠ Restriction

When you define or update role templates and attributes, observe the following configuration restrictions in [Relationship Between default-values of attribute-references and valueRequired](#).

## 4.1.6.3.4 Retrieve Credentials for Remote Applications

You need to get the credentials of a service instance for an application that runs outside SAP BTP.

### Prerequisites

- A service instance for your application is available.

#### 📘 Note

For mutual transport layer security (mTLS), the application security descriptor supports the `binding-secret` and `x509` credential types by default. For the creation of a service key that enables the `x509` credential type, you need to pass a parameter file. See [Binding Parameters of SAP Authorization and Trust Management Service \[page 2115\]](#).

### Context

#### 📘 Note

Applications that run inside the service manager instance at SAP BTP get their credentials after the respective service has been bound to the application. However, you can't use binding for an application that runs outside of the service manager instance at SAP BTP.

Instead, you use a service key that is created in the service instance of the remote application. You need to get the credentials of the service instance for the remote application. The UAA service broker manages all

credentials, including those of the remote applications. The credentials you need are the OAuth 2.0 client ID and the client secret, or X.509 certificates.

First you generate a service key for the service instance of the remote application to enable access to the UAA service broker. Then you retrieve the generated service key with the credentials, including the OAuth 2.0 client ID and the client secret or X.509 certificates, from the UAA service broker. The remote application stores the service key. The application can now use this service key with the credentials (OAuth 2.0 client ID and the client secret of the remote application).

### → Remember

Rotate credentials before they expire or, if they don't expire, rotate them regularly (see [Security Recommendations for SAP Authorization and Trust Management Service \[page 2811\]](#)).

## Procedure

1. Create a service key for the service instance of the remote application. If you want to use mutual transport layer security (mTLS), you may need to request it in a separate binding configuration file (see [Enable mTLS Authentication to SAP Authorization and Trust Management Service for Your Application \[page 489\]](#) and [Binding Parameters of SAP Authorization and Trust Management Service \[page 2115\]](#)).

```
cf create-service-key <service_instance_name> <service-key-name>
```

### ❁ Example

```
cf create-service-key rem-app-service rem-app-sk
```

(For mTLS) `cf create-service-key <service_instance_name> <service-key-name> -c <parameter_file>`

### ❁ Example

```
cf create-service-key rem-app-service rem-app-sk -c parameters.json
```

The `parameters.json` file can have the following content for the usage of XSUAA-managed certificates:

### { } Sample Code

```
{
  "credential-type": "x509"
}
```

2. You want to retrieve the credentials including the OAuth 2.0 client ID and the client secret for the service instance of your remote application. Use the following command:

```
cf service-key <service_instance_name> <service_key_name>
```

### ❁ Example

```
cf service-key rem-app-service rem-app-sk
```

Output with default `binding-secret` credential type:

#### Output Code

```
{
  "apiurl": "https://api.authentication.corpdcen.acme.ondemand.com",
  "clientid": "sb-sample-app!t1",
  "clientsecret": "<client_secret>",
  "credential-type": "binding-secret",
  "identityzone": "uaa",
  "serviceinstanceid": "cbb63529-d725-4326-880c-92cbcd92",
  "subaccountid": "194e6a6d-c590-5030-98b3-1baa6d8fcda4",
  "tenantid": "095e5a7f-c480-5030-98b3-1cbb6e8fdb4",
  "uaadomain": "authentication.corpdcen.acme.ondemand.com",
  "url": "https://host.acme.com:40654/uaa-security",
  "xsappname": "sample-app!t1",
  "..."
```

(For mTLS) Output with `x.509` credential type:

#### Sample Code

```
{
  "credentials": {
    "apiurl": "https://api.authentication.corpdcen.acme.ondemand.com",
    "certificate": "-----BEGIN CERTIFICATE-----
\nMIIFvDCCA6...KJu+8fcIaUp7MVBIVZ\n>-----END CERTIFICATE-----\n",
    "certificate-pinning": true,
    "certurl": "https://mysubaccount-
hmq7frea.authentication.cert.corpdcen.acme.ondemand.com",
    "clientid": "sb-x5app!t75135",
    "credential-type": "x509",
    "key": "-----BEGIN RSA PRIVATE KEY-----\n<private_key>\n-----END RSA
PRIVATE KEY-----\n",
    "serviceinstanceid": "cbb52529-d614-4326-880c-92ba937bcc92",
    "subaccountid": "<subaccount_ID>",
    "tenantid": "194e6b7e-c370-4941-98b3-1cbb6e8fdb4",
    "uaadomain": "authentication.corpdcen.acme.ondemand.com",
    "url": "https://<subaccount>-
hmq7frea.authentication.corpdcen.acme.ondemand.com",
    "xsappname": "x5app!t75135",
    "..."
```

If your service needs an X.509 certificate and private key for mutual transport layer security (mTLS) in a single privacy enhanced mail (PEM) file, see [Extract Certificates for Mutual Transport Layer Security](#).

## 4.1.6.3.5 Configure Redirect URLs for Browser Logout

To avoid open redirect attacks, direct users to a safe and valid URL when they log out.

### Prerequisites

- You've an application that is using the application router.
- Use application router 5.7.0 or higher. For more information, see the related link.

### Context

You've deployed an application in the Cloud Foundry environment of SAP BTP. Business users log in and out of the application. As an application developer, you want to set a redirect URI, which directs users to a specific page once they've logged out. This page can be a logout page or your organization's employee portal. For security reasons, there's a check of this redirect URI.

- In the application descriptor (`xs-app.json`), you define a public logout page.
- To avoid redirects, for example to malicious web sites, `xsuaa` compares this public URL with a list of allowed redirect URLs. You define them in the OAuth 2.0 configuration property of the application security descriptor (`xs-security.json`).

### Procedure

1. Define `xs-app.json` in the application router folder of your application. Include a logout endpoint and define a logout page (here `logout.html`) which can be accessed without authentication.

#### Sample Code

```
{
  "welcomeFile": "index.html",
  "authenticationMethod": "route",
  "logout": {
    "logoutEndpoint": "/my/logout",
    "logoutPage": "logout.html"
  },
  "routes": [{
    "source": "^/hw/",
    "target": "/",
    "destination": "hw-dest",
    "scope": {
      "GET": [
        "$XSAPPNAME.Display",
        "$XSAPPNAME.Update"
      ],
      "default": "$XSAPPNAME.Update"
    }
  ]
}
```

```

    "source": "/index.html",
    "localDir": "resources",
    "cacheControl": "no-cache, no-store, must-revalidate"
  },
  {
    "source": "/logout.html",
    "localDir": "resources",
    "authenticationType": "none"
  },
  {
    "source": "^/(.*)",
    "localDir": "resources"
  }
]
}

```

2. Open a command prompt.
3. Log in to your Cloud Foundry environment using the Cloud Foundry command-line interface (cf CLI).
4. Choose your subaccount.

### Note

The cf CLI prompts you to choose an org. To find the org of your subaccount, use the cockpit to go to your subaccount. You can find the org in the Cloud Foundry tile under *Organization* (see [Navigate to Orgs and Spaces \[page 2246\]](#)).

5. Choose the space where your application is located.
6. Deploy the application to your space.
7. To define the redirect URIs, go to the folder where `xs-security.json` is stored.
8. Define the redirect URIs in the `oauth2-configuration` property.
9. Add a URL that contains the hostname of your application.

### Sample Code

```

{
  "xsappname": "<application_name>",
  "tenant-mode": "dedicated",
  "description": "My Sample Application with Application Router",
  "oauth2-configuration": {
    "token-validity": 900,
    "redirect-uris": [ "https://
<application_hostname>.<landscape_domain>/**"
    ],
    "autoapprove": "true"
  }
}

```

### Note

The application domain is the first part of the application URL: For more information, see the related link.

### Example

`myapplication.cfapps.hana.ondemand.com/**`

### ❖ Example

For China (Shanghai) region:

```
myapplication.mycustomdomain.cn/**
```

10. Update the `xsuaa` service instance that is bound to your application.

```
cf update-service <service_instance> -c xs-security.json
```

### 📘 Note

If the service instance isn't available, create it, bind your application to the service instance (see the related links), and restage the application.

You've implemented a valid redirect after logout, and `xsuaa` checks the redirect URL against the list of allowed URIs in the OAuth 2.0 configuration.

[Application Security Descriptor Configuration Syntax \[page 511\]](#)

[Security Considerations for the SAP Authorization and Trust Management Service \[page 2804\]](#)

### 4.1.6.3.6 Create Role Collections with Predefined Roles

As an application developer, you want to create role collections for immediate use. You want to deliver role collections that administrators can use in the cockpit, and easily assign to users, for example in an onboarding process.

## Prerequisites

- You have the `Space Developer` role in this subaccount (see the related link).

## Context

You define the role collections in the application security descriptor file (`xs-security.json`). These role collections reference role templates. As soon as you've deployed your application, the cockpit displays the role collections. They contain predefined roles.

## Procedure

1. Deploy an application you want to use for creating security artifacts.
2. Edit the application descriptor file (`xs-security.json`) and add the `role-collections` property.

### Sample Code

```
{
  "role-templates": [
    {
      "name": "Viewer",
      "description": "View Users",
      "scope-references": [
        "$XSAPPNAME.Display"
      ]
    },
    {
      "name": "Manager",
      "description": "Maintain Users",
      "scope-references": [
        "$XSAPPNAME.Display",
        "$XSAPPNAME.Update"
      ]
    }
  ],
  "role-collections": [
    {
      "name": "UserManagerRC",
      "description": "User Manager Role Collection",
      "role-template-references": [
        "$XSAPPNAME.Viewer",
        "$XSAPPNAME.Manager"
      ]
    }
  ]
}
```

3. Go to the folder where the application security descriptor (`xs-security.json`) file is stored.
4. To deploy the security information, create a service using your `xs.security.json` file.

```
cf create-service xsuaa application <service_name> -c xs-security.json
```

### Example

```
cf create-service xsuaa application rolecoll-serv -c xs-security.json
```

5. (If you do not use a manifest file) Bind your application to the service.

```
cf bind-service <application_name> <service_name>
```

### ❖ Example

```
cf bind-service rcpropertyapp rolecoll-serv
```

You have created a role collection that is visible in the cockpit. It contains predefined roles. Using the cockpit, administrators can assign this role collection to users.

[Tutorials for the SAP Authorization and Trust Management Service \[page 493\]](#)

## 4.1.6.3.7 Validation and Revocation of Access Tokens

To confirm that access tokens were truly issued by the SAP Authorization and Trust Management service and are still valid, applications check the tokens for validity.

Access tokens are JSON web tokens (JWT). When the SAP Authorization and Trust Management service issues access tokens for an application, the service sets a validity and digitally signs the token. The default validity for a token is 12 hours, but you can set the validity as part of the OAuth configuration in the application security descriptor (`xs-security.json`).

Applications must reject the access token in the following cases:

- The token is no longer valid.  
The token could have expired or has been revoked.
- The signature on the token doesn't match.

## Online or Offline Validation

As an application developer, you have the design decision, whether to perform validation of the token online or offline.

In online validation, you send a request to the SAP Authorization and Trust Management service to determine that the access token is still valid and hasn't been revoked. To check the validity, use the `introspect` endpoint of the standard Cloud Foundry API.

Your application can perform offline validation with the help of our client libraries. You must get the public key from the SAP Authorization and Trust Management service and use the key to check the validity. While validating a token offline can ensure that your application can continue to operate if the SAP Authorization and Trust Management service is unavailable, your application continues to accept revoked tokens until they reach the end of their validity. A malicious user with a revoked token still has access as long as the token is still valid.

To revoke a token, use the `revoke` endpoint of the standard Cloud Foundry API.

### 4.1.6.3.8 Include Tokens from Corporate Identity Providers or Identity Authentication in Tokens of the SAP Authorization and Trust Management Service

In scenarios where your SAP BTP application interacts with applications that don't support tokens issued by the SAP Authorization and Trust Management service, but require a token from a corporate identity provider or Identity Authentication, you can configure SAP Authorization and Trust Management service to include this token.

## Prerequisites

- Trust with an Identity Authentication tenant is configured with OpenID Connect (OIDC).  
For more information, see [Establish Trust and Federation Between SAP Authorization and Trust Management Service and Identity Authentication \[page 2015\]](#).
- Trust with a corporate identity provider by your Identity Authentication is configured with OIDC.  
For more information, see [Configure Trust with OpenID Connect Corporate Identity Provider](#) in the Identity Authentication documentation.
- The initial logon of your application uses the authorization code flow.

## Context

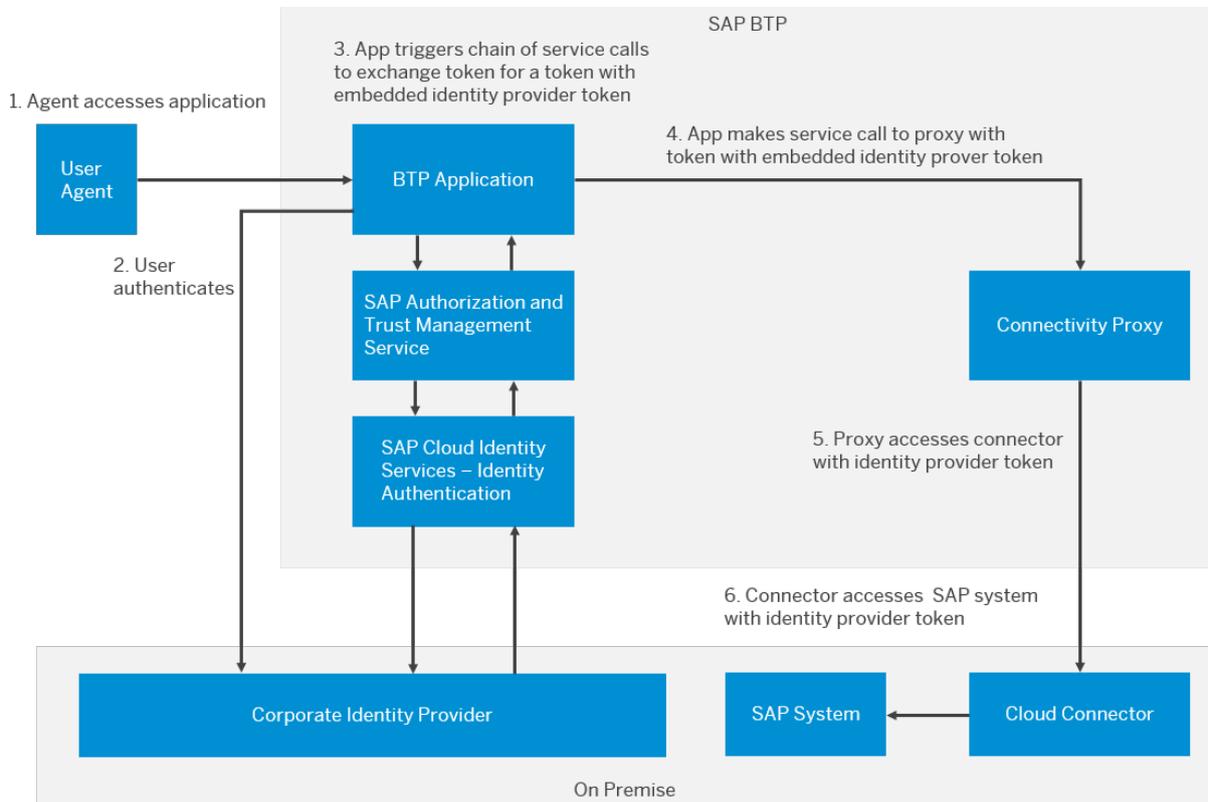

Imagine you have an on-premise SAP system that trusts your corporate provider. You want to access data in that system from an application on SAP BTP. Your application can get a token from SAP Authorization and Trust Management service, but you don't want to or can't configure your SAP system to trust that token.

In this scenario, configure the SAP Authorization and Trust Management service to embed the token of a corporate identity provider trusted by the trusted Identity Authentication tenant. In this example, before the SAP BTP application makes a service call to the Cloud Connector proxy, the application calls SAP Authorization

and Trust Management service to exchange its current token for a new token that embeds a token from the identity provider. Cloud Connector presents the identity provider token to the on-premise SAP system.

The following figure illustrates this scenario.

**Cloud Connector Using Embedded Tokens**

## Procedure

1. When deploying your application, ensure that the application security descriptor (`xs-security.json`) sets the `system-attributes` with one of the following options:

Value	Description
<code>ias-corporate-idp-token</code>	Embeds the token of the corporate identity provider trusted by your Identity Authentication tenant in the token issued by the service.
<code>ias-token</code>	Embeds the token of your trusted Identity Authentication tenant in the token issued by the service.

For more information about the application security descriptor, see [Application Security Descriptor Configuration Syntax \[page 511\]](#).

2. In the Identity Authentication application that represents your SAP BTP application, add the self-defined attribute `xsuaa-persist-corporate-idp-token` with the `Expression` source and `true` value.

This attribute ensures that the service knows to embed the tokens.

For more information, see [Configuring Attributes Based on Flexible Expressions](#) in the Identity Authentication documentation.

## Results

The service can embed tokens of trusted identity providers in its tokens.

## Next Steps

If you use Cloud Connector, ensure that the service doesn't trust SAP Authorization and Trust Management service. To use the token of the corporate identity provider, ensure that the service doesn't trust the Identity Authentication tenant, too.

For more information, see [Configure Trusted Entities in the Cloud Connector](#) in the documentation of SAP BTP Connectivity.

### 4.1.6.3.9 Best Practices When Handling Access Tokens

Calls to SAP Authorization and Trust Management service can fail for many reasons, including network latency, connection errors, service downtime, idle connections closed by routing components and so on. The following sections provide recommendations on when to retry connections and the caching of tokens.

How your application handles access tokens has an impact on its resiliency. Cache tokens to avoid running into the rate limiting restrictions of the SAP Authorization and Trust Management service. Retry with cached tokens instead of always getting a new one.

For recommended configuration settings, see [Security Considerations for the SAP Authorization and Trust Management Service \[page 2804\]](#).

## Retry Mechanism

When your application or service tries to get a token and fails, retry the connection. A retry mechanism helps your application handle temporary issues. We recommend retrying token retrieval three times by default. The following table lists when to retry and how often.

## Retry and Backoff for Different HTTP Responses

Event Type	HTTP Status Code	Retry	Backoff Policy
Connection error	None	Yes, retry up to three times.	Initial retry after 300 ms with a multiplier of 2.
Timeout	<ul style="list-style-type: none"><li>• 408: Request timeout</li><li>• 502: Bad gateway For example, request timeout from a Cloud Foundry Gorouter.</li><li>• 504: Gateway timeout</li></ul>	Yes, retry up to three times.	
Rate Limiting	429: Too many requests	Yes, retry up to three times.	Base retry on the <code>Retry-After</code> header.
Other Events	<ul style="list-style-type: none"><li>• 500: Internal server error</li><li>• 503: Service unavailable</li></ul>	Yes, retry up to three times.	Initial retry after 1000 ms with a multiplier of 3.
Access Control	<ul style="list-style-type: none"><li>• 401: Unauthorized</li><li>• 403: Forbidden</li></ul>	No, don't retry.	None.

## Token Cache

We recommend that you cache access tokens in your application as long as they're valid, instead of always getting a new token. If you constantly get a new token, you risk running up against the rate limits in the service and downtime for your application.

For more information, see [Rate Limiting \[page 2812\]](#).

However, renewing tokens before they actually expire improves the resiliency of your applications. If your application only renews tokens at their expiration and the service isn't available at that moment, your users experience a downtime. For example, if your token validity is set to 12 hours, try to renew the token after 6 hours.

Having a local cache also improves the performance of your applications.

Implement a method to remove invalid tokens from your cache. When your application calls with a token from your cache and receives the return codes in the following table, remove the token from your cache and request a new token.

## Triggers for Removing Tokens from Your Cache

HTTP Status Code	Potential Causes	Application Response
401: Unauthorized	<ul style="list-style-type: none"><li>The signing key of the token was rotated. For more information, see <a href="#">Rotate Signing Keys of Access Tokens [page 2122]</a>.</li><li>Token expired and your application hasn't removed it from your cache yet.</li></ul>	Remove the token from the cache and request a new token.
403: Forbidden	Occurs if the token is valid but a scope is missing.	

**Note**

Scopes of the client or user can have changed during the caching period.

### → Tip

SAP Authorization and Trust Management service ensures that keys remain valid for 2 hours after key rotations. Exception: When subaccount administrators force a key rotation, the key is immediately invalid. We recommend that you configure your cache with a 2-hour time-to-live (TTL). If you use a longer TTL, your application must be able to invalidate cache entries when the service responds with 401. Have your application only retry once on failure.

### ⚠ Restriction

When administrators force key rotation, applications that use cached tokens must accept a downtime until their caches have been cleared.

## Related Information

<https://github.com/SAP/cloud-security-services-integration-library/tree/main/token-client#cache-configuration>

## 4.1.6.4 Reference Information

Use additional reference information such as the syntax required to set the properties and values defined in the application security descriptor file.

You can also authenticate Node.js applications. A collection of Node.js packages developed by SAP is provided as part of the Cloud Foundry environment at SAP BTP

[Application Security Descriptor Configuration Syntax \[page 511\]](#)

The syntax required to set the properties and values defined in the `xs-security.json` application security descriptor file.

[Authentication for Node.js Applications \[page 528\]](#)

A collection of Node.js packages developed by SAP is provided as part of the Cloud Foundry environment at SAP BTP.

### 4.1.6.4.1 Application Security Descriptor Configuration Syntax

The syntax required to set the properties and values defined in the `xs-security.json` application security descriptor file.

```
{
  "xsappname" : "node-hello-world",
  "scopes" : [ {
    "name" : "$XSAPPNAME.Display",
    "description" : "display" },
    {
    "name" : "$XSAPPNAME.Edit",
    "description" : "edit" },
    {
    "name" : "$XSAPPNAME.Delete",
    "description": "delete",
    "granted-apps": [ "$XSAPPNAME(application,business-partner)" ]
    }
  ],
  "attributes" : [ {
    "name" : "Country",
    "description" : "Country",
    "valueType" : "string" },
    {
    "name" : "CostCenter",
    "description" : "CostCenter",
    "valueType" : "string" }
  ],
  "role-templates" : [ {
    "name" : "Viewer",
    "description" : "View all books",
    "default-role-name": "Viewer: Authorized to Read All Books",
    "scope-references" : [
      "$XSAPPNAME.Display" ],
    "attribute-references" : [
      {
        "name" : "Country",
        "default-values" : [
          "USA", "Germany"
        ]
      }
    ]
  }
]
```

```

    ],
    {
      "name" : "Editor",
      "description" : "Edit, delete books",
      "scope-references" : [
        "$XSAPPNAME.Edit",
        "$XSAPPNAME.Delete" ],
      "attribute-references" : [
        "Country",
        "CostCenter" ]
    }
  ],
  "authorities" : [ "$ACCEPT_GRANTED_AUTHORITIES" ],
  "oauth2-configuration" : {
    "token-validity" : 900,
    "redirect-uris" : [ "https://
myapp.cfapps.eu10.hana.ondemand.com", "https://myapp.mydomain.com/my/logout" ],
    "credential-type" : [ "binding-secret", "x509" ]
  },
  "xsenableasyncservice" : "true"
}

```

### → Tip

Try out the tutorials for the SAP Authorization and Trust Management service to get familiar with using the application security descriptor in the Cloud Foundry environment of SAP BTP.

See [Tutorials for the SAP Authorization and Trust Management Service \[page 493\]](#).

## xsappname

Use the `xsappname` property to specify the name of the application that the security description applies to.

```
"xsappname" : "<app-name>",
```

### Naming Conventions

Bear in mind the following restrictions regarding the length and content of an application name in the `xs-security.json` file:

- The following characters can be used in an application name of the Cloud Foundry environment at SAP BTP: `aA-zZ`, `0-9`, `-` (hyphen), `_` (underscore), `/` (forward slash), and `\` (backslash).
- The maximum length of an application name is 100 characters.

## tenant-mode (Custom Option)

Use the custom `tenant-mode` property to define the way the tenant's OAuth clients get their client secrets.

During the binding of the `xsuaa` service, the UAA service broker writes the tenant mode into the credential section. The application router uses the tenant mode information for the implementation of multitenancy with the application service plan.

## Sample Code

```
{
  "xsappname"      : "<application_name>",
  "tenant-mode"    : "shared",
  "scopes"         : [
    {
      "name"        : "$XSAPPNAME.Display",
      "description" : "display"
    }
  ]
}
```

### Syntax

```
"tenant-mode" : "shared"
```

The following tenant modes are available:

### Tenant Modes

Value	Description
dedicated	An OAuth client gets a separate client secret for each subaccount.
shared (default)	An OAuth client always gets the same client secret. It's valid in all subaccounts. The application service plan uses this tenant mode.
external	A tenant has multiple subscriptions to applications. For each subscription to an application, the tenant gets an OAuth client with a client secret.

## Note

If you don't specify `tenant-mode` in the `xs-security.json`, the UAA uses the `dedicated` tenant mode.

## scopes

In the application security file (`xs-security.json`), the `scopes` property defines an array of one or more security scopes that apply for an application. You can define multiple `scopes`; each scope has a name and a short description. The list of scopes defined in the `xs-security.json` file is used to authorize the OAuth client of the application with the correct set of **local** and **foreign** scopes; that is, the permissions the application requires to be able to respond to all requests.

```
"scopes": [
  {
    "name" : "$XSAPPNAME.Display",
    "description" : "display"
  },
  {
    "name" : "$XSAPPNAME.Edit",
    "description" : "edit"
  },
  {
    "name" : "$XSAPPNAME.Delete",
    "description" : "delete",
    "granted-apps" : [ "$XSAPPNAME(application,business-partner)" ]
  }
]
```

```
}  
]
```

## Local Scopes

All scopes in the `scopes` file is used to authorize the OAuth client of the application with the correct set section are local, that is, application specific. Local scopes are checked by the application's own application router or checked programmatically within the application's runtime container. In the event that an application needs access to other services of the Cloud Foundry environment on behalf of the current user, the provided access token must contain the required foreign scopes. Foreign scopes are not provided by the application itself; they're checked by other sources outside the context of the application.

In the `xs-security.json` file, "local" scopes must be prefixed with the variable `<XSAPPNAME>` at run time. The variable is replaced with the name of the corresponding local application name.

### → Tip

The variable `<XSAPPNAME>` is defined in the application's deployment manifest description (`manifest.yml`).

## Foreign Scopes

Usually, "foreign" scopes include the service plan and the name of the application to which the scope belongs. For more information, see [Referencing the Application](#) Use the following syntax:

```
<XSAPPNAME(<service_plan>,<xsappname>).<local_scope_name>
```

### 🔗 Example

```
"<XSAPPNAME(application,business-partner).Create"
```

## Granting Scopes to Another Application

If you want to grant a scope from this application to another application for a user scenario, this application needs to grant access to the scope for the application that wants to use this scope. Using the `granted-apps` property in the `scopes` section, you can specify the application you want to grant your scope to. The other application (referenced as `<service_plan>`, `<foreign_xsappname>`) receives the scope as a "foreign" scope. For more information, see the related link.

Here is the syntax in the security descriptor of the application that grants the scope. For more information, see [Referencing the Application](#).

```
"granted-apps" : [ "<XSAPPNAME(<service_plan>,<foreign_xsappname>)" ]
```

### 🔗 Example

```
"granted-apps" : [ "<XSAPPNAME(application,business-partner)" ]
```

If you want to grant a scope from this application to another application for a client credentials scenario, use the `grant-as-authority-to-apps` property in the `scopes` section. In this case, the scopes are granted as [authorities](#). Specify the other application by name. For more information, see the related link.

Here is the syntax in the security descriptor of the application that grants the scope:

```
"grant-as-authority-to-apps" : [ "<XSAPPNAME(<service_plan>,<foreign_xsappname>)" ]
```

## ❖ Example

```
"grant-as-authority-to-apps" : [ "$XSAPPNAME(application,business-partner)" ]
```

## Naming Conventions

Bear in mind the following restrictions regarding the length and content of a scope name:

- The following characters can be used in a scope name: aA–zZ, 0–9, – (hyphen), \_ (underscore), / (forward slash), \ (backslash), and : (colon).
- Scope names can't start with a leading . (period). For example, .myScopeName1.
- The maximum length of a scope name, including the fully qualified application name, is 193 characters.

For other limits when using the properties, see [Limits for the Application Security Descriptor \[page 2818\]](#).

## attributes

In the application security descriptor (`xs-security.json`), the `attributes` property enables you to define an array, listing one or more attributes that are applied to the role templates also defined in the `xs-security.json` element is only relevant for user scenarios file. You can define multiple `attributes`.

```
"attributes" : [  
  {  
    "name" : "Country",  
    "description" : "Country",  
    "valueType" : "s" },  
  {  
    "name" : "CostCenter",  
    "description" : "CostCenter",  
    "valueType" : "string" }  
],
```

The `attributes` element is only relevant for a user scenario. Each element of the `attributes` array defines an attribute. These attributes can be referenced by role templates. There are multiple sources of attributes:

- **Static attributes**  
Use the SAP BTP cockpit to assign the value of the attributes. You can use the static value.
- **Attributes from an identity provider**  
You can reference the attributes provided by an identity provider. The token is issued by the configured identity provider during authentication. You find the attribute value in the configuration of your identity provider. The attributes provided by the identity provider, appear as an attribute in the JSON web token, if the user has assigned the corresponding roles. You can use the attributes to achieve instance-based authorization checks.
- **Unrestricted attributes**  
In this case, you want to express that it's not necessary to set a specific value for this attribute. The behavior is the same as if the attribute would not exist for this role.

For more information, see the related link about attributes.

The `attributes` definition can take the following properties:

attributes Properties

Key	Description	Example
<code>name</code>	The name of the attribute with a value to apply when building the role template	<code>Country</code>
<code>description</code>	A short summary of the attribute defined	<code>Country</code>
<code>valueType</code>	The type of value expected for the defined attribute; possible values are: <code>string</code> (or <code>s</code> ), <code>int</code> (integer), or <code>date</code>	<code>int</code>
<code>valueRequired</code>	By default, every attribute needs dedicated attribute values. The default value is <code>true</code> .  For more information, see <a href="#">Relationship Between default-values of attribute-references and valueRequired</a> .	<code>true</code>

## Naming Conventions

Bear in mind the following restrictions regarding the length and content of attribute names in the `xs-security.json` file:

- The following characters can be used to declare an `xs-security` attribute name in the Cloud Foundry environment: "aA"- "zZ", "0"- "9", "\_" (underscore)
- The maximum length of a security attribute name is 64 characters.

For other limits when using the properties, see [Limits for the Application Security Descriptor \[page 2818\]](#).

## role-templates

In the application-security file (`xs-security.json`), the `role-templates` property enables you to define an array listing one or more roles (with corresponding scopes and any required attributes), which are required to access a particular application module. You can define multiple `role-templates`, each with its own scopes and attributes.

Role templates can be delivered with default values for each attribute reference. When you deploy role templates with default values for each attribute reference, you create default roles.

`attribute-references` can contain a JSON array of multiple objects.

```
"role-templates": [  
  {  
    "name"           : "Viewer",  
    "description"   : "View all books",  
    "default-role-name" : "Viewer: Authorized to Read All Books",  
    "scope-references" : [  
      "$XSAPPNAME.Display"  
    ],  
    "attribute-references": [  

```

```

    {
      "name" : "Country",
      "default-values" : [
        "USA", "Germany"
      ]
    }
  ]

```

`attribute-references` can contain a JSON array of string.

A role template must be instantiated. This is especially true with regard to any attributes defined in the role template and the specific attribute values, which are subject to customization and, as a result, can't be provided automatically. Role templates that only contain `"role-templates": [ { "name": "Viewer", "description": "View all books", "default-role-name": "Viewer: Authorized to Read All Books", "scope-references": [ "$XSAPPNAME.Display" ], "attribute-references": [ "Country" ] }, ]` "local" role-templates: [ scopes can be instantiated without user interaction. The same is also true for "foreign" scopes where the scope **owner** has declared consent in a kind of allowlist (for example, either for "public" use or for known "friends").

### Note

The resulting (application-specific) role instances need to be assigned to the appropriate user groups.

role-template Properties

Key	Description	Example
<code>name</code>	The name of the role to build from the role template	Viewer
<code>description</code>	A short summary of the role to build	View all books
<code>default-role-name</code>	The name of the role in Unicode The name can be up to 255 characters long. The naming conventions of <code>role-templates</code> don't apply here.	Viewer: Authorized to Read All Books
<code>scope-references</code>	The security <b>scope</b> to apply to the application-related role	<code>\$XSAPPNAME.Display</code>

Key	Description	Example
<code>attribute-references</code>	<p>One or more attributes to apply to the built role. You can use a JSON array of objects or of string.</p> <p>If you use an array of objects, <code>name</code> is the name of the attribute. Use the attribute name specified in the <code>attributes</code> section.</p> <p><code>default-values</code>, for example <code>"default-values"</code> : <code>[ "LeaveRequestWorkflow" ]</code>. If you don't want to configure default values, don't specify the <code>default-values</code> element.</p> <p>For more information, see <a href="#">Relationship between default-values of attribute-references and valueRequired</a>.</p>	<div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>↔ Sample Code</p> <pre>{   "name" :   "Country",   "default-values" : [ "USA",     "Germany" ] }</pre> </div> <p>(an array of objects)</p> <p><code>[ "Country" ]</code> (an array of string)</p>
	<div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>→ Tip</p> <p>If you want to deliver attributes that aren't restricted by attribute values, set <code>"valueRequired": false</code>.</p> </div>	

## Naming Conventions

Bear in mind the following restrictions regarding the length and content of role-template names in the `xs-security.json` file:

- The following characters can be used to declare an xs-security role-template name: "aA"- "zZ", "0"- "9", "." (period), "-" (hyphen), "\_" (underscore).
- The maximum length of a role-template name is 64 characters.

For other limits when using the properties, see [Limits for the Application Security Descriptor \[page 2818\]](#).

## role-collections

The optional `role-collections` property enables you to define role collections with predefined roles. Administrators use these predefined role collections. They can assign them to users during the initial setup of SAP BTP.

The `role-collections` property only makes sense if application developers reference role templates that can create default roles at deployment time.

### Note

The `role-collections` element can only reference role templates of the same subaccount.

## Sample Code

```
"role-collections": [
  {
    "name": "Employee",
    "description": "Employee roles",
    "role-template-references": [
      "$XSAPPNAME.Employee"
    ]
  }
]
```

role-collections Properties

Key	Description	Example
name	The name of the role collection to build	Employee
	<b>⚠ Caution</b> If you change the name of a role collection and update the service instance, you delete the role collection with the old name and create a role collection with the new name. This means that the newly created role collection doesn't have any user assignments.	
description	A short summary of the role collection to build	Employee roles
role-template-references	The role templates referenced by the role collections property	\$XSAPPNAME.Employee Syn- tax\$XSAPPNAME(<service_p lan>, <xsappname>)
		<b>❖ Example</b> \$XSAPPNAME(application, myapp2)

## Naming Conventions

Bear in mind the following restrictions regarding the length and content of `role-collections` names in the `xs-security.json` file:

- The maximum length of a role-collection name is 64 characters.
- The maximum length of a role-collection description is 1000 characters.
- The `role-template-references` (mandatory) element is an array with references to role template definitions from the Cloud Foundry application or from other Cloud Foundry applications.

### → Tip

We recommend that you reference all role templates using either the `XSAPPNAME` or `XSAPPNAME(<service_plan>, <XSAPPNAME>)` prefix to link to the correct application where the role template is defined (see [Referencing the Application](#)).

## Conditions

The role templates must fulfill one of the following conditions regarding attributes:

- Either they don't have attribute references.
- Or default attribute values are defined. It's also possible to add the `"valueRequired" : false` property to an attribute.

This makes sure that a default role is automatically created for the role-templates after developers have deployed the application. The role collections use the predefined roles, which have been created automatically.

For other limits when using the properties, see [Limits for the Application Security Descriptor \[page 2818\]](#).

## authorities

To enable one (sending) application to accept and use the authorization scopes granted by another application, each application must be bound to its own instance of the `xsuaa` service. This is required to ensure that the applications are registered as OAuth 2.0 clients at the UAA. You must also add an `authorities` property to the security descriptor file of the sending application that is requesting an authorization scope. In the `authorities` property of the sending application's security descriptor, you can either specify that **all** scope authorities configured as grantable in the receiving application should be accepted by the application requesting the scopes, or alternatively, only individual, named, scope authorities:

- Request and accept **all** authorities flagged as "grantable" in the receiving application's security descriptor:

### Sample Code

Specifying Scope Authorities in the Sending Application's Security Descriptor

```
"authorities" : [ "$ACCEPT_GRANTED_AUTHORITIES" ]
```

- Request and accept only the "specified" scope authority that is flagged as grantable in the specified receiving application's security descriptor. For more information, see [Referencing the Application](#).

### Sample Code

Specifying Scope Authorities in the Sending Application's Security Descriptor

```
"authorities" : [ "<ReceivingApp>.ForeignCall",  
  "<ReceivingApp2>.ForeignCall", ]
```

Since both the sending application and the receiving application are bound to UAA services using the information specified in the respective application's security descriptor, the sending application can accept and use the specified authority from the receiving application. The sending application is now authorized to access the receiving application and perform some tasks.

### 📌 Note

The granted authority always includes the prefixed name of the application that granted it. This information tells the sending application, which receiving application has granted which set of authorities.

The scope authorities listed in the sending application's security descriptor must be specified as "grantable" in the receiving application's security descriptor.

### → Tip

To flag a scope authority as "grantable", add the `grant-as-authority-to-apps` property to the respective scope in the receiving application's security descriptor.

For more information, see the related link.

## oauth2-configuration (Custom Option)

Use the custom `oauth2-configuration` property to define custom values for the OAuth 2.0 clients, such as the token validity and redirect URIs.

The `xsuaa` service broker registers and uses these values for the configuration of the OAuth 2.0 clients.

### 📄 Sample Code

```
"oauth2-configuration": {
  "token-validity": 43200,
  "redirect-uris": [
    "https://myapp.cfapps.eu10-004.hana.ondemand.com",
    "https://myapp.mydomain.com/my/content" ],
  "refresh-token-validity": 1800,
  "credential-type": [ "binding-secret", "x509" ],
  "system-attributes": [ "groups", "rolecollections" ],
  "allowedproviders": [ "origin_key1", "origin_key2" ]
}
```

The following configuration keys are available:

oauth2-configuration Properties

Key	Description	Example
<code>token-validity</code>	<p>Sets the token lifetime in seconds for access tokens issued by SAP Authorization and Trust Management service. The value ranges from 60 seconds to 86400 seconds, in other words, from 1 minute to 24 hours.</p> <p>Default: 43200 seconds (12 hours)</p> <div data-bbox="576 685 1042 1043"><p><b>→ Recommendation</b></p><p>Relaxing the token policy means that users reauthenticate less. However, increasing the token validity also means that if a malicious user manages to steal a token, that malicious user has access until the token expires. Keep token validity in the subaccount as short as possible, but not less than 30 minutes.</p></div> <div data-bbox="576 1061 1042 1397"><p><b>ⓘ Note</b></p><p>This change applies to applications, which consume or subscribe to this instance. These values override the values set for the subaccount.</p><p>For more information, see <a href="#">Configure Token Policy for SAP Authorization and Trust Management Service [page 2130]</a>.</p></div>	1800 (30 minutes)
<code>refresh-token-validity</code>	<p>Sets the token lifetime in seconds for refresh tokens issued by SAP Authorization and Trust Management service. The value ranges from 60 seconds to 31536000 seconds, in other words, from 1 minute to 1 year.</p> <p>Default: 604800 seconds (7 days)</p>	604800 (7 days)

Key	Description	Example
<code>redirect-uris</code>	<p>This key contains a list of the redirect URIs that SAP BTP checks for when redirecting. If your landscape domain or custom domain aren't on this list, including wildcards, the Authorization and Trust Management Service won't redirect users there.</p> <p>We support explicit wildcards, namely domain relaxing and arbitrary paths. For example: <code>"https://*.mydomain.com/callback/**"</code></p> <div style="border: 1px solid orange; padding: 5px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>If you use wildcards, we recommend that you make your URIs as specific as possible. By using wildcards, you open up the redirect for multiple web sites. Wildcards increase the risk of redirecting to malicious web sites.</p> </div> <p>For more information, see <a href="#">Listing Allowed Redirect URIs [page 2805]</a>.</p>	<pre>[ "https://&lt;application_ hostname1&gt;.&lt;landscape_d omain&gt;&lt;path&gt;", "https:// &lt;application_ hostname2&gt;.&lt;custom_doma in&gt;&lt;path&gt;" ]</pre>
<code>credential-type</code>	<p>Specifies the types of secrets available for binding applications to the service instance. The first type listed is the default type of secret. Otherwise, specify the type of secret when you create the binding or service key.</p> <p>For more information, see <a href="#">Service Instance Secrets [page 2108]</a>.</p> <p>The default value is <code>instance-secret</code>. With <code>instance-secret</code> all bindings of a service instance of the SAP Authorization and Trust Management service share a single instance secret.</p> <div style="border: 1px solid blue; padding: 5px; margin-top: 10px;"> <p><b>→ Recommendation</b></p> <p>Use <code>binding-secret</code> or <code>x509</code> so you can rotate the secret of a single binding without affecting other bindings of the service instance.</p> <p>For more information, see <a href="#">Rotating Secrets [page 2806]</a>.</p> </div>	<pre>[ "binding-secret" ]</pre>

Key	Description	Example
system-attributes	<p>Includes the system attributes in the JWT. If you don't define a value, the system includes the attributes for groups and role collections by default. If the size of the JWT becomes an issue for you, you can explicitly remove them. For example: "system-attributes": [ ],</p> <p>You can also have the service include a refresh token of a trusted identity provider.</p> <p>For more information, see <a href="#">Include Tokens from Corporate Identity Providers or Identity Authentication in Tokens of the SAP Authorization and Trust Management Service [page 506]</a>.</p> <p><b>Values:</b></p> <ul style="list-style-type: none"> <li>• <b>"groups"</b> includes the <code>xs.saml.groups</code> attribute.</li> <li>• <b>"rolecollections"</b> includes the <code>xs-rolecollections</code> attribute.</li> <li>• <b>"ias-corporate-idp-token"</b> includes the token of the corporate identity provider trusted by your Identity Authentication tenant.</li> <li>• <b>"ias-token"</b> includes the token of the trusted Identity Authentication tenant.</li> </ul>	[ "groups" , "rolecollections" ]
allowedproviders	<p>Includes an array of allowed identity providers. The default is that all identity providers are allowed.</p> <p>As an option, developers can configure on application level which identity providers can be used for business users to log on to a certain application. The value of <code>allowedproviders</code> is the origin key of your identity provider. You find the origin key in your subaccount in the <a href="#">Security &gt; Trust Configuration</a> page of your identity providers.</p> <div style="background-color: #e0e0e0; padding: 10px; border: 1px solid #ccc;"> <p><b>→ Recommendation</b></p> <p>We recommend that you configure allowed identity providers on subaccount level. For more information, see <a href="#">Using Multiple Identity Providers from the Same Subaccount [page 2044]</a>.</p> </div>	[ "origin_key1" , "origin_key2" ]

## xsenableasynservice (Custom Option)

The `xsenableasynservice` element controls whether the `cf create-service` and `cf update-service` commands of the Cloud Foundry command line interface (cf CLI) are executed synchronously (false) or asynchronously (true).

### → Remember

The Cloud Controller of Cloud Foundry times out after 60 seconds for the synchronous execution of the commands. For this reason, we recommend that you use asynchronous execution for multitenant applications or reuse services.

### 📌 Note

You usually need to wait for the completion of `cf create-service` and `cf update-service` even if you use asynchronous mode. Otherwise you might run into conflicts due to parallel update operations on the OAuth 2.0 clients.

### 📄 Sample Code

```
"xsenableasynservice": "true"
```

### Syntax

```
"xsenableasynservice": "false"
```

Value	Description
false (default)	Cloud Foundry command line interface commands are executed synchronously.
true	Cloud Foundry command line interface commands are executed asynchronously.

## Referencing the Application

If you want to grant scopes to an application for example, you must reference this application. Depending on where the application is located, you can reference an application in multiple ways:

- Referencing the application of the current `xs-security.json` file
- Referencing a foreign application that is located in the same subaccount

## Application References

Description	Syntax
Application in the current <code>xs-security.json</code> file	<code>\$XSAPPNAME</code>
Application in the same subaccount	<code>\$XSAPPNAME(&lt;service_plan&gt;, &lt;xsappname&gt;)</code>
	<div style="border: 1px solid #ccc; padding: 5px; margin-bottom: 5px;"> <p><b>Note</b></p> <p>Currently, you can only use the application service plan.</p> </div> <div style="border: 1px solid #ccc; padding: 5px;"> <p><b>Example</b></p> <pre>\$XSAPPNAME(application,business-partner)</pre> </div>
Reference to any service instance in the same sub-account and space	<code>\$XSSEVICENAME(&lt;service_instance_name&gt;)</code> This is the service instance name you used when you created it.

You can use these references with the following properties:

### Properties

Property	Description	Example
<code>granted-apps</code>	Granting scopes to other applications.	<p><b>Sample Code</b></p> <pre>"granted-apps" : [ "\$XSAPPNAME(application,business-partner)" ]</pre> <pre>"granted-apps" : [ "\$XSAPPNAME(application,business-partner1)", "\$XSAPPNAME(application,business-partner2)" ]</pre>
<code>grant-as-authority-to-apps</code>	Use this property if you want to grant a scope to other applications for a client credential scenario.	<p><b>Sample Code</b></p> <pre>"grant-as-authority-to-apps" : [ "\$XSAPPNAME(application,business-partner)" ]</pre> <pre>"grant-as-authority-to-apps" : [ "\$XSAPPNAME(application,business-partner1)", "\$XSAPPNAME(application,business-partner2)" ]</pre>

Property	Description	Example
authorities	Granting authorities (for a client credentials scenario)	<pre>{ Sample Code  "authorities": [ "\$XSAPPNAME(application,business-partner)" ]</pre>
scope-references	Referencing scopes in role templates	<pre>{ Sample Code  \$XSAPPNAME.Display</pre>
foreign-scope-references	Using this property, you can reference scopes in foreign applications (for a user scenario).	<pre>{ Sample Code  "foreign-scope-references": [ "\$XSAPPNAME(application,business-partner)" ]  "foreign-scope-references": [ "\$XSAPPNAME(application,business-partner1)", "\$XSAPPNAME(application,business-partner2)" ]</pre>

## Relationship Between `default-values` of `attribute-references` and `valueRequired`

When you define role templates and attributes in the `xs-security.json` file, you need to know that there's a relationship between `default-values` of `attribute-references` in the role template and `valueRequired` in the attribute. What is important to know is that you configure `valueRequired` in the current attribute definition independently from any role template. The attributes are later referenced in the role templates using the `attribute-references` element.

This means that an attribute can be referenced in multiple role templates. You can set `default-values` for the first role template and not for the second one. If you define an attribute with `"valueRequired": true` (see rows 1 and 3), a default role can be generated automatically for the first role template only, but not for the second one.

### Configuration Examples

Use Case	Role Template	Attribute
A default role with default values is generated automatically. Administrators must set attribute values for their roles.	<pre>"default-values": [ "&lt;attribute_value&gt;" ]</pre>	<pre>"valueRequired" : true</pre> <p>or no <code>valueRequired</code> key at all</p>

Use Case	Role Template	Attribute
A default role with default values is generated automatically. Administrators don't have to set attribute values for their role. A role that isn't restricted by attributes (unrestricted) is created.	<pre>"default-values": [ "&lt;attribute_value&gt;" ]</pre>	<pre>"valueRequired" : false</pre>
A default role is generated automatically. Administrators don't have to set attribute values for their roles. A role that isn't restricted by attributes (unrestricted) is created.	No default-values element	<pre>"valueRequired" : false</pre>

### ⚠ Restriction

When you define role templates and attributes, observe the following configuration restriction:

- Do not add `attribute-references` without `default-values`, where `attribute` is defined with `"valueRequired" : true`.

When you update role templates and attributes, observe the following configuration restrictions:

- Do not change `default-values` of `attribute-references`.
- Do not change the `"valueRequired"` property from `false` to `true`.

### 4.1.6.4.2 Authentication for Node.js Applications

A collection of Node.js packages developed by SAP is provided as part of the Cloud Foundry environment at SAP BTP.

SAP BTP includes a selection of standard Node.js packages, which are available for download and use from the SAP NPM public registry to customers and partners. SAP BTP only includes the Node.js packages with long-time support (LTS). For more information, see <https://nodejs.org>. Enabling access to an NPM registry requires configuration using the SAP NPM Registry.

- Besides the standard NPM Package Manager, you can use the NPM Package Manager to download the packages from the npm repository.  
<https://registry.npmjs.org>

- As an alternative option, you can use the `SAP_CLIENT_LIB 1.0`. Search for the software component named `SAP_CLIENT_LIB 1.0` on the ONE Support Launchpad.  
[ONE Support Launchpad](#)

The `SAP_CLIENT_LIB 1.0` package contains the following modules:

#### → Tip

For more details of the package contents, see the `README` file in the corresponding package.

Contents of `SAP_CLIENT_LIB 1.0`

Package Name	Description
<a href="#">@sap/approuter</a>	The application router is the single entry point for the (business) application.
<a href="#">@sap/xssec</a>	The client security library, including the XS advanced container security API for Node.js

## @sap/approuter

The application router is the single entry point for the (business) application. It has the responsibility to serve static content, authenticate users, rewrite URLs, and proxy requests to other micro services while propagating user information.

For more information, see the applications section of SAP BTP.

## @sap/xssec

The client security library includes the container security API for Node.js.

Authentication for node applications relies on the usage of the OAuth 2.0 protocol, which is based on central authentication at the User Account and Authentication (UAA) server that then vouches for the authenticated user's identity by means of a so-called OAuth access token. The implementation uses as access token a JSON web token (JWT), which is a signed text-based token formatted according to the JSON syntax.

The trust for the offline validation is created by binding the UAA service instance to your application. The key for validation of tokens is included in the credentials section in the environment variable `<VCAP_SERVICES>`. By default, the offline validation check only accepts tokens intended for the same OAuth 2.0 client in the same UAA subaccount. This makes sense and covers the majority of use cases. However, if an application needs to consume tokens that were issued either for different OAuth 2.0 clients or for different subaccounts, you can specify a dedicated access control list (ACL) entry in an environment variable named `<SAP_JWT_TRUST_ACL>`. The name of the OAuth 2.0 client has the prefix `sb-`. The content is a JSON string. It contains an array of subaccounts and OAuth 2.0 clients. To establish trust with other OAuth 2.0 clients and/or subaccounts, specify the relevant OAuth 2.0 client IDs and subaccounts.

#### ⚠ Caution

For testing purposes, use an asterisk (\*). This setting should never be used for productive applications.

Subaccounts are not used for on-premise systems. The value for the subaccount is `uaa`.

```
SAP_JWT_TRUST_ACL: [ { "clientid": "<OAuth_2.0_client_ID>", "subaccount": "<subaccount>" }, ... ]
```

### ⚠ Caution

The client libraries (java-security, spring-xsuaa, and container security api for node.js >= 3.0.6) have been updated. When using these libraries, setting the parameter `SAP_JWT_TRUST_ACL` has become obsolete. This update comes with a change regarding scopes. For a business application A that wants to call an application B, it's now mandatory that application B grants at least one scope to the calling business application A. Furthermore business application A has to accept these granted scopes or authorities as part of the application security descriptor. You can grant scopes with the `xs-security.json` file. For more information, see [Application Security Descriptor Configuration Syntax \[page 511\]](#), specifically the sections "Referencing the Application" and "Authorities".

In a typical deployment scenario, your node application consists of several parts, which appear as separate application modules in your manifest file, for example:

- Application logic  
This application module (`<myAppName>/js/`) contains the application logic: code written in Node.js. This module can make use of this *XS Advanced Container Security API for Node.js*.
- UI client  
This application module (`<myAppName>/web/`) is responsible for the UI layer; this module can make use of the application router functionality (defined in the file `xs-app.json`).

### 📌 Note

The application logic written in Node.js and the application router should be bound to one and the same UAA service instance so that these two parts use the same OAuth client credentials.

To use the capabilities of the container security API, add the module `@sap/xssec` to the dependencies section of your application's `package.json` file.

### 📌 Note

To enable tracing, set the environment variable `DEBUG` as follows: `DEBUG=xssec:*`.

## Usage

All SAP modules, for example `@sap/xssec`, are located in the namespace of the SAP NPM registry. For this reason, you must use the SAP NPM registry and the default NPM registry.

Path to the NPM registries:

NPM Registry	Path
SAP NPM registry	<code>@sap:registry = "https://registry.npmjs.org"</code>
Default NPM registry	<code>registry = "http://registry.npmjs.org/"</code>

If you use express and passport, you can easily plug a ready-made authentication strategy.

## Sample Code

```
var express = require('express');
var passport = require('passport');
var JWTStrategy = require('@sap/xssec').JWTStrategy;
var xsenv = require('@sap/xsenv');
...
var app = express();
...
passport.use(new JWTStrategy(xsenv.getServices({uaa:{tag:'xsuaa'}}).uaa));
app.use(passport.initialize());
app.use(passport.authenticate('JWT', { session: false }));
```

We recommend that you disable the session as in the example above. Each request comes with a JWT token so it is authenticated explicitly and identifies the user. If you still need the session, you can enable it but then you should also implement user serialization/deserialization and some sort of session persistency.

## Container Security API

### → Tip

For more details of the package contents, see the `README` file in the corresponding package.

Container Security API

API	Description
<code>createSecurityContext</code>	<p>Creates the "security context" by validating the received access token against credentials put into the application's environment via the UAA service binding</p> <p>Returns a structure with the following properties:</p> <ul style="list-style-type: none"><li><code>getLogonName</code></li><li><code>getGivenName</code></li><li><code>getFamilyName</code></li><li><code>getEmail</code></li><li><code>getHdbToken</code></li><li><code>getAdditionalAuthAttribute</code></li><li><code>getExpirationDate</code></li><li><code>getGrantType</code></li></ul>
<code>checkLocalScope</code>	Checks a scope that is published by the current application in the <code>xs-security.json</code> file
<code>checkScope</code>	Checks a scope that is published by an application

API	Description
<code>getToken</code>	<p>Returns a token that can be used to connect to the SAP HANA database. If the token that the security context has been instantiated with is a foreign token (meaning that the OAuth client contained in the token and the OAuth client of the current application do not match), "null" is returned instead of a token; the following attributes are available:</p> <ul style="list-style-type: none"> <li> <b>namespace</b>  Tokens can be used in different contexts, for example, to access the SAP HANA database, to access another XS advanced-based service such as the Job Scheduler, or even to access other applications or containers. To differentiate between these use cases, the namespace is used. In <code>lib/constants.js</code> we define supported name spaces (for example, <code>SYSTEM</code>). </li> <li> <b>name</b>  The name is used to differentiate between tokens in a given namespace, for example, "HDB" for the SAP HANA database. These names are also defined in the file <code>lib/constants.js</code>. </li> </ul>
<code>hasAttributes</code>	<p>Returns "true" if the token contains any XS advanced user attributes; otherwise "false".</p>
<code>getAttribute</code>	<p>Returns the attribute exactly as it is contained in the access token. If no attribute with the given name is contained in the access token, "null" is returned. If the token that the security context has been instantiated with is a foreign token (meaning that the OAuth client contained in the token and the OAuth client of the current application do not match), "null" is returned regardless of whether the requested attribute is contained in the token or not. The following attributes are available:</p> <ul style="list-style-type: none"> <li> <b>name</b>  The name of the attribute that is requested </li> </ul>
<code>isInForeignMode</code>	<p>Returns "true" if the token, that the security context has been instantiated with, is a foreign token that was not originally issued for the current application, otherwise "false".</p>
<code>getIdentityZone</code>	<p>Returns the subaccount that the access token has been issued for.</p>

## 4.1.7 Setting Up Database Artifacts

Learn how to set up database artifacts using SAP HANA.

SAP HANA is an innovative in-memory relational database management system that you can leverage when developing in the SAP BTP, Cloud Foundry environment. It minimizes data movements by making it possible for you to work with the data directly in memory.

With SAP HANA, you can leverage current hardware capabilities to increase performance and reduce costs, for example by building applications that integrate the business control logic and database layer.

#### Note

In the Cloud Foundry environment, the SAP HANA database supports up to 1,000 simultaneous connections per database.

We recommend using SAP HANA Cloud when following a multitarget application (MTA) approach.

To find out more about the tools, data modeling strategy, and development scenarios, see [Developing SAP HANA in the Cloud Foundry Environment \[page 533\]](#).

## 4.1.7.1 Developing SAP HANA in the Cloud Foundry Environment

Find here selected information for SAP HANA database development and references to more detailed sources.

This section gives you information about database development and its surrounding tasks especially if you want to explore the SAP BTP, Cloud Foundry environment. To get more into detail, we have references to other guides and the SAP HANA Cloud service documentation. The context we're looking at is multitarget application (MTA) development, whereby SAP HANA is the database module and you develop all artifacts in that module.

There are multiple scenarios when you start using SAP HANA Cloud in the SAP BTP, Cloud Foundry environment. For each of these scenarios, we give you a recommendation:

Scenario	Recommendation
You're starting a new project and want to leverage SAP HANA capabilities in the cloud.	We recommend using the SAP Cloud Application Programming Model and SAP HANA Cloud.  <a href="#">See SAP HANA Cloud [page 534]</a>
You're using SAP HANA service for SAP BTP and SAP HANA Platform 2.0 (XS advanced) on-premise.	Get to know the differences. Read about features that have been supported by other SAP HANA versions but aren't supported by SAP HANA Cloud: <a href="#">SAP HANA Cloud Compatibility Reference</a>

Scenario	Recommendation
<p>You're using SAP HANA Platform 2.0 (XS advanced) on-premise.</p>	<p>SAP HANA extended application services, advanced model, (XS advanced) as the runtime environment for SAP HANA Platform was built similar to the Cloud Foundry environment. It has been developed further and therefore contains features that aren't available in Cloud Foundry. Some features aren't supported from the SAP HANA versions in the cloud. So, there's always some effort, at least when you reach a decent amount of complexity, to make an XS advanced application run in the cloud.</p> <p>The new SAP HANA Cloud service made significant moves to reduce footprint and be cloud-ready. Therefore, previously deprecated features have been removed. Read about <a href="#">SAP HANA Cloud Compatibility and Migration Information</a>:</p> <ul style="list-style-type: none"> <li>• <a href="#">High Level Feature Compatibility</a></li> <li>• <a href="#">Design-time Content Compatibility</a></li> </ul> <p>You can find another collection of these features and elements in the following SAP Note:<a href="#">2868742</a> </p>
<p>You're using SAP HANA Platform 1.0 (XS classic) on-premise. This scenario also includes any usage of XS classic artifacts even if you use XS advanced (compatibility) or the Neo environment</p>	<p>This scenario is presumably a bigger project. The task isn't only to use a different version of SAP HANA but also to make architectural changes: from monolithic applications to microservice-based applications. To give you an overview on things you need to consider, have a look at our guide: <a href="#">Migrating from the Neo Environment to the Multi-Cloud Foundation (Cloud Foundry and Kyma)</a></p>

### 4.1.7.1.1 SAP HANA Cloud

This section is a quick introduction to the latest SAP HANA offering on SAP BTP, Cloud Foundry environment. In essence, you get to know the most important tools and information about data modeling. This content is meant to provide an overview. Please follow the links to the content you're interested in and start your learning journey.

#### Tools

There are two tools you need to know, SAP Business Application Studio and SAP HANA Cockpit.

- SAP Business Application Studio  
SAP Business Application Studio is the recommended tool to develop your SAP HANA database artifacts. You can use an [SAP HANA Native Application](#) dev space, which is preconfigured to support the creation of database artifacts.  
For SAP Cloud Application Programming Model projects, we recommend to create a [Full Stack Cloud Application](#) dev space and add the following extensions:
  - SAP HANA Calculation View Editor
  - SAP HANA Tools
  - SAP HANA Smart Data Integration Tools

With that configuration you have the editors and tools for the programming model and SAP HANA database artifacts.

- **SAP HANA Cockpit**  
The SAP HANA Cockpit is used to monitor and administer your SAP HANA instances, see [Open the SAP HANA Cockpit](#)  
To learn how to access the SAP HANA Cockpit, see [Accessing SAP HANA Cockpit for SAP HANA Cloud](#)

## Data Modeling

To develop your data model, we recommend the SAP Cloud Application Programming Model.

- The SAP Cloud Application Programming Model (CAP) provides a guide explaining the concepts and best practices of domain modeling using CAP CDS, see [Domain Modeling](#)
- To define your data models, queries and expressions, there's a CAP CDS reference guide. It contains samples and best practices that support your learning journey. See [Core Data Services \(CDS\) - Language Reference Documentation for the application programming model](#).
- You have existing database objects and want to use them with CAP CDS. Learn about facade entities in CAP CDS and how to design them. See [Native SAP HANA](#).

When you've created your data model with the SAP Cloud Application Programming Model, you want to leverage more of the SAP HANA power. The SAP HANA Cloud documentation provides an extensive library of guides. Find here selected links that make an easy start.

- [SAP HANA Cloud Modeling Guide for SAP Web IDE Full-Stack](#)
- [SAP HANA Cloud product page, development overview](#)

## References

- [Feature Scope Description for SAP HANA Cloud](#)

## 4.1.8 Deploying to the Cloud Foundry Environment

Get an overview of available deployment options.

When deploying applications and services to the cloud, you can choose from a number of different approaches and tools, depending on your development setup.

## Multitarget Applications

If you've decided to develop your application or service with the multitarget approach, you can deploy it to SAP BTP using a single `.mtar` archive file. For more information, see [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#).

## Continuous Integration and Delivery

Continuous Integration and Delivery (CI/CD) are two interrelated concepts that can enhance your development process by adding frequent integration, automated testing, and faster delivery. For more information, see [Continuous Integration and Delivery \[page 644\]](#).

## Cloud Foundry Command Line Interface

If you prefer to develop on your local machine, you can deploy your application from the folder on your computer directly to SAP BTP using the Cloud Foundry Command Line Interface (CF CLI). For more information, see [Deploy Business Applications in the Cloud Foundry Environment \[page 648\]](#).

## Docker Images

If you want a higher degree of freedom when realizing your project, you can also deploy your applications and services using Docker images and the Cloud Foundry Command Line Interface (CF CLI). Note that Docker images can't be used in combination with buildpacks. For more information, see [Deploy Docker Images in the Cloud Foundry Environment \[page 649\]](#).

### 4.1.8.1 Multitarget Applications in the Cloud Foundry Environment

A Multitarget application (MTA) is essentially a single application that consists of multiple parts. These parts are created using various technologies and share the same lifecycle.

The MTA developers outline the intended outcomes using the MTA model. This model consists of MTA modules, MTA resources, and the interdependencies between them. Afterward, the SAP Cloud Deployment service validates it, orchestrates the necessary actions, and automates the MTA deployment. The outcome is the formation of Cloud Foundry applications, services, and the generation of SAP specific content. For more information about the Multitarget Application model, see the official specification documents [The Multitarget Application Model v.2](#) and [The Multitarget Application Model v.3](#).

You can create and deploy a Multitarget Application in the Cloud Foundry environment as described below by following different approaches that can yield the same result:

- Using SAP Web IDE Full-Stack as described in [Developing Multitarget Applications](#) - both the development descriptor `mta.yaml` and the deployment descriptor `mtad.yaml` are created automatically. The `mta.yaml` is generated when you create the application project, and the `mtad.yaml` file is created when you build the project.

#### Note

You may still need to edit the development descriptor.

Development descriptors are used to generate MTA deployment descriptors, which define the required deployment data. That is, the MTA development descriptor data specifies what you want to build, how to build it, while the deployment descriptor data specifies as what and how to deploy it.

- <https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/a71bf8281254489ea8be6e323199b304.html> [https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/a71bf8281254489ea8be6e323199b304.html]
- <https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/3b533e3723674fad90f94510b92f10af.html> [https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/3b533e3723674fad90f94510b92f10af.html]
- <https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/1b0a7a0938944c7fac978d4b8e23a63f.html> [https://help.sap.com/viewer/825270ffffe74d9f988a0f0066ad59f0/CF/en-US/1b0a7a0938944c7fac978d4b8e23a63f.html]
- Using Business Application Studio - the flow is similar to WebIDE but the development is done from BAS.

- <https://help.sap.com/docs/bas/sap-business-application-studio/mta-development/> [https://help.sap.com/docs/bas/sap-business-application-studio/mta-development/]
- <https://help.sap.com/docs/bas/sap-business-application-studio/building-and-deploying-multitarget-applications> [https://help.sap.com/docs/bas/sap-business-application-studio/building-and-deploying-multitarget-applications]
- <https://help.sap.com/docs/bas/sap-business-application-studio/building-and-deploying-multitarget-applications> [https://help.sap.com/docs/bas/sap-business-application-studio/building-and-deploying-multitarget-applications]
- Using the [Cloud MTA Build Tool](#) . Afterward, you deploy the MTA using the Cloud Foundry Command Line Interface.

**Note**  
An MTA development descriptor `mta.yaml` is required. You have to create it manually.

- <https://sap.github.io/cloud-mta-build-tool/> [https://sap.github.io/cloud-mta-build-tool/]
- <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/65ddb1b51a0642148c6b468a759a8a2e.html> [https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/65ddb1b51a0642148c6b468a759a8a2e.html]

- <https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/c2d31e70a86440a19e47ead0cb349fdb.html> [<https://help.sap.com/viewer/65de2977205c403bbc107264b8eccf4b/Cloud/en-US/c2d31e70a86440a19e47ead0cb349fdb.html>]
- Manually - create the required files manually and deploy them using the Cloud Foundry Command Line Interface

### Note

An MTA development descriptor `mta.yml` is not explicitly required. In this case, a deployment descriptor is maintained instead.

1. Create the required files using an IDE of your choice.
2. To produce your custom artifacts, use a build technology of your choice.
3. Maintain your deployment descriptor document (`mtad.yml`).
  1. (Optional) If you want to have an MTA archive package, use the `mbt assemble`. For more information, see [Cloud MTA Build Tool \(MBT\)](#).
  2. Use the `cf deploy` command to deploy the MTA package or directly from the build result directory.

To learn more about	See
Multitarget Application deployment descriptor	<a href="#">Defining Multitarget Application Deployment Descriptors for Cloud Foundry [page 543]</a>

## Terms and Concepts

### Terms and Concepts

Term	Description
Multitarget application (MTA)	An application comprised of multiple software modules, which are created with different technologies and deployed to different runtimes.
Development descriptor	A YAML file named <code>mta.yml</code> that contains a list of all entities, such as modules, resources, and properties that belong to an application or are used by it at runtime, and the dependencies between them. It is automatically generated when an MTA project is created or modified, or when a module is added or removed. The developer needs to edit the descriptor manually to define resources, properties, and dependencies, as well as fill in missing information.

Term	Description
Deployment descriptor	A YAML file named <code>mt.ad.yaml</code> that contains a list of all entities which is created from either SAP Web IDE Full-Stack, SAP Business Application Studio, Cloud MTA Build Tool or manually. This file is similar to Development Descriptor but is used from the SAP Cloud Deployment service.
Module	A self-contained application of a certain type, which is developed, packaged, and deployed.
Module type	A type that defines the structure and the development technology of a module. You can see a list of the module types at <a href="#">Modules [page 560]</a> .
Resource	Any resource, such as an external service that is required by a module at runtime but not provided by the module itself.
Property	A property (key-value pair) of an application, module, or resource, that is used during deployment or at runtime.
Parameter	A reserved variable belonging to a module or resource, whose value is used during deployment or at runtime.
Dependency	<p>A relationship between a module and another module, resource, or property, such as provides and requires.</p> <ul style="list-style-type: none"> <li>• <code>provides</code>: indicates the properties or parameters that are provided by a module or resource to other modules.</li> <li>• <code>requires</code>: indicates other modules or resources that are required by a module in order to run.</li> </ul>
MTA archive (MTAR)	Archive containing a deployment descriptor, the module and resource binaries, and configuration files. The archive follows the JAR file specification.

## Prerequisites and Restrictions

You have to consider the following limits for the MTA artifacts, which can be handled by the Cloud Foundry deploy service:

- Maximum size of the MTA archive: 4 GB
- Maximum size of MTA module content: 1 GB
- Maximum size of MTA resource content: 1 MB
- Maximum size of MTA descriptors (`mt.ad.yaml` and `MANIFEST.MF`): 1 MB

## Related Information

[JAR File Specification](#) 

### 4.1.8.1.1 Benefits of the Multitarget Application Model for the Cloud Foundry Environment

The benefits of the multitarget application (MTA) approach can be related to the three “A”s that the MTA offers - Abstraction, Automation, and Assembly.

- **Abstraction** - Simply put, the MTA model uses abstraction to handle the diversity and complexity of different parts of an application, which may increase over time. This method offers a standardized way of modeling dependencies and environment-specific configurations. Without the MTA model you would have to individually handle all this heterogeneity, using custom scripts in a CI/CD tool to manage all underlying components, service dependencies and configurations. Achieving the needed automation through such custom scripts may be labor-intensive. It also demands higher effort as the technologies and services used by the application change over time. Modeling your application as an MTA highly simplifies the lifecycle of such heterogeneous applications.
- **Automation** - By defining your application's structure and dependencies (the “What”), you can use the SAP Cloud Deployment Service to manage automated tasks like deployment, service creation, updates and binding (the “How”). This reduces the work required in CI/CD pipelines to oversee all these deployment-related tasks.
- **Assembly** - By offering a standard packaging format for your applications, the MTA serves as a release artifact. This is known as an assembly. The assembly, constituting the application and all its metadata, can be useful in different contexts. One such context is audited environments, where a signed artifact is mandatory. Another use case is moving deployable artifacts through a firewall. The assembly can also be valuable in situations where different policies are applicable based on the deployment target. Furthermore, this artifact can be distributed to other consumers. For instance, a partner distributing a business application to several customers may find this useful. These customers can then deploy this application in their own accounts or tenants.

### Deciding on the Right Size for a Multitarget Application

Your business application may grow over time. When this happens, you should decide on the volume of data for your MTA or multiple MTAs by analyzing which pieces make sense to be managed together as a separate lifecycle management unit.

A popular example is the case for a “core” or “framework” application parts that could work on their own, offering the basic business capabilities. Then there might be “extension” or “plugin” applications that extend the basic business capabilities, but are not mandatory and could be released and updated separately.

Another possibility is to model just one single Cloud Foundry application in a separate MTA. This makes sense if the application can be considered a self-contained microservice. However, even one Cloud Foundry app in one MTA modeling bears the benefits of dependency management (for example, backing service creation and external API lookup), content management (Fiori Launchpad configurations, workflow definitions, and so on) and configuration management (utilizing system placeholders, default and deployment specific configuration).

## Other Benefits

- Parallel deployment - This feature enables asynchronous deployment of multiple applications, this way the deployment of the archive is faster.
- Asynchronous service instance creation - The MTA deployer creates services asynchronously, this way decreasing the deployment time.
- Parallel undeployment - This feature enables asynchronous undeployment of applications, this way decreasing the undeployment time.

### 4.1.8.1.2 Getting Started

To learn how to deploy a simple multitarget application (MTA) to SAP Business Technology Platform, Cloud Foundry environment using the MultiApps CF CLI Plugin, you can follow the steps in the tutorial [Deploy Your First Multitarget Application](#).

If you want to see more MTA examples, see [CF MTA Examples](#) on GitHub.

### 4.1.8.1.3 Defining Multitarget Application Development Descriptors

Multitarget Applications are defined in a development descriptor required for design-time purposes.

The development descriptor (`mta.yaml`) defines the elements and dependencies of a Multitarget Application (MTA) compliant with the Cloud Foundry environment.

#### Note

The MTA development descriptor (`mta.yaml`) is used to generate the deployment descriptor (`mtad.yaml`), which is required for deploying an MTA to the target runtime. If you use command-line tools to deploy an MTA, you do not need an `mta.yaml` file. However, in these cases you have to manually create the `mtad.yaml` file.

For more information about the MTA development descriptor, see [Defining Multitarget Application Deployment Descriptors for Cloud Foundry](#).

## Related Information

[Developing Multitarget Applications](#)

## 4.1.8.1.4 Defining Multitarget Application Archives

You package the MTA deployment descriptor and module binaries in an MTA archive. You can manually do so as described below, or alternatively use the Cloud MTA Build tool.

### Note

There could be more than one module of the same type in an MTA archive.

The Multitarget Application (MTA) archive is created in a way compatible with the JAR file specification. This allows us to use common tools for creating, modifying, and signing such types of archives.

### Caution

The maximum size of an MTA archive is limited to 500 MB. Deployment is denied for archives with larger size.

An MTA archive consists of the following:

- The `MANIFEST.MF` file
- The `mtad.yaml` MTA deployment descriptor file
- Application binaries, content, or configuration files

### Note

- The MTA extension descriptor is not part of the MTA archive. During deployment you provide it as a separate file, or as parameters you enter manually when the SAP BTP requests them.
- Using a `resources` directory, as shown in some examples, is not mandatory. You can store the necessary resource files on root level of the MTA archive, or in another directory with name of your choice.

The following example shows the basic structure of an MTA archive. It contains a Java application `.war` file and a `META-INF` directory, which contains an MTA deployment descriptor with a module and a `MANIFEST.MF` file.

### Example

```
/example.war
/META-INF
/META-INF/mtad.yaml
/META-INF/MANIFEST.MF
```

The `MANIFEST.MF` file has to contain a name section for each MTA module part of the archive that has a file content. In the name section, the following information has to be added:

- `Name` - the path within the MTA archive, where the corresponding module is located. If it leads to a directory, add a forward slash (/) at the end.
- `Content-Type` - the type of the file that is used to deploy the corresponding module
- `MTA-module` - the name of the module as it has been defined in the deployment descriptor

### Note

- You can store one application in two or more application binaries contained in the MTA archive.

- According to the JAR specification, there must be an empty line at the end of the file.

Sample content of the `META-INF/MANIFEST.MF` file:

#### ❁ Example

```
Manifest-Version: 1.0
Created-By: example.com
Name: example.war
Content-Type: application/zip
MTA-Module: example-java-app
```

The example above instructs the SAP BTP to:

- Look for the `example.war` file within the root of the MTA archive when working with module `example-java-app`
- Interpret the content of the `example.war` file as an `application/zip`

#### ⓘ Note

The example above is incomplete. To deploy a solution, you have to create an MTA deployment descriptor. Then you have to create the MTA archive.

#### → Tip

As an alternative to the procedure described above, you can also use the Cloud MTA Build Tool. See its official documentation at [Cloud MTA Build Tool](#) .

## Related Information

[Cloud MTA Build Tool](#) 📄

[The Multitarget Application Model v.2](#) 📄

[The Multitarget Application Model v.3](#) 📄

[JAR File Specification](#) 📄

[Defining MTA Deployment Descriptors for the Neo Environment](#)

[Defining MTA Extension Descriptors \[page 591\]](#)

[MTA Module Types, Resource Types, and Parameters for Applications in the Neo Environment](#)

### 4.1.8.1.5 Defining Multitarget Application Deployment Descriptors for Cloud Foundry

The Multitarget Application (MTA) deployment descriptor is a YAML file that defines the relations between you as a provider of a deployable artifacts and the SAP Cloud Deployment service in SAP BTP as a deployer tool.

Using the YAML data serialization language you describe the MTA in an MTA deployment descriptor (`mtad.yaml`) file following the [Multitarget Application Structure \[page 549\]](#).

### Note

As there are technical similarities between SAP HANA XS Advanced and Cloud Foundry, you can adapt application parameter for operation in either platforms. Note that each environment supports its own set of module types, resource types, and configuration parameters. For more information, see the official [Multitarget Application Model v.2](#) and [Multitarget Application Model v.3](#) specification documents.

## Schema Store

Writing YAML descriptors in plain text is often hard, so we have contributed a schema to the public Schema Store. This would provide you with an almost out of the box support when writing MTA deployment descriptors in some of the more popular IDEs. The schema would provide you with auto-completion as well as suggestions and syntax checking.

For more information, see [Editor Schema Support](#).

### 4.1.8.1.5.1 MTA Deployment Descriptor Examples

Examples of MTA deployment descriptors.

### Note

The format and available options in the MTA deployment descriptor could change with the newer versions of the MTA specification. Always specify the schema version when defining an MTA deployment descriptor, so that the SAP BTP is aware against which specific MTA specification version you are deploying.

## Example 1

Deployment descriptor with a resource (managed service)

### Example

```
_schema-version: "3.1.0"
ID: simple-mta
version: 1.0.0
modules:
- name: anatz
  type: javascript.nodejs
  requires:
    - name: hdi-service
resources:
- name: hdi-service
  type: org.cloudfoundry.managed-service
  parameters:
    service: hana
    service-plan: hdi-shared
```

## Example 2

Deployment descriptor with the `keep-existing` parameter (will keep the existing: environment, service-bindings and routes)

### ❁ Example

```
_schema-version: 3.1.0
ID: anatz-keep-existing
version: 4.0.0
modules:
- name: anatz
  type: staticfile
  path: hello-world.zip
  parameters:
    memory: 64M
    route: new-custom-route- $\{\text{space}\}$ 
    keep-existing:
      env: true
      service-bindings: true
      routes: true
```

## Example 3

Deployment descriptor with enabled parallel deployment of modules (will deploy modules in parallel)

### ❁ Example

```
_schema-version: 3.1.0
ID: hello-world
version: 1.0.0
parameters:
  enable-parallel-deployments: true
modules:
- name: hello-world
  type: staticfile
  path: content/hello_world.zip
- name: hello-world-first
  type: staticfile
  path: content/hello_world.zip

- name: hello-world-second
  type: staticfile
  path: content/hello_world.zip
- name: hello-world-third
  type: staticfile
  path: content/hello_world.zip
```

## Example 4

Deployment descriptor with docker image module

### ❁ Example

```
_schema-version: "3.1.0"
ID: docker-mtar
version: 2.0.1
modules:
- name: docker-image
  type: application
  parameters:
    docker:
      image: cloudfoundry/test-app
```

## Example 5

Deployment descriptor with optional resource

### ❁ Example

```
_schema-version: "3.1.0"
ID: ztanal
version: 1.1.0
modules:
- name: ztana
  type: javascript.nodejs
  requires:
    - name: test-resource

resources:
- name: test-resource
  type: org.cloudfoundry.existing-service
  optional: true
  parameters:
    service: non-required-service
```

## Example 6

A basic MTA deployment descriptor that is defined in an `mtad.yaml` file:

### ❁ Example

```
_schema-version: "3.1"
ID: com.sap.xs2.samples.javahelloworld
version: 0.1.0

modules:
```

```

- name: java-hello-world
  type: javascript.nodejs
  path: web/
  requires:
    - name: java-uaa
    - name: java
      group: destinations
      properties:
        name: java
        url: ~{url}
        forwardAuthToken: true
- name: java-hello-world-backend
  type: java.tomee
  path: java/target/java-hello-world.war
  provides:
    - name: java
      properties:
        url: ${default-url}
  properties:
    JBP_CONFIG_RESOURCE_CONFIGURATION: "[ 'tomee/webapps/ROOT/WEB-INF/
resources.xml': { 'service_name_for_DefaultDB' : 'java-hdi-container'}]"
  requires:
    - name: java-uaa
    - name: java-hdi-container
    - name: java-hello-world-db
- name: java-hello-world-db
  type: com.sap.xs.hdi
  path: db/
  requires:
    - name: java-hdi-container

resources:
- name: java-hdi-container
  type: com.sap.xs.hdi-container

- name: java-uaa
  type: com.sap.xs.uaa-space
  parameters:
    config-path: xs-security.json

```

### Note

The example above is incomplete. To deploy a solution, you have to create an MTA extension descriptor with the user and password added there. You also have to create the MTA archive.

## Example 7

Another basic example of an MTA deployment descriptor.

### Sample Code

```

_schema-version: "3.1"
ID: com.sap.xs2.samples.nodehelloworld
version: 0.1.0
modules:
- name: node-hello-world
  type: javascript.nodejs
  path: web/
  requires:
    name: nodejs-uaa

```

```

- name: nodejs
  group: destinations
  properties:
    name: backend
    url: ~{url}
    forwardAuthToken: true
  properties-metadata:
    name:
      optional: false
      overwritable: false
    url:
      overwritable: false
  parameters:
    host: !sensitive ${user}-node-hello-world
    memory: 128MB
  parameters-metadata:
    memory:
      optional: true
      overwritable: true
- name: node-hello-world-backend
  type: javascript.nodejs
  path: js/
  provides:
    - name: nodejs
      properties:
        url: "${default-url}"
  requires:
    - name: nodejs-uaa
    - name: nodejs-hdi-container
    - name: node-hello-world-db
  parameters:
    host: ${user}-node-hello-world-backend
- name: node-hello-world-db
  type: com.sap.xs.hdi
  path: db/
  requires:
    - name: nodejs-hdi-container
  parameters:
    tasks:
      - name: task-1 #You can model Cloud Foundry tasks
as described here. For additional information, check the Cloud Foundry
"Information for Developers" document.
      command: node deploy.js
      disk-quota: 1GB
      memory: 1GB
resources:
- name: nodejs-hdi-container
  type: com.sap.xs.hdi-container
  parameters:
    config:
      schema: ${default-container-name}
- name: nodejs-uaa
  type: com.sap.xs.uaa
  parameters:
    config-path: xs-security.json
- name: log
  type: application-logs
  optional: true

```

## Example 8

A more complex example, which shows an MTA deployment description with the following modules:

- A database model
- An SAP UI5 application (hello world)
- An application written in node.js

The UI5 application “hello-world” uses the environment variable `<ui5_library>` as a logical reference to some version of UI5 on a public Website.

### Sample Code

```
ID: com.acme.xs2.samples.javahelloworld
version: 0.1.0
modules:
  - name: hello-world
    type: javascript.nodejs
    requires:
      - name: uaa
      - name: java_details
        properties:
          backend_url: ~{url3}/
    properties:
      ui5_library: "https://sapui5.hana.acme.com/"

  - name: java-hello-world-backend
    type: java.tomee
    requires:
      - name: uaa
      - name: java-hello-world-db           # deploy ordering
      - name: java-hdi-container
    provides:
      - name: java_details
        properties:
          url3: ${url}                       # the value of the place-holder $
{url}                                       # will be made known to the deployer

  - name: java-hello-world-db
    type: com.sap.xs.hdi
    requires:
      - name: java-hdi-container
resources:
  - name: java-hdi-container
    type: com.sap.xs.hdi-container

  - name: java-uaa
    type: com.sap.xs.uaa
    parameters:
      name: java-uaa                         # the name of the actual service
```

## 4.1.8.1.6 Multitarget Application Structure

The following chapter contains information about:

- Global elements - an identifier and version that uniquely identify the MTA, including additional optional information such as a description, the providing organization, and a copyright notice for the author.

- [Modules \[page 560\]](#) - the deployable parts contained in the MTA deployment archive, most commonly Cloud Foundry applications or content.
- [Resources \[page 550\]](#) - they contain properties of resource types, which are entities not part of an MTA, but required by the modules at runtime or at deployment time.
- Dependencies between modules and resources.
- Parameters - variables which belong to a module or a resource, whose value is used during the deployment or at runtime. For more information, see [Parameters and Properties \[page 581\]](#).
- Properties - these result in the application environment variables that have to be available to the respective module at runtime. For more information, see [Parameters and Properties \[page 581\]](#).
- Technical configuration parameters, such as URLs, and application configuration parameters such as environment variables. For more information, see [Parameters and Properties \[page 581\]](#).
- Metadata - provide additional information about the declared parameters and properties. For more information, see [Metadata for Properties and Parameters \[page 590\]](#).
- [Module Hooks \[page 577\]](#) - use hooks to change the typical deployment process, for example to set them to be executed before or after the actual deployment steps for a module.
- If needed, use alternative arrangement of the properties' syntax. For more information see [Parameters and Properties \[page 581\]](#).

## 4.1.8.1.6.1 Resources

The application modules defined in the “modules” section of the deployment descriptor may depend on **resources**.

The resources may be used as:

- platform services managed by the deployer or only used by the applications
- configuration entries used by the applications and services

In the `resources` section, the following elements are mandatory:

- `name` - Must be unique within the MTA it identifies

Optional resource attributes include:

- `type` - the resource **type** is one of a reserved list of resource types supported by the MTA-aware deployment tools, for example: `com.sap.xs.uaa`, `com.sap.xs.hdi-container`, `com.sap.xs.job-scheduler`; the **type** indicates to the deployer how to discover, allocate, or provision the resource, for example, a managed service such as a database, or a user-provided service. When `type` is not defined, `resource` is used for configurations only for other modules and resources.
- `description` - non-translatable, free-text string; the string is not meant to be presented on application user interfaces (UI)
- `properties` - a structured set of name-value pairs
- `parameters` - reserved variables that affect the behavior of the MTA-aware tools, such as the deployer
- `active` - its value can be `true` or `false` and the default value is `true`. If set to `false`, the resource is not processed and it is ignored in the `requires` list of the application that requires it.
- `processed-after` - the attribute is used to create an order, in which resources should be processed. If a resource has this attribute, it will be processed after the other resources in a higher position are processed. The attribute value is a structured set of a list comprised of other resource names of the same MTA.

### → Tip

By default resources process in parallel, but if you want to enable an order of resources, see [Sequential Resource Processing \[page 623\]](#).

- optional

## Active and Inactive Resources

If you deploy an application with a resource type attribute `active` set to `false`, the resource is not provisioned and no binding is created. If you have already deployed the application with the resource type attribute `active` set to `true`, the binding to the resource is removed.

### Deployment with managed-service, existing-service and user-provided service

No binding is created and in case of `managed-service`, no service is created.

### Deployment with `org.cloudfoundry.existing-service-key`

No binding to an application environment will be done in the following cases:

- If the `org.cloudfoundry.existing-service-key` resource itself is set to `active: false`
- If the `org.cloudfoundry.existing-service-key` resource is set to `active: true`, but refers to a resource, which is set to `active: false`

### Deployment with configuration resources (cross MTA dependencies)

If the configuration resource is set to `active: false`, then:

- If the `requires` section of the module type expects a list, then the environment variable assigned to this list is empty and subscriptions between the modules is not created
- If the `requires` section does not expect a list, then no environment variable is created

See section “Optional resources” below for more information.

### ⚠ Restriction

System-specific parameters for the deployment descriptor must be included in a so-called MTA deployment extension descriptor.

## Optional Resources

To describe resources that are not mission-critical for the operation of your Multitarget Application, proceed as described below.

### 📄 Note

This option is available with schema version 3.1.

You can declare some resources as optional, which mitigates the cases when they are not listed, not available, or have failed to be created or updated. This means that when the deployer cannot allocate the required

resource due to any of these reasons, it generates a warning and continues processing. Alternatively, if a resource is not declared as optional, the deployer generates an error and stops processing.

The following excerpt is a code example for the `MANIFEST.MF` file.

#### Sample Code

```
...
resources:
...
- name: log
  type: com.sap.xs.auditlog
  optional: true
...
```

In the above example:

- If the `log` managed resource is not provided by the platform or landscape, a warning is logged and traced and the MTA deployment continues while ignoring the error.
- The available values for the `optional` parameter are `true` and `false`, with the latter being the default.

## Generic MTA Resource Types

- `org.cloudfoundry.managed-service`

In cases you have to choose a managed service and/or service plan that is not listed in [Generic MTA Resource Types \[page 552\]](#), you define it using the `org.cloudfoundry.managed-service` resource type with the following parameters:

- (Required) `service` - Name of the service to create.
- (Optional) `service-name` - Service instance name. Default value is the resource name.

#### Note

Service names that do not comply with the Cloud Foundry limitation of 50 symbols are automatically corrected. In such cases, the name is shortened and its end is replaced with a hash code.

- (Required) `service-plan` - Name of the service to create.

For example:

#### Sample Code

```
resources:
- name: my-postgre-service
  type: org.cloudfoundry.managed-service
  parameters:
    service: postgresql
    service-plan: v9.6-dev
```

#### Note

To choose a different service plan for a predefined MTA resource type, for example to change the service plan for PostgreSQL service, you define it using:

### Sample Code

```
resources:
  - name: my-postgre-service
    type: org.postgresql
    parameters:
      service-plan: v9.6-dev
```

- `org.cloudfoundry.existing-service`  
To indicate that the (named) service exists, without managing its lifecycle, you define the service name by using the `org.cloudfoundry.managed-service` resource type with the following parameters:
  - (Optional) `service-name` - Service instance name. Default value is the resource name.
- `org.cloudfoundry.existing-service-key`  
Existing service keys can be modeled as a resource of type `org.cloudfoundry.existing-service-key`, which checks and uses their credentials. For more information, see [Service Keys \[page 603\]](#).
- `org.cloudfoundry.user-provided-service`  
Create or update a user-provided service configured with the following resource parameters:
  - (Optional) `service-name` - Name of the service to create. Default value is the resource name.

### Note

Service names that do not comply with the Cloud Foundry limitation of 50 symbols are automatically corrected. In such cases, the name is shortened and its end is replaced with a hash code.

- (Required) `config` - Map value, containing the service creation configuration, for example url and user credentials (user and password)

### Example

#### Sample Code

```
resources:
  - name: my-destination-service
    type: org.cloudfoundry.user-provided-service
    parameters:
      config:
        <credential1>: <value1>
        <credential2>: <value2>
```

- `configuration`  
For more information, see [Cross-MTA Dependencies \[page 607\]](#).

## Predefined MTA Resource Types

Modify the default MTA resource types by providing specific properties or parameters in the MTA deployment descriptor.

Predefined MTA Resource Types and Mapped Services

Resource Type	Service	Service Plan	Created Service
com.sap.xs.hana-sbss	hana	sbss	Service-broker security
com.sap.xs.hana-schema	hana	schema	Plain schema

❖ Example

🔗 Sample Code

```
name: hcsp-sch
type:
  com.sap.xs.hana-
  schema
parameters:
  service-name:
  HCSP_SCH
config:
  database_id:
  9bf1f23a-123c-456e
  -b789-ff12ea34a5dc
  schema: HCSP_DB
```

com.sap.xs.hana-securestore	hana	securestore	SAP HANA secure store
com.sap.xs.hdi-container	hana	hdi-shared	HDI container

ⓘ Note

modules: When using the free trial subaccount, modify the default service:

🔗 Sample Code

```
resources:
  - name: my-
    hdi-service
    type:
    com.sap.xs.hdi-
    container
    parameters:
      service:
      hanatrial
```

com.sap.xs.jobscheduler	jobscheduler	lite	Job Scheduler
com.sap.xs.uaa	xsuaa	applicaton	Application UAA
com.sap.xs.uaa-application	xsuaa	application	Application UAA
com.sap.xs.uaa-devuser	xsuaa	application	Application UAA
com.sap.xs.uaa-space	xsuaa	application	Application UAA

Resource Type	Service	Service Plan	Created Service
com.sap.xs.application-logs	application-logs	lite	Streams logs of bound applications to a central application logging stack
<p><b>⚠ Restriction</b> This resource type is now deprecated. Use application-logs instead.</p>			
com.sap.portal.site-content	portal-services	site-content	Portal services
<p><b>⚠ Restriction</b> Use only with the SAP Node.js module @sap/site-content-deployer</p>			
com.sap.portal.site-host	portal-services	site-host	Portal services
<p><b>⚠ Restriction</b> Only for use with the SAP Node.js module @sap/site-entry</p>			
com.sap.xs.auditlog	auditlog	standard	Audit log service
auditlog	auditlog	standard	Audit log service
autoscaler	autoscaler	lite	Automatically increase or decrease the number of application instances based on a policy you define.
application-logs	application-logs	lite	Streams logs of bound applications to a central application logging stack
connectivity	connectivity	lite	Establishes a secure and reliable connectivity between cloud applications and on-premise systems
destination	destination	lite	Provides a secure and a reliable access to destination configurations
feature-flags	feature-flags	lite	Feature Flags service for controlling feature rollout

Resource Type	Service	Service Plan	Created Service
ml-foundation-services	ml-foundation-services	lite	
objectstore	objectstore	s3-standard	Highly available and distributed consistent object store
org.mongodb	mongodb	v3.0-container	MongoDB document-oriented database system.
<b>⚠ Restriction</b> This resource type is now deprecated. Use <code>mongodb</code> instead.			
mongodb	mongodb	v3.0-container	MongoDB document-oriented database system
org.postgresql	postgresql	v9.4-container	PostgreSQL object-relational database system
<b>⚠ Restriction</b> This resource type is now deprecated. Use <code>postgresql</code> instead.			
postgresql	postgresql	v9.4-container	PostgreSQL object-relational database system
com.rabbitmq	rabbitmq	v3.6-container	RabbitMQ messaging
<b>⚠ Restriction</b> This resource type is now deprecated. Use <code>rabbitmq</code> instead.			
rabbitmq	rabbitmq	v3.6-container	RabbitMQ messaging
io.redis	redis	v3.0-container	Redis in-memory data structure store
<b>⚠ Restriction</b> This resource type is now deprecated. Use <code>redis</code> instead.			
redis	redis	v3.0-container	Redis in-memory data structure store

## Resource-Specific Parameters

Resource parameters have platform-specific semantics. To reference a parameter value, use the placeholder notation `${<parameter>}`, for example, `${default-host}`.

## → Tip

It is also possible to declare metadata for parameters and properties defined in the MTA deployment description; the mapping is based on the parameter or property keys. For example, you can specify if a parameter is **required** (`optional: false`) or can be modified `overwritable: true`.

The following parameters are supported:

### MTA Development and Deployment Parameters

Parameter	Read-Only (System)	Description	Default Value	Example
<code>config</code>	Write	Defines service creation parameters. More information in <a href="#">Service Creation Parameters [page 597]</a> .	n/a	See <a href="#">Service Creation Parameters [page 597]</a> .
<code>syslog-drain-url</code>	Write	The URL to which logs for bound applications are streamed.  <b>Note</b> This feature only works for user-provided services.	n/a	<pre>resources:   - name: service-name     type:       org.cloudfoundry.user-provided-service       parameters:         syslog-drain-url:           syslog://example.log-aggregator.com</pre>
<code>default-container-name</code>	Yes	Default value for the <code>container-name</code> parameter that is used during HDI creation. It is based on the organization, space and resource name, which are combined in a way that conforms to the container-name restrictions for length and legal characters. All dash (-) symbols are replaced with an underscore (_).	Generated as described in the description.	<code>&lt;org_name&gt;_&lt;space_name&gt;_&lt;resource_name&gt;</code>

Parameter	Read-Only (System)	Description	Default Value	Example
default-service-name	Yes	The name of the service in the Cloud Foundry environment to be created for this resource, based on the resource name with or without a name-space prefix.	The resource name with or without a name-space prefix	nodejs-hdi-container com.sap.xs2.samples.xsj shelloworld.nodejs-hdi-container
default-xsappname	Yes	Default value for the xsappname parameter that is used during UAA creation. It is based on the service name, which is modified in a way that conforms to the xsappname restrictions for length and legal characters.	Generated as described in the description.	xs_-deploy-service-database (if the service name is "xs@-deploy-service-database")
service		The type of the created service	Empty, or as specified in resource-type	service: hana
service-key-name	Write	Used when consuming an existing service key. Specifies the name of the service key. See <a href="#">Consumption of Service Keys [page 603]</a> for more information.	The name of the resource.	service-key-name: my-service-key
service-name		The name of the service in the Cloud Foundry environment to be created for this resource, based on the resource name with or without a name-space prefix.	`\${default-service-name}`	nodejs-hdi-container com.sap.xs2.samples.xsj shelloworld.nodejs-hdi-container
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>Service names that do not comply with the Cloud Foundry limitation of 50 symbols are automatically corrected. In such cases, the name is shortened and its end is replaced with a hash code.</p> </div>				
service-plan		The plan of the created service	Empty, or as specified in resource-type	service-plan: hdi-shared

Parameter	Read-Only (System)	Description	Default Value	Example
service-tags	Write	Some services employ a list of custom tags, which provide an easier way for applications to parse <VCAP_SERVICES> for credentials. You can provide custom tags when creating a service instance. For more information, see <a href="#">Service Tags [page 601]</a> .	n/a	<pre>resources:   - name: nodejs-uaa     type:       com.sap.xs.uaa       parameters:         service-tags:           [ "custom-tag-A",             "custom-tag-B" ]</pre>
service-broker		Use this parameter to specify the service broker you want to employ when you create your service. This can be useful for testing purposes, among others.	Name of service broker you want to be used.	<pre>resources:   - name: test-service     type:       org.cloudfoundry.managed-service       parameters:         service: foo         service-plan:           bar-a           service-broker: test-broker-1</pre>
skip-service-updates		This parameter allows you to specify the service configuration changes to ignore, when deciding if you want to update a service instance – in particular changes of service parameters, plan, or tags.	The default value for all is false. The service instance would be updated on change in any of the configurations.	<pre>resources:   - name: service-name     type:       org.cloudfoundry.managed-service       parameters:         skip-service-updates:           plan: true         parameters: true         tags: true</pre> <p>In the example above, skip-service-updates modifies the update strategy as follows:</p> <ul style="list-style-type: none"> <li>allows users to specify which configurations should not be updated</li> </ul> <p>Note that these 3 key-value pairs can be in any order.</p>

### → Tip

For a better understanding of the interactions among the service, service broker, and service instances, see [section "Architecture and Terminology"](#) .

[Managing Services](#) 

### 4.1.8.1.6.2 Modules

The `modules` section of the deployment descriptor lists the deployable parts contained in the MTA deployment archive.

The following elements are mandatory:

- `name` - must be unique within the MTA it identifies
- `type` - defines which deployment mechanism to be used for this module

Optional module attributes include:

- `path` - the file-system path relative to the root of the MTA directory. The content of the file is used to create or update the CF app or content, depending on the module target. The `path` is used only during MTA build. In already built MTA archive (MTAR), `path` is ignored and only corresponding entry in `MANIFEST.MF` for the module is processed.  
The path is applicable only when MTA is assembled based on deployment descriptor (`mtad.yaml`), and not on development descriptor (`mta.yaml`)
- `description` - non-translatable, free-text string; the string is not meant to be presented on application user interfaces (UI)
- `properties` - a structured set of name-value pairs; if a module, which requires the resource, represents a CF application, the resource properties are injected into the environment of the application
- `parameters` - reserved variables that affect the behavior of the MTA-aware tools, such as the deployer
- `deployed-after` - the attribute is used to create an order, in which modules should be processed. If a module has this attribute, it will be processed after the other modules in a higher position are processed. The attribute value is a structured set of a list comprised of other module names of the same MTA.
- `requires` - specifies the names of `requires` sections provided in `resource` that have been declared for the same MTA. Tools check if all required names are provided within the MTA.
- `provides` - specifies the names of `provides` sections, each containing configuration data; the data provided can be `required` by other `modules` in the same MTA

#### → Tip

Modules can be deployed in parallel. See [Parallel Module Deployment \[page 622\]](#).

## MTA Module Types

Modify the following MTA module types by providing specific properties or parameters in the MTA deployment descriptor (`mtad.yaml`).

## MTA Default Modules Types

Module Type	Default Parameter Values and Description	Module Properties	Result
javascript.no dejs	No default parameter.  <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>We strongly recommend that you specify the appropriate buildpack for your application. To do so, use the <code>buildpack</code> module parameter.</p> </div>	None	CF application with automatic buildpack detection
nodejs	<code>buildpack(nodejs_buildpack)</code>	None	CF application with Node.js runtime
custom	No default parameter.  <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>We strongly recommend that you specify the appropriate buildpack for your application. To do so, use the <code>buildpack</code> module parameter.</p> </div>	None	CF application with automatic buildpack detection
application	No default parameter.  <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>Note</b></p> <p>We strongly recommend that you specify the appropriate buildpack for your application. To do so, use the <code>buildpack</code> module parameter.</p> </div>	None	CF application with automatic buildpack detection
java	<code>buildpack(sap_java_buildpack)</code>	None	CF application with Automatic runtime detection by <code>sap_java_buildpack</code>
java.tomcat	<code>buildpack(sap_java_buildpack)</code>	None	CF application with Tomcat runtime of <code>sap_java_buildpack</code>
java.tomee7	<code>buildpack(sap_java_buildpack)</code>	tomee7	CF application with TomEE 7 runtime of <code>sap_java_buildpack</code>

Module Type	Default Parameter Values and Description	Module Properties	Result
com.sap.xs.hdi	<ul style="list-style-type: none"> <li>no-route (true) Do not assign a route to the application.</li> <li>memory (256MB)</li> <li>health-check-type - (none)</li> <li>no-start (true)</li> <li>cf-task</li> <li>command (npm start)</li> <li>memory (256MB)</li> <li>name (deploy)</li> <li>dependency-type (hard) In circular module-dependencies, deploy modules with dependency type "hard" first</li> <li>buildpack (nodejs_buildpack)</li> </ul>	EXIT (1)	CF application with HDI content activation
com.sap.xs.hdi-dynamic	buildpack(nodejs_buildpack)	None	CF application with Node.js runtime
com.sap.portal.content	<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>Before using this module type, update the content deployer applications to their latest version.</p> </div> <ul style="list-style-type: none"> <li>no-route (true). Defines if a route should be assigned to the application.</li> <li>no-start - (true). Only the one-off tasks will be executed, that is, without triggering the start of the application.</li> <li>memory (256M). Defines the memory allocated to the application.</li> <li>tasks (name: deploy, memory: 256M, command: npm start) For more information, see <a href="#">Tasks [page 595]</a>.</li> <li>dependency-type(hard). Defines if this module should be deployed first, if it takes part in circular module dependency cycles. If hard means that this module is deployed first.</li> <li>buildpack (nodejs_buildpack)</li> </ul>	None	CF application with SAP Fiori launchpad content
com.sap.portal.site-content	This module type is <b>deprecated</b> . You have to use com.sap.portal.content instead.	None	CF application with SAP Fiori launchpad content

Module Type	Default Parameter Values and Description	Module Properties	Result
<code>com.sap.application.content</code>	<p>Required dependency parameters:</p> <ul style="list-style-type: none"> <li><code>content-target (false)</code> Specify that the resource would be used as a target for the module content deployment.</li> </ul>	None	Direct content deployment to backing services
<code>com.sap.html5.application-content</code>	<div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>This module type is <b>deprecated</b>. Please use <code>com.sap.html5.application-content</code> instead.</p> </div> <ul style="list-style-type: none"> <li><code>no-route (true)</code>. Defines if a route should be assigned to the application.</li> <li><code>memory (256M)</code>. Defines the memory allocated to the application.</li> <li><code>execute-app (true)</code>. Defines whether the application is executed. If yes, the application performs certain amount of work and upon completion sets a <code>success-marker</code> or <code>failure-marker</code> by means of a log message.</li> <li><code>success-marker (STDOUT: The deployment of html5 application content done. *)</code></li> <li><code>failure-marker (STDERR: The deployment of html5 application content failed. *)</code></li> <li><code>stop-app (true)</code>. Defines if the application should be stopped after execution.</li> <li><code>check-deploy-id (true)</code> - Defines if the deployment (process) ID should also be checked when checking the application execution status.</li> <li><code>dependency-type (hard)</code>. Defines if this module should be deployed first, if it takes part in circular module dependency cycles. If <code>hard</code> means that this module is deployed first.</li> <li><code>health-check-type (none)</code>. Defines if the module should be monitored for availability.</li> <li><code>buildpack (nodejs_buildpack)</code></li> </ul>	None	Deploys a content deployment application, and creates a task that performs the content deployment.

Module Type	Default Parameter Values and Description	Module Properties	Result
com.sap.html5 .application. content	<p><b>Note</b></p> <p>Before using this module type, update the content deployer applications to their latest version.</p> <ul style="list-style-type: none"> <li>• <code>no-route (true)</code>. Defines if a route should be assigned to the application.</li> <li>• <code>no-start - (true)</code>. Only the one-off tasks will be executed, that is, without triggering the start of the application.</li> <li>• <code>memory (256M)</code>. Defines the memory allocated to the application.</li> <li>• <code>tasks (name:deploy, memory:256M, command:npm start)</code> For more information, see <a href="#">Tasks [page 595]</a>.</li> <li>• <code>dependency-type(hard)</code>. Defines if this module should be deployed first, if it takes part in circular module dependency cycles. If <code>hard</code> means that this module is deployed first.</li> <li>• <code>buildpack (nodejs_buildpack)</code></li> </ul>	EXIT (1)	CF application with SAP HTML5 content

Module Type	Default Parameter Values and Description	Module Properties	Result
com.sap.business-logging.content	<p><b>Note</b></p> <p>Before using this module type, update the content deployer applications to their latest version.</p> <ul style="list-style-type: none"> <li>no-route (true). Defines if a route should be assigned to the application.</li> <li>no-start (true). Only the one-off tasks will be executed, that is, without triggering the start of the application.</li> <li>memory (256M). Defines the memory allocated to the application.</li> <li>tasks (name:deploy, memory:256M, command:npm start) For more information, see <a href="#">Tasks [page 595]</a>.</li> <li>dependency-type(hard). Defines if this module should be deployed first, if it takes part in circular module dependency cycles. If hard means that this module is deployed first.</li> <li>buildpack(nodejs_buildpack)</li> </ul>		Deploys the Business Logging for configuring text resources
business-logging	This module type is <b>deprecated</b> . You have to use com.sap.business-logging.content instead.	None	Deploys the Business Logging for configuring text resources
staticfile	buildpack (staticfile_buildpack)	None	CF application with static file runtime
go	buildpack(go_buildpack)	None	CF application with Go runtime
python	buildpack(python_buildpack)	None	CF application with Python runtime
php	buildpack(php_buildpack)	None	CF application with PHP runtime
binary	buildpack(binary_buildpack)	None	CF application with Binary runtime

To choose a binary\_buildpack, define it by using the following:

### Sample Code

```
modules:
  - name: my-binary-app
    type: custom
    parameters:
      buildpack: binary_buildpack
```

## Module-Specific Parameters

Module parameters have platform-specific semantics. To reference a parameter value, use the placeholder notation `${<parameter>}`, for example, `${default-host}`.

### → Tip

It is also possible to declare metadata for parameters and properties defined in the MTA deployment description; the mapping is based on the parameter or property keys. For example, you can specify if a parameter is **required** (`optional: false`) or can be modified `overwritable: true`.

The following parameters are supported:

MTA Development and Deployment Module Parameters

Parameter	Read-Only (System)	Description	Default Value	Example
app-name		The name of the application in the Cloud Foundry environment to be deployed for this module, based on the module name	<code>\${default-app-name}</code>	<code>node-hello-world</code>  <code>com.sap.xs2.samples.xsj</code> <code>shelloworld.node-hello-world</code>
buildpack		The name or the URL of a custom buildpack required by the application	Empty, or as specified in the deploy service configuration	<code>buildpack: git://github.acme.com/xs2-java/xs2javabuildpack</code>
buildpacks		An array of buildpacks. If a buildpack parameter already exists, it will be overwritten by the buildpacks listed in the buildpacks parameter, so that you have to include it in the array.	Empty, or as specified in the deploy service configuration	<code>buildpacks:</code> <code>[ java_buildpack,</code> <code>nodejs_buildpack,</code> <code>staticfile_buildpack]</code>
command		A custom command required to start the application	Empty, or as specified in the deploy service configuration	<code>command: node index.js</code>
create-service-broker		Specifies whether [true/false] a service broker should be registered for the application module	<code>false</code>	<code>create-service-broker:</code> <code>true</code>
default-app-name	Yes	The name of the application in the Cloud Foundry environment to be deployed for this module, based on the module name	The module name with or without a name-space prefix	<code>node-hello-world</code>  <code>com.sap.xs2.samples.xsj</code> <code>shelloworld.node-hello-world</code>

Parameter	Read-Only (System)	Description	Default Value	Example
default-host	Yes	The default host name, which is composed based on the module name to ensure uniqueness. Used with host-based routing to compose the default URI, see below. It follows the convention <code>\${org}-\${space}-&lt;module_name&gt;</code> .	Generated as described in the description	trial-a007007-node-hello-world
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>→ Tip</b></p> <p>We recommend you explicitly use the <code>routes</code> parameter. See <a href="#">Routes [page 605]</a>.</p> </div>				
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>ⓘ Note</b></p> <p>Host names that do not comply with the Cloud Foundry naming limitations are automatically corrected:</p> <ul style="list-style-type: none"> <li>Any characters that are not within the allowed a-z and 0-9 ranges are replaced by dashes (-) to prevent deployment issues.</li> <li>If the host name length exceeds 63 symbols, the name is shortened and its end is replaced with a hash code.</li> </ul> </div>				
default-instances	Yes	The number of application instances that are started during the deployment	1	default-instances: 1
default-uri	Yes	The default URI, composed as <code>\${host}.\${domain}</code> (host-based routing). Note that <code>\${host}</code> will be the same as <code>\${default-host}</code> , unless specified explicitly as a parameter. Similarly, <code>\${domain}</code> would be the same as <code>\${default-domain}</code> , unless specified explicitly.	Generated as described in the description.	trial-a007007-node-hello-world.cfapps.acme.ondemand.com
default-url	Yes	The default URL, composed as <code>\${protocol}://\${default-uri}</code> . Note that the <code>\${default-uri}</code> placeholder is resolved as <code>\${host}.\${domain}</code> (host-based routing)	Generated as described in the description.	<code>\${protocol}://\${default-uri}</code>

Parameter	Read-Only (System)	Description	Default Value	Example
dependency-type		Deployment order of modules with circular dependencies	soft	dependency-type: hard dependency-type: soft
disk-quota		The disk space that will be available to the application. This parameter requires a unit of measurement M, MB, G, or GB in upper or lower case.	1, or as specified in module-type	disk-quota: 1G
docker	Write	<p>Creates a module from a docker image. When using a docker image parameter, we do not need to specify the module in the MANIFEST.mf file. An image parameter is a docker image from the Docker Hub or somewhere else. The username and the password are optional, but if a Docker image from a private repository is uploaded, then they are mandatory.</p> <p>When uploading a docker image, the content of a module is not needed.</p>	n/a	<p><b>Sample Code</b></p> <pre>modules:   name: foo   type:     application     parameters:       docker:         image:           cloudfoundry/test-app           username:             &lt;optional             username&gt;           password:             &lt;optional             password&gt;</pre>
domain		The domain on which the application is available later	\${default-domain}	domain: \${default-domain}.acme.com
domains		The domains on which the application is available later. The resulting application routes are the Cartesian product of the domains and hosts. That is, a separate route for each host is constructed on each domain.	domains: - \${default}	domains: - \${default-domain}.acme.com - test-\${default-domain}.acme.com
default-domain	Yes	The value of this parameter is the default domain for the current organization.		
enable-ssh		Enables use of SSH within an application. Supported for the Diego container runtime environment only.	n/a	"enable-ssh": true "enable-ssh": false

Parameter	Read-Only (System)	Description	Default Value	Example
enable-parallel-service-bindings		Enables or disables the parallel binding or unbinding of services during deployment. If disabled, the services are bound and unbound sequentially in the order provided in the deployment descriptor.	true	<div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>Sample Code</b></p> <pre>- name: &lt;module name&gt;   type: &lt;module type&gt;   parameters:     enable-parallel-service-bindings: false</pre> </div>
health-check-http-endpoint		If the <code>health-check-type</code> parameter is set to <code>http</code> , the controller will do a GET request to this endpoint. The application will be considered as healthy if the response is 200 OK.	If <code>health-check-type</code> is set to <code>http</code> , the default value is <code>/</code> , otherwise there is no default value	<pre>health-check-type: http health-check-http-endpoint: /health</pre>
health-check-timeout		The application health check timeout in seconds	n/a	<pre>health-check-timeout: 120</pre>
health-check-invocation-timeout		The time period in seconds, within which the application health check should be automatically started. If the health check does not start within the defined time period, it is omitted, and the deployment process continues.	n/a	<pre>health-check-invocation-timeout: 16</pre>
upload-timeout		The application upload timeout in seconds	3600	<pre>upload-timeout: 1800</pre>
health-check-type		The application health check type	port	<pre>health-check-type: port health-check-type: http health-check-type: process</pre>
host		<p>The hostname or subdomain where an application is available later.</p> <p>If you want to create a wildcard host-name, use an asterisk in quotes ("*").</p>	<code>\${default-host}</code>	<pre>host: \${space}-node-hello-world host: "*"</pre>

Parameter	Read-Only (System)	Description	Default Value	Example
hosts		<p>The hostnames or subdomain where an application is available later.</p> <p>If you want to create a wildcard hostname, use an asterisk in quotes ("*").</p>	hosts: - \${host}	<pre>modules: - name: my-app   type: application   parameters:     hosts:       - \${space}-         node-hello-world       - "*" </pre>
idle-domain		<p>Valid for a blue-green deployment when a new application version is started on a temporary route.</p> <p>Specify this parameter if you want to use another domain for temporary routes.</p>	\${default-domain}	<pre>modules: - name: app   type: nodejs   parameters:     idle-domain:       "&lt;some.domain&gt;" </pre>
idle-domains		<p>Valid for a blue-green deployment when a new application version is started on several temporary routes.</p> <p>Specify this parameter if you want to use other domains for temporary routes by listing them in an array.</p>	\${default-domain}	<pre>modules: - name: app   type: nodejs   parameters:     idle-domains:       [ "&lt;some.domain&gt;",         "&lt;some.other.domain&gt;"       ] </pre>
idle-host		<p>Valid for a blue-green deployment when a new application version is started on a temporary route.</p> <p>Specify this parameter if you want to use another host for a temporary route.</p>	\${default-host}-idle	<pre>modules: - name: app   type: nodejs   parameters:     idle-host:       "&lt;some-hostname&gt;" </pre>

**Note**

The new application will start on a route comprised of the specified host and the default domain.

Parameter	Read-Only (System)	Description	Default Value	Example
idle-hosts		<p>Valid for a blue-green deployment when a new application version is started on temporary routes.</p> <p>Specify this parameter if you want to use other hosts for temporary routes by listing them in an array.</p>	<code>\${default-host}-idle</code>	<pre>modules: - name: app   type: nodejs   parameters:     idle-hosts: ["&lt;some-hostname&gt;", "&lt;some-other-hostname&gt;"]</pre>
		<p><b>Note</b></p> <p>The new application will start on routes comprised of the specified hosts and default domain.</p>		
idle-routes		<p>Valid for a blue-green deployment when a new application version is started on temporary routes.</p> <p>Specify this parameter if you want to use other routes for the application.</p>	<code>\${default-uri}-idle</code>	<pre>modules: - name: app   parameters:     idle-routes:       - idle-route: "&lt;your-first-idle-hostname.your.first.idle.domain&gt;"       - idle-route: "&lt;your-second-idle-hostname.your.second.idle.domain&gt;"</pre>
instances		The number of application instances that will be started during the deployment	<code>\${default-instances}</code>	<code>instances: 2</code>
keep-existing		<p>Defines the application attributes which will be kept after the deployment or blue-green deployment has finished. The supported attributes which could be kept are application environment, application bindings and application routes. If not specified, the default values are false, which indicates that each application attribute will be updated with the new values presented in the deployment descriptor.</p>	<code>false</code>	<p><b>Sample Code</b></p> <pre>keep-existing:   env: true   service-bindings: true   routes: false</pre>

Parameter	Read-Only (System)	Description	Default Value	Example
keep-existing-routes	Write	<p>When specified on module level, it indicates if the existing routes of the module's corresponding application should be kept even if they are not defined within the deployment and/or extension descriptors.</p> <p>When specified on global level, under the <code>parameters</code> section of the descriptor, it indicates if the existing routes of all applications within that MTA should be kept.</p>	false	<div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>Sample Code</b></p> <pre>parameters:   keep-existing-routes: true modules:   - name: foo     type: nodejs     parameters:       keep-existing-routes: false   - name: bar     type: nodejs   - name: baz     type: nodejs</pre> </div>
		<p><b>Note</b></p> <ul style="list-style-type: none"> <li>The module-level variant of the parameter has priority over the global parameter.</li> <li>This parameter is typically used when users want to keep the routes they have mapped manually by using the <code>cf map-route</code> command. We discourage this approach, as manual operations could lead to inconsistent deployment results and difficult troubleshooting. We recommend you to define all routes in the deployment and/or extension descriptors, which allows for their automatic management.</li> </ul>		
memory		The memory limit for all instances of an application. This parameter requires a unit of measurement M, MB, G, or GB in upper or lower case.	256M, or as specified in module-type	<code>memory: 128M</code>
no-route	Write	Configures the deployer to create or skip the creation of a route for the application described by the module	false	<code>no-route: true</code>

Parameter	Read-Only (System)	Description	Default Value	Example
<code>no-start</code>		<p>Start/do not start the application during deployment.</p> <p><b>→ Tip</b></p> <p>This parameter setting overrides the command-line option <code>--no-start</code>.</p> <p>If you explicitly set the <code>no-start</code> to <code>false</code> for the module <code>foo</code> in the example provided, then the module <code>foo</code> <b>is</b> started on deployment, even if you also specify the command-line option <code>--no-start</code> with the <code>cf deploy</code> command.</p>	Depends on the command line option <code>--no-start</code>	<code>no-start: true</code>
<code>restart-on-env-change</code>	Write	<p>Specifies whether an application should be restarted if an environment variable has been changed in one of the following categories:</p> <ul style="list-style-type: none"> <li>• <code>vcap-application</code></li> <li>• <code>vcap-services</code></li> <li>• <code>user-provided</code></li> </ul> <p><b>Note</b></p> <p>If you set these parameters to <code>false</code>, the changes in environment are not consumable by a running instances of the application. If your application depends on the latest environment, it might become outdated.</p>	<p><b>Sample Code</b></p> <pre>restart-on-env-change:   vcap-application: true   vcap-services: true   user-provided: true</pre>	<p><b>Sample Code</b></p> <pre>restart-on-env-change:   vcap-application: false   vcap-services: true   user-provided: true</pre>

Parameter	Read-Only (System)	Description	Default Value	Example
routes		A parameter that lists multiple HTTP routes. For more information, see <a href="#">Routes [page 605]</a> .	<code>\${default-uri}</code>	<div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"> <p><b>Sample Code</b></p> <pre>modules: - name: my-app   type:   application   parameters:   routes:   - route:   "*foo.my.custom.do   main/path"   - route:   foo.my.custom.doma   in/path   -   route: foo.\$   {default-domain}/   path</pre> </div>
route-path		The context "route-path" which is part of the application default URI. Context path routing is routing based not only on domain names (host header) but also the path specified in the URL.	n/a	route-path: /myapp
service-broker-name		The name of the service broker in the Cloud Foundry environment to be created and registered for the specified application module	<code>\${app-name}</code>	service-broker-name: jobscheduler  service-broker-name: \${app-name}
service-broker-password		The password used for authentication by the XS controller at the service broker when performing service-related requests. The parameter is mandatory if <code>create-service-broker: true</code> .		service-broker-password: \${generated-password}
service-broker-space-scoped		Makes the service plans of the broker visible only within the targeted space.	false	service-broker-space-scoped: true
service-broker-url		Specifies the value of the service broker universal resource locator (URL) to register; service requests are sent to this URL. The parameter is mandatory if <code>create-service-broker: true</code> .		service-broker-url: \${default-url}

Parameter	Read-Only (System)	Description	Default Value	Example
service-broker-user		The name of the user required for authentication by the XS controller at the service broker when performing service-related requests. The parameter is mandatory if create-service-broker: true.		service-broker-user: \${generated-user}
stack		Use this parameter to define which pre-built root file system (rootfs) you want to use.	n/a	<div data-bbox="1050 645 1396 936" data-label="Code-Block"> <p>↔ Sample Code</p> <pre>modules:   - name: foo     type: application     parameters:       stack: cflinuxfs3</pre> </div>
tasks		Specify tasks, which are available for execution in the current droplet of the application. Also provide use of environment variables which are specified with the env scope.	n/a	<div data-bbox="1050 969 1396 1178" data-label="Code-Block"> <pre>tasks:   - name: task-1     command: some-script.sh     env:       env1: value1       env2: value2</pre> </div>
tcp		Specifies whether the application should have TCP type routes.	false	tcp:true
tcps		Specifies whether the application should have TCPS type routes.	false	tcps:true
timestamp	Yes	Current timestamp in milliseconds	Generated as described in the description.	

## Module-Specific Properties

The following properties are supported:

MTA Development and Deployment Module Properties

Property	Description	Default Value	Example
MTA_WAIT_AFTER_APP_STOP	Adds configurable delay in seconds, after stopping the application.  <b>Note</b> Reserved environment variable for subsequent MTA operations, which is used in blue-green deployment and undeployment.  <b>Tip</b> Can be used to introduce a faux delay between stopping an application and unbinding its services, in order to avoid errors when unbinding from an application that is still in the process of stopping.	n/a	<b>Sample Code</b> <pre>modules: - name: my-app   type: application   properties:    MTA_WAIT_AFTER_APP_STOP: 30</pre>

## Shared Module Binaries

By default every module has its own binary that is uploaded and deployed in specific manner. It is possible for multiple MTA modules to reference a single deployable binary, for example, an application archive. This means that during deployment, the same application archive is executed separately in multiple applications or application instances, but with different parameters and properties. This results in multiple running applications based on the same source code, which have different configurations and setup. A development project can have one source folder, which is referenced by multiple module entries in the MTA deployment descriptor `mtad.yaml`, as illustrated in the following example:

### Sample Code

Multiple MTA Module Entries in the Deployment Descriptor (`mtad.yaml`)

```
_schema-version: "3.1.0"  
ID: hello  
version: 0.1.0  
modules:  
- name: hello-router
```

```

type: java.tomee
path: web/router.war
requires:
- name: backend
  properties:
    backend: ~{url}/content
    name: backend
    url: ~{url}

- name: hello-backend
  type: java.tomee
  path: web/router.war
  provides:
  - name: backend
    properties:
      url: "${default-url}"

```

If deployment is based on an MTA archive, it is not necessary to duplicate the code to have two different deployable modules; the specification for the MTA-module entry in `MANIFEST.MF` is extended, instead. The following (incomplete) example of a `MANIFEST.MF` shows how to use a comma-separated list of module names to associate one set of deployment artifacts with all listed modules:

### Code Syntax

Multiple MTA Modules Listed in the `MANIFEST.MF` Deployment Manifest

```

Name: web/router.war
MTA-Module: hello-router,hello-backend
Content-Type: application/zip

```

[Metadata for Properties and Parameters \[page 590\]](#)

### 4.1.8.1.6.3 Module Hooks

Define and execute hooks at specific phases of module deployment.

#### Note

The module hooks are supported from major schema version 3 onwards. If they are specified but schema version is below 3, they are ignored.

You can use hooks to change the typical deployment process, in this case to enable tasks to be executed during a specific moment of the application deployment. For example, you can set hooks to be executed before or after the actual deployment steps for a module, depending on the applications' need.

When added to the deployment descriptor, module hooks are modeled as follows:

### Sample Code

```
_schema-version: "3.3"
ID: foo
version: 3.0.0
modules:
  - name: foo
    type: javascript.nodejs
    hooks:
      - name: hook
        type: task
        phases:
          - blue-green.application.before-stop.live
          - blue-green.application.before-stop.idle
        parameters:
          name: foo-task
          command: 'sleep 5m'
```

In the example above, the hook attributes are:

- `name` – defines the name of the hook.
- `type` – defines the type of the hook. Currently, the only supported type is `task`.
- `phases` – defines the specific moment when a hook is executed. The `phases` element denotes that the hook is executed before the application is stopped. The suffixes `live` and `idle` are used during blue-green deployments and indicate when the `before-stop` phase is executed.

### Example

In the example above, the `blue-green.application.before-stop.idle` phase executes the hook when the new idle applications are redirected to the new live routes, and the `blue-green.application.before-stop.live` is used just before the deletion of the live application.

- `parameters` – defines the parameters of the hook. For the hooks of type `task`, the parameters must define a one-off task.

Depending on the deployment strategy you use, the `phases` values are:

- **For regular deployment**

Phase	Supported for types	Description
<code>deploy.application.before-stop</code>	<code>task</code>	Executed before the application corresponding to the module is stopped.
<code>deploy.application.after-stop</code>	<code>task</code>	Executed after the application corresponding to the module is stopped.
<code>deploy.application.before-start</code>	<code>task</code>	Executed before the application corresponding to the module is started.

- **For blue-green deployment**

Phase	Supported for types	Description
<code>blue-green.application.before-stop.idle</code>	task	Executed before the idle application corresponding to the module is stopped. Idle applications are created as part of blue-green deployments and are restarted (stopped and started again) after the deployment validation phase of their productization. That is after the live routes are mapped to them and their environments are rebuilt to contain only live routes.
<code>blue-green.application.before-stop.live</code>	task	Executed before the live application corresponding to the module is stopped. Live applications are the ones that are already up and running before the deployment starts.
<code>blue-green.application.after-stop.idle</code>	task	Executed after the idle application corresponding to the module is stopped.
<code>blue-green.application.after-stop.live</code>	task	Executed after the live application corresponding to the module is stopped.
<code>blue-green.application.before-unmap-routes.live</code>	task	Executed before unmapping the route of the live application that corresponds to the module.
<code>blue-green.application.before-start.idle</code>	task	Executed before the idle application corresponding to the module is started.
<code>blue-green.application.before-start.live</code>	task	Executed before the live application corresponding to the module is started.

## Module Hooks - Specific Parameters

The table below contains the parameters of the supported module hook types:

Module hooks of type task

Parameter	Is It Mandatory?	Description	Default Value	Example
<code>name</code>	No	Defines the name of the Cloud Foundry task that should be executed.	The name of the hook.	<code>name : db_migration</code>
<code>command</code>	Yes	Defines the actual command that is executed as a Cloud Foundry task.		<code>command : "bin/rails db:migrate"</code>

Parameter	Is It Mandatory?	Description	Default Value	Example
memory	No	Defines the memory that is available to the Cloud Foundry task.	Landscape specific value that is equal to the default application memory.	memory: 256M memory: 1G
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>→ Remember</b></p> <p>Do not rely on the default value, as it will probably be much higher than you need and may not fit into the limitations of your quota.</p> </div>				
disk-quota	No	Defines the disk space that is available to the Cloud Foundry task.	Landscape specific value that is equal to the default application disk quota.	disk-quota: 256M disk-quota: 1G
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>→ Remember</b></p> <p>Do not rely on the default value, as it will probably be much higher than you need and may not fit into the limitations of your quota.</p> </div>				

## Extending Module Hooks Through an Extension Descriptor

You can also extend module hooks through the extension descriptor. To do so, add the code with your specific parameters, similarly to the following example:

### 🔗 Sample Code

```

_schema-version: "3.3"
ID: foo-change-command
extends: foo
modules:
  - name: foo
    hooks:
      - name: hook
        parameters:
          command: 'sleep 1m'

```

[Legacy Blue-Green Deployment \[page 613\]](#)

### 4.1.8.1.6.4 Parameters and Properties

This section contains information about the parameters and properties of a Multitarget Application (MTA).

The values of parameters and properties can be specified at design time, in the MTA development description (`mta.yaml`) or in the MTA deployment descriptor (`mtad.yaml`). In some cases, it is better to declare certain values depending on the deployment, for example, in an extension descriptor file (`myDeployExtension.mtaext`).

The values of parameters and properties might be literals. This way, the result of each deployment will be the same every time. However, by using the placeholders described below, the values might also be set as substitution variables and therefore each deployment might end in a different result depending on the environment or other configurations.

Regardless of the defined value - literal or substitution variable, in most cases the end value for each parameter or property is definitive and well-known before the deployment. This is because the substitution variable values represent a certain template and template resolving is done in the beginning of the MTA deployment.

The module level parameter `${default-host}` follows the template `${org}-${space}-<module_name>`. For example, when it is used in a module `my-module` and the deployment is done within `org my-org`, `space my-space`, the end value of `${default-host}` will be `my-org-my-space-my-module`.

However, in some cases the parameter or property value is dynamic and cannot be predicted before the deployment. In these cases, the substitution variable is dynamic and is done in a later phase of the MTA deployment.

If you want to learn more about dynamically resolved parameters see the [Dynamic parameters \[page 588\]](#) section below.

The values of properties and parameters are used during the deployment or at runtime of the MTA.

#### Note

Both parameters and properties may have literal values, such as strings, integers, etc. This also applies to deeply nested structured values, such as arrays or maps.

#### Tip

- You can declare metadata for parameters and properties defined in the MTA deployment description; the mapping is based on the parameter or property keys. For example, you can specify if a parameter is **required** (`optional: false`) or can be modified `overwritable: true`.
- Descriptors can contain so-called placeholders (also known as substitution variables), which can be used as sub-strings within property and parameter values. Placeholder names are enclosed by the dollar sign (\$) and curly brackets ({}). For example: `${host}` and `${domain}`. For each parameter

“P”, there is a corresponding placeholder `{P}`. The value of `<P>` can be defined either by a descriptor used for deployment, or by the deploy service itself. Placeholders can also be used without any corresponding parameters; in this scenario, their value cannot be overridden in a descriptor. Such placeholders are read-only.

## Parameters

Parameters are reserved variables that affect the behavior of the MTA-aware tools, such as the Cloud MTA Build Tool (MBT) or SAP Cloud Deployment service.

Parameters might be used on various levels in the MTA descriptor - top-level, module level, resource level, and dependency level. Based on the parameter applicability it might be used in combination in several places, for example, both on resource and module levels.

Parameters can be “Read-Only” (also known as “System”) or “Read-Write” (default value can be overwritten). All parameter values can be referenced as part of other property or parameter value strings. The value of a “Read-Only” parameter cannot be changed in descriptors. Only its value can be referenced using the placeholder notation. To reference a parameter value, use the placeholder notation `{<parameter>}`, for example `{org}`

SAP Cloud Deployment service supports a list of parameters and their (default) values:

- [Module-Specific Parameters \[page 566\]](#)
- [Resource-Specific Parameters \[page 556\]](#)
- [Module Hooks - Specific Parameters \[page 579\]](#)
- Generic parameters (table below) that can have the following scopes:
  - Top-level - can be defined on top level.
  - All - can be consumed everywhere throughout the document.

### Note

Generic Parameters table contains parameters that might be used on top-level or on all levels. Other supported parameters are distributed in the dedicated pages, for example, module-specific parameters.

The example below shows the parameter `memory` on a module level which defines the amount of memory used by the Cloud Foundry application represented by the module `node-hello-world` during application runtime.

### Sample Code

```
modules:  
  - name: node-hello-world  
    type: javascript.nodejs  
    path: web/  
    parameters:  
      memory: 128M
```

- Generic Parameters

Parameter	Scope	Read-Only (System)	Description	Default Value	Example
authorization-url	All	Yes	The authorization URL as specified in the cloud controller's /v2/info endpoint.	Generated as described in the description.	https://login.cf.sap.hana.on-demand.com
controller-url	All	Yes	The URL of the cloud controller	Generated as described in the description.	https://api.cf.sap.hana.on-demand.com
default-domain	All	Yes	The default domain (configured in the Cloud Foundry environment)	Generated as described in the description.	accra6024 cfapps.acme.com
deploy-url	All	Yes	The deploy service URL for the Cloud Foundry environment	Generated as described in the description.	
generated-password	All	Yes	Randomly generated string value that is composed of 16 characters that may contain upper and lower case letters, digits and special characters (_, -, @, \$, &, #, *).	Generated as described in the description.	IG@zGg#2g-cvMvsW
generated-user	All	Yes	A generated user id that is composed of 16 characters that may contain upper and lower case letters, digits and special characters (_, -, @, \$, &, #, *).	Generated as described in the description.	uYi\$d41TzM1-Dm6f

Parameter	Scope	Read-Only (System)	Description	Default Value	Example
keep-existing-routes	Global	Write	<p>When specified on module level, it indicates if the existing routes of the module's corresponding application should be kept even if they are not defined within the deployment and/or extension descriptors.</p> <p>When specified on global level, under the <code>parameters</code> section of the descriptor, it indicates if the existing routes of all applications within that MTA should be kept.</p>	false	<pre>parameters:   keep-existing-routes: true modules:   - name: foo     type: nodejs     parameters:       keep-existing-routes: false   - name: bar     type: nodejs   - name: baz     type: nodejs</pre>

#### Note

- The module-level variant of the parameter has priority over the global parameter.
- This parameter is typically used when users want to keep the routes they have mapped manually by using the `cf map-route` command. We discourage this approach, as manual operations could lead to inconsistent deployment results and difficult troubleshooting. We recommend you to define all routes in the deployment and/or extension descriptors, which allows for their automatic management.

Parameter	Scope	Read-Only (System)	Description	Default Value	Example
org	All	Yes	Name of the target organization	The current name of the target organization	initial, trial
protocol	All	Yes	The protocol used by the Cloud Foundry environment.	http or https	http, https
space	All	Yes	Name of the target organizational space	Generated as described in the description.	initial, a007007
user	All	Yes	Name of the current user	Generated as described in the description.	
xs-type	All	Yes	The XS type, Cloud Foundry or XS advanced	CF	CF, XSA
org-guid	All	Yes	GUID (Globally Unique Identifier) of the target organization	N/A	06564ad5-1b38-458d-8c85-a2e0bcd990a9
space-guid	All	Yes	GUID (Globally Unique Identifier) of the target space	N/A	06564ad5-1b38-458d-8c85-a2e0bcd990a9
mta-version	All	Write	The version of the MTA	N/A	1.0.0
mta-id	All	Write	The ID of the MTA	N/A	1.0.0

These parameters can be used with the `provides` or `requires` dependencies:

#### Dependency-Specific Parameters

Parameter	Scope	Read-Only (System)	Description	Default Value	Example
env-var-name	required dependency	Write	Used when consuming an existing service key. Specifies the name of the environment variable that will contain the service key's credentials. See Consumption of existing service keys for more information.	The name of the service key.	env-var-name : SERVICE_KEY_CREDENTIALS

Parameter	Scope	Read-Only (System)	Description	Default Value	Example
visibility	provided dependency	Write	Specifies the organizations and spaces in which public provided dependencies are visible. See Visibility of cross-MTA configuration for more information.	In all spaces of the current organization.  visibility: - org: \${org}  space: " * "	visibility: - org: foo space: " * " - org: bar space: " * " - org: baz space: qux

As an alternative, you can also externalize such configurations in a file. See [Service Creation Parameters \[page 597\]](#).

## Properties

MTA properties are Cloud Foundry application environment variables that are used during application runtime. When an MTA property is set, the SAP Cloud Deployment service injects its key as the environment variable key and its value as the variable value in the application, represented by the corresponding MTA module.

MTA properties can be declared in different levels - module level, resource level, and dependency level.

### Cross-References to Properties

To enable resource properties to resolve values from a property in another resource or module, a resource must declare a dependency. However, these “requires” declarations do not affect the order of the application deployment.

#### ⚠ Restriction

It is not possible to reference **list** configuration entries either from resources or “subscription” functionalities (deployment features that are available to subscriber applications).

#### ↔ Code Syntax

Cross-References between Properties in the MTA Deployment Descriptor in a YAML file

```
modules:
  - name: java
    ...
    provides:
      - name: backend
        properties:
          url: ${default-url}/foo
resources:
  - name: example
    type: example-type
```

```

properties:
  example-prop: my-example-prop
- name: uaa
  type: uaa-type
  requires:
    - name: example
    - name: backend
      properties:
        prop: ~{url}
      parameters:
        param: ~{url}
  properties:
    prop: ~{example/example-prop}
  parameters:
    config:
      app-router-url: ~{backend/url}
      example-prop: ~{example/example-prop}

```

Note the following about the example above:

- The application name `backend` can depend on the provided content.
- The `java` module provides the `url` property, which can be referenced by other modules. Its value is generated using the default `url` provided to the application during deployment.
- The `java` module property `prop` contains a parameter `url`, which results in an environment variable `<prop>` containing the referenced value.
- References to other properties can also be used for parameter values, for example in values contained in the `provides` section of a module.

## Fully qualified references to properties

The SAP Cloud Deployment service supports the extension of the standard syntax for references in module properties. This extension enables you to specify the name of the `requires` section inside the property reference. You can use this syntax extension to declare implicit groups, as illustrated in the following example:

### Sample Code

Syntax Extension: Alternative Grouping of MTA Properties

```

modules:
- name: pricing-ui
  type: javascript.nodejs
  properties:
    API: # equivalent to group, but defined in the module properties
    - key: internal
      protocol: ~{price_opt/protocol} #reference to value of protocol
    defined in price_opt of module pricing-backend
    - key: external
      url: ~{competitor_data/url} # reference to string value of property
    'url' in required resource 'competitor_data'
      api_keys: ~{competitor_data/creds} # reference to list value of
    property 'creds' in 'competitor_data'
  requires:
    - name: competitor_data
    - name: price_opt
- name: pricing-backend
  type: java.tomcat
  provides:
    - name: price_opt

```

```

    properties:
      protocol: http ...
  resources:
    - name: competitor_data
      properties:
        url: "https://marketwatch.acme.com/"
        creds:
          app_key: 25892e17-80f6
          secret_key: cd171f7c-560d

```

## Dynamic parameters

In some cases, it is required to use a value that is unknown before deployment. For example, such entity could be the GUID of another service instance. The GUID of a newly created service instance is not known before the creation of said service but it might be consumed during the MTA deployment.

The feature enables an existing Cloud Foundry entity parameter value to be used inside an MTA descriptor.

### Note

Currently, the feature is limited to resolving service GUID for the following resource types:

- `org.cloudfoundry.managed-service`
- `org.cloudfoundry.user-provided-service`
- `org.cloudfoundry.existing-service`

Resolved parameters can only be referenced from other resources or from a cross-MTA dependency. If a dynamic parameter is referenced from other places, like modules, the reference won't be resolved.

### Sample Code

MTA Deployment Descriptor (`mtad.yaml`)

```

_schema-version: 3
ID: sample-dynamic-service-guid
version: 1.0.0
modules:
  - name: sample-app
    type: staticfile
    path: content.zip
    requires:
      - name: test-service
      - name: hana-service
resources:
  - name: test-service
    type: org.cloudfoundry.user-provided-service
    parameters:
      config:
        service-guid-of-db: ~{hana-service/my-db-service-guid}
    requires:
      - name: hana-service
    processed-after: [hana-service]
  - name: hana-service
    type: org.cloudfoundry.managed-service
    parameters:
      service: hana
      service-plan: schema
    properties:

```

```
my-db-service-guid: ${service-guid}
```

### Note

In order to use this feature, it is necessary to specify `${service-guid}` inside the `properties` section of the resource. Consumer of service GUID value must add respective resource name in the `requires` section and specify the `processed-after` parameter because the order of resource processing must be explicitly described.

## Dynamic parameter as a cross-MTA dependency

Resolved parameters can also be referenced from a cross-MTA dependency, allowing the service instance to be referenced from another MTA.

The following example shows the dependency declaration referencing a dynamic parameter in the deployment descriptor of the “provider” MTA:

### Sample Code

```
_schema-version: 3
ID: dynamic-service-guid-consumer
version: 1.0.0
modules:
  - name: app-consumer
    type: staticfile
    path: content.zip
    requires:
      - name: db-config
        properties:
          reference_instance: ~{db-instanceid}
resources:
  - name: db-config
    type: configuration
    parameters:
      provider-id: "dynamic-service-guid-provider:db-guid"
      version: ">=1.0.0"
      target:
        org: ${org}
        space: ${space}
```

The following example shows the dependency declaration in the deployment descriptor of the “consumer” MTA:

### Sample Code

```
_schema-version: 3
ID: dynamic-service-guid-consumer
version: 1.0.0
modules:
  - name: app-consumer
    type: staticfile
    path: content.zip
    requires:
      - name: db-config
        properties:
          reference_instance: ~{db-instanceid}
resources:
  - name: db-config
    type: configuration
    parameters:
```

```

provider-id: "dynamic-service-guid-provider:db-guid"
version: ">=1.0.0"
target:
  org: ${org}
  space: ${space}

```

For more information about cross-MTA configurations see [Cross-MTA Dependencies \[page 607\]](#).

### 4.1.8.1.6.5 Metadata for Properties and Parameters

It is possible to declare metadata for parameters and properties defined in the MTA deployment description, for example, using the "parameters-metadata:" or "properties-metadata:" keys, respectively; the mapping is based on the keys defined for a parameter or property.

You can specify if a property is required (`optional: false`) or can be modified (`overwritable: true`), as illustrated in the following (incomplete) example:

The `overwritable:` and `optional` keywords are intended for use in extension scenarios, for example, where a value for a parameter or property is supplied at deployment time and declared in a deployment-extension descriptor file (`myMTADeploymentExtension.mtaext`).

You can declare metadata for the parameters and properties that are already defined in the MTA deployment description. However, any parameters or properties defined in the `mtad.yaml` deployment descriptor with the metadata value `overwritable: false` cannot be overwritten by a value supplied from the extension descriptor. In this case, an error would occur in the deployment.

#### → Tip

Parameters or properties can be declared as sensitive. Information about properties or parameters flagged as sensitive is not written as plain text in log files; it is masked, for example, using a string of asterisks (`*****`). Note the `secret_token: element` in the example.

#### Code Syntax

Metadata for MTA Deployment Parameters and Properties

```

modules:
- name: frontend
  type: javascript.nodejs
  parameters:
    memory: 128M
    domain: ${default-domain}
  parameters-metadata:
    memory:
      optional: true
      overwritable: true
    domain:
      overwritable: false
  properties:
    secret_token: ${generated-password}
  backend_types:
    order_management: sap-erp
    data_warehouse: sap-bw

```

## 4.1.8.1.7 Defining MTA Extension Descriptors

The Multitarget Application (MTA) extension descriptor is a YAML file that contains data complementary to the deployment descriptor. The data can be environment or deployment specific, for example, credentials depending on the user who performs the deployment. The MTA extension descriptor is a YAML file that has a similar structure to the deployment descriptor. It follows the Multitarget Application Model structure with several limitations and differences. Normally, the extension descriptor extends the deployment descriptor but it is possible to build upon another extension descriptor, making an extension descriptors chain. It can add or overwrite existing data if necessary.

Several extension descriptors can be additionally used after the initial deployment.

### Note

The format and available options within the extension descriptor may change with newer versions of the MTA specification. You must always specify the schema version option when defining an extension descriptor to inform the SAP BTP which MTA specification version should be used. Furthermore, the schema version used within the extension descriptor and the deployment descriptor should always be the same.

In the examples below, we have a deployment descriptor, which has already been defined, and several extension descriptors.

### Note

Each extension descriptor is defined in a separate file with an extension `.mtaext`.

Deployment descriptor:

### Example

```
_schema-version: '3.1'
parameters:
  hcp-deployer-version: '1.0'
ID: com.example.extension
version: 0.1.0
resources:
  - name: data-storage
    properties:
      existing-data: value
```

The example above instructs SAP BTP to:

- Validate the extension descriptor against the MTA specification version 3.1
- Extend the `com.example.extension` deployment descriptor

The following is a basic example of an extension descriptor that adds data and overwrites data to another extension descriptor:

### Example

```
_schema-version: '3.1'
ID: com.example.extension.first
extends: com.example.extension
resources:
  - name: data-storage
```

```
properties:
  existing-data: new-value
  non-existing-data: value
```

The above instructs SAP BTP to:

- Extend the deployment descriptor by its ID `com.example.extension`
- Validate the extension descriptor against the MTA specification version 3.1
- Overwrite the data for the `existing-data` property
- Add a new data called `non-existing-data` to the `data-storage` properties

The following is an example of another extension descriptor that builds upon the extension descriptor from the previous example:

### ❁ Example

```
_schema-version: '3.1'
ID: com.example.extension.second
extends: com.example.extension.first
resources:
  - name: data-storage
    properties:
      second-non-existing-data: value
```

The example above instructs the SAP BTP to:

- Extend the first extension descriptor by its ID
- Add a new data called `second-non-existing-data` to the `data-storage` properties
- The examples above are incomplete. To deploy a solution, you have to create a deployment descriptor and an MTA archive.

### What is possible to do with an extension descriptor?

You can do the following using an extension descriptor:

- Add new data in properties and parameters on module level, resource level, provided section level and required section level
- Overwrite an existing data (in depth) in modules, resources, parameters, properties, provides, requires sections. This depends on the parameter or property metadata overwritable. See [Metadata for Properties and Parameters \[page 590\]](#).
- As of schema version 3.xx, by default parameters and properties are overwritable and optional. If you want to make a certain parameter or property non-overwritable or required, you need to add specific metadata. See [Metadata for Properties and Parameters \[page 590\]](#).

You cannot use an extension descriptor to:

- Add new entities such as modules or resources
- Change module or resource type
- Alter read-only (system) parameters
- Add new provided or required dependencies
- Change the processing order of modules and resources with `deployed-after` and `processed-after` parameters

### 4.1.8.1.8 SAP Business Technology Platform Capabilities

This section contains information about how to manage standard Cloud Foundry entities with MTA modelling.

- [Applications \[page 593\]](#)
- [Tasks \[page 595\]](#)
- [Services \[page 597\]](#)
- [Routes \[page 605\]](#)

#### 4.1.8.1.8.1 Applications

If you want to create an application in Cloud Foundry and use the SAP Cloud Deployment service, you must create an MTA module first.

In most of cases, an MTA module represents a Cloud Foundry application, but there are cases where they represent an entirely different type of entity, for example content. Modules can have different types and parameters that modify their behavior. See [Modules \[page 560\]](#) for more information.

##### Note

We strongly recommend that you explicitly specify the appropriate buildpack for your application. This ensures that the application is handled by the buildpack for which it is intended and tested. It also speeds up application deployment, because only the specified buildpack is downloaded for use during the staging process.

You have to use the `buildpack` module parameter, if you are using any of the following MTA module types:

- `application`
- `custom`
- `javascript.nodejs`

## MTA Deployment Optimizations

The MTA deployment is an incremental process. This means that the state of the artifacts in the Cloud Foundry environment is compared to the desired state described in the `mta.ad.yaml`. If there's a difference, a set of

operations are computed in order to make the MTA reach the desired state. The following optimizations are possible during the MTA redeployment:

- The application bits are reuploaded if:
  - The application content is changed and there is no cache of the same content for a different application, even in a different space. The Cloud Foundry environment has global caching of application bits without organizational and space isolation.
- The application is restaged and restarted if:
  - The application attributes, such as commands, buildpacks, memory, `health-check-url`, and so on, are changed
  - The application environment is changed
  - There are new services the application is bound to
  - There are services the application is bound to, which are discontinued (not available) in the new version of the MTA

#### Note

Currently, Cloud Foundry environment applications are restaged if they are bound to any service with parameters. This is necessary, because it's not possible to get the current Cloud Foundry service parameters and compare them with the desired ones.

- The application is bound to service configuration parameters that have been changed. This requires an update of the service instance and rebind, restage, and restart of the application.
- The service binding parameters are changed. This requires an update of the service binding and restage of the application.
- The MTA version is changed, which requires a change of special application environment variables, managed by the deploy service.

### 4.1.8.1.8.2 Docker Images as Part of an MTA Deployment

Deploy Docker images as part of a Multitarget application.

You can deploy your own or 3rd party Docker images in the Cloud Foundry environment by referencing them in an application module.

This type of application deployment is faster, as images are already built. Thus, staging is not required, and also all dependencies are statically included in the image.

#### Note

When you reference docker images, MTA packages are not self-sustained - they depend on external repositories hosting images for the deployment.

You can deploy Docker images as MTA modules using the Cloud Foundry command line interface.

To deploy a Docker image as a Cloud Foundry application, your deployment descriptor should reference the image in a module as described in the following example:

#### Sample Code

```
...
modules:
  name: foo
  type: application
  parameters:
    docker:
      image: cloudfoundry/test-app
      username: <username>
      password: <password>
    build-parameters: #only required for mta.yaml
      no-source: true
...
```

Using the parameters above:

- `image` - you reference the location of the image so that it can be scheduled for download by the platform. You have to provide the location of the image using the format `<registry.domain><:port>/repo/image:<tag>`. If you don't do so, images are referenced from Docker Hub. See more about deploying an application with Docker in the provided link at the end of the section.
- (Optional) `username` and `password` - you provide credentials in the descriptor only when the image repository requires them.
- `no-source` - set this parameter to `true` only when creating an MTA development descriptor (`mta.yaml`) that is meant to be used with the Cloud MTA Build Tool.

### 4.1.8.1.8.3 Tasks

Create one-off administration tasks or scripts.

During the deployment process, these tasks can be executed against staged applications. The platform creates a new container for them, where they are performed for a specific period until they are completed, after which the container is deleted.

One-off tasks are modeled in accordance to the following structure:

### Sample Code

```
_schema-version: "3.1"
ID: foo
version: 3.0.0
modules:
  - name: foo
    type: javascript.nodejs
    parameters:
      no-route: true
      no-start: true
      disk-quota: 2GB
    tasks:
      - name: example_task
        command: npm start
        memory: 1GB
```

In the structure above, the parameters stand for the following:

- When the task is triggered, the `npm start` command is executed.
- Entering a specific value in the `memory` parameter is optional. A platform-derived default memory size is used for the execution of the task. You can specify a different value if required.
- The `no-route` parameter specifies if a route is required. Applications whose only purpose is to perform a task and then be stopped usually do not require a route. The default value is `false`.
- Use the `no-start` parameter if you want only the one-off tasks to be executed, that is, without triggering the start of the application. If you do not define this parameter, tasks are automatically executed after the applications are started.

### Note

The values for application memory and task memory do not have a dependency. This is also valid for the allowed disk quota.

### Tip

For more information about one-off tasks, see [MTA Deployment Descriptor Examples \[page 544\]](#).

The following codeblock contains an example for a database migration task:

### Sample Code

```
_schema-version: "3.1"
ID: foo
version: 3.0.0
modules:
  - name: foo
    type: javascript.nodejs
    parameters:
      no-route: true
      no-start: true
      memory: 1GB
      disk-quota: 2GB
    tasks:
      - name: db_migration
        command: "bin/rails db:migrate"
        memory: 256M #This parameter is optional.
```

```
disk-quota: 128M
```

```
#This parameter is optional.
```

## Related Information

[Using Tasks](#) 

### 4.1.8.1.8.4 Services

If you want to create a service in the Cloud Foundry environment using the SAP Cloud Deployment service, you must define an MTA resource first. These resources can have different types and parameters which modify their behavior. There is a predefined set of supported resource types, that in most cases represents a certain combination of service offering and plan. See [Predefined MTA Resource Types \[page 553\]](#).

#### Sample Code

```
resources:
  - name: my-xsuaa-service
    type: com.sap.xs.uaa
```

The result will be a service instance called `my-xsuaa-service` with service offering `xsuaa` and service plan `application`.

For a more flexible approach, see [Generic MTA Resource Types \[page 552\]](#) and [Resource-Specific Parameters \[page 556\]](#).

#### Note

In most of cases, MTA resources represent a Cloud Foundry service, but there are cases where they represent a different platform entity, for example a service key. They can even serve only to a group of configurations. See [Resources \[page 550\]](#) for more information.

### 4.1.8.1.8.4.1 Service Creation Parameters

Some services support additional configuration parameters in the `create-service` request. These parameters are parsed in a valid JSON object containing the service-specific configuration parameters.

The deploy service supports the following methods for the specification of service creation parameters:

- Method A - an entry in the MTA deployment descriptor or the extension
- Method B - a JSON file with the required service configuration parameters

### Note

If service-creation information is supplied both in the deployment (or extension) descriptor **and** in a supporting JSON file, the parameters specified directly in the deployment (or extension) descriptor override the parameters specified in the JSON file.

Service creation parameters - method comparison

Method A	Method B	Combination of the two methods
<p>↔ Sample Code</p> <p>MTA deployment descriptor or extension</p> <pre>resources:   - name: java-uaa     type:       com.sap.xs.uaa       parameters:         config:           xsappname:             java-hello-world</pre>	<p>↔ Sample Code</p> <p>MTA deployment descriptor or extension</p> <pre>resources:   - name: java-uaa     type:       com.sap.xs.uaa</pre>	<p>↔ Sample Code</p> <pre>resources:   - name: java-uaa     type:       com.sap.xs.uaa       parameters:         path: &lt;path to directory&gt;         config:           xsappname:             java-hello-world</pre>
	<p>↔ Sample Code</p> <p>xs-security.json</p> <pre>{   "xsappname": "java-hello-world" }</pre>	<p>↔ Sample Code</p> <p>xs-security.json</p> <pre>{   "xsappname": "java-hello-world" }</pre>
	<p>↔ Sample Code</p> <p>Additional entry in MANIFEST.MF</p> <pre>Name: xs-security.json MTA-Resource: java-uaa Content-Type: application/json</pre>	<p>↔ Sample Code</p> <p>Additional entry in MANIFEST.MF</p> <pre>Name: xs-security.json MTA-Resource: java-uaa Content-Type: application/json</pre>

Using method A, all parameters under the special `config` parameter are used for the service creation request. This parameter is optional.

### → Tip

You can use the optional `path` parameter to navigate to a JSON file containing service-specific parameters and configurations. The content of the file is used for the creation or update of the service instance.

Note that if you are deploying from a local directory using an `mtad.yaml`, it needs to contain the path to the JSON file, so that the relevant `MANIFEST.MF` entry is generated.

Using method B, there are dependencies on further configuration entries in other configuration files. For example, if you use this JSON method, an additional entry must be included in the `MANIFEST.MF` file which defines the path to the JSON file containing the parameters as well as the name of the resource for which the parameters should be used.

### 4.1.8.1.8.4.2 Service Binding Parameters

Some services support additional configuration parameters with the bind request. These parameters are passed in a valid JSON object containing service-specific configuration parameters, provided either in-line or in a file. For a list of supported configuration parameters, see the documentation for the particular service offering.

#### Note

At the time being user-provided services do not support arbitrary binding parameters.

The SAP Cloud Deployment service supports the following methods for the specification of service-binding parameters:

- Method 1 - In-line parameters into MTA descriptors (deployment or extension descriptors)
- Method 2 - JSON file with external configuration, containing the required service-configuration parameters
- A combination of the first two methods, as described in the table below

#### Note

If service-binding information is supplied both in the MTA's deployment (or extension) descriptor **and** in a supporting JSON file, the parameters specified directly in the deployment (or extension) descriptor override the parameters specified in the JSON file.

In the MTA deployment descriptor, the `requires` dependency between a module and a resource represents the binding between the corresponding application and the service created from them (if the service has a `type`). For this reason, the `config` parameter is nested in the `requires` dependency parameters, and a distinction must be made between the `config` parameter in the `modules` section and the `config` parameter used in the `resources` section (for example, when used for service-creation parameters).

Method 1	Method 2	Combination of the two methods
<p>↔ Sample Code</p> <p>MTA deployment descriptor or extension</p> <pre>modules:   - name: node-hello-world-backend     type: javascript.nodejs     requires:       - name: node-hdi-container         parameters:           config:  permissions:   debugging</pre>	<p>↔ Sample Code</p> <p>A JSON file with the required service-configuration parameters</p> <pre>modules:   - name: node-hello-world-backend     type: javascript.nodejs     requires:       - name: node-hdi-container</pre>	<p>↔ Sample Code</p> <pre>modules:   - name: node-hello-world-backend     type: javascript.nodejs     requires:       - name: node-hdi-container         parameters:           config:  permissions:   debugging</pre>
	<p>↔ Sample Code</p> <p>Content of <code>xs-hdi.json</code></p> <pre>{   "permissions": "debugging" }</pre>	<p>↔ Sample Code</p> <p>Content of <code>xs-hdi.json</code></p> <pre>{   "permissions": "debugging" }</pre>
	<p>↔ Sample Code</p> <p>Additional entry in <code>MANIFEST.MF</code></p> <pre>Name: xs-hdi.json MTA-Requires: node-hello-world-backend/node-hdi-container Content-Type: application/json</pre>	<p>↔ Sample Code</p> <p>Additional entry in <code>MANIFEST.MF</code></p> <pre>Name: xs-hdi.json MTA-Requires: node-hello-world-backend/node-hdi-container Content-Type: application/json</pre>

**Note**

The examples are only illustrative for service-binding parameters. Each service offering supports its own set of parameters.

Method 1 shows how to define the service-binding parameters in the MTA deployment descriptor (`mtad.yaml`). If you use this method, all parameters under the special `config` parameter are used for the service-bind request. This parameter is optional.

Method 2 shows how to define the service-binding parameters for a service-bind request in a JSON file. Using this method, there are dependencies on entries in other configuration files. For example, when using the JSON method, an additional entry must be included in the `MANIFEST.MF` file. This new entry has to define the path to the JSON file that contains the parameters and the name of the resource for which the parameters should be used.

Note that when you use the combination of the two methods, the parameters defined in the descriptor have higher priority than the ones defined in the JSON file.

#### 📌 Note

To avoid ambiguities, the name of the module is added as a prefix to the name of the `requires` dependency; the name of the manifest attribute uses the following format: `<module-name>#<requires-dependency-name>`.

### 4.1.8.1.8.4.3 Service Tags

Some services provide a list of tags that are later added to the `<VCAP_SERVICES>` environment variable. These tags provide a more generic way for applications to parse `<VCAP_SERVICES>` for credentials.

You can also provide custom tags when creating a service instance. To inform the SAP Cloud Deployment service about custom tags, you can use the special `service-tags` parameter. This parameter must be located in the `resources` definition that represent the managed services, as illustrated in the following example:

#### 📄 Sample Code

Defining Service Tags in the MTA Deployment Descriptor

```
resources:
  - name: nodejs-uaa
    type: com.sap.xs.uaa
    parameters:
      service-tags: [ "custom-tag-A", "custom-tag-B" ]
```

#### 📌 Note

Some service tags are inserted by default, for example, `xsuaa`, for the XS User Account and Authentication (UAA) service.

### 4.1.8.1.8.4.4 Service Broker Creation

Service brokers are applications that advertise a catalog of service offerings and service plans, as well as interpreting calls for creation, binding, unbinding, and deletion. The `deploy` service supports automatic creation (and update) of service brokers as part of an application deployment process.

An application can declare that a service broker should be created as part of its deployment process, by using the following parameters in its corresponding module in the MTA deployment (or extension) descriptor:

#### → Tip

You can use placeholders `${ }` in the service-URL declaration.

## Sample Code

```
- name: jobscheduler-broker
  properties:
    user: ${generated-user}
    password: ${generated-password}
  parameters:
    create-service-broker: true
    service-broker-space-scoped: true
    service-broker-name: jobscheduler
    service-broker-user: ${generated-user}
    service-broker-password: ${generated-password}
    service-broker-url: ${default-url}
```

## Note

By default, defined service brokers in MTA are attempted to be registered as standard service broker which is available in all orgs and spaces. In practice, however, this is forbidden, as the registration requires CF admin access, which is not provided to anyone.

For test purposes, space-scoped brokers can be registered. In order to do that, parameter `service-broker-space-scoped` needs to be equal to `true`.

The value of the “`${generated-user}`” and “`${generated-password}`” placeholders in the `properties` section is the same as in the `parameters` section. The service-broker application uses this mechanism to inject the user-password credentials.

The `create-service-broker` parameter should be set to `true` if a service broker must be created for the specified application module. You can specify the name of the service broker with the `service-broker-name` parameter; the default value is `${app-name}`. The `service-broker-user` and `service-broker-password` are the credentials that will be used by the controller to authenticate itself to the service broker in order to make requests for creation, binding, unbinding and deletion of services. The `service-broker-url` parameter specifies the URL on which the controller will send these requests.

## Note

During the creation of the service broker, the Cloud Controller makes a call to the service-broker API to inquire about the services and plans the service broker provides. For this reason, an application that declares itself as a service broker must implement the service-broker application-programming interface (API). Failure to do so might cause the deployment process to fail.

## Note

Normally, the registration of a space-scoped broker is successful, because it requires `SpaceDeveloper` privileges of the user. However, for a global registration of the service broker, global admin privileges are needed, which the platform developer usually does not have. In such cases, the MTA deployment would fail. To solve this, do not use the `--do-not-fail-on-missing-permissions` option, which will result in skipping the step with a warning.

## 4.1.8.1.8.4.5 Service Keys

The consumption of existing service keys from applications is an alternative of service bindings. The application can use the service key credentials and consume the service.

### Creation and Update of Service Keys

A `service-keys` parameter can be created or updated when a service instance is being created or updated. It has to be defined under the resources that represent services which support service keys.

#### Sample Code

```
resources:
- name: my-service-instance
  type: org.cloudfoundry.managed-service
  parameters:
    service-keys: # Specifies the service keys that should be created for the
    respective service instance. Optional parameter.
    - name: tool-access-key # Specified the service key name. Mandatory
    element.
    config: # Specified the service key configuration. All entries under
    this map element are used for the service key creation request. Optional
    element.
      permissions: read-write
    - name: reader-endpoint
      config:
        permissions: read-only
```

As shown in the example above, every service key entry under the `service-keys` parameter supports optional configuration parameters that can be defined under the `config` parameter.

### Consumption of Service Keys

To be consumed, the existing service keys are modeled as a resource of type `org.cloudfoundry.existing-service-key`. MTA modules might be set to depend on these resources by using a configuration in the `requires` section, which results in an injection of the service key credentials in the application environment.

#### Sample Code

```
modules:
- name: app123
  type: javascript.nodejs
  requires:
    - name: service-key-1
    parameters:
      env-var-name: keycredentials
  ...
resources:
- name: service-key-1
  type: org.cloudfoundry.existing-service-key
  parameters:
    service-name: service-a
```

```
service-key-name: test-key-1
```

As a result, the application `app123` has the environment variable `keycredentials`, with value the credentials of the existing service key `test-key-1` of service `service-a`.

### Note

Note that only the parameter `service-name` is mandatory. It defines which service is used by the application.

The following parameters are optional:

- `service-key-name` - resource parameter, which defines which service key of the defined service is used. The default value is the name of the resource.
- `env-var-name` - required dependency parameter, which defines what is the name of the new environment variable of the application. The default value is the service key name.

## Automatic Service Key Renewal

It's a common use case to want an automatic service key renewal (e.g. if you want to rotate generated service credentials or certificates).

Service key renewal on MTA redeployment is supported by using changed key names. You can do this either by manually changing the service key name in the descriptor or by using a dynamic parameter as part of it - `${timestamp}`. This parameter will always resolve to the current timestamp at the time of deployment. This means that the key will have a different name on each subsequent deployment. This ensures that it will be considered as new and created. Afterwards the old key will be deleted. This functionality applies to service keys modelled under a resource using the `service-keys` parameter. Example descriptor for automated key renewal/rotation:

### Sample Code

```
...
resources:
  - name: my-service
    type: org.cloudfoundry.managed-service
    parameters:
      service-plan: plan
      service: offering
      service-keys:
        - name: my-rotating-key-${timestamp}
    ...
```

To consume a service key with a changing name in an application environment, make sure to use the parameter `env-var-name` when defining the service key `requires` section in the consuming module. This will ensure that the service key details are persisted under a static alias in the application environment. e.g.

### Sample Code

```
modules:
  - name: my-app
  ...
```

```

requires:
  - name: rotating-key
    parameters:
      env-var-name: *keycredentials*
  ...
resources:
  - name: my-service
    type: org.cloudfoundry.managed-service
    parameters:
      service-keys:
        - name: rotating-key-${timestamp}
  - name: rotating-key
    type: org.cloudfoundry.existing-service-key
    parameters:
      service-name: my-service
      service-key-name: rotating-key-${timestamp}

```

## 4.1.8.1.8.5 Routes

This section describes how developers or administrators have to configure application routes using the MTA modelling.

Routes are defined on module level by using the `routes` parameter. The parameter accepts list of one or many HTTP routes. It is a combination of the old parameters `host`, `domain`, `port` and `route-path`, which encompasses the full addresses to which to bind a module.

In case the new `routes` parameter and the old ones are available, the `routes` value is used and the values of the old parameters are ignored. Each route for the application is created if it does not already exist.

### Note

- The `routes` parameter is a list of entries, where every entry is a map of key-value pairs describing a route. Key `route` is required - this is the Cloud Foundry route (cf route) to be created and bound to the application. Multiple optional keys are supported, including `apply-namespace` and `no-hostname`.
- The deployer reads the `route` entry in a way consistent with cf App Manifest files. It interprets all included data up to the first full-stop ' . ' as the host, then everything up the forward-slash ' / ' as the domain, and the rest (if present) as the path.

### → Remember

Note the following:

- if you do not define the route using the `routes` parameter or the `host` and `domain` parameters, a placeholder `default-uri` is automatically applied. This placeholder is resolved to `${default-host}.${default-domain}`. The `default-host`, as part of the URI, is resolved to `${org}-${space}-<module_name>`. For more information about `default-` parameters, see [Module-Specific Parameters \[page 566\]](#).
- We recommend that you explicitly set the `routes` parameter instead of using the automatically set default route.

## ❁ Example

In order to reference a specific given route inside a deployment descriptor (for example for a `provides` section), use the following syntax, which provides the first given route:

```
provides:
  - name: foo
    properties:
      url: "${protocol}://${routes/0/route}"
```

If you want to create a route with a wildcard hostname, use an asterisk in quotes ("\*").

```
modules:
  - name: my-app
    type: application
    parameters:
      routes:
        - route: "*foo.my.custom.domain/path"
        - route: "foo.my.custom.domain/path"
        - route: "foo.${default-domain}/path"
```

## Deploy applications to a route without a host name

To bind an app to a route without a host name you can use the `routes` and `no-hostname` parameters. Such a route is a subdomain of an existing domain with no host attached at the front. Note that `no-hostname` is a boolean parameter, and must follow every route definition. For example, if you have 2 or more routes without host names in your MTA then you need to add that parameter under each of those routes. If for a given route the `no-hostname` parameter is missing, its value defaults to `false`.

### 📄 Sample Code

```
routes:
  - route: host1.some-domain.com
  - route: host2.some-domain.com
    no-hostname: false
  - route: subdomain.some-domain.com
    no-hostname: true
```

In the example above, `no-hostname: false` has no effect on the second route, since that is the default value, while `host2` is registered as a host to the route. The `no-hostname: true` parameter, however conveys to the deployer that `subdomain` is not a separate host, and the whole route is used as a Cloud Foundry domain - subdomain of `some-domain.com`, if present.

### ⚠ Caution

The MTA deployer attempts to create the subdomain if it does not exist, but cannot resolve any specific corner cases about subdomain/domain ownership permissions. If the subdomain has already been created, the deployer maps the application to it.

## Deploy applications to http2 routes

If you want to enable http2 routing traffic to MTA modules (applications) you can use the `protocol: http2` parameter on route level.

Note that the protocol value must be `http1` or `http2` and must be included in every route in order for it to take effect. If the `protocol` parameter is not specified, the value will be set to `http1` by default.

### Sample Code

```
routes:
- route: http1-route.some-domain.com
- route: http1- route.some-domain.com
  protocol: http1 # The default value if not provided
- route: http2- route.some-domain.com
  protocol: http2
```

## 4.1.8.1.9 Features

The section describes multitarget application-specific features available in the Cloud Foundry environment of the SAP Business Technology Platform.

Each feature has its own productive benefit. For example, the blue-green deployment enables the zero-downtime update of your multitarget application.

- [Cross-MTA Dependencies \[page 607\]](#)
- [Blue-Green Deployment of Multitarget Applications \[page 612\]](#)
  - [Legacy Blue-Green Deployment \[page 613\]](#)
  - [Blue-Green Deployment Strategy \[page 615\]](#)
- [\(Experimental\) Namespaces \[page 618\]](#)
- [Parallel Module Deployment \[page 622\]](#)
- [Sequential Resource Processing \[page 623\]](#)
- [Features Related to SAP Alert Notification service for SAP BTP \[page 625\]](#)
- [Deploying Content with Generic Application Content Deployment \[page 627\]](#)
- [Docker Images as Part of an MTA Deployment \[page 594\]](#)

### 4.1.8.1.9.1 Cross-MTA Dependencies

In addition to having dependencies to one or multiple modules or resources in the same MTA, modules can have dependencies with modules from other MTAs as well. For these so-called cross-MTA dependencies to work, the MTA that **provides** the dependencies must be set to declare them as “public”. Use the `configuration` resource to declare when one module consumes configurations from other MTAs.

### ⚠ Caution

Do not use this feature for storing sensitive content, for example credentials, as this data is stored unencrypted.

### 📌 Note

The declaration method requires adding a resource in the deployment descriptor; the additional resource defines the provided dependency from the other MTA.

## Cross-MTA Dependency Method: Resource Type “configuration”

This method can be used to access any entry that is present in the configuration registry. The parameters used in this cross-MTA declaration method are `provider-nid`, `provider-id`, `version`, and `target`. The parameters are all optional and are used to filter the entries in the configuration registry based on their respective fields. If any of these parameters is not present, the entries will not be filtered based on their value for that field. The `version` parameter can accept any valid Semver ranges.

When used for cross-MTA dependency resolution the `provider-nid` is always “mta”, the `provider-id` follows the format `<mta-id>:<mta-provides-dependency-name>` and the `version` parameter is the version of the provider MTA. In addition, as illustrated in the following example, the `target` parameter is structured and contains the name of the organization and space in which the provider MTA is deployed. In the following example, the placeholders `${org}` and `${space}` are used, which are resolved to the name of the organization and space of the consumer MTA. In this way, the provider MTA is deployed in the same space as the consumer MTA.

### 📌 Note

As of version 3.0 of the MTA specification, the provided dependencies are no longer public by default. They have to be explicitly declared public for cross-MTA dependencies to work.

The following example shows the dependency declaration in the deployment descriptor of the “consumer” MTA :

### 📄 Sample Code

Consumer MTA Deployment Descriptor (mtad.yaml)

```
_schema-version: "3.1"
ID: com.sap.sample.mta.consumer
version: 0.1.0
modules:
  - name: consumer
    type: java.tomee
    requires:
      - name: message-provider
        properties:
          message: ~{message}
resources:
  - name: message-provider
    type: configuration
    parameters:
      provider-nid: mta
      provider-id: com.sap.sample.mta.provider:message-provider
```

```
version: ">=1.0.0"
target:
  org: ${org}      # Specifies the org of the provider MTA
  space: ${space}
```

### → Tip

If no target organization or space is specified by the consumer, then the current organization and space are used to deploy the provider MTA.

The following example shows the dependency declaration in the deployment descriptor of the “provider” MTA :

### ↗ Sample Code

Provider MTA Deployment Descriptor (mtad.yaml)

```
_schema-version: "3.1"
ID: com.sap.sample.mta.provider
version: 2.3.0
modules:
  - name: provider
    type: javascript.nodejs
    provides:
      - name: message-provider
        public: true
        properties:
          message: "Hello! This is a message provided by application \"${app-
name}\", deployed in org \"${org}\" and space \"${space}\"!"
```

## Cross-MTA Configuration Visibility

A “consumer” module must explicitly declare the organizations and spaces in which a “provider” is expected to be deployed, except if it is the same space as the consumer. The “provider” can define a white list that specifies the organizations and spaces from which the consumption of configuration data is permitted. It is not required to white list all the provider's spaces in its own organization.

### 📌 Note

Previously, registry entries were visible from all organizations by default. Now, the default visibility setting is “visible within the current organization and all the organization's spaces”.

White lists can be defined on various levels. For example, a visibility white list could be used to ensure that a provider's configuration data is visible in the local space only, in all organizations and spaces, in a defined list of organizations, or in a specific list of organization and space combinations.

The options for white lists and the visibility of configuration data are similar to the options available for managed services. However, for visibility white lists, space developers are authorized to extend the visibility of configuration data beyond the space in which they work, without the involvement of an administrator. An administrator is required to release service plans to certain organizations.

Visibility is declared on the provider side by setting the parameter `visibility:` (of type 'sequence'), containing entries for the specified organization (`org:`) and space (`space:`). If no `visibility:` parameter is set, the default visibility value `org: ${org}, space: '*'` is used, which restricts visibility to consumers

deployed into all spaces of the provider's organization. Alternatively, the value `org: '*'` can be set, which allows to bindings from all organizations and spaces. The white list can contain entries at the organization level only. This, however, releases configuration data for consumption from all spaces within the specified organizations, as illustrated in the following (annotated) example.

### → Tip

Since applications deployed in the same space are always considered “friends”, visibility of configuration data in the local space is always preserved, no matter which visibility conditions are set.

### ↗ Sample Code

```
provides:
  - name: backend
    public: true
    parameters:
      visibility:           # a list of possible settings:
        - org: ${org}     # for local org
          space: ${space} # and local space
        - org: org1       # for all spaces in org1
        - org: org2       # for the specified combination (org2,space2)
          space: space2
        - org: ${org}     # default: all spaces in local org
        - org: '*'        # all orgs and spaces
        - org: '*'
          space: space3   # every space3 in every org
```

The authorization model ensures the following rules apply:

- Only those users in the white-listed spaces can read or consume the provided configuration data.
- Only users with the role “SpaceDeveloper” in the configuration-data provider's space can modify (edit or delete) configuration data.

## 4.1.8.19.1.1 Plug-ins

The SAP Cloud Deployment service supports a method that allows a multitarget application to consume multiple configuration entries for each `requires` dependency.

The following is an example for multiple `requires` dependencies in the MTA Deployment Descriptor (`mtad.yaml`):

### ↗ Sample Code

```
_schema-version: "2.1"
ID: com.acme.framework
version: "1.0" modules:
  - name: framework
    type: javascript.nodejs
    requires:
      - name: plugins
        list: plugin_configs
        properties:
          plugin_name: ~{name}
          plugin_url: ~{url}/sources
        parameters:
          managed: true # true | false. Default is false
```

```

resources:
- name: plugins
  type: configuration
  parameters:
    target:
      org: ${org}
      space: ${space}
    filter:
      type: com.acme.plugin

```

The MTA deployment descriptor shown in the example above contains a module that specifies a `requires` dependency to a configuration resource. Since the `requires` dependency has a `list` property, the deploy service attempts to find multiple configuration entries that match the criteria specified in the configuration resource.

### → Tip

It is possible to create a subscription for a **single** configuration entry, for example, where no `"list:"` element is defined in the required dependency.

### 📌 Note

The filter parameter can be used in combination with other configuration resource specific parameters, for example: `provider-nid`, `provider-id`, `target`, and `version`.

The resource itself contains a `filter` parameter that is used to filter entries from the configuration registry based on their content. In the example shown above, the filter only matches entries that are provided by an MTA deployed in the current space, which have a `type` property in their content with a value of `com.acme.plugin`.

If the `list` element is missing, the values matched by the resources filter are **single** configuration entries – not the usual list of multiple configuration entries. In addition, if either no value or multiple values are found during the deployment of the consuming (subscribing) MTA, the deployment operation fails. If a provider (plug-in) adds more configuration details after the deployment of subscriber applications, these applications won't get the new information right away. They will only receive these details when they get updated. However, this update will not be successful because there will be several configuration entries available at that point.

The XML document in the following example shows some sample configuration entries, which would be matched by the filter if they were present in the registry.

### 📄 Sample Code

#### MTA Configuration Entries Matched in the Registry

```

<configuration-entry>
  <id>8</id>
  <provider-nid>mta</provider-nid>
  <provider-id>com.sap.sample.mta.plugin-1:plugin-1</provider-id>
  <provider-version>0.1.0</provider-version>
  <target-space>2172121c-1d32-441b-b7e2-53ae30947ad5</target-space>
  <content>{"name": "plugin-1", "type": "com.acme.plugin", "url": "https://
xxx.mo.sap.corp:51008"}</content>
</configuration-entry>
<configuration-entry>
  <id>10</id>
  <provider-nid>mta</provider-nid>
  <provider-id>com.sap.sample.mta.plugin-2:plugin-2</provider-id>
  <provider-version>0.1.0</provider-version>
  <target-space>2172121c-1d32-441b-b7e2-53ae30947ad5</target-space>

```

```
<content>{"name":"plugin-2","type":"com.acme.plugin"}</content>
</configuration-entry>
```

The JSON document in the following example shows the environment variable that is created from the `requires` dependency defined in the example deployment descriptor above, assuming that the two configuration entries shown in the XML document were matched by the filter specified in the configuration resource.

### Note

References to non-existing configuration entry content properties are resolved to `null`. In the example above, the configuration entry published for `plugin-2` does not contain a `url` property in its content. As a result, the environment variable created from that entry is set to `null` for `plugin_url`.

### Sample Code

Application Environment Variable

```
plugin_configs: [
  {
    "plugin_name": "plugin-1",
    "plugin_url": "https://xxx.mo.sap.corp:51008/sources"
  },
  {
    "plugin_name": "plugin-2",
    "plugin_url": null
  }
]
```

`Requires` dependencies support a special parameter named `managed`, which registers as a “subscriber” the application created from the module containing the `requires` dependency. This registration causes the application's environment to be updated if any new configuration entries are published in the configuration registry during the deployment of another MTA. Those new entries must also match the subscription filter of the application. This will cause the application to restart so it can recognize the updated environment state.

### Tip

When starting the deployment of an MTA (with the `cf deploy` command), you can use the special option `--no-restart-subscribed-apps` to specify that, if the publishing of configuration entries created for that MTA result in the update of a subscribing application's environment, then that application should **not** be restarted.

## 4.1.8.1.9.2 Blue-Green Deployment of Multitarget Applications

Run two identical production environments to employ the blue-green deployment technique.

### Restriction

Blue-green deployment is supported only for Cloud Foundry applications. It is not supported for bound services, such as service instances and their configuration, workflow content, and HTML5 repository content, among others. Live and idle applications are bound to the same service instances.

By using the blue-green deployment technique, you can update the system without downtime and with reduced risk. During the process, you can perform tests and validation of the new application version using productive data. A classical blue-green deployment of stateless applications, which are modeled as an MTA, is supported.

In the context of Multitarget applications, you have the following options for using blue-green deployment:

- [Legacy Blue-Green Deployment \[page 613\]](#) - where the production environments are called “blue” and “green”
- [Blue-Green Deployment Strategy \[page 615\]](#) - where the production environments are called “live” and “idle”

## Related Information

[Using Blue-Green Deployment To Reduce Downtime](#) ➔

### 4.1.8.1.9.2.1 Legacy Blue-Green Deployment

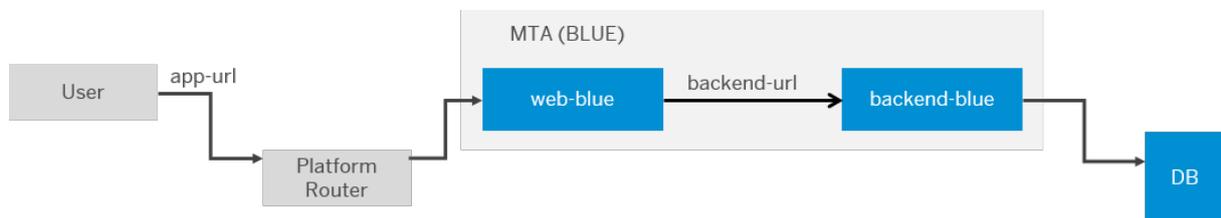

Use the legacy blue-green deployment strategy of Multitarget applications.

## Prerequisites

### ⚠ Restriction

Blue-green deployment is supported only for Cloud Foundry applications. It is not supported for bound services, such as service instances and their configuration, workflow content, and HTML5 repository content, among others. Live and idle applications are bound to the same service instances.

You have a previously deployed MTA, with functional productive applications and routes:

## Procedure

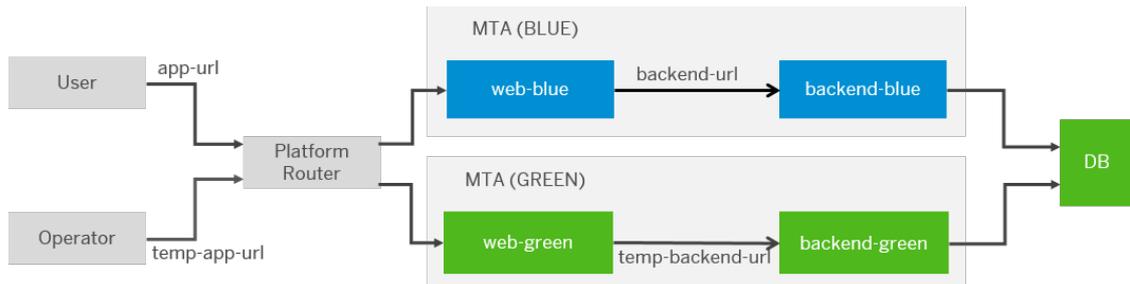

1. Deploy your updated MTA (the green version) by executing the `cf bg-deploy <your-mta-archive-v2>` command.

### Note

The first action is that all MTA services are updated. The changes between the old and the new versions must be compatible, for example, between the old and the new versions of database tables, UAA configurations, and so on.

This action:

- creates new applications adding “green” to their existing application names
- creates temporary routes to the “green” applications.

- interrupts the process showing a message similar to the following:

### Output Code

```
Process needs additional user input
Use "cf bg-deploy -i 469520 -a resume" to resume the process
Use "cf bg-deploy -i 469520 -a abort" to abort the process
```

2. Optionally, test the “green” version using the temporary routes.

### Note

You can skip this step by using one of the following command line options:

- `--no-confirm` - you have to use it when starting the process.
- `--skip-idle-start` - this option will also skip the start of the newly deployed applications on temporary routes.

3. If you do not want to make the “green” version available, abort the process using `cf deploy -i <operation ID> -a abort`.

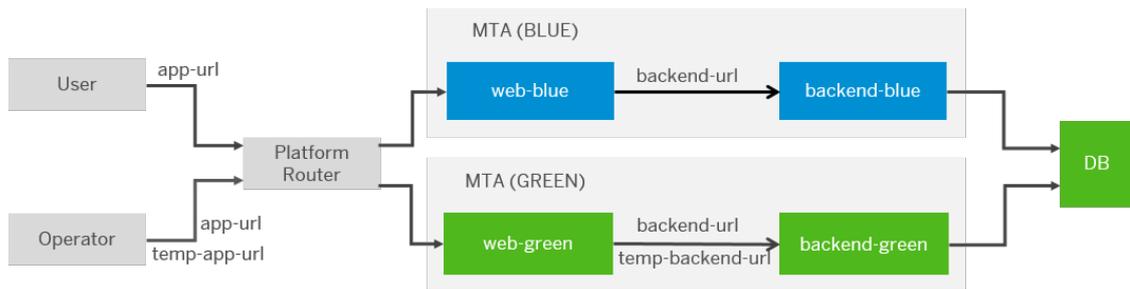

### Note

This action does not perform a rollback and the state of apps, routes and services remains unchanged. Depending on your needs, you might want to remove the new app versions and the temporary routes.

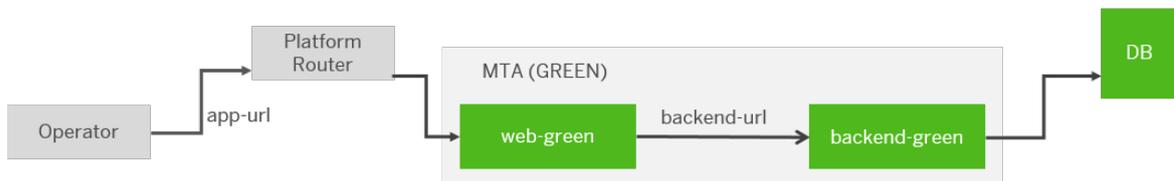

4. To make the “green” version productive, choose *Resume*.

This action:

- maps the productive routes to your green versions

- deletes the temporary routes
- restarts “green” apps with productive route configurations
- restarts the applications, so that the environment URLs are updated
- deletes the “blue” applications, which were productive before

## Related Information

[Blue-Green Deployment of Multitarget Applications \[page 612\]](#)

[Blue-Green Deployment Strategy \[page 615\]](#)

### 4.1.8.1.9.2.2 Blue-Green Deployment Strategy

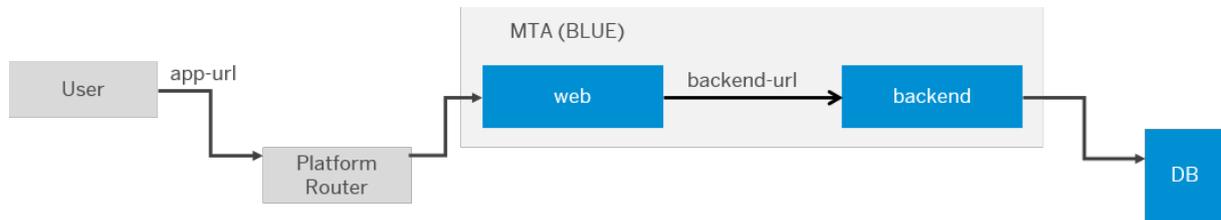

Use the current blue-green deployment of Multitarget applications.

## Prerequisites

### ⚠ Restriction

Blue-green deployment is supported only for Cloud Foundry applications. It is not supported for bound services, such as service instances and their configuration, workflow content, and HTML5 repository content, among others. Live and idle applications are bound to the same service instances.

You have a previously deployed MTA, with functional productive applications and routes:

## Context

### Note

If you already have executed deployments using the `cf bg-deploy` command and they have been successful, you can switch to the `deploy --strategy blue-green` deployment method, or vice versa. Do not begin a blue-green deployment using a given deployment command and continue with the other, as this might result in downtime.

## Procedure

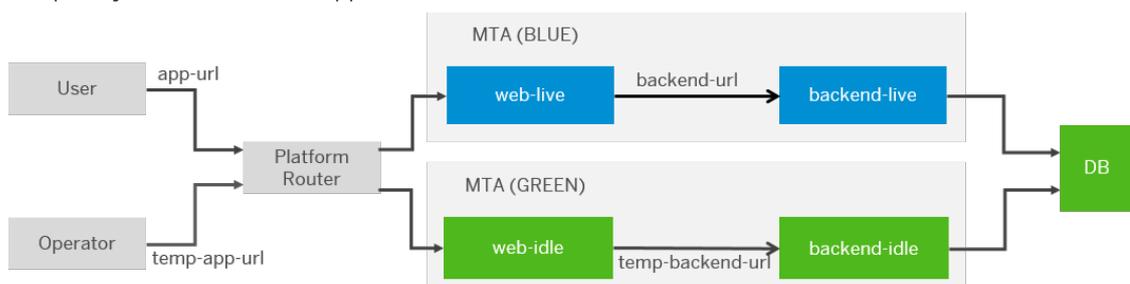

1. Deploy your updated MTA in idle state by executing the command `cf deploy <your-mta-archive-v2> --strategy blue-green`.

### Note

The first action is that all MTA services are updated. The changes between the old and the new versions must be compatible. For example, the changes between the old and the new versions of the database tables, UAA configurations, and so on.

This creates:

- new applications adding “idle” to the original application names
- temporary routes to the idle applications

- an interrupt to the process showing a message similar to the following:

## Output Code

```
Process has entered testing phase. After testing your new deployment
you can resume or abort the process.
Use "cf deploy -i 7e6233b9-6001-11ea-8959-eeee0a98a87d -a abort" to
abort the process.
Use "cf deploy -i 7e6233b9-6001-11ea-8959-eeee0a98a87d -a resume" to
resume the process.
Hint: Use the '--skip-testing-phase' option of the deploy command to
skip this phase
```

- Optionally, test the idle version of the application using the temporary routes.

### Note

You can skip this step by using one of the following command line options:

- `--skip-testing-phase` - you have to use it when starting the process.
- `--skip-idle-start` - this option will also skip the start of the newly deployed applications on idle routes.

- If you do not want to make the "idle" version available, abort the process using `cf deploy -i <operation ID> -a abort`.

### Note

This action does not perform a rollback and the state of apps, routes and services remains unchanged. Depending on your needs, you might want to remove the new app versions and the temporary routes.

- If you want to make the "idle" version productive, manually resume the process, using `cf deploy -i <operation ID> -a resume`.

This does the following:

- maps the productive routes to your idle versions
- deletes the temporary routes
- restarts "idle" apps with productive route configurations
- deletes the "live" applications, which were productive before

## Results

You can see an example of the process at [Blue-Green Deployment](#)

[Multitarget Application Commands for the Cloud Foundry Environment \[page 2263\]](#)

### 4.1.8.1.9.3 (Experimental) Namespaces

Use this feature to prevent conflicts for applications deriving from the same MTA, but with different version, features, and configuration.

#### ⚠ Restriction

- This feature is experimental. We advise you first try it out in a non-productive environment.
- The namespace can only be passed as an argument to the deployment call, and cannot be modelled directly in the descriptor.

## Prerequisites

- Make sure the version of your MultiApps Plug-in is 2.5.0 or higher. If required, use the procedure described in [Install the MultiApps CLI Plugin in the Cloud Foundry Environment \[page 2262\]](#) to update it.

## Feature Description

By using the namespaces feature, you can deploy and operate a single multitarget application multiple times within a single space. This is useful when you have to avoid conflicts among applications or entities. It modifies the modules and resources by adding a namespace at the beginning of the application names, service names, and routes.

The feature is employed by adding the parameter `--namespace`, when you input the deployment command in the Cloud Foundry Command Line Interface (CF CLI), and by modifying the deployment descriptor as described below. Using a more detailed configuration, you can include or exclude specific resources from having the namespace feature applied to them, namely:

- services
- modules
- routes.

When set so, the excluded resources are shared among all namespaces of this MTA archive.

## Procedure

To deploy several entities of a multitarget application using namespaces, proceed as follows:

1. (Optional) Descriptor modifications are not required, but you can consider using one or both of the following options:
  1. You can specify to which route the `apply-namespace` prefix should not be applied:

### Sample Code

```
modules:
- name: appA
  type: java.tomee
  path: application.war
  parameters:
    routes:
      - route: application.${default-domain}
      - route: route-without-namespace.${default-domain}
      apply-namespace: false
```

2. You can set `apply-namespace` to not be applied on the module, but to be applied to a specified route:

### Sample Code

```
modules:
- name: appA
  type: java.tomee
  path: application.war
  parameters:
    routes:
      - route: application.${default-domain}
      - route: route-with-namespace.${default-domain}
      apply-namespace: true
  apply-namespace: false
```

2. Using the CF CLI, deploy the initial MTA archive by using the following command:

```
$ cf deploy ./MyMTA.mtar
```

3. (Optional) Check the deployment by inspecting the applications and details. Use the commands:

```
$ cf app
```

```
$ cf mtas
```

```
$ cf mta MyMTA
```

4. For each subsequent deployment of the same MTA archive, use the following command:

```
$ cf deploy ./MyMTA.mtar --namespace <your namespace>
```

5. (Optional) Check whether your subsequent deployments have not removed the original MTA deployment:

```
$ cf app
```

```
$ cf mtas
```

```
$ cf mta MyMTA --namespace <your namespace>
```

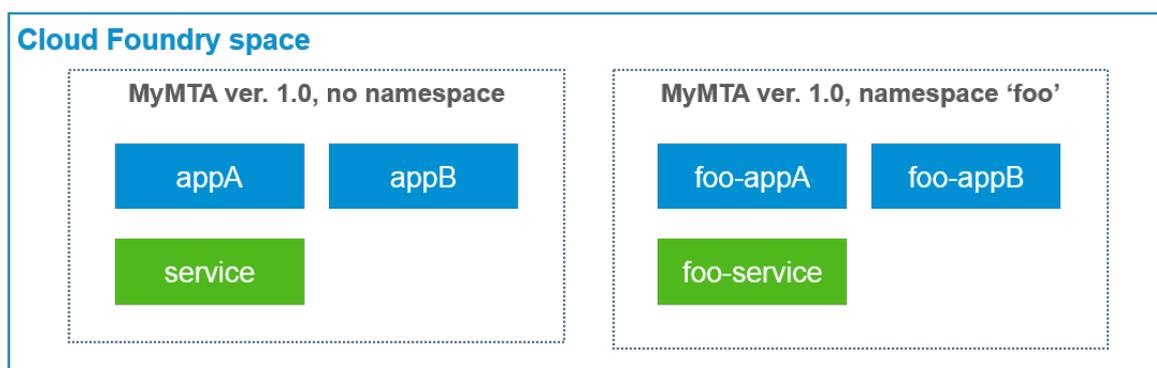

6. Validate your deployments by calling their exposed web endpoints:

```
$ cf app | grep '^appA'
```

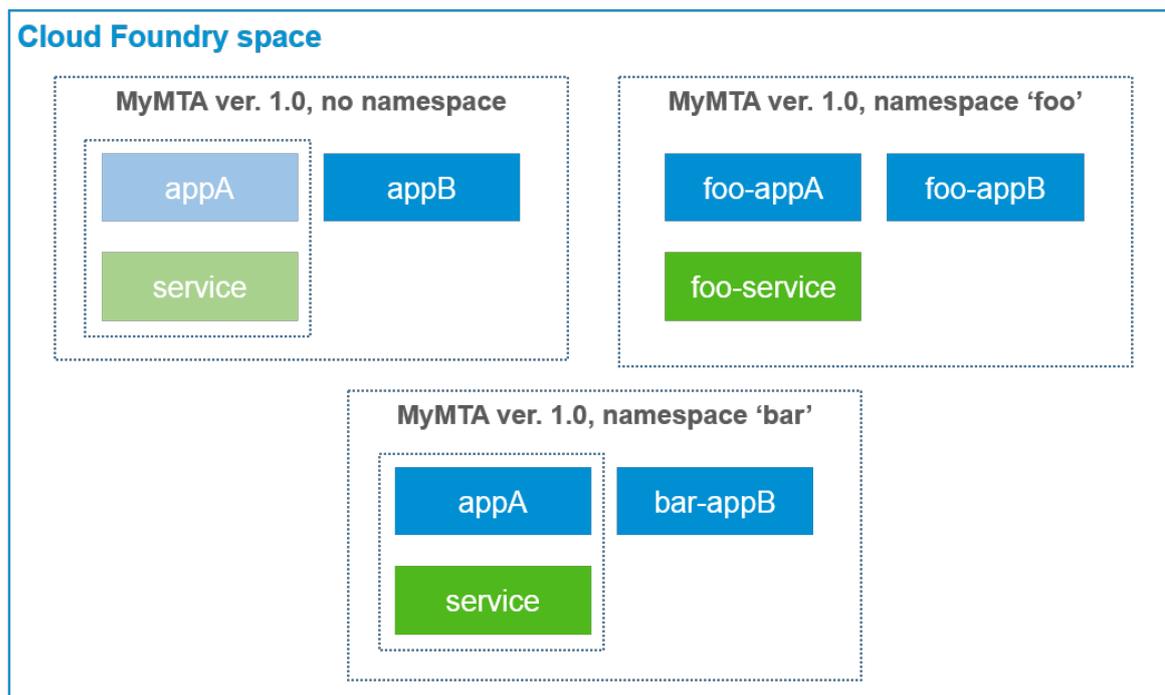

```
$ cf app | grep '^<your namespace>-appA'
```

1. when using a route without a namespace `curl https://route-without-namespace.<domain>`
2. when using a route with a namespace `curl https://<your namespace>-route-with-namespace.<domain>`

You might have one of the following results, depending on your usage

- This image shows an MTA deployed in the same space - once without a namespace (default behaviour), and once with the namespace `foo`. The second deployment creates applications `foo-appA` and `foo-appB` from modules `appA` and `appB` and service instance `foo-service` from resource `service`
- If `appA` is bound to `appA.my-domain.com`, then `foo-appA` is automatically bound to `foo-appA.my-domain.com` upon deployment
- If `appA` requires service instance `service` then `foo-appA` is bound to a different service instance called `foo-service`.

In the image above, the third MTA is deployed in the namespace `bar`, but with `appA` and `service` having the `apply-namespace` parameter set to `false`. This enables the MTAs to share `appA` and `service` between each other. Therefore the application and the service are not recreated. However they are detected as part of the latest deployed MTA because their metadata is updated.

## Special use: sharing one resource among several MTAs using namespaces

You can use deployment with namespaces in a way that only one of the resources receives a namespace. To do so, you use the parameter `apply-namespace` in the MTA deployment descriptor follows, and then deploy by using the procedure above. The deployment result should be as follows:

For the example below we use a service, but this special use can be applied to any module or resource in the descriptor.

### Sample Code

```
...
- name: serviceA
  type: auditlog
  parameters:
    apply-namespace: false
...
```

In the snippet above, the `apply-namespace: false` overrides the default value `true`, thus prohibiting the creation of additional instances of the service. This means that the service is unique in the space across all deployments of the MTA, and shared among them.

To see a practical example of the implementation above, go to [Deploying MTA in a Namespace](#).

## 4.1.8.1.9.4 Parallel Module Deployment

In some cases, it is crucial that modules and therefore applications are deployed in a predictable and consistent order. To ensure this, the module-level attribute `deployed-after` has been introduced. It contains a list of module names. If a module has this attribute, it will be deployed only after the modules specified in the attribute have already been deployed.

The relations described through this attribute are transitive, so if module A should be deployed after module B, and module B should be deployed after module C, then it means that module A should be deployed after module C.

### Sample Code

MTA Deployment Descriptor (`mtad.yaml`)

```
ID: com.sap.sample
version: 0.1.0
_schema-version: "3.2.0"
parameters:
  enable-parallel-deployments: true

modules:
  - name: ui
    type: javascript
    deployed-after: [ backend, metrics ]

  - name: backend
    type: java
    deployed-after: [ hdi-content ]
    requires:
      - name: metrics
        properties:
          METRICS_URL: ~{url}

  - name: metrics
    type: javascript
    deployed-after: [ hdi-content ]
    provides:
      - name: metrics
        properties:
          METRICS_URL: ~{url}

  - name: hdi-content
    type: hdi
```

In the example above, the `deployed-after` attributes guarantee that the `ui` module is deployed after the `backend` and the `metrics` modules, and they in turn are deployed after the `hdi-content` module. Note that the deployment order of the `backend` and the `metrics` modules is not specified in the attributes. This means that they can be deployed in any order.

## Parallel Deployment

### Note

The `deployed-after` parameter is supported from major schema version 3 onwards.

In the example above, we have also specified the global MTA parameter `enable-parallel-deployments` with a value `true`. It activates the parallel deployment of MTA modules that do not have any deployment order dependencies between each other. If the parameter is missing or its value is `false`, the module deployment will be sequential.

#### Note

The `enable-parallel-deployments` parameter has influence only on modules deployment, see section [Sequential Resource Processing](#) for the resources process.

#### Note

The `enable-parallel-deployments` parameter is supported from major schema version 3 onwards.

## Circular Dependencies

Due to a modelling error, the user can introduce direct or transitive circular deployment order dependencies between modules. In such cases, this will be reported as a deployment error.

## Compatibility with Previous Deployment Order

The previous deployment order algorithm was based on the `requires` module-level attribute, which contains a list of module names or provided dependencies from other modules. Since it is also the way to model configuration dependencies, this mechanism was not explicit enough to model a deployment order .

There are many applications that are still depending on the old deployment order algorithm. To support them until they adapt to the new modeling, the new deployment order is introduced in a backward compatible manner. This means that if there are no `deployed-after` module-level elements in the MTA descriptor and the global MTA parameter `enable-parallel-deployments` is set to `false` or is missing, the old ordering algorithm is enabled by default.

### 4.1.8.1.9.5 Sequential Resource Processing

In various cases, some resources depend on other resources to already exist in order to process. Whenever an order of resource processing is necessary, the `processed-after` attribute can be utilized.

This attribute contains a list of resource names. It creates a sequence of services, an order, in which the services should be processed. If a resource has this attribute, it will be processed after the other resources in a higher position are processed.

#### Note

If the parameter `processed-after` is not specified, the resources are processed in parallel.

## Note

The `processed-after` parameter is supported from schema version 3 onwards. If you attempt to use `processed-after` with schema version lower than 3, the deployment will ignore the attribute.

**Example:** Service A requires service B and service C to be processed first. On the other hand, both service B and service C require service D to be processed first. Service D does not require any other service to be processed. So the sequence for processing is - D → B, C → A.

## Sample Code

```
MTA Deployment Descriptor (mtad.yaml)

_schema-version: 3
ID: multiple-anatz
version: 3.0.0

modules:
- name: multiple-anatz
  type: staticfile
resources:
- name: serviceA
  type: org.cloudfoundry.managed-service
  parameters:
    service: application-logs
    service-plan: lite
    processed-after: [ serviceB, serviceC ]

- name: serviceB
  type: org.cloudfoundry.managed-service
  parameters:
    service: application-logs
    service-plan: lite
    processed-after: [ serviceD ]

- name: serviceC
  type: org.cloudfoundry.managed-service
  parameters:
    service: application-logs
    service-plan: lite
    processed-after: [ serviceD ]

- name: serviceD
  type: org.cloudfoundry.managed-service
  parameters:
    service: application-logs
    service-plan: lite
```

In the example, the `processed-after` attribute ensures that serviceD is processed first, then serviceC and serviceB are processed in parallel, and finally serviceA is processed.

## Circular Dependencies

Due to a modelling error, you can create direct or transitive circular deployment order dependencies between resources. In such cases, it is reported as a deployment error.

## 4.1.8.1.9.6 Features Related to SAP Alert Notification service for SAP BTP

Deploy and update the SAP Alert Notification service for SAP BTP using the multitarget application concept, or get notified by the service about multitarget application operation status.

### Deploying and Updating the service

As an alternative to the manual procedure, you can use a deployment descriptor to automate the initial deployment of SAP Alert Notification service. You can use the same procedure to update the service parameters. See the procedure described in [Configuration Management Using Multitarget Application Descriptors](#).

### Using the SAP Alert Notification service for BTP for alerts during deployment and undeployment of multitarget applications

You can set SAP Alert Notification service for SAP BTP to dispatch alerts to a communication channel of your choice, so that you are informed about the status of MTA deployment and undeployment operations. For example, if setup to do so, upon a successful deployment it can send you an e-mail or a Slack message. You can also get notified for problems in MTA operations, as you can also receive alerts if the deployment has encountered issues.

The integration between the services is out-of-the-box, that is, no special steps are required for its activation. If you have a service instance in the space where the MTA deployment takes place, it would automatically receive alerts from the MTA deployments in that space.

See how you can match events using about multitarget operations as described in [Multitarget Application Events](#).

To see additional details, see [Receive instant notifications...with the SAP Cloud Deployment service](#).

## 4.1.8.1.9.7 Content Deployment

SAP BTP Cloud Foundry supports the lifecycle of all standard Cloud Foundry entities, such as applications and services. To satisfy all business requirements, SAP BTP Cloud Foundry also supports the lifecycle of other entities that do not match 1-to-1 to CF native entities.

SAP traditionally provides its customers with complex business solutions, which work with their own entities and content. Every service might have its own content with a specific format that is developed, provided or consumed by end customers.

SAP Workflow Management provides the possibility for SAP partners to develop their own BPM workflows (e.g., Leave Request flow) and provide them to end customers. In turn, end customers are able to easily import and use the developed BPM workflows.

With multitarget applications you can manage the lifecycle of content provided by different SAP applications. This way, by using one standard approach via MTA, you can deploy various kinds of SAP application content in your accounts, normally done on CF space level.

### ⚠ Restriction

Content deployment used with [Blue Green deployment](#) will be done during the first phase when idle suffixes and temporary routes are used. The same rule is applicable for all content deployment mechanisms – either with direct content deployment or with content deployers (`hdi-deploy`, `html5-app-deployer`, `portal-deployer`). HTTP Destinations, created with direct content deployment, will not be updated after the validation phase, so avoid using default resolvable parameters `${default-host}`, `${default-uri}`, `${default-url}`. Configurations that include idle suffixes and temporary routes may stay after the MTA deployment finishes. Content that was already deployed during the first phase cannot be reverted or removed. It will be necessary to trigger new MTA deployment.

## Supported Content Deployment Mechanisms

- Using content applications – there is a dedicated SAP provisioned content deployer for each content type that communicates with the dedicated content backend
  - [DEPRECATED] Deploying Content with Simulated App Execution
  - Deploying Content with CF task execution
- Using direct content deploy – there is a direct communication between SAP Cloud Deployment service and content backends
  - Deploying Content with Generic Application Content Deployment
  - CPI content deployment

## Supported MTA Module Types for Content Deployment

Module Type	Content Deployment Mechanism
<code>com.sap.portal.site-content</code>	Simulated App Execution
<code>business-logging</code>	Simulated App Execution
<code>com.sap.html5.application-content</code>	Simulated App Execution
<code>com.sap.portal.content</code>	CF task execution
<code>com.sap.business-logging.content</code>	CF task execution
<code>com.sap.html5.application.content</code>	CF task execution
<code>com.sap.xs.hdi</code>	CF task execution

Module Type	Content Deployment Mechanism
<code>com.sap.application.content</code>	Generic Application Content Deployment
<code>com.sap.integration</code>	CPI content deployment
<code>com.sap.api.management</code>	CPI content deployment

For all predefined parameters and properties for each MTA module type, see [MTA Module Types](#).

### 4.1.8.1.9.7.1 Deploying Content with Generic Application Content Deployment

This approach provides a mechanism for direct content deployment from SAP Cloud Deployment service to the content backend without the need for an intermediate Cloud Foundry application.

#### ⓘ Note

This approach is supported only for MTA schema version 3.1 and higher.

#### ⓘ Note

This approach is recommended for its light-weight nature, minimal footprint in your Cloud Foundry account and avoided overhead of transient content applications.

#### ⓘ Note

The examples below are partial and they intend to show the different capabilities of content deployment. For specific application content, see the dedicated documentation linked below.

The mechanism utilizes the Generic Application Content Deployment protocol (GACD). It allows you to deploy content represented by an MTA module of type `com.sap.application.content` to a certain list of supported services.

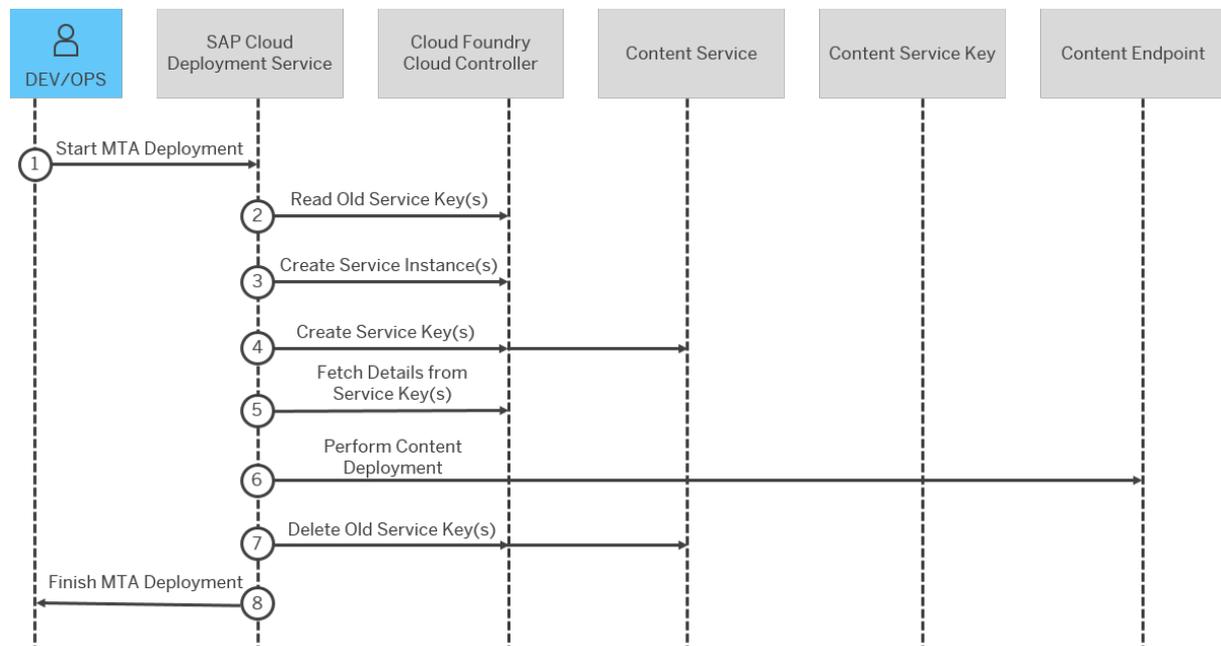

## Supported service offerings

Cloud Foundry service offerings that currently support GACD are:

- `html5-apps-repo` (For more information, see [Deploy Content Using Generic Application Content Deployer](#))
- `portal` (For more information, see [Add an SAP Fiori Launchpad Module](#))
- `workflow` (For more information, see [Create a Workflow Module](#))
- `destination` (For more information, see [Create Destinations Using the MTA Descriptor](#))
- `business logging` (For more information, see [Using GACD](#))

## How Content is Deployed with Generic Application Content Deployment

The diagram below illustrates the steps and BTP components involved in the process of content deployment with Generic Application Content Deployment:

The following steps describe the process of content deployment with Generic Application Content Deployment:

1. A developer/operator runs MTA deployment – the flow demonstrates only modules of type `com.sap.application.content` indicating content (for example - a single MTA module and multiple required services, only one of them is marked with parameter `content-target: true`).
2. SAP Cloud Deployment service prepares for the next steps. This step includes:
  1. SAP Cloud Deployment service gets the existing services and service keys which are related to previous MTA deployment. The list comprises of a content service instance, a content service key and eventually additional services keys.
  2. Based on the name, SAP Cloud Deployment service decides which of the existing service keys will be deleted, which will be kept, and whether new ones will be created. In the end, only one of them will be used as a content target.
3. SAP Cloud Deployment service creates or reuses a service instance or instances that are relevant for the content deployment, not only the one that serves as a content target.
4. SAP Cloud Deployment service creates or reuses a service key. This step might include the creation of several service keys needed for successful content deployment, not only the one that serves as a content target.
5. SAP Cloud Deployment service fetches the credentials of the required service key(s). In this step content endpoint is detected from content target service key. The credentials of all remaining service keys serve as configurations for the next step.
6. SAP Cloud Deployment service executes the content deployment to content endpoint and passes previously collected data as content configurations.
7. SAP Cloud Deployment service deletes the discontinued service keys calculated in step 2. Normally these are service keys that are not part of the current MTA and were used in the previous deployment.

8. MTA deployment completes and SAP Cloud Deployment service reports the status to the developer/operator.

## Content Target

When an MTA module of type `com.sap.application.content` is present in your MTA, SAP Cloud Deployment service processes it and delivers its module content to the content target.

The content target is explicitly set with a flag in the MTA and it is unknown to the SAP Cloud Deployment service without it.

There should be only one content target defined per MTA module of type `com.sap.application.content`. This guarantees that the content will be deployed to only one place.

The content target is defined when a content module requires a service or service key, and in that required dependency the parameter `content-target` is set to `true`. In case of a missing or duplicated `content-target` parameter in more than one required dependency, the deployment will not proceed.

Normally, content modules require MTA resources that represent Cloud Foundry service instances or service keys. When multiple service instances or keys are required, they are used by default for content deployment configuration. For more information see the [Configuration from other service instances/keys \[page 633\]](#) section.

## MTA Modelling

### Deliver file content

You can use a file or directory that is treated as content. The file or directory is part of the MTA archive, and its path is defined in the `MANIFEST.MF` file.

The following code block contains a snippet from an MTA deployment descriptor (`mtad.yaml`):

#### Sample Code

```
_schema-version: '3.1'
ID: com.sap.example.content.deployment
version: 0.0.1
modules:
  - name: content-module
    type: com.sap.application.content
    requires:
      - name: workflow_service
        parameters:
          content-target: true
resources:
  - name: workflow_service
    type: org.cloudfoundry.managed-service
    parameters:
      service-plan: standard
      service: workflow
```

The following code block contains the accompanying `MANIFEST.MF` file:

### Sample Code

```
Name: content-module/data
MTA-Module: content-module
Content-Type: application/zip
```

## Delivery text / Inline content

You can enter content definitions inline in the MTA descriptor as part of module parameter `content`. In the example below the template for new destinations (`foo-api` and `bar-api`) will be deployed to `destination-service`:

### Sample Code

```
modules:
- name: destination-content
  type: com.sap.application.content
  requires:
  - name: destination-service
    parameters:
      content-target: true
  - name: foo-api
  - name: bar-api
  parameters:
    content:
      subaccount:
        destinations:
          - Name: foo-api
            URL: ~{foo-api/url}
            forwardAuthToken: true
          - Name: bar-api
            URL: ~{bar-api/url}
            forwardAuthToken: true
    <...>
resources:
- name: destination-service
  type: org.cloudfoundry.managed-service
  parameters:
    service: destination
    service-plan: lite
```

## Service Keys in Content Deployment

When an MTA module of type `com.sap.application.content` requires an MTA resource, the SAP Cloud Deployment service will create or re-use a service key.

Service keys in content deployment are an alternative of service bindings between applications and services. When there is an intermediate content application, it might be bound to different services that provide specific capabilities. In direct content deployment, the required service keys have the same role. For example, a content module might require an `xsuaa` service instance, which might be used for secure communication at a later stage.

By default, service keys to all required services are created with the name that follows the template `<module_name>-<resource_name>-credentials`. For example, the result of the sample below will be

a service instance with name `workflow_service` which will have a service key named `content-module-workflow_service-credentials`:

### Sample Code

```
modules:
- name: content-module
  type: com.sap.application.content
  requires:
  - name: workflow_service
    parameters:
      content-target: true
resources:
- name: workflow_service
  type: org.cloudfoundry.managed-service
```

By default, the existing service keys are re-used in future deployments. This is done to save time from their re-creation and avoid potential issues if they are used outside of the MTA and their credentials are invalidated.

### Customizing service keys

You can customize the service keys created as part of the content deployment by using the required dependency parameter `service-key`. This way, you can define the service key name or pass service key creation parameters:

### Sample Code

```
modules:
- name: content-module
  type: com.sap.application.content
  requires:
  - name: workflow_service
    parameters:
      content-target: true
      service-key:
        name: workflow_service-key
        config:
          <map entries for creation parameters>
```

### Re-create custom service keys for deployment

This option extends the customization of service keys explained above. Based on its name, an existing service key may be re-used or deleted, as described in [How Content is Deployed with Generic Application Content Deployment \[page 628\]](#).

The option is particularly useful if you want to rotate and renew the credentials used for content deployment, like when they are based on user/password credentials or certificates.

You can set the service keys to automatically rotate for each new deployment by using the existing deployment parameter `timestamp` as a part of the name of the defined custom service key. Doing so ensures that the key will have a new name for each deployment, resulting in Deploy Service creating and using a new key for the related content deployment. The previously used service key will be deleted after the new one is in place.

### Sample Code

```
modules:
- name: content-module
  type: com.sap.application.content
```

```

requires:
- name: workflow_service
  parameters:
    content-target: true
    service-key:
      name: workflow_service-key-${timestamp}

```

## Using existing service keys

You can deploy content directly to an existing service key with a descriptor modeled appropriately. This option might be useful if you want to manage the lifecycle of the service key outside of the MTA:

### Sample Code

```

modules:
- name: content-module
  type: com.sap.application.content
  requires:
- name: workflow_service_key
  parameters:
    content-target: true
resources:
- name: workflow_service_key #this service key needs to exist beforehand
  type: org.cloudfoundry.existing-service-key
  parameters:
    service-name: workflow_service #this service must be created and exist beforehand

```

## Using user-provided services

Sometimes, the content endpoint might not be exposed as a standard service broker in the BTP. In these cases, neither service instance nor service key can be created. The only option to utilize content deployment to such content target is via user-provided services.

### Sample Code

```

modules:
- name: content-module
  type: com.sap.application.content
  requires:
- name: content-endpoint
  parameters:
    content-target: true
resources:
- name: content-endpoint
  type: org.cloudfoundry.user-provided-service
  parameters:
    content_endpoint: https://my-content-endpoint.com

```

## Content Deployment Configuration

Sometimes content deployment needs a configuration, which might be environment or context specific and cannot part directly in the content itself.

There are two supported ways to pass additional configuration for content deployment:

- Content Deployment Configuration from other service instances/keys
- Inline Content Deployment Configuration

### Configuration from other service instances/keys

By default, all required MTA resources from content modules are processed and used for content deployment configuration. This includes the MTA resources of types `org.cloudfoundry.managed-service`, `org.cloudfoundry.existing-service`, `org.cloudfoundry.existing-service-key` and `org.cloudfoundry.user-provided-service`. A service key is used for each of those resources, except for `org.cloudfoundry.user-provided-service`.

In the example below, the content-module requires two services and only one of them is marked as content-target. The other required service is xsuaa, which will be used for content configuration, and it will guarantee more secure communication during end-to-end flow:

#### Sample Code

```
_schema-version: '3.1'
ID: com.sap.example.content.deployment
version: 0.0.1
modules:
  - name: content-module
    type: com.sap.application.content
    requires:
      - name: xsuaa_service
      - name: html5_service
      parameters:
        content-target: true
resources:
  - name: html5_service
    type: org.cloudfoundry.managed-service
    parameters:
      service-plan: app-host
      service: html5-apps-repo
  - name: xsuaa_service
    type: com.sap.xs.uaa
```

When multiple service instances or keys are required, they are all used for content deployment configuration by default.

### Inline Content Deployment Configuration

You can provide content deployment configuration as part of the module parameter `config`:

#### Sample Code

```
modules:
  - name: content-module
    type: com.sap.application.content
    requires:
      - name: workflow_service
      parameters:
        content-target: true
    parameters:
      config: # the content deployment configuration
      env: dev
resources:
  - name: workflow_service
    type: org.cloudfoundry.managed-service
```

```
parameters:
  service-plan: standard
  service: workflow
```

## Related Information

[Deploy Content Using the Generic Application Content Deployer \[page 361\]](#)

[Create Destinations Using the MTA Descriptor](#)

### 4.1.8.1.9.7.2 Deploying Content with CF Task Execution

This approach for content deployment relies on an intermediate Cloud Foundry application that communicates with the content backend. This application includes both the content and the content specific deployer.

The content specific deployer is defined as an application dependency during design time. It is then included in the MTA archive. During deployment it serves as a client for the actual content deployment to the content backend.

#### Note

This approach is a natural successor to [Deploying Content with Simulated App Execution \[page 637\]](#). When possible, it is recommended to use the current approach instead of the legacy one. Normally, there is only one dedicated content deployer for each content type that handles both approaches.

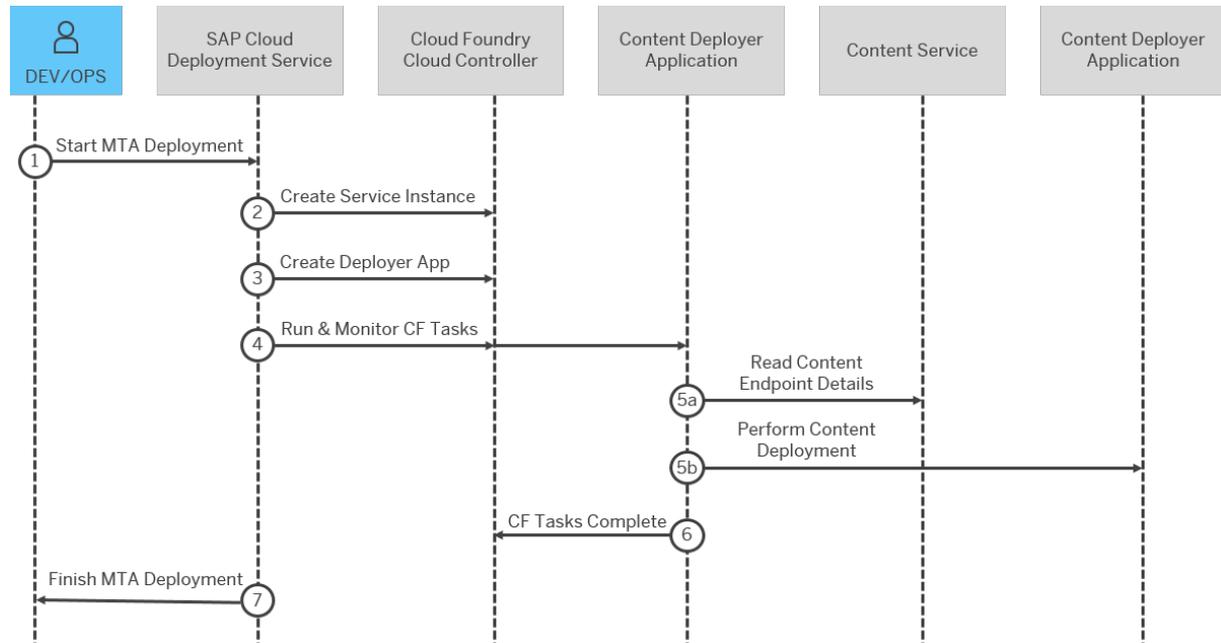

## Supported Content Types

Supported content types that currently allow deployment with CF Task execution:

- HDI content - MTA module type `com.sap.xs.hdi`. For more information see [The SAP HDI Deployer](#)
- FLP content – MTA module type `com.sap.portal.content`
- Business Logging - MTA module type `com.sap.business-logging.content`. For more information see [Using the Content Deployer](#)
- HTML5 Content – MTA module type `com.sap.html5.application.content`. For more information see [Deploy Content Using HTML5 Application Deployer](#)

## How Content is Deployed with CF Task Execution

The following diagram illustrates the steps and BTP components involved in the process of content deployment with CF task execution:

The following steps describe the process of content deployment with CF Task execution:

1. A developer/operator runs MTA deployment
2. SAP Cloud Deployment service creates or reuses a service instance provided by an SAP application
3. During this step:
  1. SAP Cloud Deployment service creates a Cloud Foundry application that serves as a content application
  2. SAP Cloud Deployment service binds the service instance to the content application
  3. SAP Cloud Deployment service uploads the combination of content and content deployer as application bits
4. SAP Cloud Deployment service runs CF tasks, including the one responsible for actual content deployment
5. The dedicated CF task of content application triggers content deployer, which in turn performs the actual content deployment. During this step:
  1. CF task reads content details from the bound service instance and identifies the content endpoint as well as the required authentication
  2. CF task executes the content deployment to the content endpoint
6. CF task completed successfully
7. MTA deployment completes and SAP Cloud Deployment service reports the status to the developer/operator

## Content Deployer and Service Instance

The Content Deployer and Service Instance follow the same rules as the ones from [Deploying Content with Simulated App Execution \[page 637\]](#).

## CF Tasks

Tasks are native to Cloud Foundry and are valuable in various scenarios which demand one-off jobs. For more information see <https://help.sap.com/docs/btp/sap-business-technology-platform/tasks?version=Cloud> from the official documentation.

CF tasks, dedicated for content deployment, are predefined from the SAP Cloud Deployment service and must not be changed by the end customer. They are represented by the module level parameter `tasks`.

## MTA Modelling

Below you can find the modelling for supporting the content deployment scenario for MTA module type `com.sap.xs.hdi`:

### Sample Code

```
_schema-version: "3.1"
ID: my.app
version: "1.1"
- name: module-db
  type: com.sap.xs.hdi
  parameters:
    buildpack: nodejs_buildpack //Predefined parameter
    no-route: true // Predefined parameter - skipping route mapping to the
app
    no-start: true // Predefined parameter - skipping start of the app
because only tasks are important in the scenario
    memory: 256M // Predefined parameter
    tasks: // Predefined parameter - all details below define the CF tasks
      - name: deploy
        memory: 256M
        command: npm start // Shell script that will be used for triggering
actual content deployment
    properties:
      EXIT: 1 // Predefined property - instructs the HDI deployer to exit
when done
    requires:
      - name: hdi-service

resources:
  - name: hdi-service // Provides content endpoint for the actual content
deployment. Content endpoint could be different based on the used database
type: com.sap.xs.hdi-container
```

### 4.1.8.1.9.7.3 Deploying Content with Simulated App Execution

This approach for content deployment relies on an intermediate Cloud Foundry application that communicates with the content backend. This application includes both the content and the content specific deployer.

The content specific deployer is defined as an application dependency during design time. It is then included in the MTA archive. During deployment it serves as a client for the actual content deployment to the content backend.

#### ⓘ Note

This approach is a legacy one. Over time it has proven to have some major drawbacks. If possible, migrate to [Deploying Content with Generic Application Content Deployment \[page 627\]](#) or at least to [Deploying Content with CF Task Execution \[page 634\]](#) of the corresponding module type.

#### ⓘ Note

All supported MTA module types for this approach will either be discontinued or will be transformed to use [CF Task Execution \[page 634\]](#).

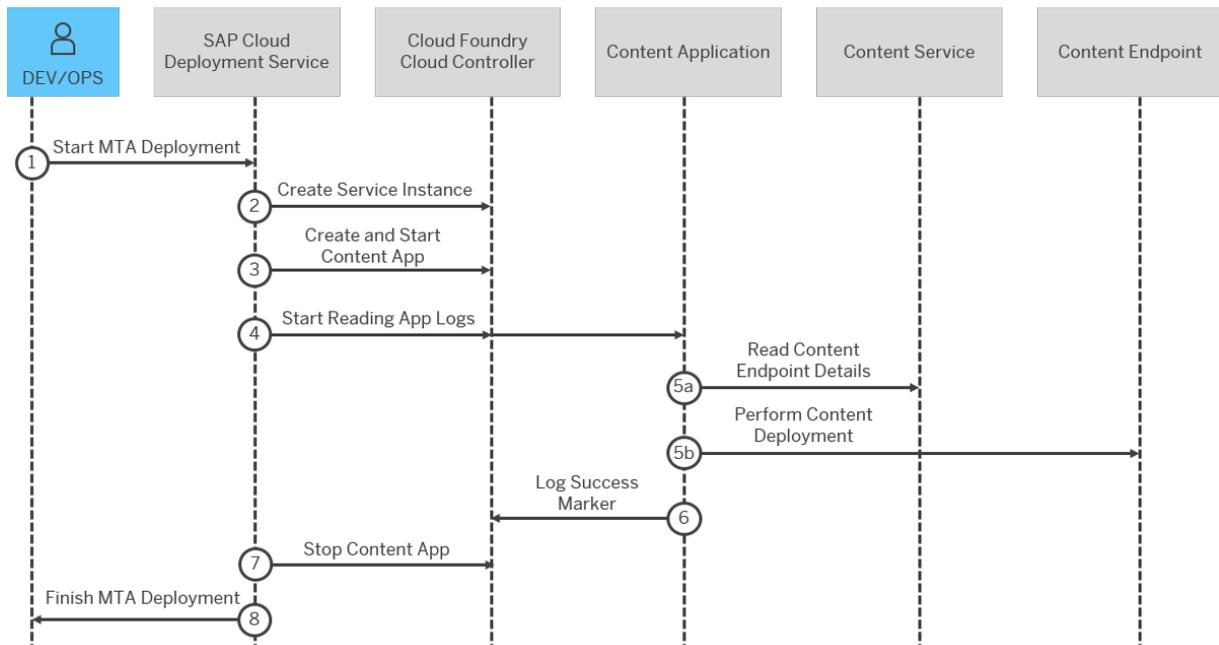

## Supported Content Types

Supported content types that currently allow deployment with simulated app execution:

- FLP content - MTA module type `com.sap.portal.site-content`
- Business Logging - MTA module type `business-logging`. For more information see [Using the Content Deployer](#).
- HTML5 Application Content – MTA module type `com.sap.html5.application-content`. For more information see [Deploy Content Using HTML5 Application Deployer](#).

## How Content is Deployed with Simulated App Execution

The following diagram illustrates the steps and BTP components involved in the process of content deployment with simulated app execution:

The steps below describe the process of content deployment with simulated app execution:

1. A developer/operator runs MTA deployment.
2. SAP Cloud Deployment service creates or reuses a service instance provided by an SAP application.
3. The third step includes:
  1. SAP Cloud Deployment service creates a Cloud Foundry application that serves as a content application.
  2. SAP Cloud Deployment service binds the service instance to the content application.
  3. SAP Cloud Deployment service uploads the combination of content and content deployer as application bits.
  4. SAP Cloud Deployment service starts the application, which in turn starts the content deployer.
4. SAP Cloud Deployment service starts to read the application logs and searches for the success-marker and/or failure-marker values.
5. Content deployer performs the actual content deployment. This step includes:
  1. Content deployer reads content details from the bound service instance and identifies the content endpoint and required authentication.
  2. Content deployer executes the content deployment to content endpoint.
6. Via certain success-marker or failure-marker, content deployer reports the status as application logs.
7. SAP Cloud Deployment service stops the content application.
8. MTA deployment completes and SAP Cloud Deployment service reports the status to the developer/operator.

## Content Deployer and Service Instance

The content deployer and service instance are provided by the SAP business application that uses the business content. This way, the content deployer will know how to communicate to the backend on which the content will be deployed. Thus the SAP Cloud Deployment service is isolated from the actual content deployment protocol and implementation.

Normally, the content deployers are simple clients that implement specific REST APIs to pass the content. When the content application is started it invokes a content deployer which calls certain endpoints and executes the actual content deployment.

The content deployer identifies the content endpoint based on the service binding. Content endpoint could be any URL either provided by an application in BTP Cloud Foundry or one outside of the BTP entirely.

It is possible that a content application will have bindings to multiple service instances to complete the content deployment. For example, there could be a reference to an XSUAA service instance, which will ensure secure communication between the content deployer and content endpoint.

## Success Marker and Failure Marker

Success and failure markers are part of the protocol between SAP Cloud Deployment service and the content deployers.

They are used to indicate when the content deployment has reached a final state. Content deployers must include the markers in its logs. Then SAP Cloud Deployment service observes the application logs (STDOUT or STDERR) and decides if the content deployment has finished successfully or failed.

Success and failure markers are predefined and must not be changed by the end customer. They are represented by the module level parameters `success-marker` and `failure-marker`.

For instance, module type `com.sap.portal.site-content` has a success-marker `STDOUT:Deployment of site content to .* done.*`

## MTA Modelling

Below you can find the modelling for supporting the content deployment scenario for MTA module type `com.sap.portal.site-content`:

### Sample Code

```
_schema-version: "3.1"
ID: my-portal
version: "1.1"
modules:
  - name: site-content
    type: com.sap.portal.site-content
    path: site-content/
    parameters:
      buildpack: nodejs_buildpack // Predefined parameter
      no-route: true // Predefined parameter - avoid route mapping to the
content app. It will not serve any HTTP requests
      memory: 256M // Predefined parameter - used memory
      execute-app: true // Predefined parameter - flag that marks the app to
be used for simulated app execution
      success-marker: STDOUT:Deployment of site content to .* done.* //
Predefined parameter - marker for success
      failure-marker: STDERR:Deployment of site content to .* failed.* //
Predefined parameter - marker for failure
      stop-app: true // Predefined parameter - flag that specifies if the app
will be stopped after the actual deployment
```

```

    check-deploy-id: true // Predefined parameter - flag that specifies
    that certain and unique id will be checked for that content deployment
    dependency-type: hard
    health-check-type: none // Predefined parameter - skips the CF health-
    check, so content app will not implement specific endpoint
    requires:
      - name: sap-portal-services-client
      - name: portal-uaa

resources:
  - name: sap-portal-services-client // Provides content endpoint for the
  actual content deployment. Content endpoint could be different based on the
  account
    type: com.sap.portal.site-content
    parameters:
      config:
        siteId : 1234

  - name: portal-uaa // Used for secure communication between content app and
  content endpoint
    type: com.sap.xs.uaa-space
    parameters:
      config-path: security/xs-security.json

```

#### 4.1.8.1.9.7.4 CPI Content Deployment

This approach provides a mechanism for direct content deployment from the SAP Cloud Deployment service to content backend without the need for an intermediate Cloud Foundry application.

##### 📌 Note

This approach is only supported for MTA schema version 3.1 and higher.

This mechanism utilizes the CPI provided protocol. The end-to-end flow and MTA modelling are very similar to [Deploying Content with Generic Application Content Deployment \[page 627\]](#).

#### Supported content type offerings

Cloud Foundry service offerings that currently support GACD are:

- API Management content - MTA module type `com.sap.api.management`
- CPI content – MTA module type `com.sap.integration`

## 4.1.8.1.10 Transporting Multitarget Applications in Cloud Foundry using CTS+

You can enable transport of SAP BTP applications and application content that is available as Multitarget Applications (MTA) using the Enhanced Change and Transport System (CTS+).

### Prerequisites

- Open the document [How to...Configure SAP BTP, Cloud Foundry environment for CTS](#).
- You have configured your SAP BTP subaccounts for transport with CTS+ as described in the document [How to...Configure SAP BTP, Cloud Foundry environment for CTS](#).
- The content that you want to transport can be made available as a Multitarget Application (MTA) archive as described in [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#).

### Context

You use the Change and Transport System (CTS) of ABAP to transport and deploy your applications running on SAP BTP in the form of MTAs, for example, from development to a test or production subaccount. Proceed as follows to be able to transport an SAP BTP application:

### Procedure

1. Package the application in a Multitarget Application (MTA) archive using the Archive Builder Tool as described in [Defining Multitarget Application Archives \[page 542\]](#).
2. Attach the MTA archive to a CTS+ transport request as described in [How to...Configure SAP BTP, Cloud Foundry environment for CTS](#).
3. Trigger the import of an SAP BTP application as described in [How to...Configure SAP BTP, Cloud Foundry environment for CTS](#).

### Related Information

[Resources on CTS+](#) 

[Setting up a CTS+ enabled transport landscape in SAP BTP](#) 

## 4.1.8.1.11 Frequently Asked Questions

### My MTA deployment failed. What could be done?

Check the [MTA Operation Failure](#) section.

### What to do when my application start-up/staging failed?

Check the [Application Start-up Failed](#) section.

### How can I find the logs of an application from a failed/succeeded deployment?

There are several ways to find the application logs:

- `OPERATION.LOG` – contains the whole deployment log.
- `<application-name>.log` – there is a separate file for each application. It holds the logs related to the application during staging and starting.

#### Note

Note that the operation logs are kept for 3 days. Make sure that you download them before the retention period expires.

To download the logs, execute the following command:

```
cf dmol -i <process-id>
```

#### Sample Code

```
cf dmol -i cbe58aeb-0c40-4a3e-972d-82a499815745
```

### Whom to contact in case of problems with deployment?

When an error occurs during deployment, there is a message which indicates whether the problem is in one of the components of the Cloud Foundry Platform. In such cases, an incident to the corresponding component could be created.

#### Example

```
"Controller operation failed: 400 Bad Request: Cannot bind application to service"
```

For more information, you can also check the [Troubleshooting \[page 644\]](#).

### How to check the state of my deployment?

Use the command `cf mta-ops` and find the id of the operation related to the desired deployment. There will be information about the status of the operation.

### How can I list the MTAs that I have deployed in my space?

Use the `cf mtas` command and locate the ID of the desired MTA. After locating the correct MTA ID, execute the command `cf mta <located-mta-id>` to get detailed information about the the MTA with the provided ID.

## What can I do with my deployment?

- If the deployment fails, see [MTA Operation Failure](#).
- If the deployment finishes successfully, you can check the deployment logs.
- If the deployment is still running, you can abort or monitor it.

The **Abort** action is described in more details in the [MTA Operation Failure](#) section.

The **Monitor** action can be executed with the following command:

```
cf <operation> -i <operation-id> -a monitor. Example: cf deploy -i 12355 -a monitor
```

## How can I redeploy my MTA when a deployment is already running?

You can abort the currently running deployment, using the command `cf <operation> -i <operation-id> -a abort` (Example: `cf deploy -i 12353 -a abort`) or you can execute the command for starting the deployment by providing the option `-f` as described in the [deploy \[page 2264\]](#) section.

### ❖ Example

```
cf deploy <path-to-mtar>.mtar -f
```

## What are the size limits of an MTA?

4GB for the whole MTA and 1GB for a single module. For more information, see [Multitarget Applications for the Cloud Foundry Environment \[page 539\]](#).

## What to do in case of service creation failure?

See [Service Create Failure](#).

## How to make my deployment faster?

You can use a parallel deployment as described in section [Parallel Deployment \[page 622\]](#).

## How can I resolve problems with the MTA descriptor modeling?

For more information, see [Defining Multitarget Application Deployment Descriptors for Cloud Foundry \[page 543\]](#).

## What is the deployment order of services, applications and other content?

Services are always deployed in parallel.

The applications and content deployment order is determined based on the `deployed-after` module parameter. If `deployed-after` is not used and parallel deployments are not enabled for the MTA, the `requires/provides` module sections define the order. For more information, see [Parallel Module Deployment \[page 622\]](#).

## How to reuse one backing service in two different MTAs?

If you want one MTA to “own” the lifecycle of the service and another to use it only as an “existing service”, use the `org.cloudfoundry.managed-service` and `org.cloudfoundry.existing-service` resource types respectively.

## How to define service instance and bindings parameters?

For more information, see [Service Binding Parameters \[page 599\]](#) as well as [Service Creation Parameters \[page 597\]](#).

## 4.1.8.1.12 Troubleshooting

Below you can find information about where you can get interactive support to troubleshoot issues and how you can create an incident.

### Troubleshooting

To get interactive support to help troubleshoot issues and navigate processes. See [Guided Answers](#).

### Creating an Incident

If the list does not contain a solution for your issue, you can contact the service support team by reporting an incident through the [SAP Support Portal](#). Here is a list of what to provide in an incident:

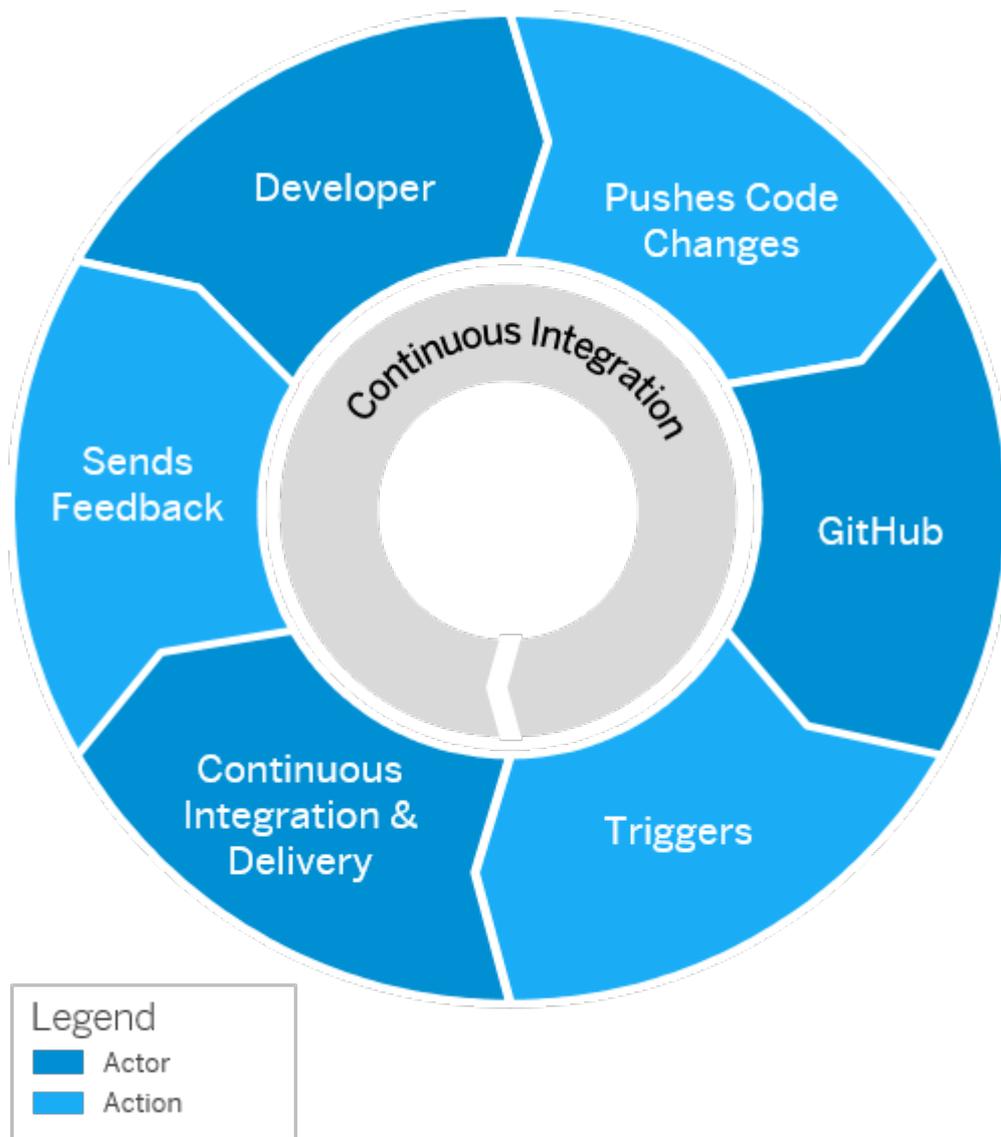

1. Select the component *BC-CP-CF-DS* from the *Component* dropdown list.
2. In the description field, provide as much information as possible about the Cloud Foundry region, Cloud Foundry organization and space names and/or Global Unique Identifiers.
3. Provide information about scenario with the exact steps to be reproduced, expected result, actual result or the error that appears, relevant logs and screenshots. In all cases, the starting point for the investigation are the Multitarget Application operation logs.

## 4.1.8.2 Continuous Integration and Delivery

Learn how to integrate CI/CD into your development with the SAP Cloud Application Programming Model (CAP).

### 4.1.8.2.1 What Are Continuous Integration and Delivery?

**Continuous integration (CI)** describes a software development process in which various team members integrate their contributions frequently into a single main line. Before each integration, the changes are verified through builds and automated testing. Thereby, you can detect errors as quickly as possible and prevent integration problems before completing the development.

- [#unique\\_516/unique\\_516\\_Connect\\_42\\_subsection-im1 \[page 645\]](#)
- [#unique\\_516/unique\\_516\\_Connect\\_42\\_subsection-im2 \[page 646\]](#)
- [#unique\\_516/unique\\_516\\_Connect\\_42\\_subsection-im3 \[page 646\]](#)

#### → Tip

Hover over each actor-action combination for a short description and click on them for more detailed information.

### Continuous Integration Basic Flow

The continuous integration basic flow comprises the following steps:

1. **The developer writes code and pushes the code changes into a central source code management system (SCM).**
2. The SCM triggers the continuous integration (CI) server.
3. The CI server runs automated builds and tests and sends feedback about their outcome to the developer.

### Continuous Integration Basic Flow

The continuous integration basic flow comprises the following steps:

1. The developer writes code and pushes the code changes into a central source code management system (SCM).
2. **The SCM triggers the continuous integration (CI) server.**
3. The CI server runs automated builds and tests and sends feedback about their outcome to the developer.

### Continuous Integration Basic Flow

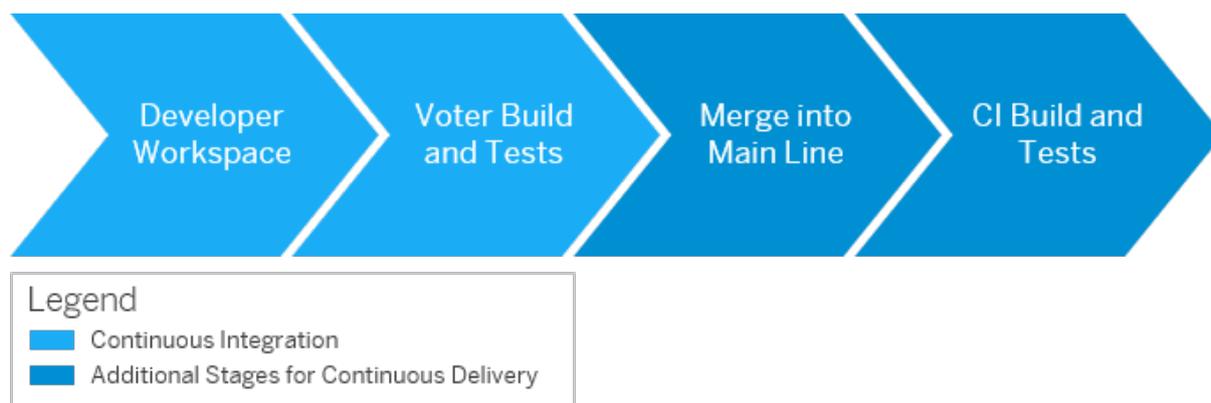

The continuous integration basic flow comprises the following steps:

1. The developer writes code and pushes the code changes into a central source code management system (SCM).
2. The SCM triggers the continuous integration (CI) server.
3. **The CI server runs automated builds and tests and sends feedback about their outcome to the developer.**

As you can see from the graphic, the basic flow for continuous integration is a cycle: As soon as the CI server has sent its feedback to the developer, the flow starts over again. The developer either corrects his or her previous code change, which must then be built and tested again, or starts working on an entirely new one.

The **continuous delivery (CD)** concept expands on the one of continuous integration. It adds the aspect that any change that has successfully passed the tests is immediately ready to be deployed to production, both from a technical and a qualitative point of view.

The following graphic shows the relation between continuous integration and continuous delivery:

Relation Between CI and CD

The continuous delivery process makes sure that the most current version of the software product is successfully built, tested, and provided in a shippable format. Based on the release decision by the development team or delivery manager, it can be shipped to customers or deployed to production at any time.

For more information about the concepts and principles of continuous integration and delivery, see the [Continuous Integration and Delivery Introduction Guide](#).

## 4.1.8.2.2 CI/CD Solutions by SAP for the SAP Cloud Application Programming Model

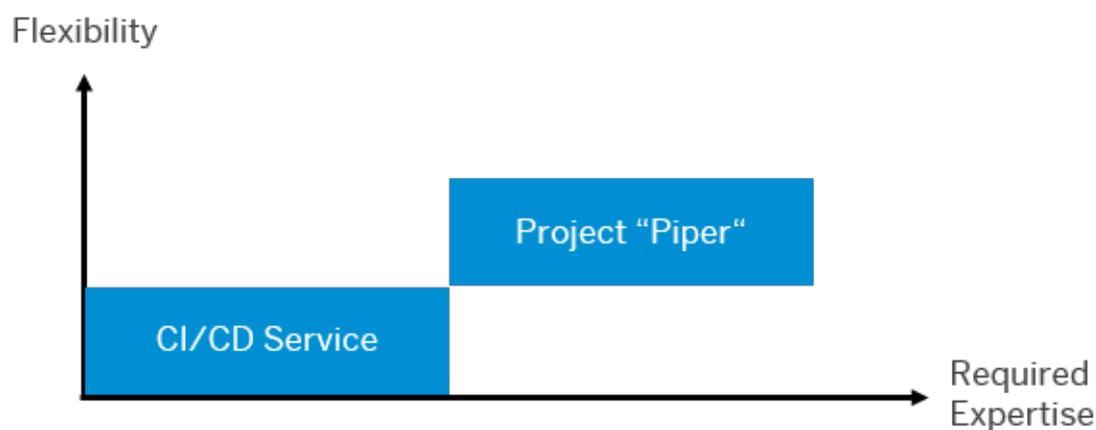

SAP offers two different solutions that help you apply CI/CD in your development with the SAP Cloud Application Programming Model (CAP):

- **SAP Continuous Integration and Delivery** is a service on SAP BTP, which lets you configure and run predefined CI/CD pipelines that test, build, and deploy your code changes.
- **Project “Piper”** is an open-source project that provides preconfigured Jenkins pipelines, which you can use in your own Jenkins infrastructure and adapt according to your needs, if necessary. It consists of a **shared library**, which contains the description of steps, scenarios, and utilities required to use Jenkins pipelines, and a **set of Docker images** that can be used to implement best practice processes.

Both solutions offer in their level of flexibility and expertise required for setup and configuration:

### Note

In the following image, click on one of the blue boxes to navigate to the corresponding solution.

- <https://sap.github.io/jenkins-library/> [https://sap.github.io/jenkins-library/]
- [https://help.sap.com/viewer/product/CONTINUOUS\\_DELIVERY/Cloud/en-US](https://help.sap.com/viewer/product/CONTINUOUS_DELIVERY/Cloud/en-US) [https://help.sap.com/viewer/product/CONTINUOUS\_DELIVERY/Cloud/en-US]

As you don't need to care about the underlying infrastructure, SAP Continuous Integration and Delivery requires the least expertise in CI/CD. Therefore, however, its flexibility is limited. Project “Piper” Docker images can be used out-of-the-box. However, this offering depends on Jenkins as underlying CI/CD tool.

For more information about the CI/CD solutions by SAP, see [SAP Solutions for Continuous Integration and Delivery](#).

The following links guide you to the SAP Cloud Application Programming Model (CAP) sections of our CI/CD solutions:

CI/CD Solution	CAP Section	Description
SAP Continuous Integration and Delivery	<a href="#">Configure an SAP Cloud Application Programming Model Job in Your Repository</a>	Configure a CI/CD pipeline for the development of applications that follow the SAP Cloud Application Programming Model in the Cloud Foundry environment.
Project "Piper"	<a href="#">Build and Deploy SAP Cloud Application Programming Model Applications</a> 	Set up a CI/CD Pipeline for an SAP Cloud Application Programming Model (CAP) project.

### 4.1.8.3 Deploy Business Applications in the Cloud Foundry Environment

When an application for the Cloud Foundry environment resides in a folder on your local machine, you can deploy it and start it by executing the command line interface (CLI) command `push`. To deploy business applications bundled in a multitarget application archive, you have to use the command `deploy-mta`.

- For more information about developing and deploying applications in the Cloud Foundry environment, see <http://docs.cloudfoundry.org/devguide/deploy-apps/deploy-app.html> .
- For more information developing Multitarget Applications, see [Multitarget Applications in the Cloud Foundry Environment \[page 536\]](#). See [Multitarget Application Commands for the Cloud Foundry Environment \[page 2263\]](#) for information about MTA deployment.

## 4.1.8.4 Deploy Docker Images in the Cloud Foundry Environment

The high-level steps to application deployment using Docker images.

### Prerequisites

- You are aware how `cf push` works when you deploy a regular Cloud Foundry application.
- You need a higher degree of freedom and know that this freedom comes with higher responsibility for application operation.
- Your Docker image resides in a highly available container registry.

### Context

A Docker image deployed to the Cloud Foundry environment has to adhere to the same boundary conditions as regular Cloud Foundry applications. Cloud Foundry applications deployed as Docker images are running in Linux containers with user namespaces enabled, which prevents certain functionality like mounting FuseFS devices. Another difference is the usage of buildpacks. Docker images can't be used in combination with buildpacks. If you want to use certain functionality provided by the buildpack, you have to build it into your Docker image.

Compared to regular Cloud Foundry applications, using a Docker image means more effort for you. If the following factors are fulfilled, using Docker on Cloud Foundry might be a viable option.

1. Managing a whole cluster on Kubernetes is too much overhead for your scenario.
2. The usual approach doesn't let you realize what you want to achieve.

Here are some features of the Cloud Foundry environment you have to implement yourself in your Docker image. The comparison is made with the SAP Java buildpack.

Supported with SAP Java buildpack	Description
Dynatrace	Enable applications for Dynatrace based monitoring.
XSUAA	Automatic validation of OAuth token and mapping of OAuth scopes to JEE roles, if <code>auth-method</code> is set to XSUAA in <code>web.xml</code> .
Dynamic Logging	Set of log level via CLI without restart.
Switch to debug via CLI	
OS & JVM management	Consume newer versions (especially patches) of the underlying OS and JVM regularly..

## Procedure

1. Your Docker image adheres to the 12 factor principles.

<https://12factor.net/> 

2. You only use supported features in the SAP BTP, Cloud Foundry environment, see [Cloud Foundry Environment \[page 44\]](#)
3. Read what the open source documentation says about deploying an application with Docker.

Pay special attention to the mentioned requirements. [Deploy an App with Docker](#) 

Requires traffic routing to the lowest numbered port. [How Diego Runs and Monitors Processes](#) 

4. Use `cf push` with the `--docker-image` parameter.

This is an example if you want to push from Docker Hub:

```
cf push <APP-NAME> --docker-image <REPO>/<IMAGE>:<TAG>
```

Also pay attention to the section on private registries and Google Container Registry. [Push a Docker Image From Docker Hub](#) 

5. Operate and patch your Docker images.

Docker images contain everything that is necessary to run a process, including the operating system and libraries into one binary blob. Consequently, staging a Docker image in Cloud Foundry does not provide the same separation of droplet and stack that is available for a Cloud Foundry application staged using a buildpack.

If there is an operating system and library security vulnerability, the developer is responsible to `cf push` a new version of the Docker images. The developer using the platform has the responsibility for watching these security vulnerabilities and for reacting accordingly.

For scale or restart operations, the image is pulled again from the container registry. The container registry has to be highly available and reachable from network side for proper operations.

## 4.2 Development in the ABAP Environment

Learn more about developing applications in the ABAP environment.

### Overview

The ABAP environment is a platform as a service that allows you to extend existing ABAP-based applications and develop ABAP cloud apps decoupled from the digital core. You can leverage your ABAP know-how in the cloud and reuse existing ABAP assets by writing your source code with ABAP Development Tools for Eclipse.

The ABAP environment enables you to **expose**:

- OData services. See [ABAP RESTful Application Programming Model](#).
- HTTP services. See [Working with the HTTP Service Editor](#).
- SQL services. See [Consumption of the SQL Service for Data Federation \[page 1124\]](#).
- RFC function modules. See [Develop a Remote-Enabled Function Module \(RFM\) \[page 997\]](#).
- SOAP provider model. See [Generate Provider Proxies From WSDL Files](#).

With your ABAP applications, you can **consume**:

- HTTP services (HTTP client). See [Set Up HTTP Communication \[page 961\]](#).
- OData services (service consumption model). See [Developing a UI Service with Access to a Remote Service](#).
- Remote Function Calls (RFC). See [Set Up RFC Communication \[page 971\]](#).
- On-premise systems via Cloud Connector. See [Integrating On-Premise Systems \[page 1070\]](#).
- SOAP-based Web services. See [Set Up SOAP Communication \[page 988\]](#).

### Technical Limits and Boundary Conditions for ABAP Applications

For elasticity, operability and protection reasons, the runtime of API or UI requests to ABAP applications is limited. After 10 minutes, running requests are automatically canceled. Tasks requiring longer runtimes have to be executed in [Application Jobs](#), as background processes via the background processing framework (bgPF), or need to be split into smaller work packages. For an optimal user experience, all ABAP applications, including application jobs, have to be prepared to be interrupted and restarted even earlier than the maximum runtime. This allows to provide a continuous application service, unimpacted from scaling operations, maintenance activities or even infrastructure failures.

1. Download and install ABAP Development Tools (ADT) from <https://tools.hana.ondemand.com/#abap>. See [Video Tutorial: Configure ABAP Development Tools](#) .

### Note

SAP GUI is not supported in the ABAP environment. You can only use ADT as your development environment.

2. Create an ABAP cloud project with ADT to connect to the ABAP system in the ABAP environment (see [Connect to the ABAP System \[page 654\]](#)).
3. Develop your application (see [Development in the ABAP Environment](#)). To learn more about how to develop applications, see [Tutorial: Create Your First ABAP Console Application](#) and [Video Tutorial: Create Application](#) .

## More Information About Development in the ABAP Environment

For more information about ABAP development, see [Development in the ABAP Environment](#).

### 4.2.1.1 Connect to the ABAP System

Set up your ABAP cloud project to connect to the ABAP system.

#### Prerequisites

- You are assigned the developer role. See [Assigning the ABAP Developer User to the ABAP Developer Role \[page 174\]](#) and [Creating Service Keys](#).
- You have downloaded and installed the front-end components of [ABAP Development Tools \(ADT\)](#). See [Video Tutorial: Configure ABAP Development Tools](#). ➔
- You are a member of the relevant space in the Cloud Foundry environment, see [Add Space Members Using the Cockpit](#), or you have a service key in JSON format, see [Creating Service Keys](#).

#### Procedure

1. Open Eclipse and select **File > New > ABAP Cloud Project** from the menu.
2. To establish a service instance connection, you have the following options:
  - a. **[Default] Service key provided by Cloud Foundry environment:**

In the *New ABAP Cloud Project* wizard, on the *System Connection to SAP BTP ABAP Environment* page, select the *Use Cloud Foundry Environment* radio button, and choose *Next*.

On the *Connection Settings* page, select *Europe (Frankfurt)* as your region, enter your email address and password, and confirm with *Next*.

On the *Connection Settings to SAP BTP Cloud Foundry Environment* page, select your service instance details.

- b. **Service key in JSON format:**

In the *New ABAP Cloud Project* wizard, on the *System Connection to SAP BTP ABAP Environment* page, select the *Service Key* radio button, and choose *Next*.

On the *System Connection Using a Service Key* page, paste your existing service key from the clipboard into the *Service Key in JSON Format* text box, or choose *Import* to import a text file containing your service key.

#### Note

If you're an SAP Universal ID user, you can only use this option to establish a service instance connection.

3. Select *Next*.
4. To log on to the service instance on the *System Connection Using a Service Key* page, you have the following options:
  - a. **Using the integrated browser:** Enter your email address and password.

#### Note

Authentication is performed in the integrated browser. Single Sign On is not supported. Tools, such as password managers, are not supported for this logon option.

- b. **Using the default browser:** Select the *Log on with Browser* button.
  - c. **Using another browser:** Choose the *Copy Logon URL* button.

The URL is copied to the clipboard of your computer.
5. To connect to your service instance, select *Log On*.

On the *Service Instance Connection* page, the following connection settings are displayed:

- **Service Instance URL:** URL of the server instance where the ABAP system is operated
- **Email:** ID of the user who is authorized in the configured identity provider for accessing the ABAP system
- **User ID:** ID of the user who is assigned to the email
- **SAP System ID:** Name of the ABAP system
- **Client:** ID of the logon client
- **Language:** Abbreviation of the logon language

#### Note

Currently, English is the only logon language.

6. Select *Next*.

The *Project Name and Favorite Packages* page is opened.
7. [Optional:] If you want to change the name of the project, enter a new name in the *Project Name* field.

#### Note

When you create the project, the ZLOCAL ABAP package is added by default to your *Favorite Packages*. This ABAP package including all subpackages contains all local objects from every user of the ABAP system.

To add further ABAP packages to your *Favorite Packages*, choose *Add...* and enter the name of the package in the corresponding input field. Note that this package must be available in the system.

To group your projects, you can add working sets. To do so, choose *New...* in the *Working sets* section and select the relevant projects.

8. To create your ABAP cloud project, select *Finish*.

## Results

You have created an ABAP cloud project that is added to the *Project Explorer*.

### Note

To verify your result, expand the first level of the project structure. Make sure that the following nodes are included:

- *Favorite Packages*: Contains the local packages and the packages that you have added to your Favorites.
- *Released Objects*: Contains all released SAP objects that are available to (re)use.

## 4.2.2 ABAP Development Tools for Eclipse: User Guides

Get an overview of all available user guides for ABAP development tools for Eclipse.

### [ABAP Development Tools for Eclipse: User Guide](#)

This guide describes the functionality and usage of the possibilities within the ABAP development tools for Eclipse. It focuses on use cases for creating, editing, testing, debugging, and profiling development objects.

### [ABAP CDS Development Tools: User Guide](#)

This guide describes the functionality and usage of tools for Core Data Services (CDS) in the ABAP environment. It focuses on use cases for creating, editing, testing, and analyzing ABAP CDS entities.

## 4.2.3 ABAP Keyword Documentation

The ABAP keyword documentation describes the syntax and meaning of the keywords of the ABAP language and its object-oriented part – ABAP objects.

## Context

The ABAP keyword documentation provides you with context-sensitive information for your ABAP source code.

## Accessing ABAP Language Help

To access the ABAP language help from the source code editor, position your cursor on an ABAP statement for which you need help, and press **F1**. The language help is displayed in a separate window.

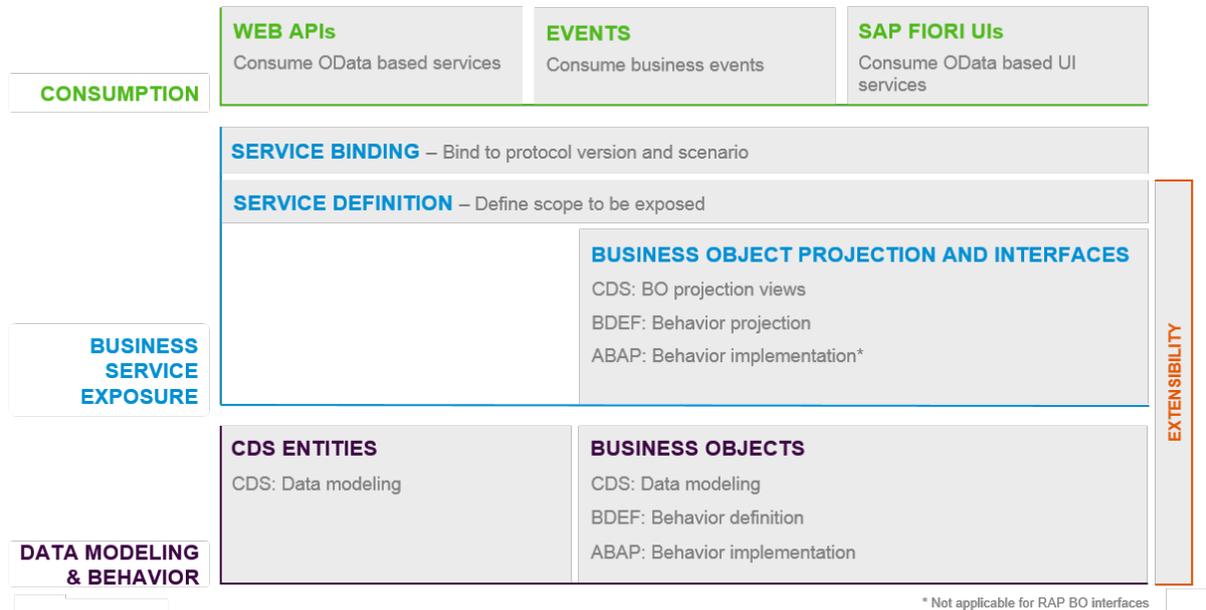

To view the entire ABAP keyword documentation, see [ABAP - Keyword Documentation](#).

## 4.2.4 ABAP RESTful Application Programming Model

The [ABAP RESTful Application Programming Model](#) defines the architecture for efficient end-to-end development of intrinsically SAP HANA-optimized OData services (such as SAP Fiori apps) in the ABAP environment. It supports the development of all types of Fiori applications as well as publishing Web APIs. It is based on technologies and frameworks such as Core Data Services (CDS) for defining semantically rich data models and a service model infrastructure for creating OData services with bindings to an OData protocol and ABAP-based application services for custom logic and SAPUI5-based user interfaces.

### Architecture Overview

#### RAP - The big picture

[Tutorial: Get to Know the ABAP RESTful Application Programming Model](#) 

### 4.2.5 Assuring Quality of ABAP Code

This is an overview of ABAP quality tools that help you to keep your custom code clean and performant.

The two most important quality tools for your custom ABAP code are:

- *ABAP Unit* for dynamic tests
- *ABAP Test Cockpit (ATC)* for static code analysis

## ABAP Unit

Writing ABAP Unit tests is the way to provide high-quality software, which can be easily evolved over time without introducing regressions. In methodologies, like extreme programming and test-driven development, the role of unit testing is even more important.

ABAP unit is the state-of-the-art unit testing framework for ABAP. It's embedded into the ABAP programming language, which supports you in writing unit tests. In the ABAP Development Tools (ADT), you have various possibilities to execute the unit tests and to evaluate the results concerning functional correctness and code coverage.

We recommend measuring the test coverage of all objects in a transport before releasing the transport. A high coverage (above 80%, for example) and a wide variety of test methods help to identify issues and make the code more robust.

For more information, see [Unit Testing with ABAP Unit](#).

## ABAP Test Cockpit (ATC)

ATC is the tool of choice for all kinds of static code analysis in ABAP. As an ABAP developer, you can use ATC in the ABAP Development Tools (ADT) to find potential bugs already during the development phase.

In particular, you can check ABAP development objects for many types of problems, including syntax errors, potential problems in performance, suboptimal or potentially faulty programming, adherence to standards, errors in ABAP Unit testing, among others.

For more information, see [Checking Quality of ABAP Code with ATC](#).

### ATC Check Variant

The basic configuration of the ATC is the so-called ATC check variant, which includes the set of checks that should be executed. The default variant is set to `ABAP_CLOUD_DEVELOPMENT_DEFAULT`. It includes all recommended checks to fulfill the ABAP cloud code quality standard incl. the execution of ABAP Unit tests.

You can create a copy of this variant and add additional checks. You can also add custom created checks to your variant.

For more information, see [Working with ATC Checks](#).

## Transports

The basic quality gate is the release of transport tasks and transport requests.

For findings with priority level 1 and 2, the release of tasks and requests is blocked by the system in the default setting. For findings with priority level 3, the developer only gets a notification. This default setting can be individually sharpened based on your needs.

For more information, see [Working with ATC During Transport Release](#).

## Test Runs

You can either set up scheduled automated test runs for the ATC, or trigger it manually via ADT.

For more information, see [Working with ATC During Development](#).

## ATC Exemptions

Sometimes ATC findings can't be corrected. For example, it's possible that a correction is planned for an upcoming development cycle or only a test program is affected. It could also happen, that checks return false positives.

In this case, you can still process the issue by requesting an exemption. Once approved, it masks an ATC error or warning message. The finding then isn't displayed as an open issue in the ATC results anymore.

In the ABAP environment, exemptions are transportable objects of the type CHKE. The full workflow for the request and approval of exemption is integrated in ABAP Development Tools (ADT).

For more information, see: [Working with ATC Exemptions](#).

## ABAP Test Cockpit Configurator App

You can use the ATC Configuration app to set up the default variant. You can also change the priorities of check messages, set priority levels that block or interrupt transport releases, and set the handling of pseudo comments and pragmas.

For more information, see [ABAP Test Cockpit Configurator](#).

## 4.2.6 ABAP Lifecycle Management

This chapter helps you to plan and set up your landscape and lifecycle management by describing how software components can be used and which possibilities you have for transportation of development objects and business configuration.

### 4.2.6.1 Basic Concepts and Terms

To better understand how software lifecycle management with gCTS in the ABAP environment can be implemented, let's start off with some basic concepts and terms.

## Classical Git

### Git

Git is a distributed version-control system.

Distributed version control is a form in which development objects and all their versions and metadata are mirrored from a central place to every developer's computer. The developer can switch locally and offline between different versions and change all of them before updating the central originals later.

### Repository

A repository is a collection of objects, their directory structure, and metadata, for example, a historical record of changes in the repository, a set of commit objects, and a set of references to commit objects.

The central place that all objects are mirrored from and saved to, after having finished changes on a developer's computer, is the so-called remote repository. Every developer's computer holds a so-called local repository to work on.

## Branch

Git repository branches can be used to control the flow of changes through the test and production landscape. They are used to separate changes from each other, which shall or might not be delivered together (i.e. development vs. correction, feature A vs. feature B). A branch is created on the current state of another branch, the parent branch, and reflected by a new copy of all included objects, that is, the commit history of the parent branch. Depending on which branch is supposed to be changed, the corresponding copy is worked on.

## Pull

Pulling means getting the code that is currently in the remote repository into the local repository.

## Push

Pushing means getting the code that is currently in the local repository into the remote repository.

## Commit

A commit records the state and content changes of a file. It bundles multiple changes and saves it to the local repository. When you perform a git push, all commits are transferred to the remote git.

## Check Out

Checking out means that, if several branches are available, the one that is selected is added to the working tree. The working tree consists of the objects of the branch you are currently working on. It contains the state of these objects since they were last pulled and the changes that were made locally but are not yet pushed to the central remote repository. This checked out branch/working tree is what is displayed in the application to edit the objects.

## ABAP and ABAP with gCTS

### ABAP System/Instance

SAP Business Technology Platform offers a service called ABAP System (abap). If you want to develop with ABAP in the cloud, you have to create an instance of that service, see [Create an ABAP System](#). This service instance provides the ABAP system that you are developing in. The terms ABAP system and ABAP instance can and are often used synonymously, however, we refer to the term ABAP system.

### Transport Request

A transport request records all the changes in your ABAP development system. Once a transport request is released, the changes are pushed into your central Git repository, to be more precise a branch of it, which is by default the main branch, in the cloud as a commit represented by a commit ID. During the import (pull or checkout), the delta of the Git repository branch content between the ABAP system and central Git repository is imported.

#### Note

Transport requests cannot be imported selectively into subsequent ABAP systems but as part of software component branches their changes were added to.

## Release

A release, for example with the format YYYY-<nn>, is a set of changes that are tested successfully in your quality ABAP system(s) and imported into your production ABAP systems after a release decision. It is represented by a release branch in the Git repository. Once the release decision has been made, you have to create and pull (import) the new release branch into the production ABAP system.

### 4.2.6.2 Transport Mechanisms

There are two git-based transport mechanisms in the ABAP environment.

**Git-based CTS (gCTS)** is the evolution of the classical Change and Transport Management System (CTS). It is the recommended approach for transporting objects between ABAP systems in your global account. It offers built-in and easy to use functionalities provided by the Manage Software Components app in your SAP Fiori launchpad.

**abapGit** is an open-source Git client that allows you to import existing code into your ABAP system. You should use it for the following use cases:

- Migrate on-premise code to the cloud. See [Use abapGit to Transform ABAP Source Code to the Cloud](#).
- Transfer your code from the cloud to on premise. See [Transfer Your ABAP Source Code With SAP BTP ABAP Environment via abapGit](#).
- Export your code when the development ABAP system is decommissioned.
- Transfer your code from one cloud to another to share it with others, for example as open source, or from a partner to a customer account.
- Implement mechanisms for distributed development and testing in dedicated development/test ABAP systems. This can be useful for special projects, such as proof of concepts or features that are dependent on regular development of a solution but shall run independent from its lifecycle.
- To learn more about abapGit, see [Working with abapGit \[page 665\]](#).

For a quick start on transportation, see [Transport a Software Component Between Two ABAP Systems](#). For more information about the according delivery process, see [Delivery via Add-On or gCTS](#).

#### 4.2.6.2.1 Software Components

Your development, including transportation, is organized and managed in so-called software components. A software component is designed to contain all coding and development objects of at least one application and should be runnable itself.

##### ❖ Example

If you think of an application for bonus management, this is how your application could be structured:

- `Z_BONUS_MANAGEMENT` (top-level package, corresponds to the software component and is created automatically, type `Structure`)
  - `Z_BONUS_CALCULATION` (sub-package, type `Development`)
  - `Z_BONUS_CONFIGURATION` (sub-package, type `Development`)

## → Tip

Your development can also be loosely coupled in different software components.

## 📌 Note

You must not create objects in the structure package. You have to create a sub-package of type `Development` first to start developing.

## ⚠️ Restriction

- Objects of one software component cannot be used in another software component by default because software components provide their functionality via explicitly released APIs to other software components. This means you must set the API state of the object to *Released* if you want to use an object from another software component. See [Released APIs](#), [Finding Released APIs and Depreciated Objects](#).
- Software components should not have cyclic dependencies (objects in software component A use objects in software component B and vice versa). If you create dependencies between software components, we recommend that you do this in a layered way, for example, for grouping basic reuse functions in a dedicated software component.
- You can't move development objects from one software component to another. Thus, the introduction of software components should be planned carefully.
- You can't move objects between packages that reside in different transportable software components.
- You can't move objects between packages that reside in a transportable software component to `ZLOCAL`.  
For more information about moving development objects into ABAP packages, see [Changing the Package Assignment of Development Objects](#).
- You can use the same ABAP systems regarding development, testing, and production (your system landscape) for all your software components. Lifecycle processes for software components can even be independent from each other, as long as there are no development dependencies.
- gCTS only supports certain object types. For a complete list of the restricted object types, see SAP note [2888887](#).
- gCTS repositories are currently always stored on the AWS data center **Europe - Frankfurt EU Access**, independent of the chosen hyperscaler and the data center where the ABAP environment instance was created.

You create your software components in the development system:

- The software component `ZLOCAL` is available by default. It serves a similar role like `$TMP` in an on-premise system.
- Create your software components with the SAP Fiori app `Manage Software Components` (business catalog `Lifecycle Management - Software Components SAP_A4C_BC_MSCL_PC`). Afterwards, pull the software component into the ABAP system to start developing in it.
- You can use an ABAP namespace in the ABAP environment. If you have registered a namespace at SAP, it is automatically provided during provisioning. For more information on namespaces, see SAP note [105132](#) on how to reserve a namespace and ONE Support Launchpad [Namespace Application](#). A developer key and repair key are created and assigned automatically by the ABAP system. In the namespace application, you can search for your key assignments by filtering the installation number (`CLOUDSYSTEM`).

- If you want to transport business configuration content across ABAP systems, create a software component. You have to decide which type you want to use for transporting business configuration:
  - You can create a software component of type `Business Configuration` and transport all your configuration via this software component. If a software component of type `Business Configuration` is available in a tenant, applications can automatically select or create a customizing transport request for this software component.

#### ⓘ Note

You can only import one software component of type `Business Configuration` per ABAP system.

- You can transport the configuration using the software components that you also use for your development objects, which is typically the same software component for tables and table content. This is advisable if you run multiple projects on the same landscape that are well separated and have decoupled time schedules.

See [Transport of Business Configuration \[page 702\]](#).

#### ⓘ Note

In your system you will see all software components linked to the same global account. Region or infrastructure provider do not matter. You only have to ensure that all systems are created within the same global account.

### 4.2.6.3 ABAP Environment Specifics

gCTS and the SAP Fiori app Manage Software Components provide a simplified git UI adapted to the possibilities of ABAP. This means:

- There is a remote Git repository for each software component managed by SAP in the cloud. Using the SAP Fiori app Manage Software Components, a software component can be created from any ABAP system in the same global account. Alongside with the software component creation, the corresponding remote repository is created. Afterwards, the software component needs to be cloned and pulled into the ABAP system. With this step, a corresponding structure package is created in the ABAP system that acts as a local repository so that you can start developing (software component = repository in gCTS).
- The creation of a Git repository branch is also performed in the Git repository. It does not matter in which ABAP system you create the branch. However, you have to check it out in each ABAP system where you want to use it, be it for development, testing or productive use.
- In an ABAP system
  - there is only one branch of a software component at a time
  - all developers work on the same object versions
  - an object can be edited by one developer at once
- Pulling a software component does not simply copy object files, but, depending on the object type, also activates the objects, for example a data element, or even generates additional invisible objects in Eclipse, for example authorization artifacts for business catalogs used in business roles.
- You have no merge functionality. If you pull the current branch while changes have been added from another ABAP system, all the changes in the ABAP system the branch is pulled into are discarded. Consequently, you should not work on the same branch in two different ABAP systems.

- Before being able to pull a software component again or before checking out a different branch, you have to release all open transport requests. There is no way of saving them without releasing, like a git stash.
- Releasing a transport request combines the git actions of committing and pushing. The Transport Request Id and description are displayed in the commit message.
- A new branch is created remotely in the Git repository. This means that if the new branch shall be derived from the one currently checked out, changes in the ABAP system that are not yet committed and pushed by releasing the transport that contains these changes are not part of the new branch. The `Last Commit Message` text consists of the Transport Request ID and description, and helps you to ensure that the expected changes are part of the new branch. If you don't want to hold back any new changes, you must release all open transports before creating a new branch.
- If you need to discard changes, you have to do this manually. This can be done with the help of the *History* view in Eclipse, which offers a compare editor to revert to the last transported version. Afterwards, you have to remove all the discarded objects from their modifiable transport request in the *Transport Organizer* view.
- Branches cannot be deleted or set to *obsolete*, therefore consumers have to be informed about a branch that they shall not use, for example, if you skipped a release branch that could not be finished in time.
- Basic change logging using the “traditional” ABAP server capabilities is available in the development ABAP system: e.g. the *Revision History* for ABAP objects and the *Responsible* and *Last Changed By* contacts. However, if you de-provision the development ABAP system, this information is lost. The Git repository still stores the version (see [Information for Audit \[page 705\]](#)) and the person who released the transport request(s) but the information on the *Last Changed By* contact per object is only available in the development ABAP system.
- You cannot work offline because you need access to the ABAP system.

## 4.2.6.4 Working with abapGit

abapGit is an open source developed Git client for the ABAP server to import and export ABAP objects between ABAP systems.

With abapGit, you can export your ABAP objects from any system to another, typically from on-premise to cloud or from one cloud system to another. See [Use abapGit to Transfer Your On-Premise ABAP Source Code to the Cloud](#) and [Push Your ABAP Source Code from SAP BTP, ABAP Environment to a GitHub Repository Using abapGit](#).

### Note

While the ABAP environment comes with a preinstalled cloud version of abapGit, you can only use abapGit in an on-premise system if you have installed the [official community version](#) of abapGit. However, the official community version is not supported by SAP.

With the official SAP distribution of abapGit, you can use ABAP Development Tools (ADT) in combination with the abapGit feature for ADT, which allows easier access to the import/export functionality provided by abapGit. For more information on how to install and work with ABAP Development Tools, see [Installing ABAP Development Tools](#) and [abapGit Repositories ADT Plug-In](#).

## Restrictions and Errors

There are certain restrictions to the export and import functionality when using abapGit in the ABAP environment. This is due to the cloud-optimized set of supported ABAP object types that change with each release as new ABAP object types are added continuously. See [Released ABAP Object Types \[page 678\]](#). Depending on your application, you may face the following issues when using abapGit in cloud systems:

- Export errors when pushing unsupported objects
- Import errors when pulling unsupported objects
- Activation errors when activating imported objects

### Export Errors

If you try to export objects that are not supported, you receive a warning during the push operation, and the unreleased object is skipped.

The only work-around for this is to manually copy the missing ABAP objects to the target system. First, you have to create these objects using the same name in the target system. Afterwards, you either have to manually copy the code or reconfigure the objects in the target system.

Some objects are deliberately not exported because they are considered as compiled or generated so that they can be regenerated when activating their originating objects in the target system. For example, certain service definitions (SRVD) are generated from service consumption models (SRVC) so that they are not exported to git.

### UI Artifacts

The same reasoning regarding compiled/generated objects currently also applies to UI/SAP Fiori artifacts (SMIM, UIAD, WAPA). Originating UI objects have their own lifecycle in SAP Business Application Studio and therefore have to be deployed separately to the target ABAP system via SAP Business Application Studio using SAP Fiori Tools, see [Generate Deployment Configuration ABAP](#). If the deployment target is in a different global account, you have to push the UI project to a Git repository using SAP Business Application Studio as described in [Git Source Control](#). After the initial deployment of the UI to the target ABAP development system, the generated artifacts follow the same transport lifecycle from development to test and production systems as all the other artifacts.

### Import Errors

When importing objects with abapGit for ADT, you may get error messages in the import log. Possible reasons can be:

- You are importing object types (for example from an on-premise system) that are not supported in the ABAP environment and the programming model of the ABAP environment. You may have to change your application in the cloud environment to work without these objects.
- You are importing objects with missing dependencies. These dependent objects can't be exported because they are not on the list of Released ABAP Object Types. You must copy/recreate these missing dependent objects and restart the import.
- You are importing objects using ABAP namespaces. Make sure these namespaces have been imported into the target system before importing your application with abapGit.

### 📘 Note

Local changes to ABAP objects that have not been saved are overwritten by the import. Open transport requests for any of the imported ABAP objects must be released before they can be changed. Otherwise, they get locked.

## Activation Errors

All objects imported with abapGit are imported in an inactive state, except the ones that do not offer an inactive state, to ensure that their consistency can be properly checked during activation. Hence, you have to activate all imported objects after importing them so that ABAP activation can verify that only released APIs have been used.

During the activation process, some objects may depend on other objects, which need to be activated beforehand. However, not all object types consider the objects they depend on during mass activation. For example:

- Data dictionary (DDic) and core data service (CDS) objects do not always resolve their dependencies in the first mass activation attempt so that you have to activate them in multiple cycles.
- Service bindings need to be activated after service definitions.

If activation issues occur, repeatedly try to activate objects in the right sequence. If that does not work, try reimporting and reactivating objects multiple times until all objects of your application are active.

### → Tip

If you face any issues with the official abapGit distribution of SAP, create an incident using component BC-CP-ABA.

For issues related to the community open-source distribution of abapGit, create an issue at <https://github.com/abapGit/abapGit/issues> .

### 📘 Note

It is possible to define the external systems, the ABAP system is allowed to communicate with, by maintaining a list of trusted certificate authorities. Please use the Maintain Certificate Trust List app to do so. This app can be used by administrators, users with the SAP\_BR\_ADMINISTRATOR role. For further information, please go to [Maintain Certificate Trust List \[page 2556\]](#)

## Related Information

[Released ABAP Object Types \[page 678\]](#)

## 4.2.6.4.1 Install and Set Up abapGit

Learn how to install and set up abapGit.

### Prerequisites

- You have signed up for a Git account of your choice, for example GitHub.
- You have access to an on-premise system with the required root CA of the Git server (STRUST).
- You have downloaded and installed the front-end components of [ABAP Development Tools \(ADT\)](#). See [Video Tutorial: Configure Developer Tools](#) .

#### ⚠ Restriction

Please be aware that abapGIT is an open-source project owned by the community. Therefore, we do not provide support for abapGIT. We only support the GIT integration in the ABAP environment.

### Procedure

1. Log on to your github.com account.
2. Create an abapGit repository by clicking on *New repository*.
3. Enter a repository name, tick the *Initialize this repository with a README* checkbox, and select *Create repository*.

Your repository is set up.

4. Copy the content of the latest build from program `zabapgit` to your clipboard. You can find the content in the abapGit repository <https://github.com/abapGit/abapGit> .

#### ⚠ Caution

Check with your system administrator before installing `zabapgit`.

5. Log on to an on-premise system of your choice, create a new program, and paste the content from your clipboard.

#### ℹ Note

Select `EN` as your logon language.

6. Activate and execute the program.

abapGit is installed and launched. See also [Video Tutorial: abapGit Installation](#) .

7. Log on to ABAP Development Tools in Eclipse.
8. Navigate to `Help > Install New Software...` .
9. To install the abapGit repositories ADT plug-in, add the following URL: <https://eclipse.abapgit.org/updatesite/> and provide a name for the repository.

10. To display all the available features, press enter, and select *abapGit for ABAP Development Tools (ADT)*.
11. Select *Next* to finish the installation.

## Next Steps

[Create Content in an On-Premise System and Push it to abapGit Repository \[page 669\]](#)

### 4.2.6.4.2 Create Content in an On-Premise System and Push it to abapGit Repository

## Prerequisites

You have installed and set up abapGit. See [Install and Set Up abapGit \[page 668\]](#).

### ⚠ Restriction

Please be aware that abapGit is an open-source project owned by the community. Therefore, we do not provide support for abapGIT. We only support the Git integration in the ABAP environment.

## Procedure

1. After installing and launching abapGit, select *Clone or download*, and copy the URL of your repository.
2. Call up transaction ZABAPGIT, and select + *Online*.
3. Paste the URL of your repository.
4. Select *Create package*.

### 📘 Note

If you have already created a software component with gCTS, you can skip steps 4 to 6 and use this software component in step 7.

5. Add a package name and short description, and select *Continue*.
6. Confirm with *OK*.

The cloned abapGit repository is displayed in abapGit.

7. Log on to ABAP Development Tools in Eclipse, and navigate to your newly created package.
8. Add ABAP development objects to your package. See [Released ABAP Object Types \[page 678\]](#).
9. Navigate back to the abapGit UI, and select *Refresh* to display the development objects that you have created in Eclipse.

10. Choose *Stage*.
11. Select single objects or choose *Add all and commit*.

#### Note

You can also select structure packages to be exported.

12. Enter a *committer name*, *committer e-mail*, and *comment*.
13. Select *Commit*.
14. In the Login popup, enter your abapGit repository server credentials, and select *Execute*.  
The pushed ABAP objects are displayed in your abapGit repository.

## Next Steps

[Import Content from abapGit Repository into the ABAP Environment \[page 670\]](#)

### 4.2.6.4.3 Import Content from abapGit Repository into the ABAP Environment

Learn how to import content from your abapGit repository into your ABAP environment, and transfer it across multiple instances.

## Prerequisites

- You have installed the abapGit repositories ADT plug-in. See <https://eclipse.abapgit.org/updatesite/> .
- You have created content in your on-premise system and pushed it to your abapGit repository. See [Create Content in an On-Premise System and Push it to abapGit Repository \[page 669\]](#).

#### Note

The repository has to be accessible from the Internet. Cloud Connector is not supported.

- You have access to an ABAP cloud system. See [Creating an ABAP System \[page 163\]](#).
- You have assigned a developer user in the ABAP environment to the developer role. See [Assigning the ABAP Developer User to the ABAP Developer Role \[page 174\]](#).

#### Restriction

Please note that abapGit is an open-source project owned by the community. Therefore, we do not provide support for abapGit. We only support the abapGit integration in the ABAP environment.

## Procedure

1. Log on to ABAP Development Tools in Eclipse.
2. In the *Project Explorer*, select your cloud project system, and navigate to **Window** > *Show View* > *Other..* to open the abapGit repositories view.
3. Search for *ABAP*, choose *abapGit Repositories*, and select *Open*.
4. In the *abapGit repositories view*, select the clone button (green + icon).
5. Enter your abapGit repository URL, and select *Next*.
6. Select a *Branch* and *Package*, where you want your abapGit repository to be cloned, and confirm with *Next*.

### Note

If there are no packages, you have to create a structure package and add a development package.

7. Select the default transport request, and choose *Finish*.  
The imported objects are displayed in your package. See [Released ABAP Object Types \[page 678\]](#).

### Note

The number of imported objects can differ from the number of exported objects because only released ABAP object types are considered during the import.

## 4.2.6.4.4 Folder Logic in abapGit

### Folder Logic

AbapGit in Steampunk offers two folder logics, either "Prefix" or "Full". The folder logic has to be selected when linking a repository in ABAP Developer Tools in the popup. Afterward, the information can also be found in the abapGit Repositories ADT plugin. The folder logic information defines the way how subpackages of the root package that needs to be linked will be converted to folders in the linked repository. Therefore, this setting affects only the folder structure in the remote repository and has no implication to the object structure in the ABAP system.

#### Prefix

The folder logic PREFIX allows the installation of a repository into a different parent package (in different systems). This can even be a local package (ZLOCAL), in which case no transport request is required. A package name must contain its parent package name as a prefix. This means that the names of the subpackages will start with the name of the parent package, for example:

- TESTMYTEST01 (parent)
- TESTMYTEST01\_RUN\_01 (child1)
- TESTMYTEST01\_RUN\_02 (child2)

### Note

The prefix folder logic will not work correctly if you do not follow the convention.

Other examples, including valid package prefix:

- ZFOO
- ZFOO\_BAR
- ZFOO\_BAR\_QUX

This will produce the following folder structure:

/src

/src/bar

/src/bar/qux

Invalid package prefix:

- ZFOO
- ZBAR

### Full

The folder logic FULL forces the installation of a repository into packages with exactly the same name. Any package name is accepted. Folders will be named like packages. Any package name is accepted

- ZBASE
- ZSOMETHING
- ZHELLO

This will produce the following folder structure:

/src

/src/zsomething

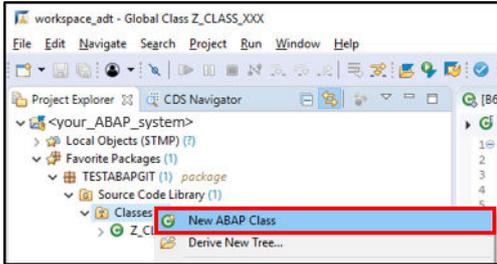

/src/zsomething/zhello

In general, the folder logic setting is stored in the *.abapgit.xml* file in the remote repository, too. It is highly recommended to take over this information during the linkage process, in case the file already exists. Otherwise, a mixture of different folder logic information on the local and remote side would lead to inconsistencies.

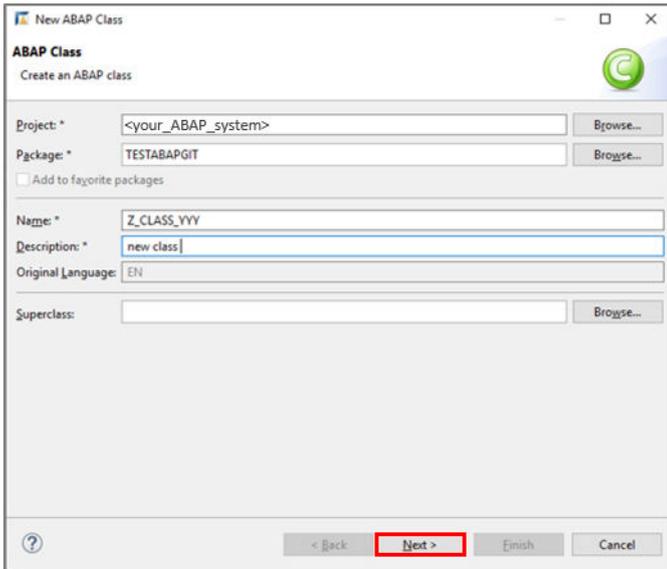

## 4.2.6.4.5 Transfer your ABAP Source Code via abapGit

Use abapGit to transfer your ABAP source code from an ABAP environment instance back to your repository.

1. Create or adapt your source code in the ABAP environment instance:
  1. Open **ABAP Development Tools** and logon to your ABAP system.
  2. Add an ABAP development object, e.g. an ABAP class, to your already existing *TESTABAPGIT* package. To do this, click on *Classes* and select *New ABAP Class*.

3. Enter a name and description for your new ABAP class and click *Next*.

4. Click *Finish*.

**New ABAP Class**

**Selection of Transport Request**

① For Z\_CLASS\_YYY (Global Class), the selected transport request will be used

Choose from requests in which I am involved

type filter text

Transport Request	Owner	Target	Description	CTS Pro
Y11K900283	CB0000000357		TRMS	

Create a new request

Request\_Description: \*

CTS\_Project:

Enter a request number

Request Number:

5. Now you can implement your newly created class.

```

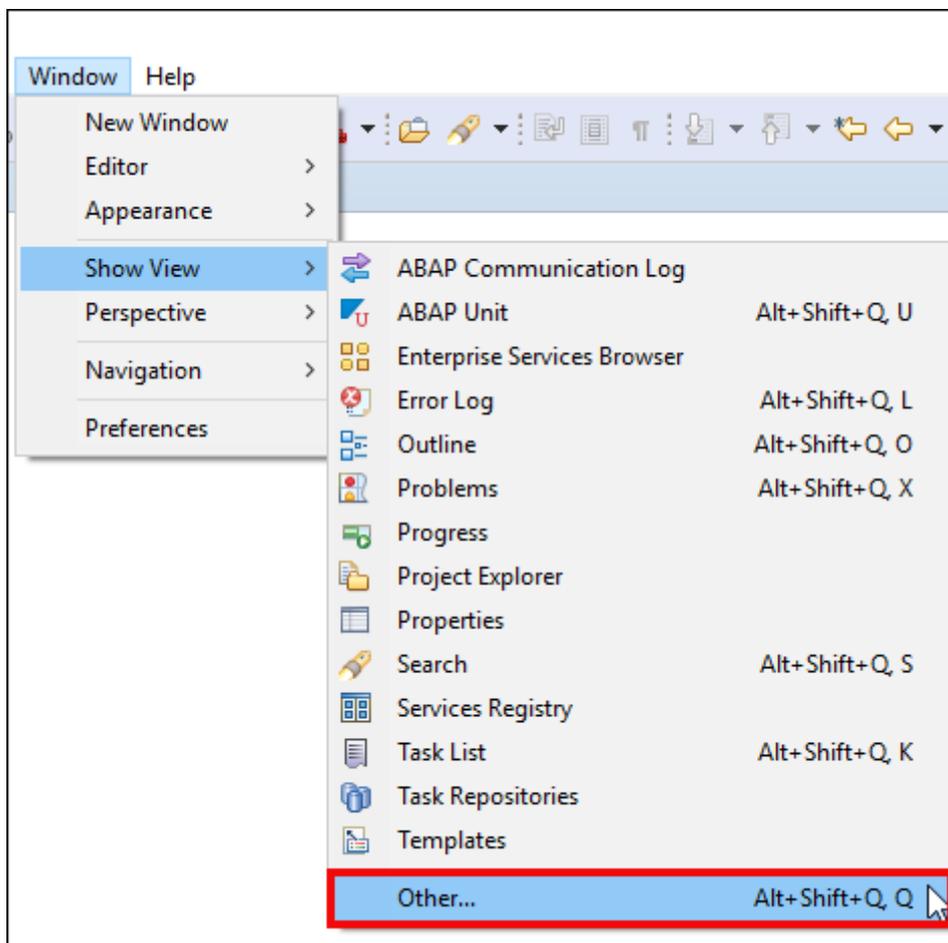

[Y11] Z_CLASS_YYY [Y11] Z_CLASS_XXX
  Z_CLASS_YYY
1  class Z_CLASS_YYY definition
2  public
3  final
4  create public .
5
6  public section.
7  interfaces if_oo_adt_classrun.
8  protected section.
9  private section.
10 ENDCLASS.
11
12 CLASS Z_CLASS_YYY IMPLEMENTATION.
13 METHOD IF_OO_ADT_CLASSRUN~MAIN.
14   out->write('Hello world!').
15 ENDMETHOD.
16 ENDCLASS.

```

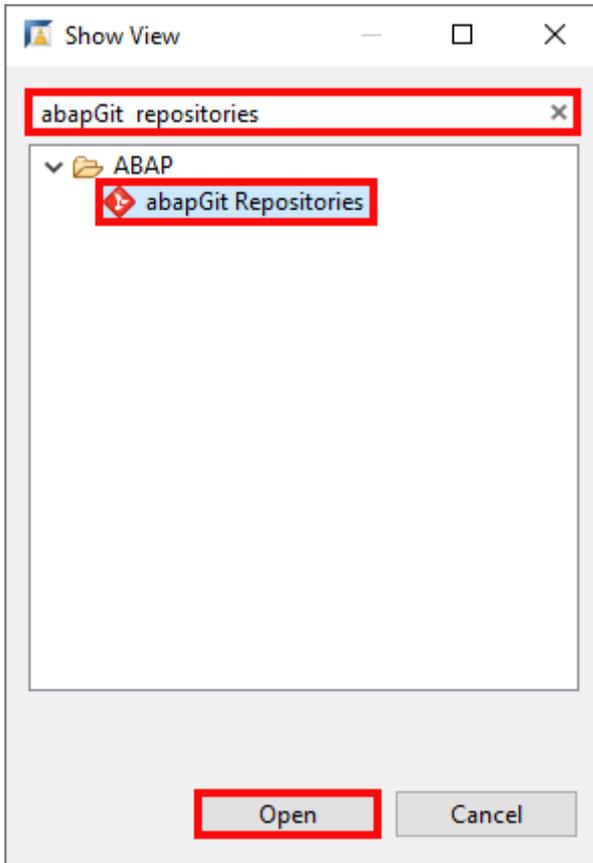

6. Save and activate.

2. Open abapGit repositories:

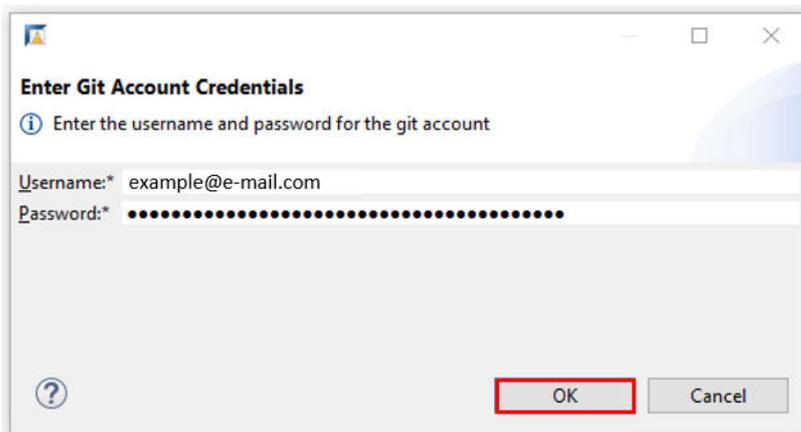

1. Select your **ABAP system** in the Project Explorer and select **Windows > Show View > Other...** to open the *abapGit* repositories.

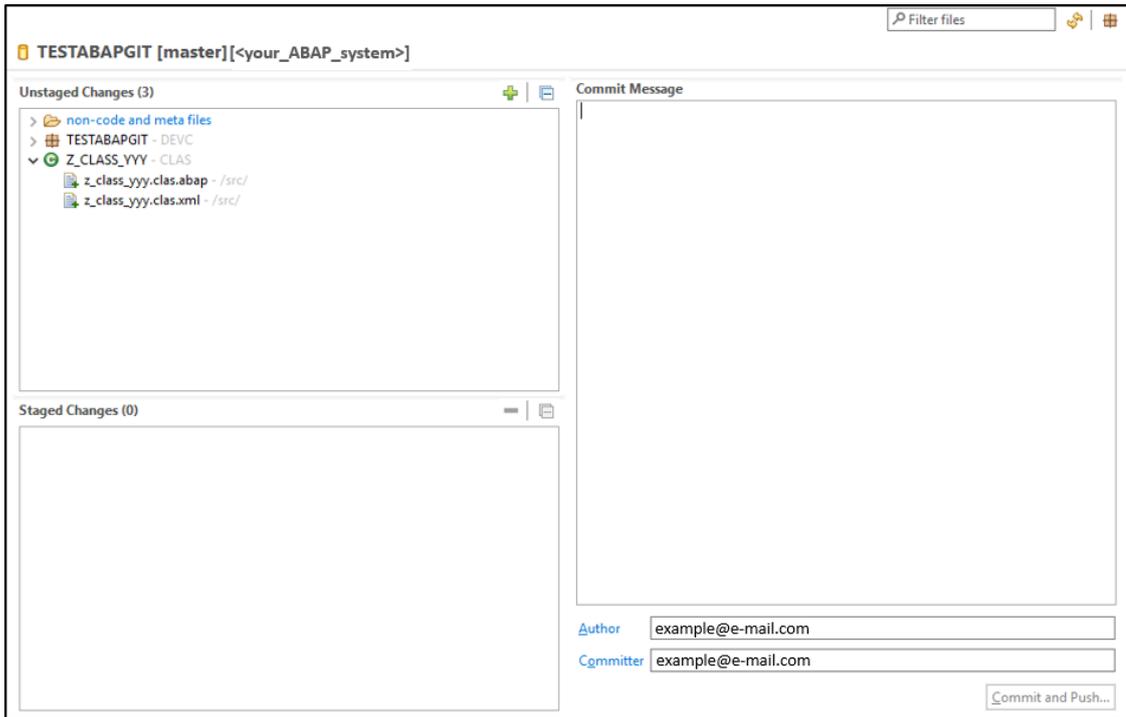

2. Search for *abapGit repositories*, select it and click *Open*.

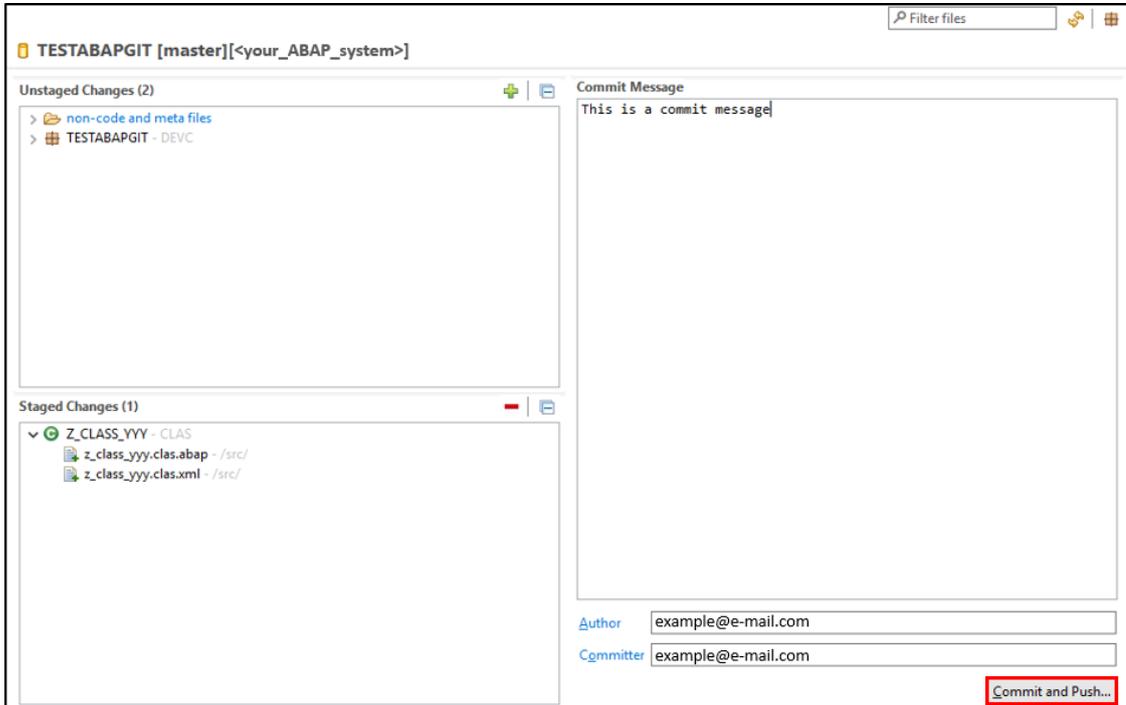

3. Stage and commit your ABAP development objects.
  1. Right-click your *TESTABAPGIT* package and click *Stage and Push*.
  2. Enter your repository credentials in the popup and click *OK*.

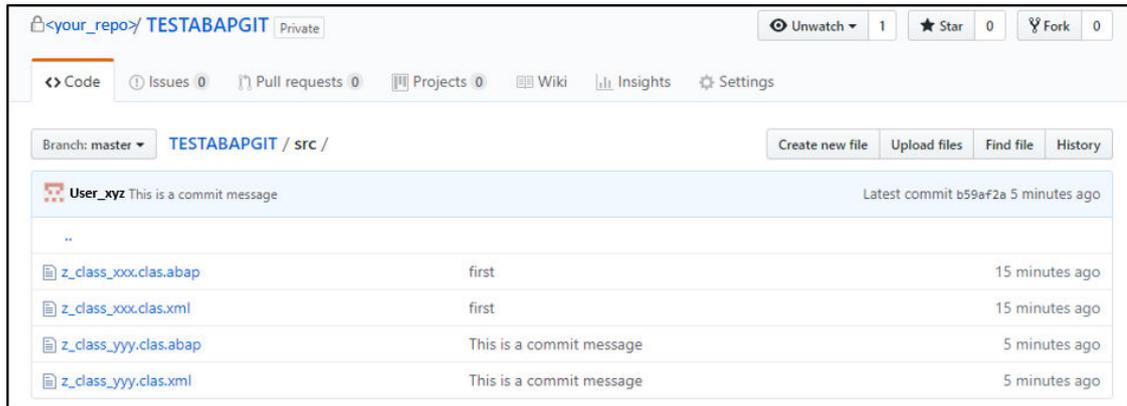

3. In the staging view you will see a list of changed, created or deleted ABAP development objects which can be transferred to your repository. The icon of the respective file indicates whether a file was created, modified, or deleted.

4. ABAP development objects which should become staged can be selected by drag and drop from the *unstaged* box to the *staged* box or by clicking on the + button. Enter your commit message and click **Commit and Push**.

5. You'll see a notification telling you that your push has started. Click *OK*.
6. The staged objects have now been transferred to your repository.

## 4.2.6.4.6 Released ABAP Object Types

The following table contains all the released ABAP object types that can be imported into your ABAP environment tenant.

### Note

If you try to import or export objects that are not supported, you receive a warning during the transport operation. The objects that are not released are skipped and not transported. To avoid this, you have to manually copy the ABAP objects to the target system. Note that you have to create these objects using the same name in the target system, unless they already exist. Afterwards, you either have to manually copy the code or reconfigure the objects identically in the target system.

APIS	API Release State of Objects
APLO	Application Log Object
AUTH	Authorization Check Fields
BDEF	Behavior Definition
CFDF	Custom Field
CHDO	Change Document
CHKC	ATC Check Category
CHKO	ATC Check Object
CHKV	ATC Check Variant
CLAS	Class
DCLS	ABAP Data Control Language Sources
DDLS	Data Definition Language Source
DDLX	Core Data Services Metadata Extensions
DEVC	Package
DOMA	Domain

DRTY	Dictionary: CDS Type Definitions
DTEL	Data Element
EEEC	Event Consumption Modell
ENHO	Enhancement Implementation Object
ENHS	Enhancement Spot Object
EVTB	Event Binding
ENQU	Lock Object
FUGR	Function Group
FUNC	Function Module
GSMP	Metric Provider
HTTP	HTTP Service
INTF	Interface
MSAG	Message Class
NONT	SAP Object Node Type
NROB	Number Range Object
RONT	SAP Object Type
SAJC	Application Job Catalog Entry
SAJT	Application Job Template
SC01	Communication: Communication Scenario
SC02	Communication: Inbound Service
SC03	Outbound Service
SIA1	IAM: Business Catalog
SIA2	IAM: Restriction Type
SIA3	IAM: Authorization Object Extension
SIA5	IAM: Restriction Field
SIA6	IAM: App
SIA7	IAM: Business Catalog App Assignment
SIA8	IAM: Business Role Template
SIA9	IAM: Business Role Templ. Bus. Catalog Assignment
SIAD	Business Role Template Fiori Space Assignment
SKTD	Knowledge Transfer Document
SMBC	Maintainable Business Configuration
SRVD	Service Definition
SUSH	Assignment: Service --> Authorization Objects
SUSO	Authorization Object
TABL	Table Definition
TTYP	Table Type

## Restrictions

- All objects imported with abapGit are imported as inactive, except the ones that don't have an inactive state. Therefore, you have to activate all the imported objects after the import.

### Note

During the activation process, some objects may depend on other objects which need to be activated beforehand.

Also note that mass activation is not supported.

- All local changes to ABAP objects that are not saved are overwritten by the import.
- Open transport requests for any of the imported ABAP objects must be released before they can be changed. Otherwise, they get locked.

## Known Issues

- Changes in table definitions could lead to data loss.

### 4.2.6.5 Setting Up and Working with Your Landscape

Depending on your requirements, you need to adjust the setup of your software lifecycle management and the underlying landscape. The following sections give you examples for the most common setups

In general, the number of ABAP systems in your landscape is the result of the processes (development (DEV), quality assurance (QAS), and production (PRD)) that need to run in parallel and the number of branches of your biggest software component that is worked on or tested in parallel.

The number of ABAP systems = (number of branches x DEV systems) + (number of branches x QAS systems) + (number of PRD systems)

This is due to the fact that an ABAP system always checks out only one branch of a software component. Yet, several software components represented by one branch can run in one ABAP system in parallel.

#### 4.2.6.5.1 Required Tools

Different actions require different tools. In the process descriptions, the following tools are used:

- SAP BTP cockpit (web-based administration interface)
- SAP Fiori app [Maintain Business Roles \(Deprecated\)](#) [page 2452]
- SAP Fiori app [Maintain Business Users](#) [page 2444]
- SAP Fiori app [Manage Software Components](#) [page 2592]
- SAP Fiori app [Export Customizing Transports](#) [page 2380]
- SAP Fiori app [Maintain Business Configurations](#) [page 2373]
- Eclipse Tool for the ABAP environment is an Eclipse installation with ABAP Development Tools (ADT) plugin (see [Eclipse Tool for the ABAP Environment](#))
- Custom SAP Fiori apps: these apps are the result/aim of your development
- External test tools, for example for OData tests
- External documentation tool to document test results and release decision if required

## 4.2.6.5.2 Required Business Roles

Different actions require different roles as well. In the process description, the following role proposals are used:

- System Administrator
  - Creates ABAP systems in the SAP BTP cockpit
  - Needs authorization for space/organization management in the Cloud Foundry environment subaccount
- User Administrator
  - Maintains business roles and assigns users to them
  - Needs authorization for business catalogs

Catalog ID	Catalog Description	Needed For
SAP_CORE_BC_IAM_UM	Identity and Access Management – User Management	Creating and maintaining business users with <a href="#">Maintain Business Users</a> app
SAP_CORE_BC_IAM_RM	Identity and Access Management – Role Management	Maintaining business roles with <a href="#">Maintain Business Roles</a> app

- Release Manager
  - Performs tasks that are executed centrally for a release, such as software component creation and import, making the release decision, approving corrections, creating and releasing transports etc.
  - Needs authorization for business catalogs

Catalog ID	Catalog Description	Needed For
SAP_A4C_BC_MSCL_PC	Lifecycle Management - Software Components	Creating and importing software components with <a href="#">Manage Software Components</a> app

Catalog ID	Catalog Description	Needed For
SAP_A4C_BC_TRN_REL_PC	Development - Transport Release Management	Releasing transport requests in ABAP Development Tools for Eclipse
SAP_A4C_BC_DEV_OBJ_DIS_PC	Development – Development Objects Display	Show development objects in transport organizer in ABAP Development Tool
SAP_CORE_BC_IAM_UM	Identity and Access Management - User Management	Un-/locking developers for corrections in correction ABAP systems with <a href="#">Maintain Business Users</a> app
SAP_CORE_BC_IAM_RA	Identity and Access Management – Role Assignment	En-/disabling developers for corrections in correction ABAP systems by role assignment with <a href="#">Maintain Business Users</a> app
SAP_CORE_BC_BCT_TRN_REL_PC	Business Configuration - Transport Release Management	Creating, editing, and releasing customizing transports with <a href="#">Export Customizing Transports</a> app

- Developer
  - Develops the code and performs tests
  - Needs authorization for business catalogs

Catalog ID	Catalog Description	Needed For
SAP_A4C_BC_DEV_PC	Development – ABAP Development Tools	Developing in ADT for Eclipse
SAP_A4C_BC_TRN_MNG_PC	Development – Transport Management	Creating transport requests in ADT for Eclipse

- Tester
  - Tests the software

#### ⓘ Note

Depending on your organization, the tasks of this role can be performed by automatic test tools, developers, or dedicated persons that are responsible for executing manual tests.

- Needs authorizations for custom business catalogs created via IAM business catalogs for custom apps.

#### ⚠ Caution

Do not assign catalog SAP\_CORE\_BC\_EXT\_TST (Extensibility - Custom Apps and Services) to a tester.

As this catalog is used to provide an easy test of custom apps or their underlying services in a development ABAP system only by adding them automatically to it during activation, real service tests with own catalogs might not be tested securely. In non-development systems, automatic authorization via business catalog SAP\_CORE\_BC\_EXT\_TST is not enabled, instead custom authorization is required.

- Business Configuration Expert

- Maintains and tests business configuration

Catalog ID	Catalog Description	Needed For
SAP_CA_BC_IC_LND_PC	Customizing - Business Configuration	General business configuration tasks, such as uploading business configuration or viewing the change log for business configuration
SAP_CORE_BC_BCT_TRN_MNG_PC	Business Configuration - Transport Management	Creating and editing customizing transports
Application-specific catalog with configuration apps, for example SAP_CA_BC_IC_LND_NUM_PC	Example: Number Range Management - Configuration	Configuring number ranges

### 4.2.6.5.3 Important Notes

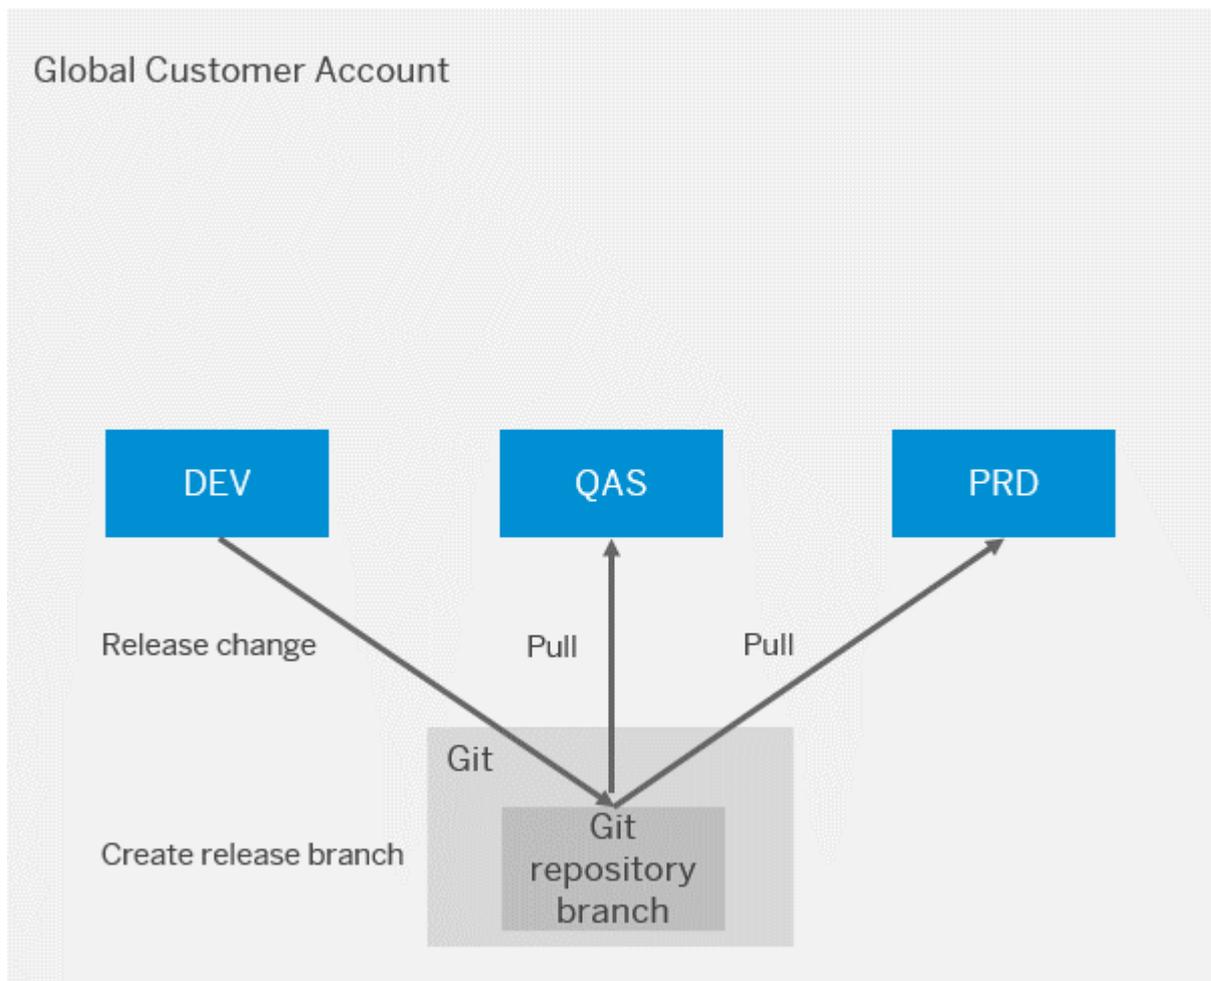

- The creation of a Git repository branch creates a clone of the parent branch. If you create a branch immediately after the release decision, you have a “frozen” state. You can import this state safely into one or multiple production systems, “pre-production” systems, etc., or you may use it later for auditing.
- In the different system setups, the production systems can either be provisioned once development starts or later on, when needed for the first time for the Go Live, which is the point in time, when the first release is used productively in the production system.
- A classical 3-system setup comprising a development, quality assurance, and production system can be enhanced by pre-production systems, multiple test systems, etc. Test systems can be provisioned on demand (temporary) or permanently.

### 4.2.6.5.4 Use Case 1: One Codeline in a 3-System Landscape

You can apply this setup if you have occasional development activities for larger applications where testing needs to run in parallel to development or should take place in a non-development system to ensure the solution also runs in a non-development system. In this setup, you either need to be able to pause development for a fix that has to be delivered before the next release or you have to deliver fixes as part of the next possible release.

This landscape consists of a development, quality assurance, and production system.

## Global Customer Account

### For Go Live/Development After Go Live (Including Deferrable Corrections)

#### Starting situation for Go Live

The Go Live process is characterized by creating different systems only when needed for the first time, however, you can provision the systems already beforehand. Furthermore, the software component of a planned solution does not exist from the beginning. The resulting release branch is YYYY-01. Apart from this, the Go Live process does not differ from the release development processes afterwards.

#### Starting situation after Go Live

- Development system DEV is based on the main branch
- Quality Assurance system QAS and production system PRD are based on the latest release branch YYYY-<nn>. In case of a first release after the Go Live, YYYY-<nn> is YYYY-01

System QAS has always the same software state as the PRD system, unless a new change is tested and released. This means, transport requests are released in development ABAP systems only if development is completed and it is planned to import the changes to the production system.

This process can also be used for deferrable corrections, which do not need to reach production before the next development release. These corrections are handled like regular development.

Step	System	Role	Task	Tool
0	DEV	Release Manager	At Go Live only: Create the software component and clone it initially  If required, create a customizing transport request and tasks for the relevant business configuration expert(s).	<a href="#">Manage Software Components</a> app  <a href="#">Export Customizing Transports</a> app
1a	DEV	Developer	Develop new functionality or a deferrable correction. All changes are collected in workbench transport requests	ABAP Development Tools for Eclipse
1b	DEV	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests	<a href="#">Maintain Business Configurations</a> app
2 a	DEV	Developer in ADT	Release the development transport request(s).	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
2 b	DEV	Release Manager	Release only export customizing transports.	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
2 c	DEV	Release Manager	The changes are now in the main branch	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app

Step	System	Role	Task	Tool
2 d	DEV	Release Manager	<p>The released API has to be part of development and the development has to be finished.</p> <p>Snapshots are pulled after development after the API objects are released. The snapshot has to be set to check-relevant. Then, the ATC compatibility check should run.</p>	<a href="#">Manage API Snapshots</a> app
3	QAS	Release Manager	<p>At Go Live: Pull software component(s) into system QAS.</p> <p>After Go Live: Check out main branch of software component(s)</p>	<a href="#">Manage Software Components</a> app
4	QAS	Tester	<p>Test the change and report test result</p> <p>If changes are required, repeat steps 1-4</p>	<p>ABAP Development Tools for Eclipse and custom SAP Fiori apps as well as external test tools</p> <p>External documentation tool</p>
5	QAS	Release Manager	<p>Release decision: the changes are successfully tested and approved</p>	External documentation tool
6	QAS	Release Manager	<p>Create a release branch YYYY-&lt;nn+1&gt; for each software component (at Go Live: YYYY-01)</p>	<a href="#">Manage Software Components</a> app
7	QAS	Release Manager	<p>Check out the new release branch YYYY-</p>	<a href="#">Manage Software Components</a> app

Step	System	Role	Task	Tool
8	PRD	Release Manager	Check out the new release branch YYYY-<nn+1> for each software component (at Go Live: YYYY-01) into system PRD	<a href="#">Manage Software Components</a> app

## Urgent Corrections

- Development system DEV is based on the main branch
- Quality assurance system QAS and production system PRD are based on the latest release branch YYYY-<nn>. In case of a correction after the Go Live before the second release, YYYY-<nn> is YYYY-01

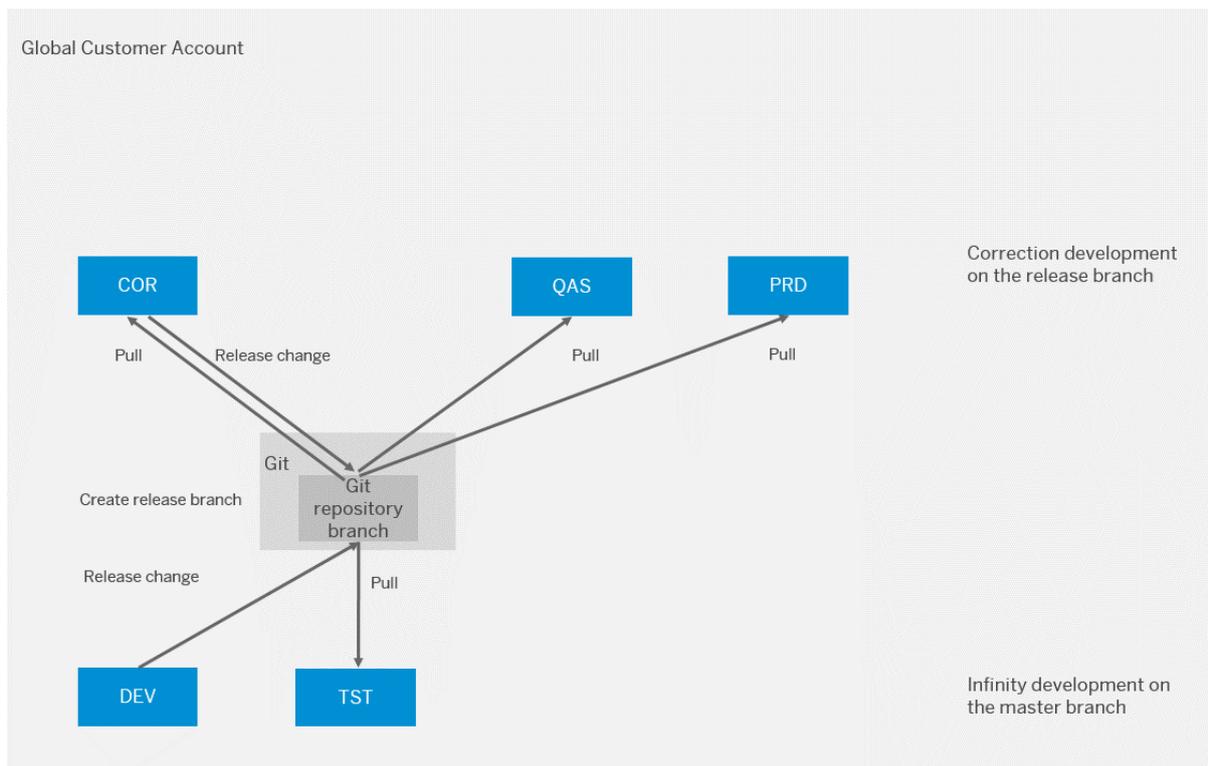

This process differs from the previous one in the branch it is developed in. As the correction is too urgent to release it with the next development release only, it is done in the release branch. To achieve this separation, all current development activities need to be paused because the DEV system needs to check out the latest release branch instead of the main branch.

Step	System	Role	Task	Tool
1	DEV	Release Manager	Check out the release branch YYYY-<nn> for each software component  If required, create a customizing transport request and tasks for the relevant business configuration expert(s)	<a href="#">Manage Software Components</a> app  <a href="#">Export Customizing Transports</a> app
2a	DEV	Developer	Fix existing functionality. All changes are collected in workbench transport requests	ABAP Development Tools for Eclipse
2b	DEV	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests	Custom Business Configurations app
3a	DEV	Developer	Releases the development transport requests.	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app

Step	System	Role	Task	Tool
3b	DEV	Release Manager	Releases the customizing transport requests.	ABAP Development Tools for Eclipse: Transport Organizer or <i>Export Customizing Transports</i> app
4	QAS	Release Manager	Pull the software component(s) to get the correction into the already checked out release branch YYYY- <nn>	<i>Manage Software Components</i> app
5	QAS	Tester	Test the change and report the test result	ABAP Development Tools for Eclipse and custom SAP Fiori apps as well as external test tools  External documentation tool
6	QAS	Release Manager	If changes are required, repeat steps 2-5  Fix is successfully tested and approved	External documentation tool
7	PRD	Release Manager	Pull the software component(s) to get the correction into the already checked out release branch YYYY- <nn>	<i>Manage Software Components</i> app
8	DEV	Release Manager	Check out the main branch in system DEV for each software component	<i>Manage Software Components</i> app
9	DEV	Developer, Business Configuration Expert	Perform the same changes as for the correction in the main branch and release them	ABAP Development Tools for Eclipse  <i>Maintain Business Configurations</i> app  <i>Export Customizing Transports</i> app

## 4.2.6.5.5 Use Case 2: One Development and Correction Codeline in a 5-System Landscape

You can apply this setup if you have permanent/infinite development activities for large applications with many developers, where development cannot be paused to implement an urgent correction. Corrections need to run in parallel to development and on a released state. You need to separate testing from development to ensure the solutions also runs in a non-development system before being delivered to production.

General considerations:

- Systems COR and QAS have the same software state as production system PRD, unless a new change is tested and released. This means transport requests are released in the DEV system only if development is completed and if it is planned to import the changes to the production system.
- Releases are planned and communicated to development in advance:
  - Upon cut-off date, development is finished. All development that is released at this time must be tested and be of good quality. From then on, you have to fix defects in the COR system and maintain them in parallel in the DEV system.
  - Upon release date, all defects must be fixed. If you make the decision during testing in the QAS system that a complete functionality is not delivered, developers must delete, revert, or disable the functionality in the COR system and release the corresponding transport requests. You cannot remove objects from the release branch, e.g. by deselecting transport requests. To revert objects to an older transported state, use the compare editor of the Eclipse *History* view. If the withdrawal of the functionality shall be performed in the DEV system as well it is considered as a correction and you have to perform double maintenance of corrections into the DEV system. The released software state from the COR system is imported into the production system(s) PRD.

- System COR is usually locked for development. First, this means developers cannot do changes by default and there are two approaches how to handle this:

	<b>User Locking</b>	<b>Read-Only + Write Developer Role</b>
How-to Details	Unlock user on demand	Assign write role on demand
Pros	No additional role needed	No generic read user needed No logon with different user for read access needed User-specific auditing
Cons	Generic read user needed if you want to provide read access	Additional role needed

Second, developers are also not allowed to create transport requests and tasks on their own, but it's the release manager who creates them for all developers. This separation is achieved by giving business catalog SAP\_A4C\_BC\_TRN\_MNG\_PC (Development - Transport Management) to the release manager instead of the developer role in correction system COR.

## For Go Live/Development after Go Live (Including Deferrable Corrections)

### Starting Situation for Go Live:

Recently created development system DEV and other already existing ABAP systems cannot be based on some branch yet, as the software component does not exist yet.

The Go Live process is characterized by creating different systems only when needed for the first time, however, you can provision the systems already beforehand. Additionally, the future solution's software component does not exist from the start. The resulting release branch is YYYY-01. Apart from this, the Go Live process does not differ from the release development processes.

### Starting Situation after Go Live:

- Development system DEV and test system TST are on the main branch
- Correction system COR, quality assurance system QAS, and production system PRD are on release branch YYYY-<nn>

This process can also be used for deferrable corrections, which do not need to reach production before the next development release. These corrections are handled like normal development.

Step	System	Role	Task	Tool
0	DEV	Release Manager	<p>At Go Live only: create a software component of type <i>Development</i> and, if required, a software component of type <i>Business Configuration</i>. Pull the software component(s) into the system.</p> <p>If required, create a customizing transport request and create tasks for the relevant business configuration expert(s)</p>	<p><i>Manage Software Components</i> app</p> <p><i>Export Customizing Transports</i> app</p>
1a	DEV	Developer	Develop a new functionality or a deferrable correction. All changes are collected in Workbench transport requests	ABAP Development Tools for Eclipse
1b	DEV	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests	<i>Maintain Business Configurations</i> app
2 a	DEV	Developer	Once development is finished, release the transport request(s). The changes are now in the main branch	ABAP Development Tools for Eclipse: Transport Organizer or <i>Export Customizing Transports</i> app
2 b	DEV	Release Manager	<p>The released API has to be part of development and the development has to be finished.</p> <p>Snapshots are pulled after development after the API objects are released. The snapshot has to be set to check-relevant. Then, the ATC compatibility check should run.</p>	<i>Manage API Snapshots</i> app
3	TST	Release Manager	Pull the software component(s) into system TST	<i>Manage Software Components</i> app

Step	System	Role	Task	Tool
4	TST	Tester	Test the change and report the test result	ABAP Development Tools for Eclipse and custom SAP Fiori apps as well as external test tools  External documentation tool
			If changes are required, repeat steps 1-4	
5	QAS or any other	Release Manager	Cutoff: at cutoff date, create a release branch YYYY-<nn+1> for each software component (at Go Live: YYYY-01) (release candidate)	<a href="#">Manage Software Components</a> app
6	QAS	Release Manager	Check out the release branch YYYY-<nn+1> of each software component (at Go Live: YYYY-01) into system QAS	<a href="#">Manage Software Components</a> app
7	QAS	Tester	Test the release candidate and report the test result	ABAP Development Tools for Eclipse with ADT and custom SAP Fiori apps as well as external test tools  External documentation tool
8	COR	Release Manager	Check out the branch YYYY-<nn+1> of each software component (at Go Live: YYYY-01) into system COR	<a href="#">Manage Software Components</a> app
9	COR	Release Manager	Enable the respective development users for development in system COR, depending on the process you decided for, either by unlocking or assigning a different role	<a href="#">Maintain Business Users</a> app

Step	System	Role	Task	Tool
			If required, create a customizing transport request and create tasks for the relevant business configuration expert(s)	<a href="#">Export Customizing Transports</a> app
10a	COR	Developer	Implement development-related corrections	ABAP Development Tools for Eclipse
10b	COR	Business Configuration Expert	Implement corrections to business configuration content	<a href="#">Maintain Business Configurations</a> app
11	COR	Developer	Release the development transport request(s). The changes are now in the release candidate.	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
12	QAS	Release Manager	Pull the software component(s) to get the correction into the already checked out release branch YYYY-<nn+1> (@Go Live: YYYY-01)	<a href="#">Manage Software Components</a> app
13	QAS	Tester	Test the change and report the test result	ABAP Development Tools for Eclipse and custom SAP Fiori apps as well as external test tools  External documentation tool
			If changes are required, repeat steps 11-13	
14	QAS	Release Manager	Release decision: the changes are successfully tested and approved	External documentation tool
15	PRD	Release Manager	Check out the release branch YYYY-<nn+1> of each software component (at GoLive: YYYY-01) into system PRD	<a href="#">Manage Software Components</a> app

Step	System	Role	Task	Tool
16	COR	Release Manager	Disable the respective development users for development in system COR	<a href="#">Maintain Business Users</a> app
	DEV		If required, create a customizing transport request for the double maintenance of the correction, and create tasks for the relevant business configuration expert(s)	<a href="#">Export Customizing Transports</a> app
17a	DEV	Developer	Perform double maintenance of your development-related corrections in the main branch	ABAP Development Tools for Eclipse
17b	DEV	Business Configuration Expert	Perform double maintenance of your business configuration corrections in the main branch	<a href="#">Maintain Business Configurations</a> app
17c	DEV	Release Manager	Release the transport request(s). The corrections are now implemented both in the main branch and in the current release branch.	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
18	TST	Release Manager	Pull the software component(s) to get the correction into the already checked out main branch	<a href="#">Manage Software Components</a> app

## Skipping a Release

If issues during the test phase of YYYY-<nn+1> cannot be fixed in a reasonable time frame until the next release date, you can skip that release, especially if you have a tight release schedule (“continuous delivery” model). In that case, you have to perform double maintenance for the unfinished corrections from YYYY-<nn+1> in the main branch of the development ABAP system, release them, and create the new release branch YYYY-<nn+2> derived from that main branch. That way, branch YYYY-<nn+2> contains finished new development as well as the unfinished corrections from branch YYYY-<nn+1>. Afterwards, you can bring system COR and QAS to branch YYYY-<nn+2> and continue with that.

### Note

Branches cannot be deleted or marked as obsolete. Therefore, it's important to use other tools to inform consumers about not using branch YYYY-<nn+1>.

## Urgent Corrections

### The starting situation:

- Development system DEV and test system TST are on the main branch
- Correction system COR, quality assurance system QAS, and production system PRD are on release branch YYYY-<nn>

This process is a subset of the previous development process and can be applied to corrections that are too urgent to release with the next development release.

Step	System	Role	Task	Tool
1	COR	Release Manager	Enable the respective development users for development in system COR, depending on the process you decided for, either by unlocking or assigning a different role.  If required, create a customizing transport request, and create tasks for the relevant Business Configuration Expert(s)	<a href="#">Maintain Business Users</a> app  <a href="#">Export Customizing Transports</a> app
2a	COR	Developer	Create a Workbench transport request and implement the correction	ABAP Development Tools for Eclipse
2b	COR	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests	<a href="#">Maintain Business Configurations</a> app
3	COR	Release Manager	Release the transport request(s). The changes are now in the release candidate	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
4	QAS	Release Manager	Pull the already checked out branch YYYY-<nn+1> of each software component into system QAS	<a href="#">Manage Software Components</a> app or external tool calling the pull service of communication scenario <a href="#">Test Integration</a>

Step	System	Role	Task	Tool
5	QAS	Tester	Test the change and report the test result	ABAP Development Tools for Eclipse and custom SAP Fiori apps as well as external test tools  External documentation tool
			If changes are required, repeat steps 2-5	
6	QAS	Release Manager	As the correction was successfully tested before it gets approved now.	External documentation tool
7	PRD	Release Manager	Pull the already checked out release branch YYYY-<nn+1> of each software component into system PRD	<a href="#">Manage Software Components</a> app
8	COR	Release Manager	Disable the respective development users for development in system COR	<a href="#">Maintain Business Users</a> app
	DEV		If required, create a customizing transport request for the double maintenance of the corrections, and create tasks for the relevant business configuration expert(s)	<a href="#">Export Customizing Transports</a> app
9a	DEV	Developer	Perform double maintenance of your development-related corrections in the main branch	ABAP Development Tools for Eclipse
9b	DEV	Business Configuration Expert	Perform double maintenance of your business configuration corrections in the main branch	<a href="#">Maintain Business Configurations</a> app
9c	DEV	Release Manager	Release the transport request(s). The corrections are now implemented both in the main branch and in the current release branch.	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app

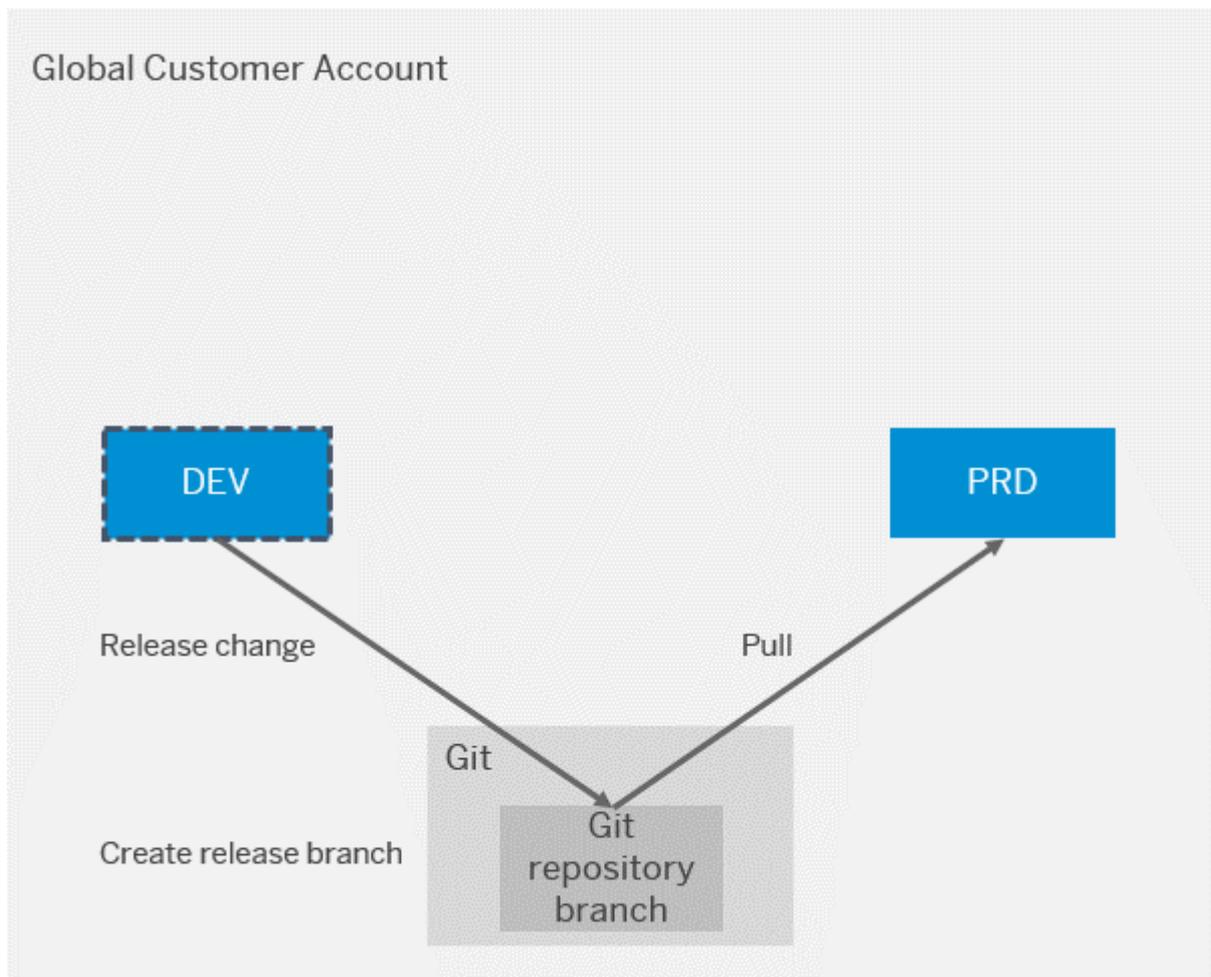

Step	System	Role	Task	Tool
10	TST	Release Manager	Pull the software component to get correction into already checked out main branch	<i>Manage Software Components</i> app

### 4.2.6.5.6 Use Case 3: One Codeline with On-Demand Development Systems

You can apply this setup if you have:

- Small development projects (for example one SAP Fiori application, one developer)
- Occasional development activities (for example after an initial development phase, it is expected to only implement new features on a yearly basis)

The ABAP system landscape consists of a permanent production system and an on-demand development system.

The advantage of this setup is that you have to administer few systems and only pay for the development system during the development periods. The payment model according to the lifetime of a system requires an SAP BTP enterprise agreement contract.

The disadvantages of this setup are that de-commissioning the development system means losing the change history as well as the configuration and application data.

The user base and authorizations have to be set up each time the development system is provisioned.

Not testing with a transported version of the solution always comes with the risk of forgetting to transport an object. This can be avoided by testing in the development system on the release branch.

A much more production-like test can only be ensured in a non-development system, where the objects of the solution are initially created and changed by pulls, and where there is no authorization automatism for testing, see tester role in [Required Business Roles \[page 681\]](#).

We thus strongly recommend developing with [Use Case 1: One Codeline in a 3-System Landscape \[page 683\]](#) instead of use case 3. The quality assurance system might be de-/commissioned on demand then.

## For the Go Live

### Starting situation:

- A (temporary) development system is set up
- The production system is set up
- Both systems are based on the main branch

Step	System	Role	Task	Tool
1	DEV, PRD	System Administrator	Provision a development and a production system	SAP BTP cockpit
2	DEV, PRD	User Administrator	Create users and maintain roles	<a href="#">Maintain Business Users</a> and <a href="#">Maintain Business Roles</a> app
3	DEV	Release Manager	Create a software component of type <a href="#">Development</a> and, if required, a software component of type <a href="#">Business Configuration</a> . Pull the software component(s) into the development system.	<a href="#">Manage Software Components</a> app
4	PRD	Release Manager	Pull the (empty) software component(s) into the production system	<a href="#">Manage Software Components</a> app

Step	System	Role	Task	Tool
5a	DEV	Developer	Develop new functional requirements or correct existing functionalities. All required changes are collected in Workbench transport requests	ABAP Development Tools for Eclipse
5b	DEV	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests.	<a href="#">Maintain Business Configurations</a> app
6	DEV	Tester	Test the change and report the test results	ABAP Development Tools for Eclipse with and custom SAP Fiori apps as well as external test tools  External documentation tool
		Release Manager	If changes are required, repeat steps 5-6	
7	DEV	Release Manager	Release decision: the changes are successfully tested and approved.	External documentation tool
8	DEV	Release Manager	Release the transport request(s)	ABAP Development Tools for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
9	DEV	Release Manager	Create a release branch YYYY-<nn> for each software component	<a href="#">Manage Software Components</a> app
10	PRD	Release Manager	Check out the release branch YYYY-<nn> of each software component	<a href="#">Manage Software Components</a> app
11	DEV	System Administrator	De-provision system DEV	SAP BTP cockpit

## Productive Usage

- The production ABAP system is based on the main branch

- Since no development can be performed in the production ABAP system, a temporary development ABAP system must be set up if occasional development is required

## Occasional Development

- The production ABAP system is based on the main branch
- A temporary development ABAP system is set up
  - All software components are imported

Step	System	Role	Task	Tool
1	DEV	Release Manager	Provision a new development system	SAP BTP cockpit
2	DEV	Release Manager	Create users, maintain and assign roles	<a href="#">Manage Business Users</a> and <a href="#">Manage Business Roles</a> app
3	DEV	Release Manager	Import main branch of each software component into the newly provisioned development system	<a href="#">Manage Software Components</a> app
4a	DEV	Developer	Develop features. All required changes are collected in Workbench transport requests.	ADT for Eclipse
4b	DEV	Business Configuration Expert	Maintain business configuration. All changes are collected in customizing transport requests.	<a href="#">Maintain Business Configurations</a> app
5	DEV	Developer	Release all transport requests	ADT for Eclipse: Transport Organizer or <a href="#">Export Customizing Transports</a> app
6	DEV	Tester	Test new developments/fixes	ADT for Eclipse and custom SAP Fiori apps as well as external test tools
			If changes are required, repeat steps 3-5	
7	PRD	Release Manager	Pull the main branch of each software component into system PRD	Manage Software Components app
8	DEV	Release Manager	Delete the development system	SAP BTP cockpit

## 4.2.6.5.7 Double Maintenance of Corrections into Development

For corrections, double maintenance is necessary so that everything that had to be fixed during release testing or usage can be retrofitted into the development system.

### ⚠ Caution

Missing double maintenance can lead to data loss in production systems.

As there is no selective picking of transport requests to merge corrections back into the main branch, this is manual effort.

You can use the *Compare Editor* in ABAP Development Tools for Eclipse to merge corrections back to the main branch.

The process would be as follows:

You can compare the latest version of an object in your ABAP Development Tools project in a hotfix system with the latest version of the same object in the development system. If there are newly created objects, you have to create an object manually in the development ABAP system.

To make a comparison, from the context menu of the object in the *Project Explorer* or in the source code editor, choose **Compare With > ABAP project**, where ABAP project is one of the ABAP projects defined in ABAP Development Tools.

Step	System	Role	Task	Tool
1	COR	Developer	Select the corrected objects in the transport request and open them.  This can be done selectively object by object.	ABAP Development Tools for Eclipse: Transport Organizer View
2	COR, DEV	Developer	<ol style="list-style-type: none"> <li>1. Select the resources in the Project Explorer in correction system COR</li> <li>2. From the resource's pop-up menu, select Compare With</li> <li>3. Select the ABAP project that points to your development system DEV</li> </ol>	ABAP Development Tools for Eclipse: Project Explorer

Step	System	Role	Task	Tool
3	DEV	Developer	Merge the changes into the DEV system	ABAP Development Tools for Eclipse

## 4.2.6.5.8 Transport of Business Configuration

Business configuration is client-dependent, just like master or transactional data, and after being imported, it is only available in the client where you have executed the import.

You usually maintain business configuration content in a non-productive environment and import it into test and productive environments. To do so, you record business configuration changes on transport requests of type *Customizing*. Once you release the request, all the changes are pushed into the remote repository associated with the used software component, just as for Workbench transport requests. Therefore, you can import business configuration content by pulling that same software component in the target system/client 100.

Depending on your scenario, you can use one of the following transport patterns:

- Isolated tenants – no transport  
If you use an isolated tenant, you don't have to clone and transport a software component of type *Business Configuration*. You can still create content but it is not imported or exported. Since a customizing transport request is a technical prerequisite for business configuration changes, the changes are written to a local customizing transport request. That means, you just have to create a transport request. The system then generates a local request and sets its category to *Default*. See [Working in the Export Customizing Transports App \[page 2382\]](#).

### Note

All consumer tenants ( $\geq 200$ ) in multitenant systems are isolated tenants because the administration of software components is not supported in these tenants.

- Simple – transports via software component of type *Business Configuration*. See [Transport Business Configuration via Software Component of Type Business Configuration \[page 703\]](#).  
You can transport business configuration for simple solutions via a software component of type *Business Configuration*. Since you can only clone one software component of this type in each system, all business configuration content is pushed to the same remote repository.  
In this scenario, you have to create and manage customizing transport requests with the *Export Customizing Transports* SAP Fiori app. See [Export Customizing Transports \[page 2380\]](#).
- Multiple software components/Git repositories – transports via software components/Git repositories of type *Development*. See [Transport Business Configuration via Software Components of Type Development \[page 704\]](#).  
If you want to work on multiple separated development projects in parallel in one development system with decoupled release schedules and in multiple software components, it is not advisable to use a software component of type *Business Configuration* because you may need to transport different sets of business configuration content independently from one another. Instead, transport the configuration together with the development via the corresponding software components of type *Development*.

In all of these scenarios you may create and manage customizing transport requests with the Export Customizing Transports SAP Fiori app. See [Export Customizing Transports](#).

To use the [Manage Software Components](#) app, business role `SAP_BR_ADMINISTRATOR` has to be assigned.

To use the [Export Customizing Transports](#) app, business role `SAP_BR_BPC_EXPERT` or `SAP_BR_ADMINISTRATOR` has to be assigned.

1. In the [Manage Software Components](#) app, create a software component of type [Business Configuration or Development](#) according to your scenario if transport of business configuration is required. And clone it to the tenant where you want the business configuration to be created. See [How to Create Software Components](#) and [How to Clone Software Components](#).

#### Note

If you have already started development, such components may already be available.

2. In the [Export Customizing Transports](#) app, create a transport request. See [Working in the Export Customizing Transports app](#). The system automatically sets its category to [Default](#). Any user that is assigned to one of the transport request's tasks can use the request for change recording. In case transport is required, assign the [transport target](#) according to the software component that has been created. An empty transport target results in a local transport and should be used in case of isolated tenants.

#### Restriction

There can only be one open transport request of type [Default](#) at a time.

3. Release the transport request. See [Working in the Export Customizing Transports app](#).

#### Note

In exceptional cases, for example for an urgent preimport that must be performed in parallel to the default request, you can create additional customizing transport requests. To create an additional customizing transport request in the [Export Customizing Transports](#) app, change the transport category from [Default](#) (`SAP_CUS_TRANSPORT_CATEGORY = DEFAULT_CUST`) to [Manual](#) (`SAP_CUS_TRANSPORT_CATEGORY = MANUAL_CUST`).

## 4.2.6.5.8.1 Transport Business Configuration via Software Component of Type Business Configuration

Learn how to transport business configuration via a software component of type [Business Configuration](#).

### Prerequisites

To use the [Manage Software Components](#) app, business role `SAP_BR_ADMINISTRATOR` has to be assigned.

To use the [Export Customizing Transports](#) app, business role `SAP_BR_BPC_EXPERT` has to be assigned.

## Procedure

1. In the *Manage Software Components* app, create a software component of type *Business Configuration* and clone it to the tenant where you want the business configuration to be created. See [How to Create Software Components \[page 2595\]](#) and [How to Clone Software Components \[page 2596\]](#).
2. In the *Export Customizing Transports* app, create a transport request. See [Working in the Export Customizing Transports App \[page 2382\]](#). The system automatically associates the request to the previously cloned software component and sets its category to *Default*. Any user that is assigned to one of the transport request's tasks can use the request for change recording.

### ⚠ Restriction

There can only be one open transport request of type *Default* at a time.

3. Release the transport request. See [Working in the Export Customizing Transports App \[page 2382\]](#).

### 📌 Note

In exceptional cases, for example for an urgent preimport that must be performed in parallel to the default request, you can create additional customizing transport requests. To create an additional customizing transport request in the *Export Customizing Transports* app, change the transport category from *Default* to *Manual*. Alternatively, you can use ABAP Development Tools for Eclipse. See [Transport Business Configuration via Software Components of Type Development \[page 704\]](#).

## 4.2.6.5.8.2 Transport Business Configuration via Software Components of Type Development

Learn how to transport business configuration via a software component of type *Development*.

### Prerequisites

To use the *Manage Software Components* app, business role `SAP_BR_ADMINISTRATOR` has to be assigned.

To use the *Export Customizing Transports* app or to create a customizing request in ABAP Development Tools for Eclipse, business role `SAP_BR_BPC_EXPERT` has to be assigned.

To use the Transport Organizer view in ABAP Development for Eclipse, business role `SAP_BR_DEVELOPER` has to be assigned. See [Transport Organizer](#).

### Procedure

1. In the *Manage Software Components* app, create software components of type *Development* and clone them to the tenant where you want the business configuration to be created. See [How to Create Software Components](#) and [How to Clone Software Components](#).

### Note

If you have already started development, such components may already be available.

2. In ABAP Development Tools for Eclipse, use the *Transport Organizer* view to create customizing transport requests for each software component, making sure to assign the correct target layer for each of the components used.
3. In the Transport Editor, assign the following attributes to all the created customizing transport requests so that they are displayed in the *Export Customizing Transports* app:
  - `SAP_ATO_TRANSPORT_TYPE = BC`
  - `SAP_CUS_TRANSPORT_CATEGORY = MANUAL_CUST`
4. In the *Export Customizing Transports* app, release the transport request. See [Working in the Export Customizing Transports App](#).

### Note

When developing custom business configuration objects, you can decide if you want to provide a transport selection screen for change recording. If you are using this transport pattern, we recommend autofilling the transport request based on the software component of the business configuration object.

## 4.2.6.6 Information for Audit

The following information is relevant for audit:

- Git repository: The creation of a Git repository branch creates a clone of the parent branch (including all development objects in the branch)
  - During a pull or checkout, all objects that differ from the previously checked out commit and the pulled commit are imported into the ABAP system. Transport requests cannot be imported selectively into subsequent ABAP systems. Together with the information which branch and commit ID was pulled into an ABAP system, you can reproduce which version of an object was in an ABAP system at which point in time.
  - The content of the Git repository with all its commits and objects is not directly accessible to users of an ABAP system. Only SAP employees have access to it for support purposes because the information is typically not required for an audit. In exceptional cases, the content of the Git repository can be requested via a service request.
- In the Manage Software Components SAP Fiori app and in ABAP Development Tools (ADT), the following information is available for a regular audit.
  - Manage Software Components app:
    - Action history of imports (pulls and branch checkouts), which also contains an execution log and a transport log per import. As these two logs are only saved temporarily in the ABAP system, we recommend to save them to an excel if they are needed for error analysis or audit.
    - Information on the last commit (commit ID, commit message consisting of the transport request number and description, commit author and last commit timestamp) for each branch
  - ADT

- In the *Transport Organizer*, you can find the transport requests together with the piece list
- In the *Revision History*, you can find the history of an object

## 4.2.6.7 Automate the Software Lifecycle Management Process

To facilitate your software lifecycle management process, you can automate it by using communication scenario SAP\_COM\_0510 and SAP\_COM\_0735. See [Pulling Git Repositories to an ABAP Environment System \[page 730\]](#) and [Executing ABAP Unit Test Runs \[page 707\]](#).

These communication scenarios contain several tools that can be used to craft a continuous integration process.

To make the setup of continuous integration pipelines as easy as possible, the open source project "Piper" was created. In general, there are various functions (Library steps) as well as whole pipelines available for reuse. You can find various steps that implement the functionality of the APIs of SAP\_COM\_0510 and SAP\_COM\_0735.

The reusable continuous integration pipeline contains the following steps:

- Creating an SAP BTP, ABAP environment system
- Setting up a communication arrangement for the APIs
- Cloning a software component / Git repository
- Running ABAP Test Cockpit checks
- Running ABAP unit tests
- Deprovisioning the SAP BTP, ABAP environment system

### Note

You can only dynamically create SAP BTP, ABAP environment systems during the pipeline execution if you are using a consumption-based model. See [What Is the Consumption-Based Commercial Model?](#)

## Related Information

[Project "Piper" !\[\]\(7e009d9c98ecae1c1ba3f1003882e6c6\_img.jpg\)](#)

## 4.2.6.7.1 Executing ABAP Unit Test Runs

### Prerequisites

- You have an SAP BTP ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You've selected the communication scenario **SAP\_COM\_0735** for your communication arrangement and have mapped it to your communication system.

### Context

ABAP Unit is the standard tool for executing unit tests. In this help topic, you'll learn how to trigger an ABAP Unit Test Run via REST Service.

For more information about ABAP Unit, see [Ensuring Quality of ABAP Code](#).

### Procedure

1. **Get CSRF token:** The first step serves for the authentication on the server. The response header contains a CSRF token, which is used as authentication for the POST request following in step 2.

#### Request

**Authentication Type:** Basic Authentication

**GET** https://<host.com>:<port>/sap/bc/adt/api/abapunit/runs/  
00000000000000000000000000000000

#### Headers

KEY	VALUE
accept	application/vnd.sap.adt.api.abapunit.run-status.v1+xml
x-csrf-token	fetch

#### Response

#### Headers

KEY	VALUE
x-csrf-token	<token>
location	/sap/bc/adt/api/abapunit/runs/ 00000000000000000000000000000000

2. **Trigger an ABAP Unit Run:** To trigger an ABAP Unit run, insert the **CSRF token** that was retrieved in the first request in the header parameters.

### Request

**POST** https://<host.com>:<port>/sap/bc/adt/api/abapunit/runs

### Headers

KEY	VALUE
x-csrf-token	<token>
content type	application/vnd.sap.adt.api.abapunit.run.v1+xml

### Body

You can specify arbitrary object sets. See also [Object Sets](#) and [XML Representations of Object Sets](#) for more details.

You can provide additional parameters to control the selection of tests. You can restrict the amount of tests to certain risk level and durations. Furthermore, you can decide to execute foreign tests, which are connected via test relations.

```
<?xml version="1.0" encoding="UTF-8"?>
<aunit:run title="My Run" context="AIE Integration Test" xmlns:aunit="http://www.sap.com/adt/api/aunit">
  <aunit:options>
    <aunit:measurements type="none"/>
    <aunit:scope ownTests="true" foreignTests="true"/>
    <aunit:riskLevel harmless="true" dangerous="true" critical="true"/>
    <aunit:duration short="true" medium="true" long="true"/>
  </aunit:options>
  <osl:objectSet xsi:type="unionSet" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:osl="http://www.sap.com/api/osl">
    <osl:set xsi:type="osl:packageSet">
      <osl:package includeSubpackages="true" name="PACKAGE_ONE"/>
    </osl:set>
    <osl:set xsi:type="osl:flatObjectSet">
      <osl:object name="ZCL_TEST_ONE" type="CLAS"/>
      <osl:object name="ZIF_TEST_TWO" type="INTF"/>
    </osl:set>
  </osl:objectSet>
</aunit:run>
```

### Response

#### Headers

KEY	VALUE
location	/sap/bc/adt/api/abapunit/runs/{runId}

3. **Tracking the Status of the Test Run:** To track the status of the test run, you can make a GET request using the URI contained in the location header.

#### Request

**GET** https://<host.com>:<port>/sap/bc/adt/api/abapunit/runs/{runId}

#### Headers

KEY	VALUE
accept	application/vnd.sap.adt.api.abapunit.run-status.v1+xml

#### Response

While the tests are still running, the returned status will be "In Process".

If all tests have been executed, the status "Completed" is returned. You'll find the link /sap/bc/adt/api/atc/results/<UUID> at the bottom of the body. Use this link to retrieve the ABAP Unit test results in the next step.

#### Body

```
<?xml version="1.0" encoding="UTF-8"?>
<aunit:run xmlns:aunit="http://www.sap.com/adt/api/aunit" title="MyTitle"
context="MyContext">
  <aunit:progress status="FINISHED" percentage="100" />
  <aunit:executedBy user="JOHNDOE" />
  <aunit:time started="2021-02-12T17:09:19Z" ended="2021-02-12T17:09:22Z" />
  <atom:link xmlns:atom="http://www.w3.org/2005/Atom"
href="/sap/bc/adt/api/abapunit/results/0123821392189313" rel="http://
www.sap.com/adt/relations/api/abapunit/run-result" type="application/
vnd.sap.adt.api.junit.run-result.v1+xml"/>
</aunit:run>
```

4. **Retrieve Results:** To get the ABAP Unit results, use the following request.

#### Request

**GET** https://<host.com>:<port>/sap/bc/adt/api/abapunit/results/{resultId}

#### Headers

KEY	VALUE
Accept	application/vnd.sap.adt.api.junit.run-result.v1+xml

#### Response

The results are submitted in the JUnit format.

#### Body

As an example, the result may look like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<testsuites tests="3" asserts="2" skipped="1" errors="0" failures="1"
timestamp="2021-01-22T19:17:30Z" time="0.36" executedBy="JOHNDOE"
client="000" system="UIA">
```

```

    <testsuite tests="2" asserts="2" skipped="1" errors="0" failures="1"
timestamp="2021-01-22T19:17:30Z" time="0.28 " hostname="ldai3uia"
package="test_cars" name="">
    <testcase asserts="1" time="0.01 " name="order"
classname="fugr:zmg_cars.ltc_finder">
    <failure type="Assert Failure" message="Critical Assertion Error:
'Cds_View: ASSERT_EQUALS'">
        Character string different as of position 4Expected
[CL_AUNIT_TESTABLE_OBJECT=====CP]Actual [CL_CAR=====CP]
Test 'LTC_FINDER->ORDER' in Main Program 'SAPLZMG_CARS'
        Stack: Include: <LZMG_CARST99> Line: <38> (ORDER)
    </failure>
    </testcase>
    <testcase asserts="1" time="0.01 " name="preview"
classname="fugr:zmg_cars.ltc_finder">
    <skipped message="Missing Prerequisites - Dummy: ABORT">
        Test execution skipped due to missing prerequisites Test
'LTC_FINDER->PREVIEW' in Main Program 'SAPLZMG_CARS'
        Stack: Include: <LZMG_CARST99> Line: <44> (PREVIEW)
    </skipped>
    </testcase>
    <testcase asserts="0" time="0.01 " name="drive"
classname="fugr:zmg_cars.ltc_finder"/>
    </testsuite>
</testsuites>

```

## 4.2.6.7.2 Reading and Deploying ATC Configurations

### Prerequisites

- You have an SAP BTP ABAP environment system.
- You've created a *Communication User* and generated a **password** as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).

#### ⓘ Note

The URL displayed for the inbound service of the communication arrangement will be needed for the GET requests described below.

- You have selected the communication scenario **SAP\_COM\_0763** for your communication arrangement and have mapped it to your communication system.

### Context

The communication scenario **SAP\_COM\_0763** offers an OData V4 API for maintenance of ABAP Test Cockpit (ATC) configurations on the business objects SATC\_CI\_CF\_RT\_E, SATC\_CI\_CF\_E, and SATC\_CI\_CF\_P\_V.

Therefore, you have to create a valid communication arrangement as described in the prerequisites before performing the actual test steps.

## Procedure

1. **Get CSRF token:** The first step serves for the authentication on the server. Use the URL you've obtained from the *Communication Arrangement's* inbound service for the **GET** request. The response header contains an CSRF token, which is used as authentication for the GET request following in step 2.

### Request

**Authentication Type:** Basic Authentication. Enter the name of your *Communication User* (not the technical user ID) and the generated password.

**GET** <URL\_from\_Communication\_Arrangement>

### Headers

KEY	VALUE
x-csrf-token	fetch

### Response

#### Headers

KEY	VALUE
x-csrf-token	<token>

2. **Read ATC configurations:** To read ATC configurations, prepare a GET request using the following parameters:

### Request

#### Header

KEY	VALUE
x-csrf-token	<token>

- All configurations:  
**GET** <URL\_from\_Communication\_Arrangement>/configuration
- By name:  
**GET** <URL\_from\_Communication\_Arrangement>/configuration?\$filter=conf\_name eq '<CONFNAME>'
- Default configuration:  
**GET** <URL\_from\_Communication\_Arrangement>/configuration?\$filter=is\_default eq true

If you want to look deeper into configuration data (e.g. the priorities of the configuration), you can use expands by adding:

- to all priorities: &\$expand=\_priorities

- filtered only on priorities changed from default\_priority: &\$expand=\_priorities(\$filter=priority ne default\_priority)
3. **Deploy ATC configurations:** To deploy an ATC configuration, prepare a POST request and use the body to provide a json (or XML) representing the configuration you want to deploy.

#### Request

##### Header

KEY	VALUE
content-type	application/json
x-csrf-token	<token>

**POST** <URL\_from\_Communication\_Arrangement>/configuration

- Flat Insert of changed priorities:  
When you pass the json from the `get_configuration` with no expand by creating a valid configuration, the default priorities will also be created.
- Deep Insert of changed priorities:  
You can pass the json from the `get_configuration` with expand to filtered priorities and potentially change the `confname` if desired.

## 4.2.6.7.3 Executing ABAP Test Cockpit (ATC) Check Runs

### Prerequisites

- You have an SAP BTP, ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You've selected the communication scenario **SAP\_COM\_0901** for your communication arrangement and have mapped it to your communication system.

#### ⚠ Restriction

The communication scenario **SAP\_COM\_0510** is deprecated and should no longer be used.

- You've defined a business user in the additional properties in the communication arrangement. To do so, choose the *Additional Properties* link for ATC Check Run in the *Inbound Services* section. Specify a business user (CB) or select a user from the value help. ATC runs started via the service will be scheduled and executed with the specified business user.

### Note

The assigned business user needs development authorization for ADT, which is contained in the business catalog `SAP_A4C_BC_DEV_ATC_RUN_PC`. In case the ATC is used to execute ABAP Unit Tests, further specific authorizations might be required.

When you assign the catalog to a dedicated role, do not forget to remove the restriction to read-only access before saving the role.

## Context

The ABAP Test Cockpit (ATC) is the standard tool for checking the quality of ABAP development objects using static checks and ABAP unit tests. In this help topic, you'll learn how to trigger an ATC Check Run via REST Service.

For more information about the ABAP Test Cockpit, see [Checking Quality of ABAP Code with ATC](#).

## Procedure

1. **(Get CSRF token)** The first step serves for the authentication on the server. The response header contains an CSRF token, which is used as authentication for the POST request following in step 2.

### Request

**Authentication Type:** Basic Authentication

**GET** `https://<host.com>:<port>/sap/bc/adt/api/atc/runs/00000000000000000000000000000000`

### Headers

KEY	VALUE
accept	application/vnd.sap.atc.run.v1+xml
x-csrf-token	fetch

### Response

#### Body

```
<?xml version="1.0" encoding="utf-8"?>
<atc:run status="Not Created" xmlns:atc="http://www.sap.com/adt/atc">
  <atc:progress description="No run was created, no objects had to be
checked"/>
  <atc:phases/>
</atc:run>
```

### Headers

KEY	VALUE
x-csrf-token	<token>
location	/sap/bc/adt/atc/runs/ 00000000000000000000000000000000

2. **(Trigger an ATC Check Run)** To trigger an ATC check run, insert the **CSRF token** that was retrieved in the first request in the header parameters.

### Request

**POST** https://<host.com>:<port>/sap/bc/adt/api/atc/runs?clientWait=false

### Headers

KEY	VALUE
x-csrf-token	<token>
content type	application/vnd.sap.atc.run.parameters.v1+xml

### Body

You can specify components, packages or both. If you specify both components and packages, only those objects will be checked that are assigned to packages that belong to the specified software components.

For the package value, enter the name of the package you want to have checked.

You can provide an ATC configuration as additional parameter that is used instead of the default configuration of your system.

You can also provide an ATC check variant as additional parameter. This is used instead of the default check variant of your ATC configuration, regardless of whether an ATC configuration was explicitly provided via parameter or not.

You can specify arbitrary object sets. See also [Object Sets](#) and [XML Representations of Object Sets](#) for more details.

```
<?xml version="1.0" encoding="UTF-8"?>
<atc:runparameters xmlns:atc=http://www.sap.com/adt/atc
  xmlns:obj=http://www.sap.com/adt/objectset
  checkVariant="CHECKVARIANT_NAME"
  objectProvider="OBJECTPROVIDER_NAME"
  configuration="CONFIGURATION_NAME">
  <osl:objectSet xsi:type="unionSet" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns:osl="http://www.sap.com/api/osl">
  <osl:set xsi:type="osl:multiPropertySet">
    <osl:property key="softwareComponent" value="Z_MY_COMPONENT" />
  </osl:set>
  <osl:set xsi:type="osl:packageSet">
    <osl:package includeSubpackages="false" name="Z_MY_PACKAGE" />
  </osl:set>
</osl:objectSet>
</atc:runparameters>
```

### Response

### Headers

KEY	VALUE
location	/sap/bc/adt/api/atc/runs/<UUID>

3. **(Tracking the Status of the Check Run)** To track the status of the check run, you can make a GET request using the URI contained in the location header.

#### Request

**GET** https://<host.com>:<port>/sap/bc/adt/api/atc/runs/<UUID>

#### Headers

KEY	VALUE
accept	application/vnd.sap.atc.run.v1+xml

#### Response

While the check is still running, the ATC phases will show the status "In Process" or "Undefined" in the body.

The check run is finished when all ATC phases show the status "Completed". You'll find the link `/sap/bc/adt/api/atc/results/<UUID>` at the bottom of the body. Use this link to retrieve the ATC check run results in the next step.

#### Body

```
<?xml version="1.0" encoding="utf-8"?>
<atc:run status="Completed" xmlns:atc="http://www.sap.com/adt/atc">
  <atc:progress description="Run Completed"/>
  <atc:phases>
    <atc:phase title="Determine Object Keys" status="Completed"
number="1"/>
    ...
  </atc:phases>
  <atom:link href="/sap/bc/adt/api/atc/results/<UUID>" rel="http://
www.sap.com/abap/checks/atc/relations/results/displayid" type="application/
xml" title="Result" xmlns:atom="http://www.w3.org/2005/Atom"/>
</atc:run>
```

4. **(Retrieve Results)** To get the ATC results, use the following request.

#### Request

**GET** /sap/bc/adt/api/atc/results/<UUID>

#### Headers

KEY	VALUE
Accept	application/vnd.sap.atc.checkstyle.v1+xml

#### Response

The results are submitted in the checkstyle format. You can find the checkstyle XSD here: <https://github.com/linkedin/pygradle/blob/master/pygradle-plugin/src/test/resources/checkstyle/checkstyle.xsd> .

## Body

As an example, the result may look like this:

```
<?xml version="1.0" encoding="utf-8"?>
<checkstyle version="1.0">
  <file name="PACKAGE/OBJECT_NAME.OBJECT_TYPE">
    <error message="Hard-coded user name (@User's formatted name)"
source="CL_CI_TEST_EXTENDED_CHECK_SEC#0821" line="2" severity="error"/>
  </checkstyle>
```

In this example, the error message shows a hard-coded username. Ideally, the formatted user name corresponds to the developer that edited the object for the last time. In case "last changed by" shouldn't be available for the object, the author is used instead. In case the formatted user name can't be determined, the business user id is displayed as fallback.

### Note

In the output, the namespace slashes will be replaced by dashes. That means `/NAMESPACE/OBJECT_NAME` will be output as `-NAMESPACE-OBJECT_NAME`.

## 4.2.6.7.4 Configuring Remote ATC Using a Central Check System

You can perform remote code analysis in ATC which allows to analyze custom code remotely with the latest checks.

When using SAP BTP ABAP environment as central check system, you will use the `Custom Code Migration` app to scope and analyze custom code in an on-premise SAP system for SAP S/4HANA Cloud.

To use this SAP Fiori app, your SAP administrator must enable the app provide access for the relevant users. In addition, you also need to establish an RFC connection for the Cloud Connector. This enables you to access the on-premise system as checked system from the ABAP environment as central check system remotely.

## Related Information

[Configuring the Checked System \[page 717\]](#)

[Configuring and Administrating the Cloud Connector \[page 720\]](#)

[Maintaining Communication Arrangements \[page 724\]](#)

[Configuring the ATC Developer Scenario \[page 725\]](#)

[Custom Code Migration App](#)

## 4.2.6.7.4.1 Configuring the Checked System

You need to configure an RFC destination from your on-premise system (checked system) to the SAP BTP ABAP environment as central check system. This enables you to run ATC checks in the central check system for your custom code in the checked system.

### Related Information

[Configuring the User \[page 717\]](#)

[Installing Remote Stubs \[page 719\]](#)

### 4.2.6.7.4.1.1 Configuring the User

In the **checked system**, the RFC user needs the following authorizations:

Authorization Object Value	Parameter	Value
S_RFC	ACTVT	16 (Execute)
	RFC_TYPE	FUGR
	RFC_NAME	SCA_REMOTE_DATA_ACCESS
		SABP_COMP_PROCS_E
		SYCM_APS_REMOTE
		SYST
		S_CODE_INSPECTOR_TESTS
		IQAPI_QUERY_CONTENT
		IQAPI_INFOSET_CONTENT
		IQAPI_CHECK_INFOSET
S_RFC	ACTVT	16 (Execute)
	RFC_TYPE	FUNC

**Authorization Object Value**

Authorization Object Value	Parameter	Value
	RFC_NAME	FUNCTION_EXISTS REPOSITORY_ENVIRONMENT_ALL RFC_GET_NAMETAB SVRS_GET_VERSION_DIRECTORY_46 RFCPING SLINRMT_RUN TRINT_PROGRESS_INDICATOR TRINT_TP_UPDATE_TPSTAT
S_DEVELOP	ACTVT	03 (Display)
	DEVCLASS	*
	OBJNAME	*
	OBJTYPE	*
	P_GROUP	*
S_SYS_RWBO	ACTVT	01 (Create or generate) 02 (Change) 03 (Display)
	DOMAIN	*
	DESTSYS	*
	TTYPE	TRAN
S_TRANSPRT	ACTVT	01 (Create or generate) 02 (Change) 03 (Display)
	TTYPE	TRAN
S_DATASET	ACTVT	34 (Write)
	FILENAME	*
	PROGRAM	SAPLSABC SAPLSTRF

In the **Central Check System**, you need the following user to use transaction `ATC` to perform custom code checks:

User Role	Description
SAP_SATC_ADMIN	Authorization for setting up ABAP Test Cockpit (ATC) for central quality checking

In addition, you need the following authorization object for importing the Simplification Database into the Central Check System:

Name of Authorization Object	Name of the Authorization Field	Value of the Authorization Field	Description
S_YCM	SYCM_AREA	SDB	Authorization for importing the Simplification Database
	ACTVT	UL	

## 4.2.6.7.4.1.2 Installing Remote Stubs

During ATC execution, the central check system accesses the systems in your landscape remotely through so-called remote stubs using RFC connection. Thus, remote stubs serve as an interface between the central check system and on-premise systems; they return a model of custom code that needs to be checked.

### Prerequisites

In the on-premise system, implement SAP Note [2599695](#) (Custom Code Migration Fiori App: Remote Stubs for the Checked System) in advance.

### Context

You want to analyze your custom code in your on-premise system using the `Custom Code Migration` app.

### Procedure

1. In the on-premise system, perform transaction `SNOTE`.
2. Download SAP Note [2599695](#).

The *Note Assistant: Note Download* dialog is opened.

3. To implement the remote stubs, select and confirm the displayed SAP Note.
4. It is also recommended to apply SAP Notes in checked systems. Update your check system by following these steps:
  - a. Perform transaction SNOTE.
  - b. In the menu bar, select *Goto > Other tools > Launch Note Analyzer*.
  - c. Upload the file *SAPNote\_2436688\_Checked\_System.xml* available as attachment in SAP Note [2436688](#). You can now process the notes using SAP Note Analyzer.

#### Note

In case you don't want to use the Note Analyzer, please also apply the following SAP Notes:

- [2485231](#) - Remote ATC Checks of Modifications and Enhancements
- [2270689](#) - RFC Extractor for performing static checks
- [2190065](#) - ATC/CI: Remote Code Analysis - Object Provider Stub

## Results

The Custom Code Migration app now has access to the on-premise system. You can now start the custom code analysis.

### 4.2.6.7.4.2 Configuring and Administrating the Cloud Connector

The *Cloud Connector* enables the connection between the SAP BTP ABAP environment and on-premise systems in a secured network.

#### 4.2.6.7.4.2.1 Connecting the Cloud Foundry Environment Subaccount to the Cloud Connector

#### Prerequisites

- You have created a subaccount for the Cloud Foundry environment.
- You have installed the Cloud Connector.

## Context

You want to add and connect your subaccount for the Cloud Foundry environment to the Cloud Connector.

For more information, see

- [Managing Subaccounts](#)
- [Cloud Connector](#)

## Procedure

1. Go to your *Cloud Connector* and select the *Connector* navigation pane.
2. Choose the *Add Subaccount* button in the title toolbar.
3. In the *Add Subaccount* wizard, enter the *Region* of your server. Make sure that you choose the exact same region as in your Cloud Foundry subaccount.
4. Enter the ID of the *Subaccount* that you have created for the Cloud Foundry environment in the *SAP BTP Cockpit*. You will find the subaccount ID under **▶ SAP BTP Cockpit ▶ your Global Account ▶ your Cloud Foundry Subaccount ▶ Subaccount Details ▶**.
5. *Cloud Connector*, enter the [Optional:] To label the subaccount in the *Display Name*.
6. Enter the login email address of the *Subaccount User*.
7. Enter the *Password* of the subaccount user.
8. [Optional: To overwrite the default location ID of the data center in the Cloud Foundry environment, enter the relevant *Location ID*.
9. [Optional:] Provide a *Description* for further details.
10. To add your subaccount to the *Cloud Connector*, choose *Save*.

## Results

A new entry for the Cloud Foundry subaccount is added in the *Subaccount Dashboard* table in the Cloud Connector.

## 4.2.6.7.4.2.2 Configuring the Access Control (RFC) for the Remote Connection

The resource accessible represents the on-premise system that can be accessed through the *Cloud Connector*.

### Context

You want to enable the connection for SAP BTP ABAP environment to an on-premise system.

For more information, see [Configure Access Control \(RFC\)](#)

### Procedure

1. In the *Cloud Connector*, select the ► *[Display Name of the Cloud Foundry Subaccount]* ► *Cloud to On-Premise* navigation pane.
2. To add a new system mapping, choose + from the section toolbar of the *Mapping Virtual To Internal System* table.
3. In the *Add System Mapping* wizard, provide the following data:
  - a. Choose *ABAP System* from the *Back-end Type* drop-down list box.
  - b. Choose *Next*.
  - c. Choose *RFC* as *Protocol* from the drop-down listbox.
  - d. Choose *Next*.

#### 4. ⓘ Note

To use a connection **with** load balancing, skip this step and proceed with the next step.

To use a connection **without** load balancing, proceed as follows:

- a. Choose the *Without load balancing (application server and instance number)* radio button.
- b. Choose *Next*.
- c. Enter the following connection details of the on-premise system:

#### ⓘ Note

You will find these details in the SAP Logon of your On-Premise system.

- *Application Server*.
  - *Instance Number* of your Application Server ABAP.
  - Name of the *SAProuter*, if applicable.
- d. Enter a virtual name for the *Application Server*.
  - e. Enter a virtual *Instance Number*.
  - f. Choose *Next*.
  - g. Optional: Enter a description.

h. Choose *Next*.

5. **Note**

If you use a connection **without** load balancing, skip this step. Follow the instructions in the previous step instead.

To use a connection **with** load balancing, proceed as follows:

- a. Choose the *With load balancing (system ID and message server)* radio button.
- b. Choose *Next*.
- c. Enter the following connection details of the on-premise system:

**Note**

You will find these details in the SAP Logon of your On-Premise system.

- *Message Server*.
  - *System ID*.
  - Name of the *SAProuter*, if applicable.
- d. Choose *Next*.
  - e. Define and enter a virtual name for the *Message Server*.
  - f. Define and enter a virtual *System ID*.
  - g. Optional: Enter a description.
  - h. Choose *Next*.
6. Optional: You can mark the checkbox *Check Internal Host* to immediately check the connection during creation.
7. To trigger creation, choose *Finish*.

You have added the relevant on-premise system as resource accessible.

Now, you want to define the permitted function modules as resources for a specific back-end system.

To do this, proceed as follows:

8. In the *Cloud To On-Premise* navigation pane, select the relevant system mapping in the *Mapping Virtual to Internal System* section.
9. To define which function modules are executable in the on-premise, choose  *Import resources belonging to a scenario* from the section toolbar in the *Resources Of...* section.

**Note**

To get the relevant import file for the Custom Code Migration scenario, see SAP Note [2861842](#) - Custom Code Migration in SAP BTP ABAP environment: Set up SAP Cloud Connector.

10. *Browse* the *Scenario File* and choose *Select*.

## Results

You have defined the on-premise system(s) that are accessible from the ABAP environment.

Now, you can call the defined function modules in the on-premise system.

## 4.2.6.7.4.3 Maintaining Communication Arrangements

A communication arrangement describes a communication scenario with a remote system during configuration time. It provides the required metadata for the service configuration.

### Prerequisites

To create these communication arrangements, you need the `Administrator` role.

You have created a destination to your on-premise system in the *Cloud Connector* that is connected to your BTP subaccount.

### Context

You want to enable communication from your ABAP environment to your on-premise systems using Remote Function Calls (RFC).

To do this, you need to use the communication arrangement `SAP_COM_0464` (SAP Custom Code Migration Integration).

### Procedure

1. Log on to the *SAP Fiori launchpad* of your ABAP environment.
2. In the *Communication Management* section, select the *Communication Arrangements* tile.
3. Choose *New*.
4. Use the value help to choose the `SAP_COM_0464` scenario.
5. Define and enter an *Arrangement Name*.

If not yet available or defined, create a new communication system for the communication arrangement to define an endpoint for your checked system.

- a. For the *Communication System*, choose *New*.
- b. In the *New Communication System* dialog, enter the *System ID* and *System Name* of the checked system.
- c. Choose *Create*.
- d. In the *Technical Data* tab under *General*, enter the virtual host as specified in your *Cloud Connector* as *Host Name*. The field *Port* has already been filled in automatically with the default `443`.
- e. Turn on the slider for *Cloud Connector*.
- f. Filling in the field *SCC Location ID* is optional.
- g. Under *RFC Settings*, fill in the fields *Client*, *Instance Number* and *Target Host* as specified as virtual host in your *Cloud Connector*.
- h. Under *User for Outbound Communication*, choose `+` to assign the RFC user you created in the checked system to the communication system.

- i. Choose [Create](#) and then [Save](#) to save the communication system and to be navigated back to the Communication Arrangement creation page.
6. Under [Additional Properties](#), fill out the fields [Object Provider](#) and [System Group](#) (both freely selectable). This is the name you then select as your [Object Provider to Remote System](#) for your custom code migration project in the `Custom Code Migration` app.
7. Under [Outbound Services](#) [Retrieve Custom Code](#), ensure that the [Service Status](#) is set to [Active](#).
8. Choose [Save](#) to save the communication arrangement. A message should now pop up at the bottom of the screen informing you that the activation was successful.

## Results

You can now select the communication arrangement in the [Object Provider to Remote System](#) field in the `Custom Code Migration` app to establish the connection to your on-premise system.

### 4.2.6.7.4.4 Configuring the ATC Developer Scenario

You can use a system in SAP BTP ABAP environment as a central check system to run ATC checks from an on-premise system against this system (ATC Developer Scenario).

## Prerequisites

- You've defined communication arrangement `SAP_COM_0464` (SAP Custom Code Migration Integration) to enable communication from your ABAP environment to your on-premise systems using remote function calls (RFC). For more information, see [Maintaining Communication Arrangements \[page 724\]](#).
- You've implemented [SAP Note 3358660 - Developer Scenario Cloud](#) in your checked system.

## Context

To enable the ATC Developer Scenario, you've to define communication arrangement `SAP_COM_0936` for your cloud system.

## Procedure

1. Log on to the [SAP Fiori launchpad](#) of your ABAP environment.
2. In the [Communication Management](#) section, select the [Communication Arrangements](#) tile.
3. Choose [New](#).

4. Use the value help to choose the SAP\_COM\_0936 scenario.
5. Define and enter an *Arrangement Name*.
6. If not yet available or defined, create a new communication system for the communication arrangement to define an endpoint for your checked system.
  - a. For the *Communication System*, choose *New*.
  - b. In the *New Communication System* dialog, enter the *System ID* and *System Name* of the checked system.
  - c. Choose *Create*.
  - d. In the *Technical Data* tab under *General*, select the *Inbound Only* check box.

Be aware that you should only select the *Inbound Only* check box if you are using a new communication system. Please do not check this box when you are re-using a communication scenario.

- e. In the *Users for Inbound Communication* tab, choose + to add a new inbound communication user.
  - f. Choose *User Name and Password* as *Authentication Method*, and enter a user name, description, and password for the user.
  - g. Choose *Create*.
7. In the Communication Arrangement in the *Inbound Communication* tab, enter the *User Name* you've previously defined as described in step 6.
8. In the *Additional Properties* tab, select the *Object Provider* you've defined in SAP\_COM\_0464.
9. Choose *Save*.
10. In the *Code Inspector* section, enter the *Reference Check System*. This is the RFC connection to your cloud system. If not yet available or defined, create a new RFC destination in transaction SM59. To do this, follow these steps (see also [Maintaining Remote Destinations](#)):

#### Note

In order to setup your RFC connection, you first need to open a **service channel** (on-premise to cloud connection) in your respective Cloud Connector. See [Configure a Service Channel for RFC](#) to learn how to create one.

- a. Choose connection type "3" (ABAP Connection) to connect to your cloud system via [Cloud Connector](#). Connection type "W" (WebSocket RFC) isn't yet supported for the developer scenario
  - b. In the *Technical Settings* tab, enter the host of your Cloud Connector as *Target Host*. As instance number, choose the instance number that you have defined for your service channel.
  - c. In the *Logon & Security* tab, enter the correct client of your cloud system. The user to be entered here is the inbound communication user that you have assigned to communication scenario SAP\_COM\_0936. Here you need to enter the **alias name** of this user. However, be aware that it cannot exceed 12 characters.
  - d. As an optional step, you can run a connection test, which should be successful.
  - e. Save your destination.
11. In your checked system, run transaction ATC.  
The *ABAP Test Cockpit* is opened.
12. You can now proceed and maintain your destination in **▶ ATC ▶ Basic Settings ▶** as *Reference Check System*.
13. Choose **▶ ATC Administration ▶ Setup ▶ Basic Settings ▶**.

14. Go to transaction `SCI` and create a proxy variant (as described in step 2 in [Configuring the Checked System](#)).

You can reference one of the SAP delivered ATC variants in your cloud system, for example `SLIN_SEC`, or one of your own variants that you've created in the cloud system. Go to [Creating ATC Check Variants](#) for guidance on how to create ATC check variants.

15. Go back to transaction `ATC`. In the *Basic Settings*, enter the name of this proxy variant as *Global Check Variant*.
16. Confirm.

## Results

You've enabled a cloud system as central check system for remote ATC checks from an on-premise system against the cloud system. In SAP GUI or ABAP Development Tools for Eclipse, you can now run ATC checks in your checked system. In ABAP Development Tools for Eclipse in the *ATC Problems* view, you can create exemptions that you can then manage in the [Approve ATC Exemptions](#) app.

### 4.2.6.7.5 Test Integration (SAP\_COM\_0510)

Communication scenario `SAP_COM_0510` enables you to create continuous integration pipelines for SAP BTP, ABAP environment systems.

You can use this communication scenario to create continuous integration processes. See [Automate the Software Lifecycle Management Process \[page 706\]](#).

#### 4.2.6.7.5.1 API to Manage Git Repositories

You can use the `MANAGE_GIT_REPOSITORY` API to pull or clone Git repositories to ABAP environment systems and to create and checkout branches. The `MANAGE_GIT_REPOSITORY` API belongs to the Communication Scenario `SAP_COM_0510`.

##### Note

In ABAP environment, Git repositories are wrapped in software components. These are currently managed in the **Manage Software Components** app. The technical parameter `sc_name` used in this API needs to be the name of the Git repository on the ABAP environment system – the name of the software component.

##### Note

It is currently not possible to execute/trigger multiple actions (clones/pulls/deletes) in parallel on one system, regardless of the fact that the calls run asynchronously.

## Related Information

[Cloning Git Repositories to an ABAP Environment System \[page 728\]](#)

[Pulling Git Repositories to an ABAP Environment System \[page 730\]](#)

[Working with Branches on a Git Repository \[page 733\]](#)

### 4.2.6.7.5.1.1 Cloning Git Repositories to an ABAP Environment System

#### Prerequisites

- You have an ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You have selected the communication scenario **SAP\_COM\_0510** for your communication arrangement and have mapped it to your communication system.

#### Context

If a software component is not in your system yet, you will first need to clone it once to import it into your system. Please note that you can clone a software component only once into your system.

##### Note

In ABAP environment, Git repositories are wrapped in software components. These are currently managed in the *Manage Software Components* app. The parameter `sc_name` passed to this API needs to be the name of the Git repository on the ABAP environment system – the name of the software component.

#### Procedure

1. **(Authentication on the server)** The first step serves the authentication on the server. The response header contains an `x-csrf-token`, which is used as authentication for the POST request following in [step 2](#).

##### Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY HTTP/1.1
```

```
Host: host.com
Authentication: basicAuthentication
X-csrf-token: fetch
```

## Response

```
HTTP/1.1 200 OK
X-csrf-token: xCsrfToken
```

2. **(Cloning a Git repository)** To trigger the clone, you need to insert the x-csrf-token that was retrieved in the first request in the header parameters. The Git repository and the branch you want to clone are passed in the body of the request. If you don't enter a branch name, the main branch is automatically selected. Alternatively you can clone a specific tag by entering the tag name. Make sure that the tag exists on the branch. If that's not the case, no clone is executed.

## Request

```
POST /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json

{
  "sc_name" : "/DMO/GIT_REPOSITORY",
  "branch_name": "main",
  "tag_name": "my-release-tag"
}
```

3. **(View all clones)** To view all clones that have been made, you can make a GET request.

## Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "d": {
    "results": [
      {
        "__metadata": {
          "id":
            "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones(uuid=guid'02ceab7d-ff04-1eda-blea-eb7fdbf28bc4',sc_name='ZHM_INITIAL_TEST',branch_name='')",
          "uri":
            "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones(uuid=guid'02ceab7d-ff04-1eda-blea-eb7fdbf28bc4',sc_name='ZHM_INITIAL_TEST',branch_name='')",
          "type": "cds_sd_a4c_a2g_gha_sc_web_api.ClonesType"
        },
        "uuid": "02ceab7d-ff04-1eda-blea-eb7fdbf28bc4",
        "sc_name": "/DMO/GIT_REPOSITORY",
        "branch_name": "",
        "import_type": "Clone",
        "namespace": "",
        "status": "S",
        "status_descr": "Success",
        "criticality": 3,

```

```

        "user_name": "administrator@example.com",
        "start_time": "/Date(1594898863000+0000)/",
        "change_time": "/Date(1594898891000+0000)/"
    },
    // all clones for this system instance will be listed here ...
}
]
}
}

```

## 4.2.6.7.5.1.2 Pulling Git Repositories to an ABAP Environment System

### Prerequisites

- You have an ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You have selected the communication scenario **SAP\_COM\_0510** for your communication arrangement and have mapped it to your communication system.
- You have cloned the Git repository to the ABAP Environment system. See [Cloning Git Repositories to an ABAP Environment System \[page 728\]](#).

### Context

You can use the communication scenario *SAP\_COM\_0510* to pull Git repositories to an ABAP environment system.

#### 📘 Note

In ABAP environment, Git repositories are wrapped in *Software Components*. These are currently managed in the App *Manage Software Components*. The parameter passed to this API needs to be the name of the Git repository on the ABAP environment system – the name of the Software Component.

### Procedure

1. **(Authentication on the Server)** The first step serves the authentication on the server. The response header contains an x-csrf-token, which is used as authentication for the POST request following in [step 2](#).

## Request

```
GET/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: fetch
```

## Response

```
HTTP/1.1 200 OK
X-csrf-token: xCsrfToken
```

2. **(Pull a Git Repository)** To trigger the pull of a Git repository, you have to insert the *x-csrf-token* that was retrieved in the first request in the header parameters. The Git repository you want to pull is passed in the body of the request.

## Request

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
{
  "sc_name" : "/DMO/GIT_REPOSITORY"
}
```

## Response

```
HTTP/1.1 200 OK
Content-Type: application/json
```

```
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "type": "cds_sd_a4c_a2g_gha_sc_web_api.PullType"
    },
    "uuid": "UUID ",
    "sc_name": "/DMO/GIT_REPOSITORY ",
    "namespace": "",
    "status": "R",
    "status_descr": "Running",
    "start_time": "/Date(1571227437000+0000)/",
    "change_time": "/Date(1571227472000+0000)/",
    "criticality": 2,
    "user_name": "CC0000000001",
    "to_Execution_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Execution_log"
      }
    },
    "to_Transport_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Transport_log"
      }
    }
  }
}
```

```
}  
}
```

3. **(Tracking the Status of the Pull)** To track the status of the pull, you can make a GET request using the uuid contained in the response. You can also read the URI directly from the “\_\_metadata” of the response.

#### Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID') HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication  
Accept: application/json
```

The response contains the same entity as the second request. The Pull is successful, when the “status” in the response body has the value **S**. The status description “status\_descr” will then return **Successful**. In case of an error “status” will have the value **E** and “status\_descr” the value **Error**.

4. **(Retrieving Logs)** To get the Execution Log and the Transport Log after the Pull is finished, you can use the following requests. Alternatively, you can use the URIs from the response of the POST request. You can also check both logs in the [Manage Software Components](#) app for better readability.

#### For the Execution Log:

##### Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/  
to_Execution_log HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication  
Accept: application/json
```

##### Response

```
HTTP/1.1 200 OK  
Content-Type: application/json
```

```
{  
  "d": {  
    "results": [ {  
      "__metadata": {  
        "id": "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/  
ExecutionLogs(index_no=1m,uuid=guid'UUID')", "uri": "host.com/sap/opu/  
odata/sap/MANAGE_GIT_REPOSITORY/ExecutionLogs(index_no=1m,uuid=guid'UUID')",  
"type": "cds_sd_a4c_a2g_gha_sc_web_api.ExecutionLogsType"  
      }  
      ,  
      "index_no": "1",  
      "uuid": "UUID",  
      "type": "Information",  
      "descr": "Step X: MESSAGE",  
      "timestamp": "/Date(1571227438000+0000)/",  
      "criticality": 0,  
    }  
  ]  
}
```

#### For the Transport Log:

## Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/
to_Transport_log HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

```
HTTP/1.1 200 OK
Content-Type: application/json
```

```
{
  "d": {
    "results": [ {
      "__metadata": {
        "id": "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
ExecutionLogs(index_no=1m,uuid=guid'UUID')", "uri": "host.com/sap/opu/
odata/sap/MANAGE_GIT_REPOSITORY/ExecutionLogs(index_no=1m,uuid=guid'UUID')",
"type": "cds_sd_a4c_a2g_gha_sc_web_api.ExecutionLogsType"
      },
      "index_no": "1",
      "uuid": "UUID",
      "type": "Information",
      "descr": "Step X: Message",
      "timestamp": "/Date(1571227438000+0000)/",
      "criticality": 0,
    }
  ]
}
```

## 4.2.6.75.1.3 Working with Branches on a Git Repository

### Prerequisites

- You have an ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You have selected the communication scenario **SAP\_COM\_0510** for your communication arrangement and have mapped it to your communication system.
- You have a Git repository/ software component with a main branch. A main branch is created when you push content to the repository for the first time, i.e. you release a transport request for the repository/ software component.

## Context

You can use the communication scenario `SAP_COM_0510` to work with Git repositories on an SAP BTP, ABAP environment system.

### Note

In ABAP Environment, Git repositories are wrapped in software components. These are currently managed in the *Manage Software Components* app. The technical parameter `sc_name` used in this API needs to be the name of the Git repository on the ABAP Environment system – the name of the software component.

## Procedure

1. **(Authentication on the Server)** The first step serves the authentication on the server. The response header contains an `x-csrf-token`, which is used as authentication for the `POST` request following in [step 2](#).

### Request

```
GET/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: fetch
```

### Response

```
HTTP/1.1 200 OK
X-csrf-token: xCsrfToken
```

2. **(Clone a Git Repository)** If a software component is not yet in your system, you first need to clone it once to import it into your system. For more information on how to do this, see [Cloning Git Repositories to an ABAP Environment System \[page 728\]](#).
3. **(Pull a Git Repository)** In order to work with branches, the Git repository needs to be pulled to the system. For more information on how to do this, see [Pulling Git Repositories to an ABAP Environment System \[page 730\]](#).
4. **(Create a Branch)** To create a branch, you perform a `POST` request on the `Branches` entity. In the header parameters, you should include the `x-csrf-token` that was retrieved in the first request. Fill in the following data in your request body:
  1. `"sc_name"`: the name of your Git repository
  2. `"branch_name"`: the name of your new branch
  3. `"derived_from"`: the branch that your new branch should derive from

### Request

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
{
  "sc_name" : "/DMO/GIT_REPOSITORY",
```

```
"derived_from" : "main",
"branch_name" : "newBranch"
}
```

## Response

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "type": "cds_sd_a4c_a2g_gha_sc_web_api.BranchesType"
    },
    "branch_name": "newBranch",
    "sc_name": "/DMO/GIT_REPOSITORY",
    "is_active": false,
    "criticality": 0,
    "derived_from": "main",
    "created_by": "CC0000000001",
    "created_on": "/Date(1584967657000+0000)/",
    "last_commit_on": "/Date(1584634658000+0000)/"
  }
}
```

5. **(GET the Branch)** To read the branch entity, you can use the following request:

## Request

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY' HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "type": "cds_sd_a4c_a2g_gha_sc_web_api.BranchesType"
    },
    "branch_name": "newBranch",
    "sc_name": "/DMO/GIT_REPOSITORY",
    "is_active": false,
    "criticality": 0,
    "derived_from": "main",
    "created_by": "CC0000000001",
    "created_on": "/Date(1584967657000+0000)/",
    "last_commit_on": "/Date(1584634658000+0000)/"
  }
}
```

## Note

Please note that the newly created branch is not yet active.

6. **(Checkout a Branch)** Simply creating a branch did not change the state of the system. In order to work with the newly created branch, you need to import the branch to the system. This action is called "checkout branch". You need to pass the Git repository and the name of the branch as query parameters.

### Request

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/checkout_branch?
branch_name='newBranch'&sc_name=" '/DMO/GIT_REPOSITORY' HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
```

### Response

```
HTTP/1.1 200 OK
Content-Type: application/json
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Pull(guid'UUID')",
      "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Pull(guid'UUID')",
      "type": "cds_sd_a4c_a2g_gha_sc_web_api.PullType"
    },
    "uuid": "UUID ",
    "sc_name": "/DMO/GIT_REPOSITORY ",
    "namespace": "",
    "status": "R",
    "status_descr": "Running",
    "start_time": "/Date(1571227437000+0000)/",
    "change_time": "/Date(1571227472000+0000)/",
    "criticality": 2,
    "user_name": "CC0000000001",
    "to_Execution_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/
MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Execution_log"
      }
    },
    "to_Transport_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/
MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Transport_log"
      }
    }
  }
}
```

Behind the scenes, a Pull entity is created. It can be used to track the status of the checkout (see steps 3 and 4 in [Pulling Git Repositories to an ABAP Environment System \[page 730\]](#)). This entity is specified in the `__metadata` of the response body.

7. **(Delete a Branch)** You can delete existing branches. Keep in mind, however, that neither the current active branch nor the main branch can be deleted. Both parameters are mandatory.

## Request

```
DELETE /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches(branch_name='my-to-be-deleted-branch',sc_name='/DMO/GIT_REPOSITORY') HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

Since you're using a DELETE request, an HTTP 204 code is returned as confirmation that your branch has successfully been deleted.

```
HTTP/1.1 204 No Content
```

## 4.2.6.7.6 Software Assembly Integration (SAP\_COM\_0582)

The communication scenario SAP\_COM\_0582 enables partners to assemble a software product via integration in Build pipelines for SAP BTP, ABAP environment systems. With the APIs belonging to this communication scenario, you can assemble a software package, upload the assembly and export logs to the Build pipeline, and upload the software package for registration in the Add-on Assembly Kit as a Service (AAKaaS).

To make the setup of Build pipelines as easy as possible, the open source project "Piper" was created. In general, there are various functions ("Library steps"), as well as whole pipelines, available to reuse. There, you can find the step **abapEnvironmentAssemblePackages** (see [abapEnvironmentAssemblePackages](#)), that implements the functionality of the APIs belonging to SAP\_COM\_0582. The step **abapEnvironmentAssemblePackages** is embedded in a sequence of steps which are needed to produce and distribute software packages, see the Library steps on [Project "Piper"](#) and [Build and Publish Add-on Products on SAP BTP ABAP Environment](#).

Additionally, there is an example pipeline for a Build process (see [ABAP Environment Pipeline](#)) that comprises the following:

- performing the Addon.yml and AAKaaS steps
- creating a SAP BTP, ABAP environment system
- setting up Communication Arrangement for the APIs
- importing a software component / Git repository
- building software package
- registering the software package in AAKaaS
- deprovisioning the SAP BTP, ABAP environment system

Please find the documentation regarding project "Piper" here: [Project "Piper"](#)

## 4.2.6.7.6.1 Assembling a Software Package

### Prerequisites

- You have fulfilled all prerequisites mentioned in [Build and Publish Add-on Products on SAP BTP ABAP Environment](#).
- Ideally, you have set up and configured a pipeline with stages and steps as recommended in [ABAP Environment Pipeline](#), and [Configuration](#).

In doing so, the following activities are performed automatically:

- You have an ABAP environment system.
- You've created a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- You've created a *Communication System* as described in [How to Create Communication Systems](#).
- You've created a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- You have selected the communication scenario *SAP\_COM\_0582* for your communication arrangement and have mapped it to your communication system.
- You have pulled a repository to the SAP BTP, ABAP environment system using communication scenario *SAP\_COM\_0510*.
- You have provided information on build essentials in an `addon.yml` file which has already been validated by the Add-On Assembly Kit as a Service (AAKaaS).

### Procedure

1. During the build pipeline run, the step **abapEnvironmentAssemblePackages** is executed (see [abapEnvironmentAssemblePackages](#)). This step runs the assembly of a list of provided installations, support packages or patches in an SAP BTP, ABAP environment system and saves the corresponding SAR archive to the pipeline.
2. An example for the configuration in `config.yml` as well as input arguments and values can be found here: [Examples](#).

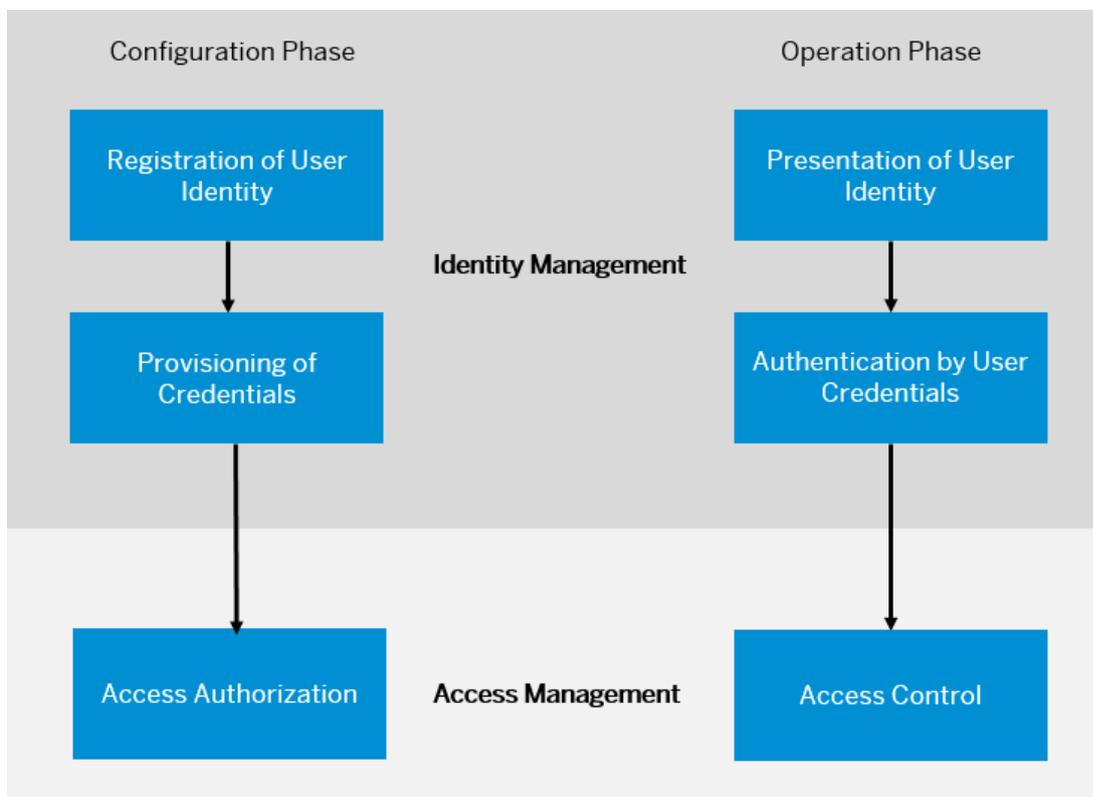

## 4.2.7 Identity and Access Management (IAM)

Learn more about the basic concepts and procedures for managing users and defining authorizations for business services and SAP Fiori applications.

### What Is Identity and Access Management?

The main components of Identity and Access Management are:

- User and Identity Management
- Roles and Authorization
- Authentication

In the configuration phase, an administrator registers and authorizes access rights.

In the operation phase, business users identify and authenticate themselves. The access to applications is based on previously authorized access rights.

In a business scenario, this means that an administrator manages the authentication and authorization of business users, including configuring [trust and identity federation](#) in the subaccount usually by configuring a [custom identity authentication service tenant \[page 183\]](#). As a fallback, [SAP ID service](#) is configured as the default identity provider. Additionally, an administrator also creates roles using templates, adds roles to role collections, and assigns role collections to business users. The business users can then log on to SAP Fiori applications and get authenticated.

## Who Is This Guide For?

If you're an SAP customer **developer** or partner developer and you create business services in the ABAP environment using ABAP Development Tools for Eclipse, this guide is for you. It guides you through an example of a business service based on a service binding. Note that http services work in a similar way.

In addition, the guide also covers activities that need to be performed by an **administrator**, such as assigning users to business roles.

## What Is This Guide About?

The guide starts with an overview of the basic concepts of identity and access management. It then leads you step by step through the design and implementation of your authorization model using an example.

Why should you care about access control and authorizations? You must know that every new service is automatically available to all developers in a development system, provided the system administrator has assigned them a role that is derived from the developer role `SAP_BR_DEVELOPER` (which is typically the case). However, business users in nondevelopment systems can only access the business service if a developer has defined the appropriate authorizations and an administrator grants the business users access for each relevant system. The same is true for communication users that are needed in scenarios where you work with an API business service (inbound or outbound) from or into the ABAP environment.

The **Identity Management** section gives you an overview about Identity and User Management, which includes identity federation, user types, and user provisioning.

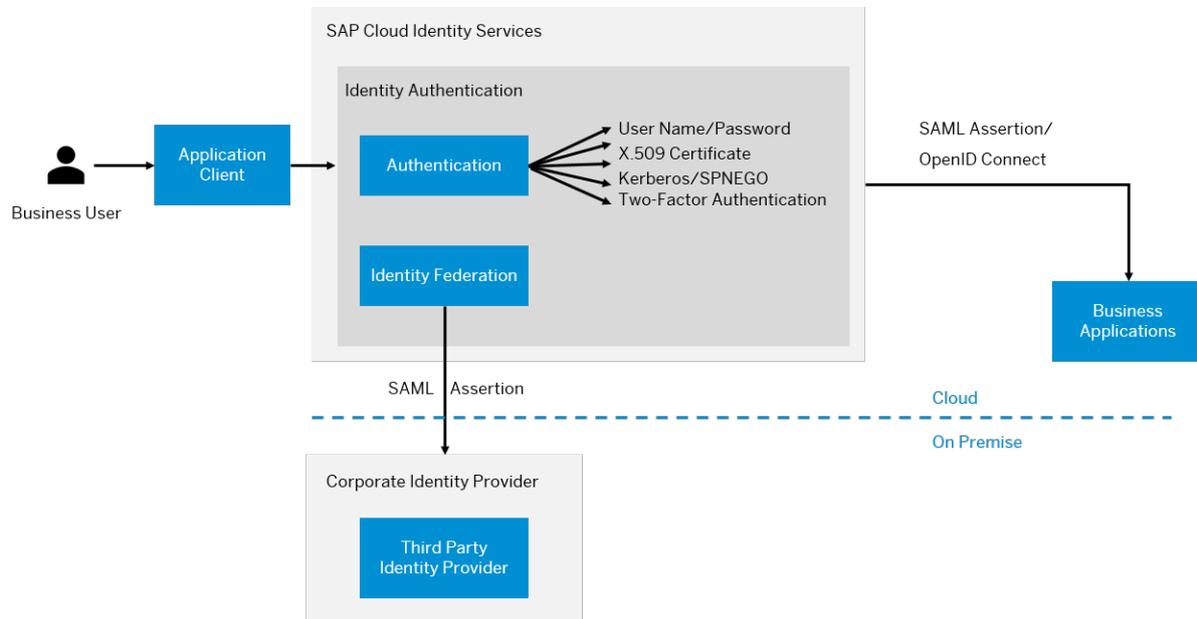

The **Access Management** section includes the following main scenarios about how you can implement and provide authorizations for your services:

- In chapter [Providing \(Unrestricted\) Access for Business Users \[page 757\]](#), you learn how to provide users in a nondevelopment system access to the service.  
Providing unrestricted access is the simplest scenario with only a few steps. The access is unrestricted, though, which means, for example, that you can't differentiate between write and read access.
- In chapter [Providing Access Based on Activities for Business Users \[page 761\]](#), you learn how to implement access for different activities, for example, separate read and write authorizations.
- In chapter [Providing Access Based on Field Values for Business Users \[page 771\]](#), you learn how to fine-tune your access restrictions depending on field values.

OData services that you develop using ADT can also be consumed in SAP Fiori applications (developed using the Business Application Studio). In this guide, you also learn how to provide access to an SAP Fiori application that consumes a business service.

## 4.2.7.1 Identity Management

Identity management comprises setting up trust and providing credentials for business users.

When setting up your identity management architecture, the following uses cases are possible:

- Using the default identity provider SAP ID service, an instance of Identity Authentication service. It is used to set up trust for business users and supports identity federation, which enables user access across various systems by exchanging identity information based on a trust relationship. See [Identity Federation \[page 742\]](#).
- Establishing trust to a custom identity authentication service tenant. See [Setup of a Custom Identity Service \[page 183\]](#).
- Using a corporate identity provider in a hybrid landscape. In this case, we recommend using the Identity Authentication service as a proxy for the corporate identity provider. See [Corporate Identity Providers](#). Note that there is no direct trust relationship between the authenticating identity provider and the service provider that the business user is trying to access.

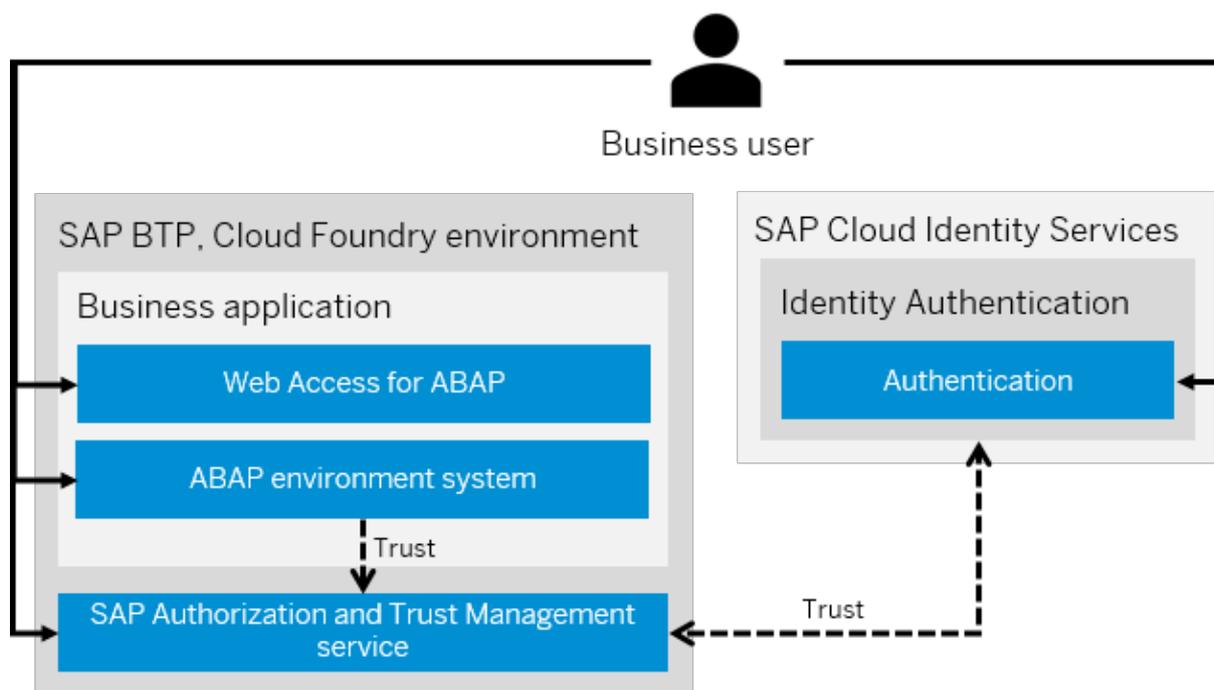

### Related Information

[Trust and Federation with Identity Providers](#)  
[SAP Cloud Identity Services - Identity Authentication](#)

## 4.2.7.1.1 Identity Federation

Identity federation is the process of sharing identity information between two parties by delegating the authentication responsibility to a trusted external party through the use of a common token.

In the ABAP environment, the authentication of business users is based on OAuth 2.0 authorization code flow, using either the [SAML 2.0](#) or [OpenID Connect](#) protocol and [JSON web token \(JWT\)](#) as a common access token.

The business application (OAuth 2.0 client) is on one hand represented by the Web Access for ABAP as the gateway component or a standalone approuter application deployed to the SAP BTP, Cloud Foundry environment. See [Subscribing to the Web Access for ABAP](#) and [Application Router](#).

On the other hand, an ABAP environment system is serving the business application resources (OAuth 2.0 resource server). See [Creating an ABAP System](#).

The SAP Authorization and Trust Management service in the SAP BTP, Cloud Foundry environment is providing endpoints to retrieve and exchange the authorization code for an access token (OAuth 2.0 authorization/authentication server). See [SAP Authorization and Trust Management Service](#).

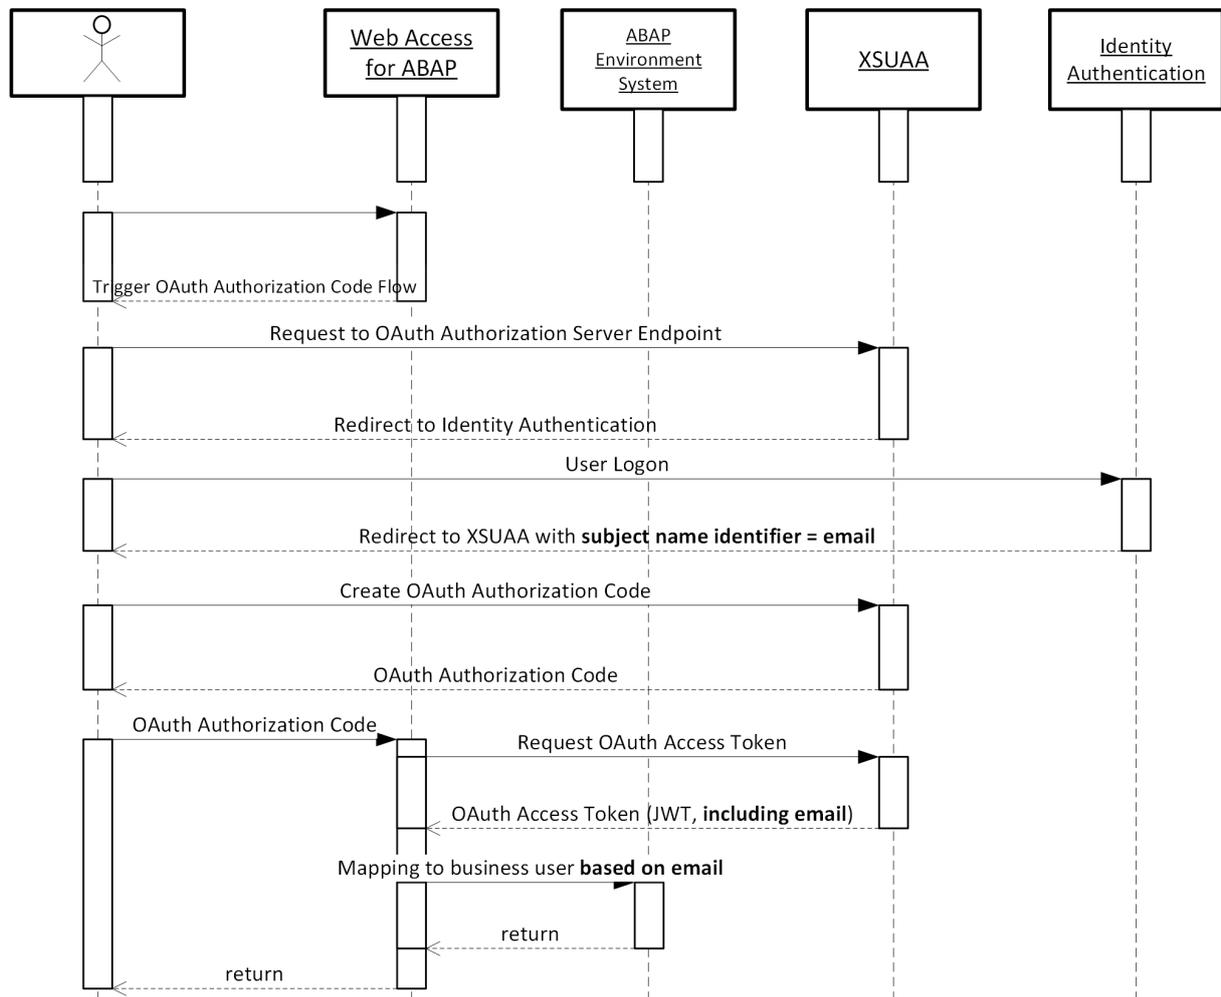

The Identity Authentication service is configured as an identity provider in the SAP BTP subaccount where the ABAP environment system has been created. The same subaccount is created as an application in the Identity Authentication service. See [Configuring Applications](#).

This configuration establishes a mutual trust relationship between SAP Authorization and Trust Management service (XSUAA) and the Identity Authentication service as identity provider. See [Trust and Federation with Identity Providers](#).

The ABAP environment system in turn trusts SAP Authorization and Trust Management service.

The business user is federated based on its e-mail address or user name, depending on the configuration of the `login_attribute` during system provisioning (See [Creating ABAP System](#)) and the subject name identifier in the Identity Authentication application (see [Configure the Subject Name Identifier Sent to the Application](#)).

If a resource in the ABAP environment system is requested to be accessed by a business user, the steps to acquire the required access token are as follows:

1. The business user accesses the ABAP environment system through the Web Access for ABAP or a standalone approuter application. If no access token is available, the OAuth 2.0 authorization code flow is triggered.
2. A request to the authorization server endpoint in the SAP Authorization and Trust Management service (XSUAA) checks if the business user is already logged on. If the business user is not logged on, the business user is redirected to the Identity Authentication service as the identity provider used for logon.
3. After logging on, the response of the Identity Authentication service, including the e-mail address of the business user as the subject name identifier, is redirected to the authorization server endpoint of SAP Authorization and Trust Management service (XSUAA) to retrieve the authorization code. The authorization code is necessary to retrieve the access token in the following steps. Finally, the authorization code is redirected again to the Web Access.
4. Based on the authorization code, a JSON web token (JWT) is retrieved from the access token endpoint in SAP Authorization and Trust Management service (XSUAA). This OAuth access token includes the e-mail address or login name of the business user that serves as a subject name identifier.
5. To consume resources, such as business services in the ABAP environment system, the JSON web token is forwarded as part of such requests and mapped internally to the business user.

### Note

Authentication of users other than communication users does not require identity federation as these technical users are authenticated locally in the ABAP environment system.

## 4.2.7.1.2 User Types

### SAP BTP, ABAP environment Users

In the ABAP environment, there are different types of users such as business users, communication users, and support users.

	Business User	Communication User	SAP Support User	Provider Support User
<b>Owner</b>	Customer	Customer	SAP	Provider
<b>Purpose</b>	Accessing business applications (SAP Fiori Applications) and using ABAP Development Tools	System to system communication	Analyzing and troubleshooting	Analyzing and troubleshooting consumer tenants
<b>Authentication</b>	Identity Provider	Local	Local	Local
<b>Authorization</b>	Business Role	Communication Scenario Role	Support Role	Access to Identity and Access Management and Communication Management apps
<b>User ID</b>	CB*	CC*	_SAP*	PS*
<b>Access</b>	<host>.abap-web.<region>...	<host>.abap.<region>...	<host>.abap-support.<region>...	<host>.abap-provider-web.<region>

**Business users** are customer-owned end users that use SAP Fiori applications as well as applications and services in SAP BTP, such as SAP Business Application Studio. They are authorized by being assigned a specific business role. See [User Provisioning \[page 745\]](#).

### Note

Developers using ABAP Development Tools are also considered business users.

**Communication users** are customer-owned technical users that are assigned to a communication system to enable integration with other solutions. For authentication, they can either be assigned a password or X.509 client certificate. See [Communication User \[page 848\]](#) and [Maintain Communication Users \[page 2391\]](#).

**Support users** are SAP-owned technical users that can access customer systems. See [SAP Support User Request Log \[page 2499\]](#).

**Provider support users** are technical users of the provider of a SaaS solution that can access consumer tenants in customer systems. See [Create Support Users \[page 1307\]](#).

## SAP BTP Users

In SAP BTP, there are platform and business users.

**Platform users** operate in the SAP BTP cockpit by deploying, administering, and troubleshooting applications and services. They are authorized by using role collections or by user assignment in the Cloud Foundry space as space or org members, such as space developers.

**Business users** use the applications that are deployed to SAP BTP and are authorized by using role collections.

To learn more about platform and business users in SAP BTP, see [User and Member Management](#).

## Related Information

[Business Catalogs for Identity and Access Management Apps \[page 2510\]](#)

### 4.2.7.1.3 User Provisioning

User provisioning is the automated process of creating users, that are later granted permissions to access business services and applications, to allow system to system communication, or to perform troubleshooting.

#### Note

Please make sure that employee and business user data is maintained in accordance with the `login_attribute` system provisioning parameter (see [Creating ABAP System](#)) and the subject name identifier configured in the Identity Authentication application (see [Configure the Subject Name Identifier Sent to the Application](#)): If `login_attribute = email` is used, the email address at employee level needs to be maintained for identity federation to work, if `login_attribute = user_name` is configured, the username on business user level needs to match the login name provided in the identity authentication user.

## Creating SAP BTP, ABAP environment Users

Each business user created in the ABAP environment system has a unique and stable employee ID. Employees are maintained in the SAP Fiori app [Maintain Employees](#). See [Maintain Employees \[page 2419\]](#).

#### → Recommendation

We recommend setting the employee ID by an HR system, which allows you to update master data in the [Maintain Employees](#) app, for example, when a business user has a new email address because of a name

change, or if you want to edit the user information of the initial admin of an ABAP environment service instance.

The following provisioning methods to automate identity lifecycle processes for business users are available:

- SAP Fiori app *Maintain Employees* with CSV file upload. See [Maintain Employees \[page 2419\]](#).
- SOAP service using communication scenario Identity Management Integration SAP\_COM\_0093. See [Inbound Service: Business User \[page 1004\]](#) and [Inbound Service: Business User - Read \[page 1021\]](#).
- Identity Provisioning service using communication scenario SAP Cloud Identity Services - Identity Provisioning SAP\_COM\_0193. See [Identity Provisioning - SAP BTP ABAP Environment as a Target System](#).

#### → Recommendation

To create new business users in the ABAP environment, we recommend using the Identity Provisioning service.

This requires setting up the Identity Authentication service as a source system for identity provisioning and managing employee information in the user store. The Identity Provisioning service can then read this information and map the Identity Authentication logon name to the ABAP environment employee ID. See [Identity Authentication as a Source System](#) and [Tutorial: Provision Users into your SAP BTP ABAP Environment](#).

To create **communication users**, see [How to Create Communication Users \[page 2393\]](#).

SAP support users are owned and created by SAP. However, in the *Display Technical Users* SAP Fiori app, you can check when and why SAP support users accessed your customer system in the past 12 months. See [SAP Support User Request Log \[page 2499\]](#).

## Creating SAP BTP Users

To create **platform users** and **space members**, see [User and Member Management](#) and [Creating New Space Members and Assigning Space Developer Roles to Them](#).

## Related Information

[What Is Identity Provisioning?](#)

### 4.2.7.2 Access Management

Access management comprises the process of implementing and providing authorizations for your services.

[Authorization Basics \[page 747\]](#)

If you haven't worked with an ABAP system before, you might find this introduction to the basic authorization concepts useful before you proceed.

[Example: Authorizations for a Bonus Calculation Service \[page 753\]](#)

Let's assume that you have a bonus calculation service, which, in the example used here, is represented by an active service binding. You want to model authorizations for this service.

[Providing Access to a Business Service for Business Users \[page 754\]](#)

For a newly created business service, you must define how business users can access it and which activities are allowed.

[Providing Access to the SAP Fiori Application \[page 788\]](#)

Learn what developers and administrators need to do so that an SAP Fiori application appears in the SAP Fiori launchpad of an authorized business user.

[Providing Access to a Business Service for Communication Users \[page 791\]](#)

For a newly created business service, you must define how communication users can access it and which activities are allowed.

[Providing Read or Write Access to a Business Service Using Privileged Mode \[page 802\]](#)

With enablement of privileged mode for a business object, it's possible to consume the business object without the need for additional business authorizations.

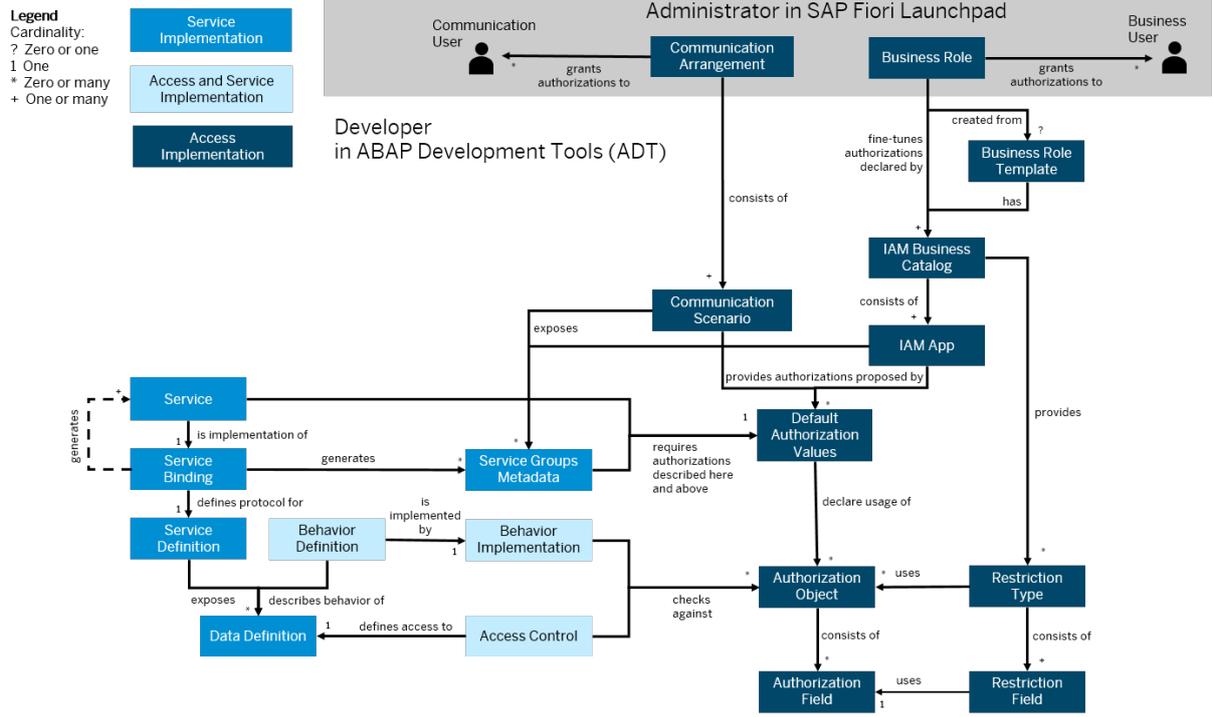

[Troubleshooting \[page 804\]](#)

Learn more about apps and tools that help you identify and solve authorization issues.

## 4.2.7.2.1 Authorization Basics

If you haven't worked with an ABAP system before, you might find this introduction to the basic authorization concepts useful before you proceed.

Let's assume that you create business services. During the service implementation, you create a service definition, which exposes a data definition. In the ABAP RESTful Application Programming Model (RAP), you use behaviors to specify the operations and field properties of an individual business object. You can later enhance the behavior definition and implementation to include an authorization control. For more information about the ABAP RESTful Application Programming Model (RAP), see the documentation for the [ABAP RESTful Application Programming Model](#). The documentation of the ABAP RESTful Application Programming Model also describes the service implementation, that is, the creation of all objects highlighted in medium blue in the following graphic.

To provide access to your business service, you also create additional development objects in ABAP Development Tools (ADT). These additional objects help define which users can eventually access which data with their authorizations. Such objects can be authorization objects, authorization fields, IAM apps, IAM catalogs, and so on (highlighted in light and dark blue in the graphic above).

Let's have a look at each object.

### Authorization Field

An authorization field is the smallest unit in the area of authorizations. It's defined by a data element and its values; it's an attribute of a business object. An example of an authorization field is *Product Type*, with values such as *Material* or *Service* and the corresponding business object *Product*. In the example of a bonus management solution that is used in this guide, a possible authorization field is *Bonus Variant* with the values *Rate* and *Amount*.

A standard authorization field, which is already predefined in the system and which you can reuse to protect custom applications, is *Activity*. Like every authorization field, *Activity* has multiple values, such as create, update, delete, release, and so on, for which you can check the user's authorization.

You can assign a check table to each authorization field. This table will serve as a value help when the field is consumed during the configuration of authorizations in the business role maintenance.

### Authorization Object

An authorization object groups up to 10 authorization fields that are related by AND. An authorization object ensures that complex authorization checks can run for multiple conditions. For example, you can create an

authorization object that defines which products users can access, such as products of type *Material*, of type *Service*, or both. Typically, you have the authorization field *Activity* in an authorization object because you want to define what kind of activities users can perform or not. Depending on the business context, you add more authorization fields, such as a purchase order type. In an authorization object, you also define which values of the *Activity* field you think are relevant.

After you have created authorization fields and authorization objects, you must implement checks against the authorization object to make sure that only authorized users can perform certain activities. During this check, the values specified in the program are compared with the values contained in the user's authorizations.

## Authorization Check

An authorization check determines whether the current user of a program has a certain authorization. The check compares programmed (fix or actual runtime) values that are required for a specific authorization field within a specific authorization object against the granted authorizations of the current user. As a developer, you can implement authorization checks in ABAP coding using the statement `AUTHORITY-CHECK` or using access controls.

## Access Control

ABAP Core Data Services (CDS) have their own concept for data protection and authorization: access controls. Access controls provide an easy way to implement protection against unauthorized read access based on field values.

For more information about access control, see [Access Controls](#) in the ABAP CDS Development User Guide.

## Authorization Control

Authorization control in the RESTful Application Programming Model protects your business object against unauthorized access to data. You can use global and instance-based authorization control. Global authorization is used for all authorization checks that only depend on the user. You can define global authorization to check if users are allowed to execute an operation in general. Instance authorization is used for all authorization checks that additionally depend on the state of the entity instance in question. With instance authorization, you can define authorization that depends on a field value of the instance.

Authorization control is part of the behavior implementation of a business service.

For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

## Default Authorization Values

You can define default authorization values for each authorization object and business service. These default authorization values are then automatically assigned when the business service is added to an IAM app or to a

communication scenario. Note, however, that the default authorization values can be overwritten by values set in the IAM app and by restrictions in the business role or communication scenario.

## Restriction Field

A restriction field is based on an authorization field. It's used to restrict the access to instances of a business object, for example, a product. Restrictions are only available when access to business users is provided.

With restriction fields, you can empower an administrator to create multiple business roles with different values in the restriction field. Without restriction fields, you, as a developer, need to create a separate IAM app and a business catalog for each business role.

For example, an administrator wants to create different business roles for product master specialists who maintain products in the system. With a restriction field that contains values for the different available product types, you can fine-tune business roles in such a way that some product master specialists only get the authorizations for maintaining products of type *Materials* and others also of type *Service*.

## Restriction Type

A restriction type is an authorization entity that bundles the available restriction fields according to a logical definition, for example, product type and product category. In a restriction type, you also define for which authorization object the restrictions are relevant. You can add restriction types to business catalogs.

For example, you can create a number of restriction fields that are relevant for creating business roles in product master data. You can, for example, create restriction fields such as *Product Type* and *Product Category*, and then bundle them using the restriction type *Product*.

## IAM App

An IAM app is a development artifact that you can use to define necessary authorizations for business users for one or more services that you created in ADT. You create the IAM app in ADT, add the services, and define the necessary authorizations needed for the services. After that, you can include the IAM app in a business catalog, which then allows you to include the IAM app and its related authorization definitions into a business role.

## IAM Business Catalog

In an IAM business catalog, you bundle multiple IAM apps and their predefined authorizations, for example, for a specific business area. The business catalog links what has been defined by development with settings done by administration. Business catalogs consist of IAM apps with their predefined authorizations, which can be reused in business roles. If you define an IAM business catalog with restriction types, you allow the administrator later to fine-tune the authorizations during business role maintenance.

You create an IAM business catalog in ADT. After you, as a developer, have published the business catalog in ADT, it's available in the SAP Fiori apps for business catalog and business role maintenance of the development system and can be used for user tests.

## Business Role Template

You can define business role templates to make it easier for administrators to find the business catalogs that are relevant for the corresponding role in your company.

For SAP Business Technology Platform, role templates for administrators and developers are available: The business role template `SAP_BR_DEVELOPER` includes permissions for using ABAP Development Tools (ADT) and for creating the development objects mentioned here. The business role template `SAP_BR_ADMINISTRATOR` includes permissions for creating business roles.

## Business Role

A business role is the administrative object that administrators use to group and fine-tune authorizations and assign them to business users. To create a business role, an administrator adds one or multiple IAM business catalogs to it. These IAM business catalogs contain predefined authorizations that allow users to access IAM apps. In business roles, administrators can set the authorizations for each access category, including available restrictions for different instances of a business object. If the IAM business catalog contains restrictions, administrators can also override authorizations for these restriction fields during business role maintenance.

## Access Categories

An access category defines what kind of access is granted to the business users assigned to a business role, for example, read, write, or value help.

Each activity from the corresponding standard authorization field is typed with an access category, for example, the activity *Display* has the access category *Read* and the activity *Create* has the access category *Write*.

The activities for which permissions are assigned using a business role are defined in the IAM apps. The activities that a business user is allowed are the result of restriction settings for each access category in a business role and the corresponding activities defined in the IAM apps in the business role.

If the business role doesn't give write access, the *Create* activity, for example, isn't allowed. While it's possible to block write access, it's not possible to forbid read access completely in a business role because a *No Access* option isn't available. Therefore, read access is either allowed or, with the use of restriction fields, it's restricted by the allowed values of the restriction fields. In this case, display is only allowed for business object instances matching the allowed restriction field values.

## Authorization Context

A CDS behavior definition can define authorization contexts that list multiple authorization objects. These authorization objects are used for the ABAP statement `AUTHORITY-CHECK OBJECT` in the implementation methods of the ABAP behavior pool of the business object.

The authorization contexts can be defined as follows:

- Own authorization context: Such an authorization context is defined using the statement `define own authorization context`.

### → Recommendation

We recommend that you define the own authorization context for all your custom business objects to document which authorization objects are checked in the logic of each business object.

- An authorization context with a specific name: Such an authorization context is defined using the statement `define authorization context`. With the authorization context with a specific name, you can define an authorization context that contains only a subset of the authorization objects from the own authorization context.

An authorization context can be useful, for example, to enable privileged mode for a business object (see [Providing Read or Write Access to a Business Service Using Privileged Mode \[page 802\]](#)).

For more information, see the ABAP keyword documentation that you can find in the ABAP Development Tools.

## Privileged Mode

With privileged mode in the behavior definition, RAP business object consumers can circumvent authorization checks, such as RAP authorization control or CDS access control. After enabling privileged mode, privileged read and write access to the business object is possible. In this case, the authorization checks for all listed authorization objects always return the value `authorized`.

For more information, see the ABAP keyword documentation in the ABAP Development Tools and [Authorization Control](#) in the guide to the ABAP RESTful Application Programming Model (RAP).

## Communication Scenario

A communication scenario in the ABAP environment is a development artifact that describes how two communication partners communicate with each other. It provides technical information, such as the used inbound and outbound services and their service type, for example OData or SOAP, and the number of allowed communication arrangement instances. It is also the place where you define the required authorizations that a communication user must have to use the services of the communication scenario.

For more information, see [Communication Scenario](#).

## Communication Arrangement

A communication arrangement in the ABAP environment is a runtime instance of a specific communication scenario. It grants the authorizations for the inbound and outbound services of the communication scenario to communication users. It grants the authorizations only from and to a specified partner, the so-called communication system. The administrator of the ABAP environment creates the communication arrangement in the SAP Fiori launchpad.

For more information, see [Communication Arrangement](#).

## Putting It All Together: Authorization

A user's authorization is influenced by the combination of permissible values in each authorization field of an authorization object. An authorization enables a user to perform an activity in the system, based on a set of authorization field values. However, the authorization object isn't the only entity in the system that influences what a user is allowed to do. IAM apps, communication scenarios, business roles, and restrictions in business roles can still change what was defined in the authorization object.

### 4.2.7.2.2 Example: Authorizations for a Bonus Calculation Service

Let's assume that you have a bonus calculation service, which, in the example used here, is represented by an active service binding. You want to model authorizations for this service.

#### The Bonus Calculation Service

The bonus calculation service is part of a sales bonus program where the sales revenues that sales reps were able to generate are used as the basis for their bonus plan. In the ABAP RESTful Application Programming Model (RAP), the bonus plan is modeled as a business object *Bonus Calculation* of type managed.

With the bonus calculation service, users, for example, managers in sales, can create, update, display, and delete bonus calculations as standard operations. As part of a bonus calculation, users enter an employee name, a bonus variant and validity period can be set, and the bonus be calculated, which is a non-standard, business object-specific activity. In the example used in this guide, the available bonus variants are based on *Rate* or *Amount*, that is, the bonus recipient either gets a bonus based on a rate or a fixed amount.

The service can be consumed either by business users via a user interface (UI) or by technical communication users as a Web API. For both consumption types access has to be provided at least for nondevelopment systems because this access isn't automatically available in such systems.

## Consumption in a UI for Business Users

If the business service is consumed by a UI, the available UI enables business users easily, depending on their authorizations, to set data or to execute the actions the service is offering. For example, a UI for managers lets them perform activities on bonus calculations. The UI wraps the underlying service calls for the business users into intuitive UI elements. Changes that the business user isn't authorized for can either be made unavailable on the UI or their corresponding service call is done and an appropriate error returned from the service. The UI can act as a kind of authorization filter. This kind of service consumption always requires business user action.

## Consumption as API with a Communication User

If the business service is consumed as API, no UI wraps the allowed changes to the business service. Instead, the service caller can try to change all data and execute all actions directly and always gets errors if there are missing authorizations to do it.

In the example used here, the bonus calculation is an inbound business service that business users use to create new bonus calculations. There's no dedicated bonus calculation in the HR system, but instead, the HR business service calls the bonus calculation business service in the ABAP environment to set data and execute actions.

Where you work with an API business service (inbound or outbound) from or into the ABAP environment, you need to provide authorizations to technical users, so-called communication users, instead of business users. This service consumption can be performed automatically without any user action.

### 4.2.7.2.3 Providing Access to a Business Service for Business Users

For a newly created business service, you must define how business users can access it and which activities are allowed.

#### Motivation

If you have the developer role `SAP_BR_DEVELOPER`, for example, you can test your new service immediately without having to create an IAM app and assign it to a business catalog and a business role. Activating the service binding, for example, creates the IAM app and assigns it to the business catalog `SAP_CORE_BC_EXT_TST` that is shipped to customers for testing purposes. This business catalog is assigned to the developer role template `SAP_BR_DEVELOPER`. Therefore, when you create a new service in a development system and activate the service binding, all users with this developer role can automatically access and use the service. Of course, all users with another role containing this catalog are then also able to access and use the service.

This kind of access isn't available anymore when you pull the business service into nondevelopment systems, for example, where this test catalog feature isn't enabled.

For business users, you must provide access to a newly created service because access isn't automatically available. However, all activities are allowed as long as you don't protect your business service. Therefore, you must develop identity and access management artifacts, which is explained in detail in this guide. They ensure that you can define the necessary authorizations and enable business users to consume the business service.

## Overview of Development Options

Now, let's assume you would like to achieve that certain business users are able to view and edit bonus calculations:

- Under *Providing Unrestricted Access*, you learn how to provide users read and write access to all bonus calculations.  
This scenario is simple to implement. It's enough if you have one user group that is allowed to make full use of the business service while all other users don't need access, not even read access. In this case, if managers have access to the business service, they can create, update, display, and delete all available bonus calculations.
- Under *Providing Access Based on Activities*, you learn how to create two business roles for separate read and write authorizations.  
With this scenario, you can keep business users with read access only from changing bonus calculations.
- Under *Providing Access Based on Field Values*, you learn how to fine-tune your access restrictions to particular fields, that is, on the level of data elements, such as the bonus variant.  
This is the most complex scenario, but it allows administrators to define business roles that authorize users to view and change only particular data; other data is filtered. For the bonus calculation service, managers can only create, view, update, and delete bonus calculations that have a specific bonus variant. The advantage of this scenario is that you, as a developer, can delegate some decisions about the business role design to the administrator. The administrator can decide which data is visible to business users, based on restriction fields in the business role.

After you've implemented access based on one of the scenarios mentioned, you can then also go on and implement access to the corresponding SAP Fiori application for the business service.

## Tutorial

In addition to this documentation, the following tutorial is also available:

[Create Authorization Model with SAP BTP, ABAP Environment](#) 

### 4.2.7.2.3.1 Considerations for Implementing Access and Authorizations

You can implement data access and authorizations for a service differently, depending on how you want to implement differences on the UI for different target groups. It also matters how you want to design business roles. Therefore, before you start with the actual implementation of data access and authorizations, you need to consider how you want to proceed.

There are different points in application development where you can start separating data access for different user groups. As a result, you get different business roles that are assigned to business users.

## Different Services for Different User Groups

With this approach, you create different services that grant different data access, depending on the user group and its corresponding role. Here, you already consider the required data access for the various user groups when you implement the services. As a result, you also implement different UIs, authorization defaults, IAM apps, and business catalogs, at least one per service. That way, you invest more effort in service development, but less in UI development because it's already clear from the data exposed by the service what the UI will provide.

Since you create different services for the user groups, system administrators would then also assign different business roles to business users that authorize them for one of the services, depending on the user's tasks.

## Different UIs for Different User Groups

If different user groups require a different structure or layout, another option is to implement different UIs for different user groups. While you need to invest more time to implement many separate UIs, especially if you need many of them, the effort for each UI is lower in comparison to dynamic UI handling.

A typical use case would be to use service bindings on different projections for the same business object. For example, a business object *Leave Request* has *Create*, *Delete*, and *Approve* activities. There could be two projections: one for the employees that allows them to create and delete leave requests, whereas another projection is for the manager who approves them.

If you decide to create different UIs for different user groups, this means you need to create an IAM app for each UI. Each IAM app needs to be included into a separate business catalog, which in turn is then included into a separate business role. As a result, an administrator creates a different business role for each UI.

## Dynamic UI Handling

With dynamic UI handling, you implement a UI that changes dynamically, depending on the user group. For example, while one user group has full access to all data, another user group can only see data in display mode and actions are disabled, or data and possible actions aren't even shown. Dynamic UI handling is useful if there are only small UI differences for different user groups.

For example, you implement an app that calculates bonuses for sales representatives. With dynamic UI handling, you can define a business role for a user group where users can view all bonus calculations and create, change, and delete bonus variants. Other user groups can only display the bonus calculations (possibly only for one bonus variant), but buttons for creating, changing, or deleting bonus variants are grayed out.

The development of a dynamic UI can result in more effort because you need to model and implement authorization access, for example. However, you also save efforts because you only implement one UI for all user groups and thus you avoid redundancies that arise when you maintain multiple UIs for different user groups.

In the ABAP RESTful Application Programming Model (RAP), you realize dynamic UI handling using dynamic behavior implementation. For more information about dynamic behavior implementation, see [Implementing a Protection Against Unauthorized Write Activities \[page 779\]](#).

## Business Role Design

In addition to the choices you make for the implementation of different UIs for different user groups, you also need to consider how business roles need to be implemented for your services. Depending on the use case of your service or services, you want the administrator to create different business roles. It's crucial to understand that the possible design of business roles depends on the choices you make when you implement the service, its UI, and the authorizations.

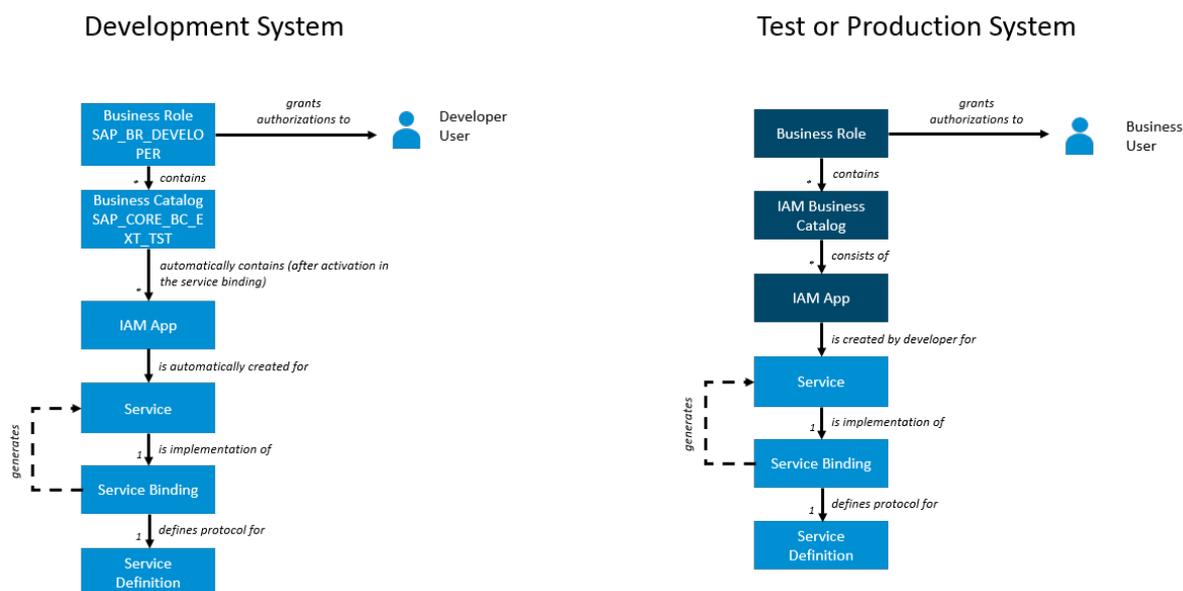

One possible approach is that you envisage business roles that can differentiate between the access categories of read, write, and value help (F4). This is possible using different business roles and doesn't require different authorization implementations.

The exception is when you need a finer distinction of activity authorizations, for example, between create/update and delete. In this case, you must implement different IAM apps for your service. On the basis of these IAM apps, you create different business catalogs, which the administrator uses to create different roles.

### 4.2.7.2.3.2 Providing (Unrestricted) Access for Business Users

In this scenario, you get information about how to provide unrestricted access with a few steps.

In this scenario, to provide access to the business service, you must create an IAM app and assign it to a business catalog. Administrators then create a business role that contains the business catalog and assigns the role to business users. Note that all objects that need to be created are highlighted in dark blue in the graphic.

This scenario requires only a few steps to provide authorizations, and it's the minimum that you must do to make your service available to business users. However, with this scenario, you always provide unrestricted write **and** read access. If you want to fine-tune the authorizations in more detail, check the scenarios *Providing Access Based on Activities* and *Providing Access Based on Field Values*.

## Related Information

[Providing Access Based on Activities for Business Users \[page 761\]](#)

[Providing Access Based on Field Values for Business Users \[page 771\]](#)

### 4.2.7.2.3.2.1 Developing Authorizations for Business Users (Developer)

For providing unrestricted access to a business service for business users, as a developer, you first create an IAM app, a business catalog, and, optionally, a business role template.

#### 4.2.7.2.3.2.1.1 Creating an IAM App for the Business Service

As a developer, you need to define an IAM app for the business service that you created in ABAP development tools (ADT). Creating an IAM app is the first step to be able to create a business role for your business service.

## Context

You create the IAM app in ADT. After the IAM app has been created, you can include the IAM app in a business catalog, which, in turn, can be included in a business role. This business role then can be used to control access to the app. For more information about IAM apps, see the [user guide](#) for ABAP development tools.

Instead of creating a new app, you can also use an existing IAM app for the service.

## Procedure

1. Follow the procedure in the user guide for ABAP development tools.

### Note

In this scenario, there are no authorizations that you need to change on the *Authorization* tab page.

2. Save and publish the newly created IAM app locally.

## 4.2.7.2.3.2.1.2 Creating a Business Catalog

To be able to assign an IAM app to a business role, you first need to include the IAM app in a business catalog.

### Context

In a business catalog, you can bundle several IAM apps for which users should get authorized. You can assign a business catalog to a business role template.

In this simple scenario, no predefined, detailed authorizations are available for the IAM app, but you still need to create a business catalog. By including the IAM app in the business catalog, you simply create the prerequisites for allowing users a full access to your business service once they have the business role with the business catalog assigned.

Instead of creating a new business catalog, you can also reuse an existing business catalog.

#### → Recommendation

We recommend that you add the information to the business catalog description that the IAM app belongs to an unprotected service, so that this important information is available to administrators.

### Procedure

To create a business catalog, follow the instructions in the [user guide for ABAP development tools \(ADT\)](#).

Also follow the instructions to assign your IAM app to the business catalog.

## 4.2.7.2.3.2.1.3 Creating a Business Role Template (Optional)

In addition to a business catalog, you can also create a business role template with ABAP Development Tools (ADT). Creating a business role template is optional, but it can ease the business role creation for the administrator.

### Context

Creating a business role template especially makes sense if you have more than one business catalog to assign to a business role.

## Procedure

1. In the project explorer, right-click the package *Cloud Identity and Access Management*.
2. In the context menu, choose ► *New* ► *Business Role Template* ▾.
3. Follow the steps of the creation wizard.
4. After the business role template has been created, add the business catalog to it.
5. Choose *Publish Locally* to make the business role template available for use in the development system.

### 4.2.7.2.3.2 Creating a Business Role and Assigning Business Users (Administrator)

As an administrator, to be able to grant authorizations to business users, you need to create a business role that you then assign to the business users.

## Context

Perform this task in every system. Alternatively, you can also create a business role once, download it, and upload it to other systems. For more information, see [How to Download and Upload Business Roles](#).

## Procedure

Follow the instructions of the documentation to create a business role from a template or from scratch (but omit the steps for maintaining instance-based restrictions and for managing launchpad space):

- [How to Create a Business Role from Scratch](#)
- [How to Create a Business Role from a Template](#)

### ⚠ Caution

Even if you leave the write restrictions to their default *No Access*, business users still have write access with this business role in this scenario. Users always have full access because you haven't implemented an authorization check in the service behavior.

We recommend that you set the restrictions in the business role to unrestricted write authorizations to make it transparent to other administrators that this business role provides users with full read and write access.

## Results

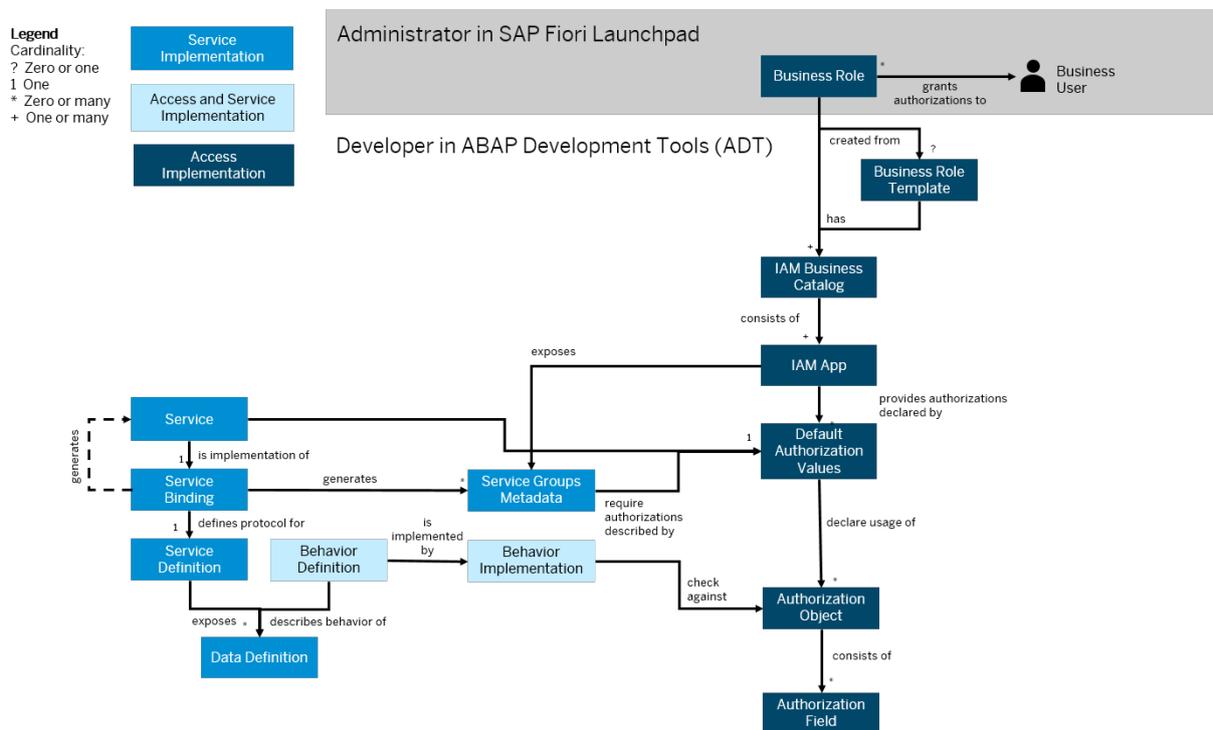

Users in the system have full read and write access to the service.

### 4.2.7.2.3.3 Providing Access Based on Activities for Business Users

In this scenario, you provide access depending on what the user should be allowed to do, for example, read or write access.

This scenario is more complex than a simple unrestricted access implementation because you must also create an authorization object and implement authority checks in the behavior implementation. However, you benefit from the extra efforts because you can enable the administrator to create separate business roles for different activities, that is, based on the authorization field `ACTVT` (*Activity*) for create, read, update, and delete.

## Overview

In the following, you get a more detailed overview of how to implement a separate read and write access. You can achieve such a separation by creating an authorization object with the standard authorization field `ACTVT` (*Activities*), an authority check to protect the service, an IAM app, and a business catalog. The administrator can then create two business roles for read and for write access each. If you want to enable the administrator to create more fine-tuned business roles, for example, to differentiate between the activities of create and

delete, you proceed in a similar fashion, but you need to create two IAM apps (see also [Considerations for Implementing Access and Authorizations \[page 755\]](#)).

## Process

To create access protection and provide authorizations, you perform the following steps:

### Protecting the Service from Unauthorized Use

As a developer, you perform the following steps in ABAP Development Tools (ADT):

1. Create an authorization object with standard authorization field *Activity* (ACTVT) and permitted values 01,02,03,06.
2. Implement authority checks in the behavior implementation of the service to allow create, update, and delete activities only to users who have the authorizations of the authorization object.

As a result, users cannot create, update, or delete the relevant business objects anymore, for example, bonus calculations.

### Developing Authorizations for the Service

As a developer, you perform the following steps in ADT:

1. Add the required authorization objects to the list of default authorization values.
2. Create an IAM app and assign the service binding to it. Under *Authorizations*, select all activities (*01 Add or Create, 02 Change, 03 Display, 06 Delete*) to allow them for business users.
3. Create a business catalog and assign the IAM app to it.
4. Optional: Create a business role template and assign the catalog to it.

### Granting Authorizations to Business Users

As an administrator in the ABAP environment, you can now grant authorizations to business users for this service:

1. Create a business role. For business roles with write access, set unrestricted write authorization. For read-only business roles, keep the default, which is no access.
2. Assign the business role to the business users.

As a result, business users can view, create, update, or delete bonus calculations again, depending on their business roles.

## 4.2.7.2.3.3.1 Protecting the Service (Developer)

With creating an authorization object for your service and with the implementation of a protection against unauthorized creation and change activities, you implement a basic protection of your service.

After this, you can implement how authorizations are granted to business users.

## Related Information

[Developing Authorizations for Business Users \(Developer\) \[page 766\]](#)

### 4.2.7.2.3.3.1.1 Defining Permitted Activities in an Authorization Object

To define the permitted activities for a service, create an authorization object with the standard authorization field *Activity* (ACTVT) for the permitted activities.

## Procedure

To define the permitted activities, follow the procedure for defining authorization objects in the [user guide for ABAP development tools](#) (ADT).

### Note

In our example, in the newly created authorization object, under *Authorization Fields*, you only need the predefined *Activity* authorization field to define the permitted activities for the business users of your service. In our example, these activities would be *01 Add or Create*, *02 Change*, *03 Display*, and *06 Delete* for standard activities. In addition, you need *93 Calculate* for the business object-specific activity *Calculate Bonus*. If you click on an empty row and choose , the list of available values is shown.

In theory, by using the syntax `authorization: update` on an operation in the entity's behavior definition, you could use the authorization check that is implemented for the update operation for the annotated operation. This is also referred to as "authorization delegation". However, for security reasons, we recommend that you carefully consider whether you want to use authorization delegation because in this case, a user who is allowed to update a business object is then also allowed to perform all other activities on the business object.

## Results

In the following, the newly created authorization object for the bonus calculation example is called ZBNSCLC\_AO.

## 4.2.7.2.3.3.1.2 Modeling a Protection Against Unauthorized Write Activities

To protect your service from activities such as create, update or delete by unauthorized users, you can use the authorization controls that are available for services based on managed business objects.

### Context

In the example used here, the service is based on a managed business object *Bonus Calculation*. The use of a managed business object allows you to benefit from the global authorization for managed business objects, which is part of the ABAP RESTful Application Programming model. For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

### Procedure

1. In ABAP development tools, call up the behavior definition of your service.
2. In the behavior definition, define authorization controls for your service.

In the bonus calculation example, they can be as follows:

#### Sample Code

```
managed;
define own authorization context
{
  'ZBNSCLC_AO';
}
define behavior for z_i_bonus_calculation alias calculation
implementation in class zbp_bonus_calculation unique
persistent table zbonusclc
lock master
// Identity and Access Management:
// Enable RAP managed authorization check at create, update, and delete
// -> requires implementation of two methods, one with the addition "FOR
INSTANCE AUTHORIZATION"
// and one with the addition "FOR GLOBAL AUTHORIZATION"
authorization master ( instance, global )
```

With the line `authorization master ( global )`, an authorization check for the standard operations create, update, and delete and for non-standard operations, for example, `calculate bonus`, is defined. You must implement the authorization check using a method with addition `FOR GLOBAL AUTHORIZATION` in the behavior implementation.

The sample code also contains the definition of your own authorization context. The own authorization context documents all authorization objects that are used by the business object implementation. In the bonus calculation example used in this documentation, this is the authorization object `ZBNSCLC_AO` because it's checked in the authorization control. The own authorization context is also used to prefill authorization defaults.

## 4.2.7.2.3.3.1.3 Implementing a Protection Against Unauthorized Write Activities

To protect a service such as the example of bonus calculation against unauthorized bonus creations, updates, or deletions, enhance the behavior implementation of the service in ABAP development tools (ADT). The implementation is required by what has been defined in the behavior definition.

### Context

Among the methods of the behavior implementation, you add methods that check the authorizations for creation and for update and delete.

### Procedure

1. In the *Source Code Library* folder of your package, under *Classes*, choose the behavior implementation of your service.
2. In the `PRIVATE` SECTION in the handler class of the behavior implementation, define the methods for authorization checks for creation, update, and deletion.

#### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR <behavior definition or
  its alias> RESULT result.
```

In the bonus calculation example, these method definitions could be the following:

#### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR calculation RESULT
  result.
```

3. Add a method implementation that checks the authorizations for creations, updates, and deletions.

#### Note

For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

In the bonus calculation example, this method could be the following:

#### Sample Code

```
METHOD get_global_authorizations.
  IF requested_authorizations-%create EQ if_abap_behv=>mk-on.
```

```

*   check create authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '01'.
    result-%create = COND #( WHEN sy-subrc = 0 THEN
    if_abap_behv=>auth-allowed ELSE
    if_abap_behv=>auth-unauthorized ).
    ENDIF.
    IF requested_authorizations-%update EQ if_abap_behv=>mk-on.
*   check update authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '02'.
    result-%update = COND #( WHEN sy-subrc = 0 THEN
    if_abap_behv=>auth-allowed ELSE
    if_abap_behv=>auth-unauthorized ).
    ENDIF.
    IF requested_authorizations-%delete EQ if_abap_behv=>mk-on.
*   check delete authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '06'.
    result-%delete = COND #( WHEN sy-subrc = 0 THEN
    if_abap_behv=>auth-allowed ELSE
    if_abap_behv=>auth-unauthorized ).
    ENDIF.
    ENDMETHOD.

```

## Results

The implemented methods provide the desired protection from unauthorized uses:

- With the implementation of the method defined with the addition `FOR GLOBAL AUTHORIZATION`, an unauthorized business user gets an error message when trying to create a business object instance (in the example, a bonus calculation) or when trying to update or delete it via service call.
- Unauthorized business users can't use the *Delete* button in the list view on the service UI. In addition, the *Edit* and *Delete* buttons are hidden in the detail view on the service UI for a business object instance.

Now, the service is secured against unauthorized operations. As a next step, you must make sure that business users who need to use the service get the corresponding authorizations.

### 4.2.7.2.3.3.2 Developing Authorizations for Business Users (Developer)

After you've protected your service against unauthorized use, you can now create the objects that are needed to grant authorizations for business users: authorization default values, an IAM app, a business catalog, and a business role.

Follow the steps for editing authorization default values and for creating an IAM app, a business catalog, and a business role template. You should define own `authorization context` in the behavior definition first, which can be used to prefill authorization defaults.

#### Note

For developing authorizations for communication users, the procedure is different. For more information, see [Developing Authorizations for Communication Users \(Developer\) \[page 799\]](#).

## 4.2.7.2.3.3.2.1 Editing Authorization Default Values

Authorization default values are automatically created when you create a service binding. You can add authorization objects and change the default authorization values.

### Context

The authorization default values are the authorizations that are assigned to business users by default if they have a business role based on the service. Note, however, that the authorization default values can be overwritten by values set in the IAM app. Therefore, if you want to avoid double maintenance, try and define the authorization default values in such a way that they can be used by all derived IAM apps.

For more information about authorization default values, see the [user guide for ABAP development tools](#).

### Procedure

1. Open the service binding and choose the [Maintain Authorization Default Values](#) link.
2. Choose [Synchronize](#) to add the latest authorization objects from the own context.

#### Note

The [Synchronize](#) function only **adds** authorization objects that are not yet part of the list of authorization objects; it does not remove objects.

3. To check or change the authorization default values that are assigned automatically, select the authorization objects in the list.

You can now specify what activities you want to authorize.

4. Choose the authorization object from the list and choose [Default With Field Values](#) from the dropdown list.

In our example, we authorize for the standard activities [Create](#), [Display](#), [Change](#), and [Delete](#) as well as the business object-specific activity [Calculate](#).

### Results

Now, the standard authorizations for the service are defined and will be applied to an IAM app based on the service. You still can change them later in the IAM app itself.

### Related Information

[Defining an IAM App for the Business Service \[page 768\]](#)

## 4.2.7.2.3.3.2 Defining an IAM App for the Business Service

To assign a business user to a business role for your service, you need to create an IAM app, which can then be included into a business catalog, which, in turn, can be assigned to a business role.

### Context

Since you want to make your service available to users with a certain business role, you need to define an IAM app for the service that you created in ADT. The IAM app is only relevant for identity and access management (IAM), and you create the IAM app in ADT. You can use an IAM app to define authorizations for one or more business services.

Instead of creating a new IAM app, you can also use an existing IAM app for the service.

For more information, see the information about IAM apps in the [user guide for ABAP development tools \(ADT\)](#).

### Procedure

To create an IAM app, follow the instructions in the user guide for ABAP development tools.

For the bonus calculation IAM app used as an example here, you have already specified before in the authorization default values what you want to authorize. If needed, you can overwrite these defaults again here.

#### 📘 Note

In this example scenario, we assume that you create only one IAM app for access using all permitted activities and their access categories (write, read, value help). Be aware at this point that in the business role Fiori app, the administrator can later separate authorizations depending on the access categories (write, read, or value help). Therefore, there's no need to develop different types of access if you just want to separate write, read, and value help.

However, it's different if you want to have different business roles for activities within one access category, for example, one for the create and update activities and another for the delete activity, which are all write activities. In this case, you must start here to separate authorizations: Create separate IAM apps, one for each write activities group that should be separated, go on with separate business catalogs, and finally enable the administrator to create separate business roles based on the business catalogs.

### 4.2.7.2.3.3.2.3 Creating a Business Catalog

To make predefined authorizations for your business service available to administrators to use, create a business catalog.

#### Context

In the business catalog, you can bundle multiple IAM apps and their predefined authorizations. You assign a business catalog to a business role. If you have more than one business catalog for the same business role, you might also consider creating a business role template.

Instead of creating a new business catalog, you can also reuse an existing business catalog for the app.

#### Procedure

To create a business catalog, follow the instructions of the ABAP development user guide: [Creating a Business Catalog](#).

Also follow the instructions to assign your IAM app to the business catalog.

### 4.2.7.2.3.3.2.4 Creating a Business Role Template (Optional)

In addition to a business catalog, you can also create a business role template with ABAP Development Tools (ADT). Creating a business role template is optional, but it can ease the business role creation for the administrator.

#### Context

Creating a business role template especially makes sense if you have more than one business catalog to assign to a business role.

#### Procedure

1. In the project explorer, right-click the package *Cloud Identity and Access Management*.
2. In the context menu, choose ► *New* ► *Business Role Template* 📄.
3. Follow the steps of the creation wizard.

4. After the business role template has been created, add the business catalog to it.
5. Choose *Publish Locally* to make the business role template available for use in the development system.

### 4.2.7.2.3.3 Creating a Business Role and Assigning Business Users (Administrator)

To be able to grant authorizations to business users, you need to create a business role that you then assign to the users.

#### Context

You can create a business role from a business role template or from scratch.

Perform this task in every system. Alternatively, you can also create a business role once, download it, and upload it to other systems.

#### Procedure

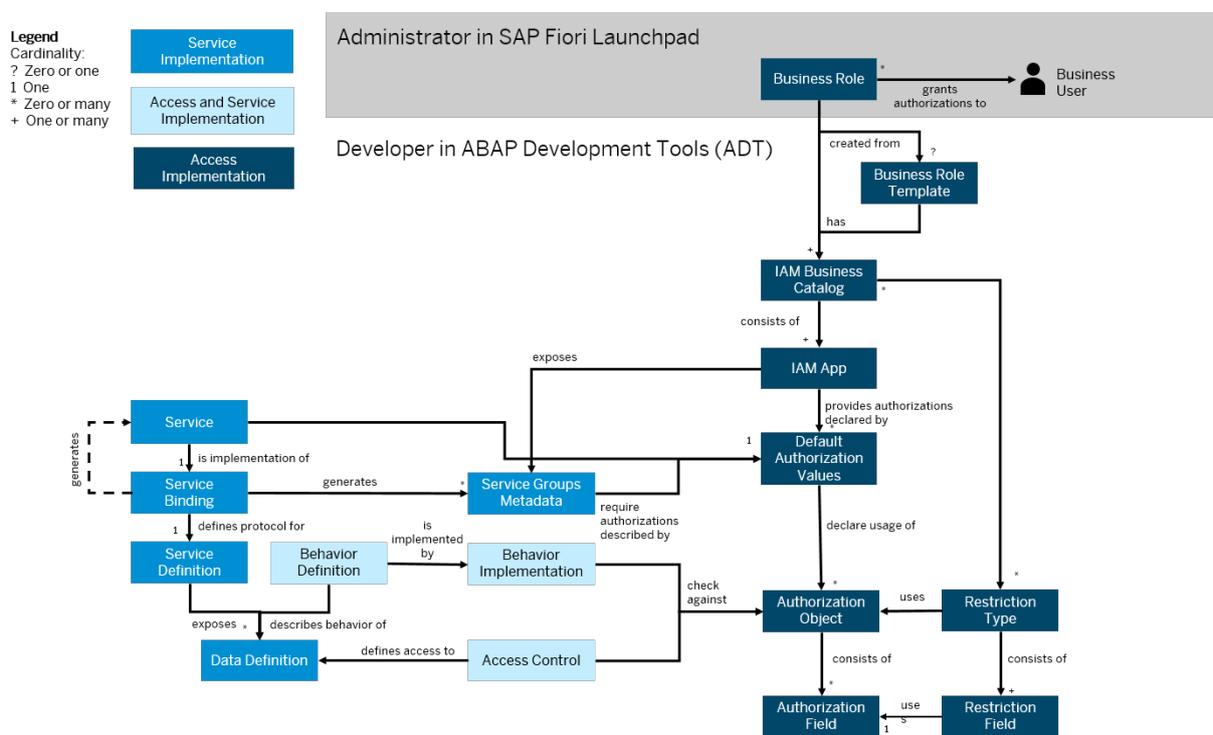

1. To create a business role, proceed as follows:
  - To create a business role from scratch and assign business users, follow the instructions in [How to Create a Business Role from Scratch](#).
  - To create a business role from a business role template and assign business users, follow the instructions in [How to Create a Business Role from a Template](#).
2. For roles with write access, set unrestricted write authorization. For read-only roles, leave the write restrictions as they are (the default is no access).

For more information about restrictions, see [How to Maintain Restrictions](#).

## 4.2.7.2.3.4 Providing Access Based on Field Values for Business Users

You can enable access to a service in such a way that it's dependent on the field values of a business object. As a result, business users can view or change only business object instances where the field values match their authorizations.

### Overview

The central concept in this scenario is the restriction field: In a restriction field, you can expose an existing authorization field as a restrictable field in a business role. You first create an authorization object and implement an access control and authority checks in the behavior implementation to protect your service from unauthorized use. Then you create an IAM app and a business catalog to make it available to administrators, who want to include the service (or, rather, the corresponding business catalog) into a business role. With the restriction field, you as a developer, can define which authorization fields should be available for the administrator during business role maintenance. Administrators can then decide which values of the restriction fields are relevant for some business roles. In the example of the bonus calculation service, administrators can create business roles to restrict the access for bonus calculations to selected bonus variants only.

## Process

To create access protection and provide authorizations, you perform the following steps:

### Protecting the Service from Unauthorized Use

As a developer, you perform the following steps in ABAP Development Tools (ADT):

1. Create an authorization field. For example, create an authorization field `ZBNS_VARN` for the bonus variant.
2. Create an authorization object with the standard authorization field `ACTVT` and other authorization fields if needed, for example, bonus variant.
3. Implement an access control as a read protection for the service.
4. Model authority checks in the behavior definition of the service.
5. Implement authority checks in the behavior implementation of the service to allow create, update, and delete activities only to users who have the authorizations of the authorization object.

As a result, no user can access the service to display bonus calculations or create, update, or delete bonus calculations anymore.

### Developing Authorizations for the Service

As a developer, you perform the following steps in ADT:

1. Add the required authorization objects to the list of default authorization values.
2. Create an IAM app and assign the service binding to it.
3. For each authorization field that you want to expose and consider in a business role, create a corresponding restriction field.
4. Assign the restriction fields to a restriction type.
5. Create a business catalog and assign the IAM app to it. Add the restriction types to the business catalog.
6. Optional: Create a business role template and assign the catalog to it.

Now, administrators can start granting access to business users. Development is finished and testing can start.

### Granting Authorizations to Business Users

As an administrator in the ABAP environment, you can now grant authorizations to business users for this service:

1. Create business roles and assign them to business users.  
For each business role, set the access category *Write* to restricted. Select the values for which you want to authorize the users. For example, create a business role with the authorization to create, update, and delete only bonus calculations that are based on specific bonus variants.

As a result, business users with the business role assigned can access the service to display bonus calculations or create, update, or delete bonus calculations again.

## 4.2.7.2.3.4.1 Protecting the Service (Developer)

With creating authorization fields and an authorization object for your service and with the implementation of a protection against unauthorized read and creation, you can implement a protection of your service against unauthorized use on field level.

After this, you can implement authorizations on field level that can be granted to business users.

### 4.2.7.2.3.4.1.1 Creating a Check Table for Authorization Fields

Create a check table that you can provide to the administrator as value help during business role maintenance.

#### Context

The advantage of having a check table is that the administrator has a value help when maintaining business roles with restricted access. As a developer, you provide access to a table where the field values are stored. When administrators create business roles and assign them to business users, they can call up the check table in the format of a value help and select the relevant values from the table.

In the bonus calculation example, the check table contains the bonus variants.

#### Procedure

1. In ABAP Development Tools, in the project explorer, right-click on the relevant package node.
2. In the context menu, choose ► *New* ► *Other ABAP Repository Object* ▾.
3. In the following popup, choose ► *Core Data Services* ► *Data Definition* ▾ and *Next*.
4. Enter a name, description, and, as referenced object, enter the table where the values are stored that you want to provide for the administrator. In the bonus calculation example, this table is the table where the bonus variants are stored for the app. Choose *Next*.
5. Select a transport request and choose *Next*.
6. From the list of templates, choose *Define View* and choose *Finish*.
7. In the coding, choose the fields that you need to expose.

For the CDS view, it's sufficient that you use only those fields that are needed for a field help.

8. To provide some UI texts for the field help, add `@EndUserText . label1` with a good label for each field that is exposed as part of the CDS view. The labels will be displayed as column headings in the field help of the business role maintenance.
9. Make sure that the annotation `@AbapCatalog . sqlViewName` is added at the beginning of the CDS view code.

For example, the code of such a CDS view can look as follows:

#### Sample Code

```
@AbapCatalog.sqlViewName: 'ZVARCHHECK'
@AbapCatalog.compiler.compareFilter: true
@AbapCatalog.preserveKey: true
@AccessControl.authorizationCheck: #CHECK
@EndUserText.label: 'Check Table for bonus variants'
define view Z_VARIANTS_CHECK_TABLE as select from zbonusvar {
  @EndUserText.label: 'Bonus Variant'
  key variant as BonusVariant,

  @EndUserText.label: 'Category'
  category as Category,

  @EndUserText.label: 'Description'
  description as Description,

  @EndUserText.label: 'Created By'
  createdby as Createdby,

  @EndUserText.label: 'Created At'
  createdat as Createdat
}
```

10. Copy the SQL view name from `@AbapCatalog.sqlViewName` for later use (see [Defining an Authorization Field \[page 774\]](#)).

## 4.2.7.2.3.4.1.2 Defining an Authorization Field

As in the scenario for granting access based on activities, you define an authorization object. However, for this scenario, you first define authorization fields to fine-tune access on field level.

### Context

In the following, we assume that the bonus calculation service has a bonus variant field of type domain. You create an authorization field based on this data element.

### Procedure

1. To create an authorization field `ZBNS_VARN` for the bonus variant, following the procedure for defining authorization fields in the [user guide for ABAP development tools \(ADT\)](#).
2. In the *Data Element* field, enter the data element for the bonus variant.
3. In the *Check Table* field, enter the SQL view name that you have created as a check table for all possible bonus variants (see [Creating a Check Table for Authorization Fields \[page 773\]](#)).

#### Note

You can use the [Search Help](#) button to simulate the field help as it's shown to the administrator during the business role maintenance.

### 4.2.7.2.3.4.1.3 Defining an Authorization Object

As in the scenario for granting access based on activities, you define an authorization object. However, for this scenario, you also add the authorization field `ZBNS_VARN` for the bonus variant.

#### Procedure

Follow the instructions for defining authorization objects in the [user guide for ABAP development tools](#) (ADT).

#### → Tip

In our example, in the newly created authorization object, under *Authorization Fields*, you need the following:

- You need the predefined *Activity (ACTVT)* authorization field to define the permitted activities for the business users of your business service: *01 Add or Create*, *02 Change*, *03 Display*, and *06 Delete* as standard activities.
- If you have non-standard activities such as *Calculate Bonus* that you need to protect (and to permit later), check the list of existing values. If you click on an empty row and choose , the list of available values is shown. For the bonus calculation example, let's choose *93 Calculate* for the business object-specific activity *Calculate Bonus*.
- You need the newly created authorization field `ZBNS_VARN` for the bonus variant.

### 4.2.7.2.3.4.1.4 Implementing a Read Protection

Prevent unauthorized read access to the data exposed by your service using access control. For this purpose, you create an access control and then implement it for the CDS view on which your service is based.

## Defining the Use of Access Control in the Data Definition

#### Context

For the data definitions that you want to protect, you need to define the use of access control.

### Note

If you're using additional data definitions of type projection view, you need to define the use of an access control in them.

## Procedure

1. Add the following line to the data definition of the interface:

```
@AccessControl.authorizationCheck: #CHECK
```

For more information, see [Access Control Annotations](#) in the documentation of the ABAP RESTful Application Programming Model.

2. If you're using additional data definitions of type projection view, you also need to define the use of an access control in them.

## Creating an Access Control

### Context

Even if you have modeled necessary authorizations for your service by creating a new authorization object, the authorization object itself doesn't protect your service from being accessed by a business user in the ABAP environment. Therefore, as a next step, you implement a read protection for your service. In our example, this means that business users should only be allowed to view bonus calculations whose bonus variant matches with the users' authorization. You implement a read protection using access control, which uses the authorization object that you created.

### Procedure

1. Go to the core data service (CDS) view on which your service is based.

You can find this CDS view under the data definitions of the core data services of your package.

2. To create an access control for the CDS view, follow the instructions of the ABAP CDS Development User Guide: [Creating Access Controls](#) and use the template *Define Role with PFCG Aspect*.
3. If you're using additional data definitions of type projection view, you also need to create additional access controls for them using the template *Define Role with Inherited Conditions*.

# Implementing the Access Control

## Context

You must edit the access control code to implement access control for the CDS view on which your service is based. Access control is based on the authorization object that you created before.

## Procedure

1. Choose the access control that you've created, which currently looks like the following:

### Sample Code

```
@EndUserText.label: '<your access control description>'
@MappingRole: true
define role <your access control name> {
    grant
        select
            on
                ${cds_entity}
            where
                (${entity_element_1}, ${entity_element_2}) =
aspect pfcg_auth(${authorization_object}, ${authorization_field_1}, ${
authorization_field_2}, ${filter_field_1} = '${filter_value_1}');
}
```

2. Adapt the code so that it grants access if the requesting business user has authorizations that contain authorization object ZBNSCLC\_AO (*Bonus Calculation*) with allowed activity (ACTVT) *03 Display* and bonus variant (ZBNS\_VARNT) values that match the bonus variant (bonusvariant) of the existing bonus calculation:

### Sample Code

```
@EndUserText.label: 'Access Control for CDS Z_I_BONUS_CALCULATION'
@MappingRole: true
define role Z_I_BONUS_CALCULATION {
    grant
        select
            on
                z_i_bonus_calculation
            where
                (bonusvariant) = aspect pfcg_auth(ZBNSCLC_AO,
ZBNS_VARNT, ACTVT = '03');
}
```

In our example, `cds_entity` is the `z_i_bonus_calculation` CDS view.

3. If you're using additional data definitions of type projection view, enhance the coding as follows:

### Sample Code

```
@EndUserText.label: '<your access control description>'
@MappingRole: true
```

```

define role <your access control name> {
  grant
    select
      on
        <your projection view name>
      where
        inheriting conditions from entity
z_i_bonus_calculation;
}

```

## Results

As a result, only business users with the corresponding authorizations get bonus calculations from the service, and they only get bonus calculations with allowed bonus variant values.

### 4.2.7.2.3.4.1.5 Modeling a Protection Against Unauthorized Write Activities

To protect your service from activities such as create, update or delete by unauthorized business users, you can use the authorization controls that are available for services based on managed business objects.

## Context

In the example used here, the service is based on a managed business object *Bonus Calculation*. The use of a managed business object allows you to benefit from the global and instance-based authorizations for managed business objects, which are part of the ABAP RESTful Application Programming model. For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

## Procedure

1. In ABAP development tools, call up the behavior definition of your service.
2. In the behavior definition, define authorization controls for your service.

In the bonus calculation example, they can look as follows:

### Sample Code

```

managed;
define own authorization context
{
  'ZBNSCLC_AO';
}
define behavior for z_i_bonus_calculation alias calculation

```

```

implementation in class zbp_bonus_calculation unique
persistent table zbonusclc
lock master
// Identity and Access Management:
// Enable RAP managed authorization check at create, update, and delete
// -> requires implementation of two methods, one with the addition "FOR
INSTANCE AUTHORIZATION"
// and one with the addition "FOR GLOBAL AUTHORIZATION"
authorization master ( instance, global )

```

With the line `authorization master ( instance, global )`, an authorization check for the standard operations `create`, `update`, and `delete` and for non-standard operations, for example, `calculate bonus`, is defined. You must implement the authorization check using methods with addition `FOR GLOBAL AUTHORIZATION` (for `create`) and `FOR INSTANCE AUTHORIZATION` (for `update`, `delete`) in the behavior implementation.

The sample code also contains the definition of your own authorization context. The own authorization context documents all authorization objects that are used by the business object implementation. In the bonus calculation example used in this documentation, this is the authorization object `ZBNSCLC_AO` because it's checked in the RAP authorization control and the CDS access control. The own authorization context can also be used to prefill authorization defaults.

## 4.2.7.2.3.4.1.6 Implementing a Protection Against Unauthorized Write Activities

To protect a service, such as the example of bonus calculation from unauthorized creations, updates, or deletions, enhance the behavior implementation of the service in ABAP development tools (ADT). The implementation is required by what has been defined as authorization control in the behavior definition.

### Context

Among the methods of the behavior implementation, you add methods that check the authorizations for creation and for update and delete.

For more information about authorization control, see see the documentation for the [ABAP RESTful Application Programming Model](#).

### Procedure

1. In the *Source Code Library* folder of your package, under *Classes*, choose the behavior implementation of your service.
2. In the `PRIVATE` SECTION in the handler class of the behavior implementation, define the method for authorization checks for update and deletion:

### Sample Code

```
METHODS get_instance_authorizations FOR INSTANCE AUTHORIZATION
  IMPORTING it_entity_keys REQUEST requested_authorizations FOR
  <behavior definition or its alias> RESULT result.
```

In the bonus calculation example, this method definition can look as follows:

### Sample Code

```
METHODS get_instance_authorizations FOR INSTANCE AUTHORIZATION
  IMPORTING keys REQUEST requested_authorizations FOR calculation RESULT
  result.
```

3. In the PRIVATE SECTION in the handler class of the behavior implementation, also define the method for authorization checks for creation:

### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR <behavior definition or
  its alias> RESULT result.
```

In the bonus calculation example, this method definition can look as follows:

### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR calculation RESULT
  result.
```

4. Add a method implementation that checks the authorizations for updates and deletions.

In the bonus calculation example, this method can look like this:

### Sample Code

```
METHOD get_instance_authorizations.
*   As import table contains only keys, we need to get complete bonus
calculation data for bonus variant value
  READ ENTITIES OF z_i_bonus_calculation IN LOCAL MODE
    ENTITY calculation
      ALL FIELDS
      WITH CORRESPONDING #( it_bonus_calc_keys )
      RESULT DATA(lt_bonus_calcs).
*   fill result list with authorizations per bonus calculation
  LOOP AT lt_bonus_calcs INTO DATA(ls_bonus_calc).
*   check update authorization for bonus calculation, incl. bonus
variant dependency
  AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '02' ID
  'ZBNS_VARIANT' FIELD ls_bonus_calc-bonusvariant.
*   set variable for update authorization
  DATA(lv_update_allowed) = COND #( WHEN sy-subrc = 0 THEN
if_abap_behv=>auth-allowed ELSE if_abap_behv=>auth-unauthorized ).
*   check calculate bonus authorization for bonus calculation, incl.
bonus variant dependency
  AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '93' ID
  'ZBNS_VARIANT' FIELD ls_bonus_calc-bonusvariant.
*   set variable for calculate bonus authorization
```

```

        DATA(lv_calculate_bonus_allowed) = COND #( WHEN sy-subrc = 0 THEN
if_abap_behv=>auth-allowed ELSE if_abap_behv=>auth-unauthorized ).
*      check delete authorization for bonus calculation, incl. bonus
variant dependency
        AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '06' ID
'ZBNS_VARIANT' FIELD ls_bonus_calc-bonusvariant.
*      set variable for delete authorization
        DATA(lv_delete_allowed) = COND #( WHEN sy-subrc = 0 THEN
if_abap_behv=>auth-allowed ELSE if_abap_behv=>auth-unauthorized ).
*      fill result list
        APPEND VALUE #( id = ls_bonus_calc-id %update = lv_update_allowed
%delete = lv_delete_allowed ) TO result.
    ENDMETHOD.
ENDMETHOD.

```

5. Add a method that checks the authorizations for creation.

In the bonus calculation example, such a method could look like this:

### Sample Code

```

METHOD get_global_authorizations.

    IF requested_authorizations-%create EQ if_abap_behv=>mk-on.
*      check create authorization
        AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '01'.
        result-%create = COND #( WHEN sy-subrc = 0 THEN
if_abap_behv=>auth-allowed ELSE
if_abap_behv=>auth-unauthorized ).
    ENDIF.
ENDMETHOD.

```

## Results

The implemented methods provide the desired protection from unauthorized uses:

- With the implementation of the method `get_instance_authorizations`, an unauthorized business user gets an error message when trying to update or delete a business object instance (in the example, a bonus calculation) via service call.
- With the implementation of the method `get_global_authorizations`, an unauthorized business user gets an error message when trying to save the creation of a new business object instance.
- Unauthorized business users can't use the [Delete](#) button in the list view on the service UI. In addition, the [Edit](#) and [Delete](#) buttons are hidden in the detail view on the service UI for a business object instance.

Now, the service is secured against unauthorized operations. As a next step, you must make sure that business users who need to use service get the corresponding authorizations.

## 4.2.7.2.3.4.2 Developing Authorizations (Developer)

After you've protected your service against unauthorized use, you create the objects that are needed for granting authorizations to business users to use your service.

For granting authorizations, follow the steps for restriction fields and types and for creating an IAM app, a business catalog, and a business role template. You should define your own authorization context in the behavior definition first, which can be used to prefill authorization defaults.

### 4.2.7.2.3.4.2.1 Editing Authorization Default Values

Authorization default values are automatically created when you create a service binding. You can add authorization objects and change the authorization default values.

#### Context

The authorization default values are the authorizations that are assigned to business users by default if they have a business role based on the service. Note, however, that the authorization default values can be overwritten by values set in the IAM app or by restrictions in the business role. Therefore, if you want to avoid double maintenance, try and define the authorization default values in such a way that they can be used by all derived IAM apps.

For more information about authorization default values, see the [user guide for ABAP development tools \(ADT\)](#).

#### Procedure

1. Open the service binding and choose the [Maintain Authorization Default Values](#) link.
2. Choose [Synchronize](#) to add the latest authorization objects from the own context.

##### Note

The [Synchronize](#) function only **adds** authorization objects that are not yet part of the list of authorization objects; it does not remove objects.

3. To check or change the authorization default values that are assigned automatically, select the authorization objects in the list.

An authorization object that is used in the read-protecting access control automatically gets the settings [Default with Field Values](#) and the required activity value for [Display](#). Other authorization objects get [Default Without Field Values](#).

4. For the bonus calculation, you can now specify what you want to authorize, which are, in the example used here, the standard activities [Create](#), [Change](#), and [Delete](#) as well as the business object-specific activity [Calculate](#).

## Results

Now, the standard authorizations for the service are defined and will be applied to an IAM app based on the service. You still can change them later in the IAM app itself or delegate the value definition to the administrator during business role maintenance (only if restrictions are used).

## Related Information

[Defining an IAM App for the Business Service \[page 768\]](#)

[Creating Restriction Fields Based on Authorization Fields \[page 784\]](#)

### 4.2.7.2.3.4.2.2 Defining an IAM App for the Business Service

To assign a business user to a business role for your service, you need to create an IAM app, which can then be included into a business catalog, which, in turn, can be assigned to a business role.

## Context

Since you want to make your service available to users with a certain business role, you need to define an IAM app for the service that you created in ADT. The IAM app is only relevant for identity and access management (IAM), and you create the IAM app in ADT. You can use an IAM app to define authorizations for one or more business services.

Instead of creating a new IAM app, you can also use an existing IAM app for the service.

For more information, see the information about IAM apps in the [user guide for ABAP development tools \(ADT\)](#).

## Procedure

To create an IAM app, follow the instructions in the user guide for ABAP development tools.

For the bonus calculation IAM app used as an example here, you have already specified before in the authorization default values what you want to authorize. If needed, you can overwrite these defaults again here.

### Note

In this example scenario, we assume that you create only one IAM app for access using all permitted activities and their access categories (write, read, value help). Be aware at this point that in the business role Fiori app, the administrator can later separate authorizations depending on the access categories

(write, read, or value help). Therefore, there's no need to develop different types of access if you just want to separate write, read, and value help.

However, it's different if you want to have different business roles for activities within one access category, for example, one for the create and update activities and another for the delete activity, which are all write activities. In this case, you must start here to separate authorizations: Create separate IAM apps, one for each write activities group that should be separated, go on with separate business catalogs, and finally enable the administrator to create separate business roles based on the business catalogs.

### 4.2.7.2.3.4.2.3 Creating Restriction Fields Based on Authorization Fields

For each authorization field that you want to expose and consider in a business role, you must create a corresponding restriction field and assign it to a restriction type.

#### Context

In the example used here, create a restriction field for the bonus variant field.

#### Procedure

For the procedure, see the ABAP development user guide: [Defining Restriction Fields](#).

### 4.2.7.2.3.4.2.4 Creating Restriction Types

Create a restriction type containing a restriction field and authorization object.

#### Context

Restriction types bundle restriction fields. In the example used here, there's one restriction type for the bonus calculation.

## Procedure

For the procedure, see the ABAP development user guide: [Defining Restriction Types](#).

### 4.2.7.2.3.4.2.5 Creating a Business Catalog with Restriction Types

Create a business catalog and add the restriction types to it.

## Context

In the business catalog, you can bundle multiple IAM apps and their predefined authorizations. You assign a business catalog to a business role. If you have more than one business catalog for the same business role, you might also consider creating a business role template.

In the business catalog, you can also define for which fields and access categories an administrator can maintain restriction values during business role maintenance.

Instead of creating a new business catalog, you can also reuse an existing business catalog for the app.

## Procedure

1. Create a business catalog and assign the IAM app to it.

For more information about creating business catalogs, see [Creating a Business Catalog](#) in the ABAP development user guide.

2. On the *Restriction Type* tab, enter the restriction type that you created.

In our example, add the restriction type *Bonus Calculation*.

3. For each field, choose the appropriate checkboxes for write access, read access, and value help (F4).

#### Note

Even if you defined fewer values for the authorization field on which the restriction field is based in the IAM app (for example, one bonus variant only), the checkboxes here enable the administrator to allow all bonus variants again during business role maintenance.

4. Save the business catalog and publish it locally.

## 4.2.7.2.3.4.2.6 Creating a Business Role Template (Optional)

In addition to a business catalog, you can also create a business role template with ABAP Development Tools (ADT). Creating a business role template is optional, but it can ease the business role creation for the administrator.

### Context

Creating a business role template especially makes sense if you have more than one business catalog to assign to a business role.

### Procedure

1. In the project explorer, right-click the package *Cloud Identity and Access Management*.
2. In the context menu, choose ► *New* ► *Business Role Template* ▾.
3. Follow the steps of the creation wizard.
4. After the business role template has been created, add the business catalog to it.
5. Choose *Publish Locally* to make the business role template available for use in the development system.

## 4.2.7.2.3.4.3 Granting Authorizations to Business Users (Administrator)

As an administrator, create business roles to grant authorizations to business users.

After a business catalog and optionally a business role template have been created by the developer, administrators take over. They grant authorizations to business users by creating and assigning business roles. The business role needs to contain the business catalog created by the developer to get all the predefined authorizations needed for the business service. If a business role template is available, the administrator can also use the business role template to create a new business role.

## 4.2.7.2.3.4.3.1 Creating a Business Role with Restrictions and Assigning It to Users

You can create a new business role where you can benefit from the predefined values and restrictions that were defined before.

### Context

The default is always no write access and unrestricted read access. You can have dedicated business roles that use these default settings. In the bonus calculation example, you can create multiple roles for changing only bonus calculation instances of a bonus variant.

For more information about maintaining restrictions, see [How to Maintain Restrictions](#).

Perform this task in every system. Alternatively, you can also create a business role once, download it, and upload it to other systems.

### Procedure

1. Create a business role from scratch or from a business role template, add the business catalog with the restrictions that the developer has created for the service.
2. Choose [Maintain Restrictions](#).
3. On the [Write, Read, Value Help](#) tab page, choose [Restricted](#).

The available restriction types and their fields are now shown, which is, in our example, the bonus calculation and its bonus variant.

4. Choose the edit button next to the restriction type.

In the following popup, the list of available values from the restriction field is shown.

5. Select the values for which you want to authorize the users.

In our example, the value would be one or multiple bonus variants that have been saved to the check table that the developer has assigned to the authorization field for the bonus variant (see [Defining an Authorization Field \[page 774\]](#)). As a result, business users with the business role assigned can create, update, and delete bonus calculations with the selected bonus variants only.

6. On the [Read, Value Help](#) tab page, choose [Unrestricted](#).

This means that business users with this business role can still view all bonus calculations independently of their bonus variant, even if they can only change bonus calculations with a particular bonus variant.

7. On the [Assigned Business Users](#) tab, assign the business users to your new business role

These business users get the authorizations as defined in the business role.

8. Save the business role to activate it.

## 4.2.7.2.4 Providing Access to the SAP Fiori Application

Learn what developers and administrators need to do so that an SAP Fiori application appears in the SAP Fiori launchpad of an authorized business user.

### Overview

For business services created in ABAP Development Tools, developers can also create SAP Fiori application UIs. Let's assume that they created UIs using, for example, SAP Business Application Studio or Visual Studio Code and deployed them back to the ABAP environment. To ensure that business users have access to the SAP Fiori application in their SAP Fiori launchpad, developers and administrators need to perform a few steps.

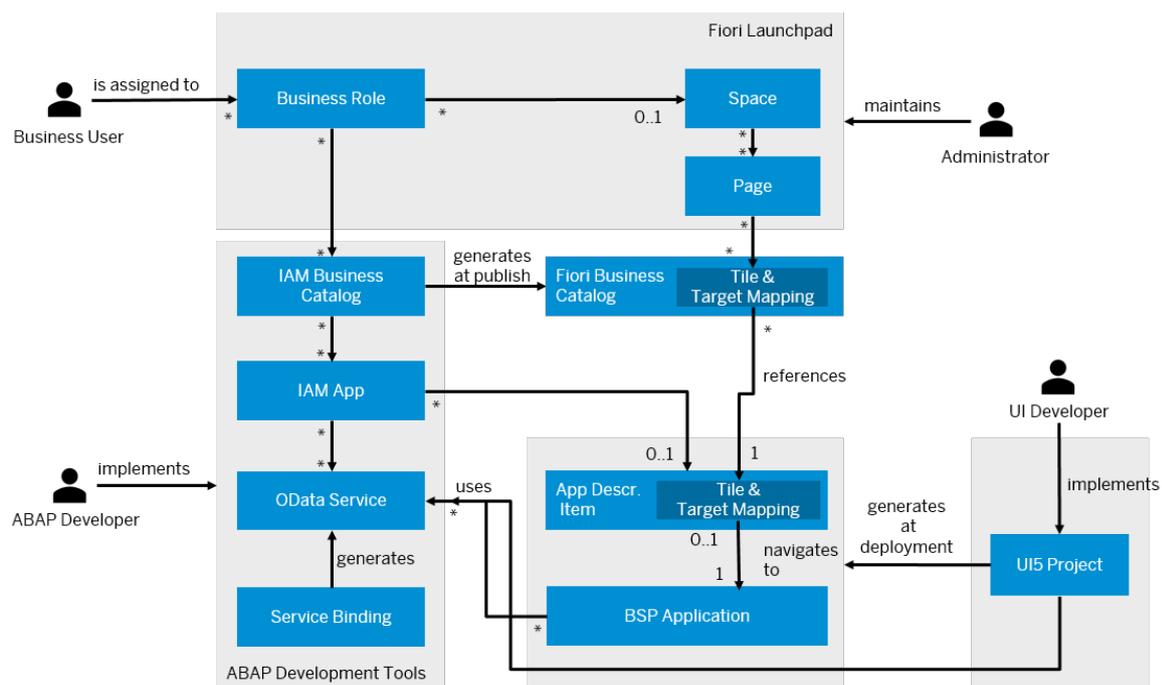

When you deploy an SAP Fiori application to the ABAP environment, the following objects, among others, are created automatically:

- A business server page (BSP) application, which stores the code of the SAP Fiori application
- An SAP Fiori launchpad app descriptor item, which contains the tile and navigation target for the SAP Fiori launchpad integration  
The SAP Fiori launchpad app descriptor item is created from the `manifest.json` file of the UI5 app, where the tile and navigation parameters are configured.

You can find the BSP application and the SAP Fiori launchpad app descriptor item as objects in your deployment package in ABAP Development Tools.

After an SAP Fiori application has been deployed, it can't be immediately consumed in the SAP Fiori launchpad. You have already created an IAM app and added the business service for which you've created your UI to the IAM app. You must now also assign the automatically created SAP Fiori launchpad app descriptor item to this IAM app.

As an administrator, you must create and enable an SAP Fiori launchpad space and page for business users.

This guide outlines the steps that are needed after you've followed the procedures outlined in one of the scenarios *Providing (Unrestricted) Access*, *Providing Access Based on Activities*, or *Providing Access Based on Field Values*. For a general overview of all steps for developing an SAP Fiori application UI in the ABAP environment, see [Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#).

## Tutorial

In addition to this documentation, the following tutorial is available:

[Integrate List Report into ABAP Fiori Launchpad](#) 

### 4.2.7.2.4.1 Assign the SAP Fiori Application to the IAM App (Developer)

To ensure consistent authorizations for the business service and its UI, you need to assign the SAP Fiori launchpad app descriptor item and the business service to the same IAM app.

## Context

After an SAP Fiori application has been deployed, it can't be immediately consumed in the SAP Fiori launchpad. You have already created an IAM app and added your business service to it. You must now also assign the SAP Fiori launchpad app descriptor item, which was automatically created during deployment, to this IAM app.

You can find the SAP Fiori launchpad app descriptor item as an object in ABAP Development Tools in the package to which you deployed the SAP Fiori application.

## Procedure

1. In ABAP Development Tools, open your IAM app.
2. In the *UI5 Application ID* field, enter the technical name of the SAP Fiori launchpad app descriptor item or use the field value help.
3. Save and publish locally.

## Results

If you haven't already done so, assign the IAM app to an IAM business catalog, and publish the IAM business catalog in ABAP Development Tools. Publishing generates a corresponding SAP Fiori business catalog that is listed in the SAP Fiori launchpad app [Business Catalogs](#).

### 4.2.7.2.4.2 Integrating the SAP Fiori Application into the SAP Fiori Launchpad (Administrator)

To ensure that an SAP Fiori application appears in the SAP Fiori launchpad of the business users, you, as an administrator, need to perform a few configuration steps.

## Prerequisites

You, as an administrator, have already created one or multiple business roles and assigned them to business users.

## Context

You must integrate the SAP Fiori app into the IAM structure of the SAP Fiori launchpad of SAP Business Technology Platform.

## Procedure

1. Create a space for the business role.
2. Add a page to this space and add the app tile to the page.

For more information about how to proceed, see [Create a New Space and Page for a Business Role](#) in the SAP Fiori launchpad documentation on SAP Help Portal.

## Results

You've now enhanced the business roles for the business service with authorizations for the UI. All users that have been assigned to the business roles before can now view the page and SAP Fiori application in their SAP Fiori launchpad.

### Note

The SAP Fiori application only appears in the spaces mode for the user. The spaces mode was developed to offer more flexibility to influence the launchpad layout for specific user groups. The business role defines which users see a specific space. For more information, see [Managing Launchpad Spaces and Pages](#) on SAP Help Portal.

## 4.2.7.2.5 Providing Access to a Business Service for Communication Users

For a newly created business service, you must define how communication users can access it and which activities are allowed.

Instead of accessing a business service using a business user, it is also possible to access a business service using a communication user. Communication users are relevant in scenarios where you work with an API business service (inbound or outbound) from or into the ABAP environment.

For communication users, you must provide access to a newly created service because access isn't automatically available. However, on instance level, all activities are allowed as long as you don't protect your business service. Therefore, you must develop identity and access management artifacts.

The main difference to providing access to a business user is that, as a developer, you do not create an IAM app and a business catalog but a communication scenario. Authorizations are maintained in the communication scenario. Administrators cannot restrict the authorizations defined in the communication scenario later on when they create communication arrangements based on the communication scenario. Therefore, you as a developer decide which authorizations are granted for the communication user by the administrator.

### Overview of Development Options

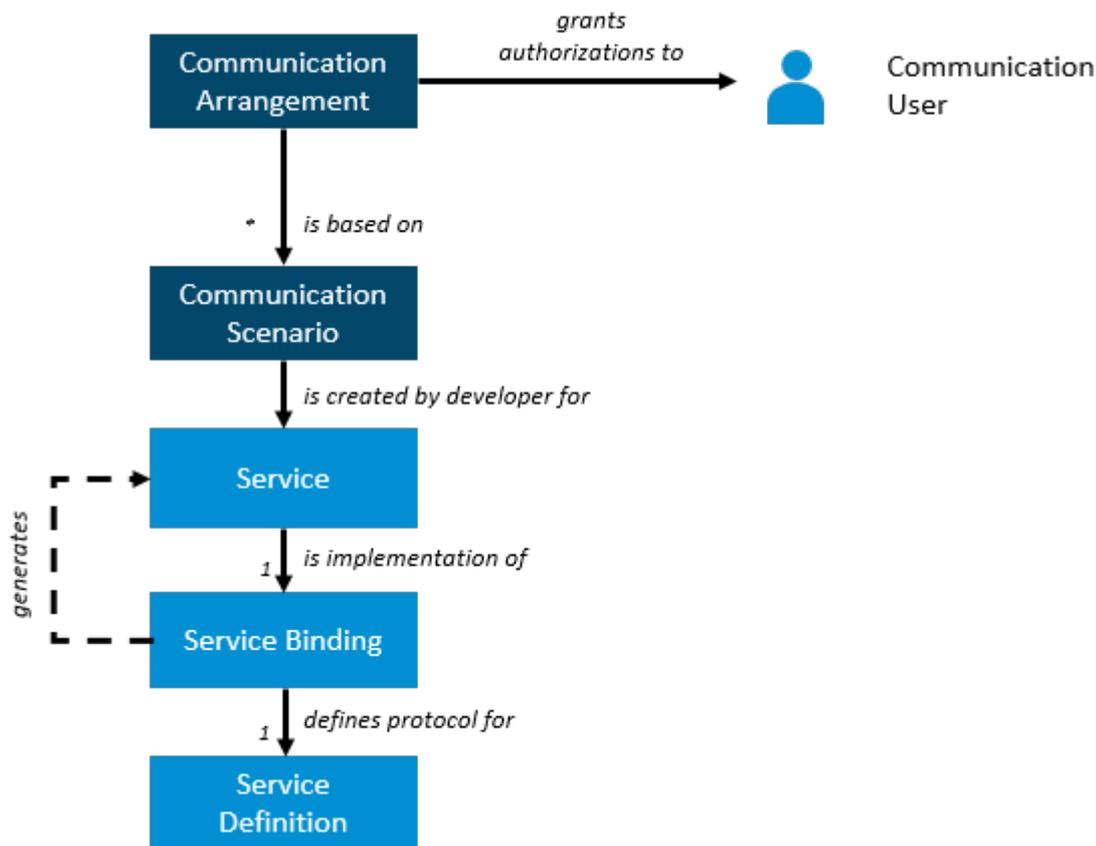

You can provide access the following ways:

- Unrestricted access
- Access based on activities from an authorization object

#### 4.2.7.2.5.1 Granting (Unrestricted) Access for Communication Users

In this scenario, you get information about how to grant unrestricted access for communication users with a few steps.

In this scenario, to provide access to the business service, you must create a communication scenario. Administrators then create a communication arrangement based on this communication scenario. Note that all objects that need to be created are highlighted in dark blue in the graphic.

This scenario requires only a few steps to grant authorizations, and it's the minimum that you must do to make your service available to communication users. However, with this scenario, you always grant unrestricted write **and** read access. If you want to fine-tune the authorizations in more detail, check the scenario *Granting Access Based on Activities*.

#### 4.2.7.2.5.1.1 Creating a Communication Scenario for Unrestricted Access (Developer)

In ABAP Development Tools, you can define communication scenarios, which can be used to access business services using a technical communication user.

### Context

In ABAP Development Tools, you define a communication scenario and add the required services to the scenario. An administrator can then use this communication scenario and create a communication arrangement based on it. This communication arrangement is the basis for accessing the business service using a communication user. If you don't include an authorization object to the communication scenario, the communication user will have unrestricted access to the business service.

For more information, see the information about consuming services in the context of APIs in the [user guide for ABAP development tools \(ADT\)](#).

## Procedure

1. Choose the relevant package in the project explorer.
2. Right-click to open the context menu and choose ► *New* ► *Other* ► *ABAP Repository Object* ► to launch the creation wizard.
3. Choose ► *Communication Management* ► *Communication Scenario* ► and choose *Next*.
4. Enter a name and a description and choose *Next*.
5. Choose *Finish* to create a transport request.
6. On the *Inbound* or the *Outbound* tab, add your inbound or an outbound business service to the communication scenario.
7. If you want to test your communication scenario directly in the development system, publish it locally to make sure that the required services have been generated.

## Related Information

[Communication Management \[page 846\]](#)

### 4.2.7.2.5.1.2 Creating a Communication Arrangement (Administrator)

To grant authorizations to a communication user, as administrator, you create a communication arrangement. In this example, the communication arrangement is based on the communication scenario created by the developer.

## Prerequisites

You have created a communication user that is used for data exchange with other systems. To create a communication user, you use the [Maintain Communication Users](#) app on the SAP Fiori launchpad (see also [How to Create Communication Users](#)).

You have created a communication system, which represents the communication partner within a communication. To create a communication system, you use the [Maintain Communication Systems](#) app (see also [How to Create Communication Systems](#)).

## Procedure

1. Open the SAP Fiori Launchpad.
2. Choose *Communication Arrangements*.
3. Create a new communication arrangement based on the communication scenario, using the communication user and system that you have already created.

For more information, see [How to Create a Communication Arrangement](#).

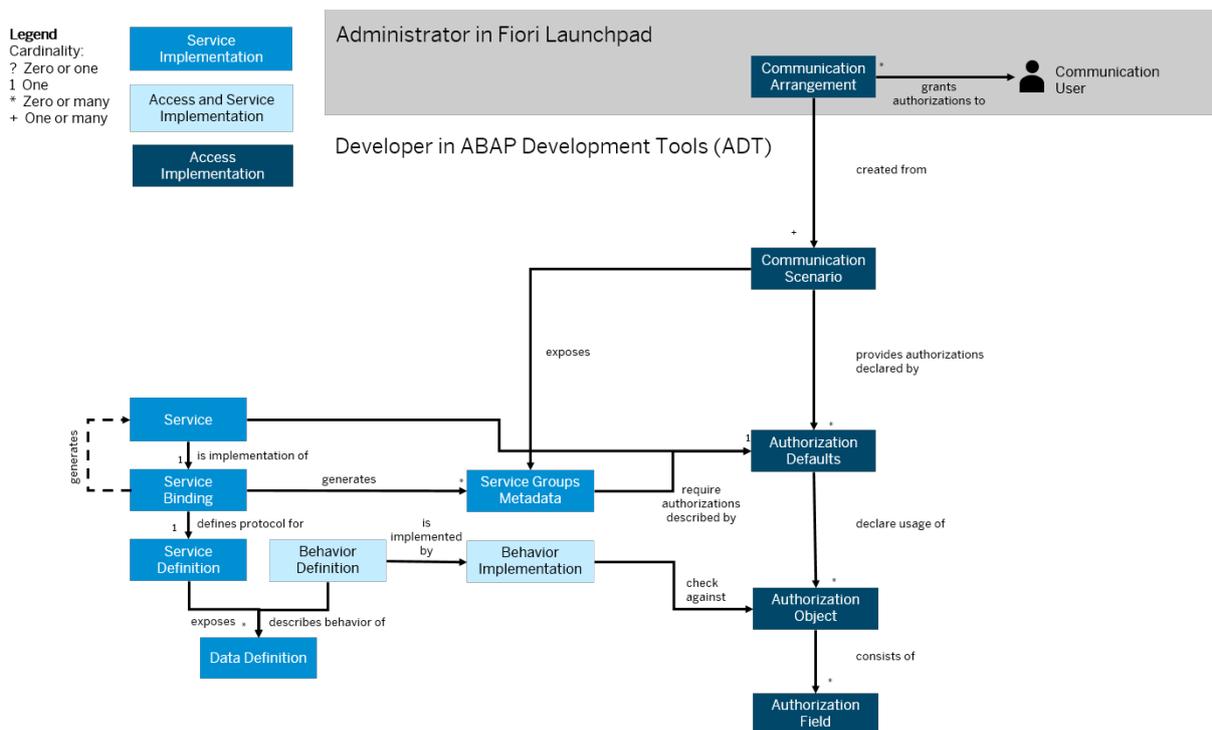

## Results

The communication user in the communication arrangement gets the authorizations that have been defined as part of the communication scenario by the developer. In the example of unrestricted access, no authorization object or fields have been defined, so the communication user gets full access to the business service.

### 4.2.7.2.5.2 Granting Access Based on Activities for Communication Users

In this scenario, you grant access depending on what the communication user should be allowed to do, for example, read or write access.

This scenario is more complex than a simple unrestricted access grant because you also need to create an authorization object and implement authority checks in the behavior implementation.

In this documentation, you get a more detailed overview of how to implement a separate read and write access. You can achieve such a separation by creating an authorization object with the standard authorization field for activities, an authority check to protect the service, and a communication scenario with authorization fields and activities defined. The administrator can then create two communication arrangements for read and write access each, for example.

## 4.2.7.2.5.2.1 Protecting the Service (Developer)

With creating an authorization object for your service and with the implementation of a protection against unauthorized creation and change activities, you implement a basic protection of your service.

After this, you can implement how authorizations are granted to communication users.

### Related Information

[Developing Authorizations for Communication Users \(Developer\) \[page 799\]](#)

### 4.2.7.2.5.2.1.1 Defining Permitted Activities in an Authorization Object

To define the permitted activities for a service, create an authorization object with the standard authorization field *Activity* (ACTVT) for the permitted activities.

### Procedure

To define the permitted activities, follow the procedure for defining authorization objects in the [user guide for ABAP development tools](#) (ADT).

#### Note

In our example, in the newly created authorization object, under *Authorization Fields*, you only need the predefined *Activity* authorization field to define the permitted activities for the business users of your service. In our example, these activities would be *01 Add or Create*, *02 Change*, *03 Display*, and *06 Delete* for standard activities. In addition, you need *93 Calculate* for the business object-specific activity *Calculate Bonus*. If you click on an empty row and choose , the list of available values is shown.

In theory, by using the syntax `authorization: update` on an operation in the entity's behavior definition, you could use the authorization check that is implemented for the update operation for the annotated operation. This is also referred to as "authorization delegation". However, for security reasons, we recommend that you carefully consider whether you want to use authorization delegation because in this case, a user who is allowed to update a business object is then also allowed to perform all other activities on the business object.

## Results

In the following, the newly created authorization object for the bonus calculation example is called ZBNSCLC\_AO.

### 4.2.7.2.5.2.1.2 Modeling a Protection Against Unauthorized Write Activities

To protect your service from activities such as create, update or delete by unauthorized users, you can use the authorization controls that are available for services based on managed business objects.

## Context

In the example used here, the service is based on a managed business object *Bonus Calculation*. The use of a managed business object allows you to benefit from the global authorization for managed business objects, which is part of the ABAP RESTful Application Programming model. For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

## Procedure

1. In ABAP development tools, call up the behavior definition of your service.
2. In the behavior definition, define authorization controls for your service.

In the bonus calculation example, they can be as follows:

#### Sample Code

```
managed;
define own authorization context
{
  'ZBNSCLC_AO';
}
define behavior for z_i_bonus_calculation alias calculation
implementation in class zbp_bonus_calculation unique
persistent table zbonusclc
lock master
// Identity and Access Management:
// Enable RAP managed authorization check at create, update, and delete
// -> requires implementation of two methods, one with the addition "FOR
INSTANCE AUTHORIZATION"
// and one with the addition "FOR GLOBAL AUTHORIZATION"
authorization master ( instance, global )
```

With the line `authorization master ( global )`, an authorization check for the standard operations `create`, `update`, and `delete` and for non-standard operations, for example, `calculate bonus`, is

defined. You must implement the authorization check using a method with addition `FOR GLOBAL AUTHORIZATION` in the behavior implementation.

The sample code also contains the definition of your own authorization context. The own authorization context documents all authorization objects that are used by the business object implementation. In the bonus calculation example used in this documentation, this is the authorization object `ZBNSCLC_AO` because it's checked in the authorization control. The own authorization context is also used to prefill authorization defaults.

### 4.2.7.2.5.2.1.3 Implementing a Protection Against Unauthorized Write Activities

To protect a service such as the example of bonus calculation against unauthorized bonus creations, updates, or deletions, enhance the behavior implementation of the service in ABAP development tools (ADT). The implementation is required by what has been defined in the behavior definition.

#### Context

Among the methods of the behavior implementation, you add methods that check the authorizations for creation and for update and delete.

#### Procedure

1. In the *Source Code Library* folder of your package, under *Classes*, choose the behavior implementation of your service.
2. In the `PRIVATE` SECTION in the handler class of the behavior implementation, define the methods for authorization checks for creation, update, and deletion.

##### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR <behavior definition or
its alias> RESULT result.
```

In the bonus calculation example, these method definitions could be the following:

##### Sample Code

```
METHODS get_global_authorizations FOR GLOBAL AUTHORIZATION
  IMPORTING REQUEST requested_authorizations FOR calculation RESULT
result.
```

3. Add a method implementation that checks the authorizations for creations, updates, and deletions.

## Note

For more information about authorization control, see the documentation for the [ABAP RESTful Application Programming Model](#).

In the bonus calculation example, this method could be the following:

## Sample Code

```
METHOD get_global_authorizations.

  IF requested_authorizations-%create EQ if_abap_behv=>mk-on.
*   check create authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '01'.
    result-%create = COND #( WHEN sy-subrc = 0 THEN
      if_abap_behv=>auth-allowed ELSE
      if_abap_behv=>auth-unauthorized ).
  ENDIF.
  IF requested_authorizations-%update EQ if_abap_behv=>mk-on.
*   check update authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '02'.
    result-%update = COND #( WHEN sy-subrc = 0 THEN
      if_abap_behv=>auth-allowed ELSE
      if_abap_behv=>auth-unauthorized ).
  ENDIF.
  IF requested_authorizations-%delete EQ if_abap_behv=>mk-on.
*   check delete authorization
    AUTHORITY-CHECK OBJECT 'ZBNSCLC_AO' ID 'ACTVT' FIELD '06'.
    result-%delete = COND #( WHEN sy-subrc = 0 THEN
      if_abap_behv=>auth-allowed ELSE
      if_abap_behv=>auth-unauthorized ).
  ENDIF.
ENDMETHOD.
```

## Results

The implemented methods provide the desired protection from unauthorized uses:

- With the implementation of the method defined with the addition `FOR GLOBAL AUTHORIZATION`, an unauthorized business user gets an error message when trying to create a business object instance (in the example, a bonus calculation) or when trying to update or delete it via service call.
- Unauthorized business users can't use the [Delete](#) button in the list view on the service UI. In addition, the [Edit](#) and [Delete](#) buttons are hidden in the detail view on the service UI for a business object instance.

Now, the service is secured against unauthorized operations. As a next step, you must make sure that business users who need to use the service get the corresponding authorizations.

## 4.2.7.2.5.2.2 Developing Authorizations for Communication Users (Developer)

After you've protected your service against unauthorized use, you can now create the objects that are needed to grant authorizations for communication users: authorization default values and a communication scenario.

Follow the steps for editing authorization default values and for creating a communication scenario in ABAP Development Tools. You should define `own authorization context` in the behavior definition first, which can be used to prefill authorization defaults.

### Note

For developing authorizations for business users, the procedure is different. For more information, see [Developing Authorizations for Business Users \(Developer\) \[page 766\]](#).

### 4.2.7.2.5.2.2.1 Editing Authorization Default Values

Authorization default values are automatically created when you create a service binding. You can add authorization objects and change the authorization default values.

### Context

The authorization default values are shown when you include an authorization object into a communication scenario. These values are assigned to communication user if you leave them unchanged. Note, however, you can overwrite the authorization default values by values set in the communication scenario.

For more information about authorization default values, see the [user guide for ABAP development tools](#).

### Procedure

1. Open the service binding and choose the [Maintain Authorization Default Values](#) link.
2. Choose [Synchronize](#) to add the latest authorization objects from the own context.

### Note

The [Synchronize](#) function only **adds** authorization objects that are not yet part of the list of authorization objects; it does not remove objects.

3. To check or change the authorization default values that are assigned automatically, select the authorization objects in the list.

You can now specify what activities you want to authorize.

4. Choose the authorization object from the list and choose [Default With Field Values](#) from the dropdown list.

In our example, we authorize for the standard activities *Create*, *Display*, *Change*, and *Delete* as well as the business object-specific activity *Calculate*.

## 4.2.7.2.5.2.2 Defining a Communication Scenario Including Authorization Values

In ABAP Development Tools, you can define communication scenarios, which can be used to access business services using a technical communication user.

### Context

In ABAP Development Tools, you define a communication scenario and add the required services to the scenario. As part of the communication scenario definition, you also define the relevant authorization fields and activities. An administrator can then use this communication scenario and create a communication arrangement based on it.

#### Note

Administrators can't change the authorization activities and values that you define as part of the communication scenario when they create their communication arrangements.

For more information, see the information about consuming services in the context of APIs in the [user guide for ABAP development tools](#) (ADT).

### Procedure

1. Choose the relevant package in the project explorer.
2. Right-click to open the context menu and choose ► *New* ► *Other* ► *ABAP Repository Object* ► to launch the creation wizard.
3. Choose ► *Communication Management* ► *Communication Scenario* ► and choose *Next*.
4. Enter a name and a description and choose *Next*.
5. Choose *Finish* to create a transport request.
6. On the *Inbound* or the *Outbound* tab, add your inbound or an outbound business service to the communication scenario.
7. On the *Authorizations* tab, add the authorization object that you created for the business service.
8. On the *Authorizations* tab, also add the relevant authorization fields and activities. For each authorization field, you can now enter the values that you allow for the communication user. Similarly, you can select which activities are allowed for the communication user.

For example, you could define that only bonus variant V0 can be created using the communication user, but you would allow all possible activities.

The communication user will be defined by the administrator as part of the communication arrangement that is based on this communication scenario.

9. If you want to test your communication scenario directly in the development system, publish it locally to make sure that the required services have been generated.

### 4.2.7.2.5.2.3 Creating a Communication Arrangement (Administrator)

To grant authorizations to a communication user, as administrator, you create a communication arrangement. In this example, the communication arrangement is based on the communication scenario created by the developer, including all authorization restrictions.

#### Prerequisites

You have created a communication user that is used for data exchange with other systems. To create a communication user, you use the [Maintain Communication Users](#) app on the SAP Fiori launchpad (see also [How to Create Communication Users](#)).

You have created a communication system, which represents the communication partner within a communication. To create a communication system, you use the [Maintain Communication Systems](#) app (see also [How to Create Communication Systems](#)).

#### Procedure

1. Open the SAP Fiori Launchpad.
2. Choose [Communication Arrangements](#).
3. Create a new communication arrangement based on the communication scenario, using the communication user and system that you have already created.

For more information, see [How to Create a Communication Arrangement](#).

#### Results

The communication user in the communication arrangement gets the authorizations that have been defined as part of the communication scenario by the developer. If any authorizations based on authorization fields or activities have been defined or values set in the communication scenario, these also apply.

## 4.2.7.2.6 Providing Read or Write Access to a Business Service Using Privileged Mode

With enablement of privileged mode for a business object, it's possible to consume the business object without the need for additional business authorizations.

### Use Case for Business Users

A typical use case for privileged mode is the execution of an application job. In the bonus calculation example used in this documentation, such an application job could be required to schedule calculations of the target bonus amounts of valid bonus calculations that haven't been calculated yet. For this purpose, you can enable privileged access for the *Bonus Calculation* business object.

As a result, the business user for which the bonus calculation job is scheduled doesn't require all the authorizations that a typical business user of the business service would need. So, there's no need to define an IAM app, a business catalog, and a business role for the authorization to calculate the bonus.

### Use Case for Communication Users

During the execution of instance A of a business object X, write access might be needed to instance B of business object B. This is where privileged mode comes into play. Let's turn to a concrete example: You've created a custom business object for employees and a bonus business object. The employee business object has a performance indicator, such as *Exceeds Expectations*, *Consistently Exceeds Expectations*, and so on.

Now, when the bonus of the employee is calculated using the action *Calculate Bonus*, then the performance indicator of the employee is also updated at the same time, for example, using the action *Update Performance Indicator*. At this point, it makes sense to check whether the user (human or machine) has the authority to calculate the bonus. If so, then the system could also automatically update the performance indicator even if the user doesn't have a dedicated authority for it. What's more, the user might not even be allowed to display the information.

### 4.2.7.2.6.1 Modeling the Authorization Context for Privileged Mode

To enable privileged mode, you need another authorization context named `NoCheckWhenPrivileged`.

#### Context

Let's assume that you want to enable privileged mode for the bonus calculation object that's used as an example in this documentation. First, you define an authorization context called `NoCheckWhenPrivileged`

in the behavior definition. This authorization context is needed in addition to the `own authorization` context of the business object that you've already defined in the behavior definition. Then, you enable privileged mode for the business object by disabling `NoCheckWhenPrivileged` using the clause `with privileged mode disabling NoCheckWhenPrivileged`. As a result, authorization objects in the context `NoCheckWhenPrivileged` aren't checked during privileged access.

## Procedure

In the behavior definition, add the following code, for example:

### Sample Code

```
managed;
define authorization context NoCheckWhenPrivileged
{
  'ZBNSCLC_AO';
}
with privileged mode disabling NoCheckWhenPrivileged;
define own authorization context
{
  'ZBNSCLC_AO';
}
define behavior for z_i_bonus_calculation alias calculation
implementation in class zbp_bonus_calculation unique
persistent table zbonusclc
lock master
// Identity and Access Management:
// Enable RAP managed authorization check at create, update, and delete
// -> requires implementation of two methods, one with the addition "FOR
INSTANCE AUTHORIZATION"
// and one with the addition "FOR GLOBAL AUTHORIZATION"
authorization master ( instance, global )
```

## 4.2.7.2.6.2 Providing Read Access Using Privileged Mode

Use the keyword `WITH PRIVILEGED ACCESS` to provide read access using privileged mode.

### Context

For the bonus calculation job in the example used in this documentation, all valid bonus calculations with empty bonus amount are retrieved for calculation in the job. By using the keyword `WITH PRIVILEGED ACCESS` after the entity `z_i_bonus_calculation`, the CDS access controls with checks for authorization objects defined in authorization context `NoCheckWhenPrivileged` are disabled. As a result, unfiltered access to the `z_i_bonus_calculation` entity is possible.

## Procedure

In the example used in this documentation, you can use the following code for selecting bonus calculations:

### Sample Code

```
SELECT * FROM z_i_bonus_calculation
WITH PRIVILEGED ACCESS
WHERE z_i_bonus_calculation~validityenddate >= @sy-datum
AND z_i_bonus_calculation~bonusamount_v = 0
INTO TABLE @DATA(lt_bonus_calculation).
```

## 4.2.7.2.6.3 Providing Write Access Using Privileged Mode

Use the keyword `PRIVILEGED` to provide write access using privileged mode.

## Context

After open bonus calculations have been retrieved, the bonus calculation action `calculatebonus` is triggered in the *Bonus Calculation* business object with privileged access. By using the keyword `PRIVILEGED` after the behavior definition `z_i_bonus_calculation`, you enable privileged mode. As a result, the bonus calculation is executed without further authorization checks in the RAP authorization control.

## Procedure

In the example used in this documentation, you can use the following code:

### Sample Code

```
MODIFY ENTITIES OF z_i_bonus_calculation
PRIVILEGED
ENTITY calculation
EXECUTE calculatebonus FROM CORRESPONDING #( lt_bonus_calculation )
RESULT DATA(result)
REPORTED DATA(reported)
FAILED DATA(failed).
```

## 4.2.7.2.7 Troubleshooting

Learn more about apps and tools that help you identify and solve authorization issues.

## 4.2.7.2.7.1 Authorization Trace

There's an app for troubleshooting available: With the [Display Authorization Trace](#) app you can enable an authorization trace for a business user, which helps you to find out if the user's authorizations are insufficient.

### More Information

[Display Authorization Trace](#)

## 4.2.7.2.7.2 Debugging

You can use the ABAP Debugger in ABAP development tools to gain more insights about authorization checks. You can do so by activating a breakpoint next to the performed `AUTHORITY-CHECK` as well as by adjusting the breakpoint activation to be effective for the relevant developer user.

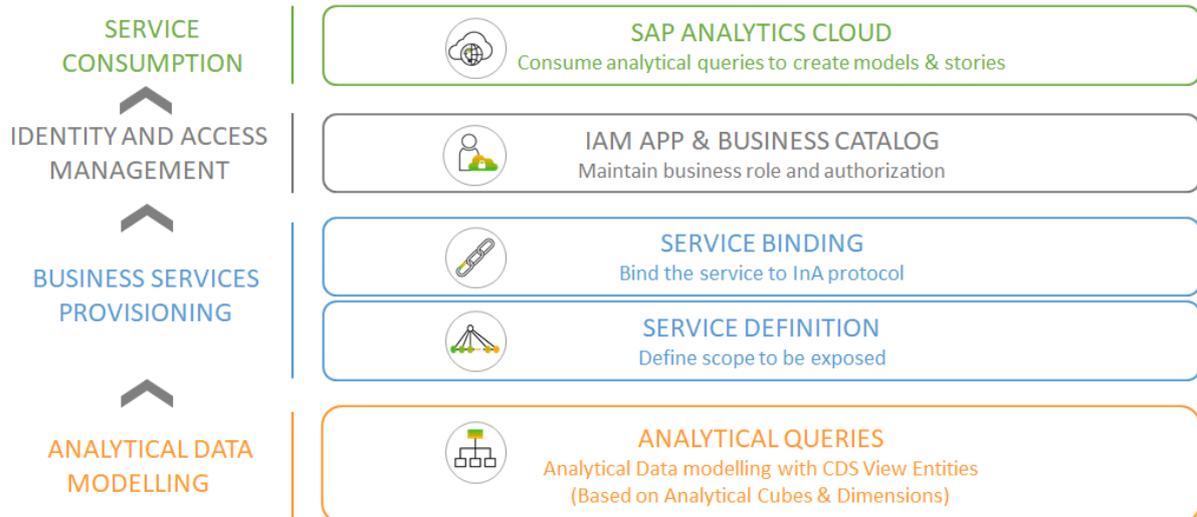

### More Information

For more information about the ABAP debugger, see the [user guide for ABAP development tools](#) (ADT).

## 4.2.8 Analytical Data Modeling & Live Data Connection to SAP Analytics Cloud

As an ABAP environment developer with your own standalone SAP Analytics Cloud (SAC) tenant, you can use analytical queries that reside in your ABAP environment system as data sources for a SAC story.

The new RAP-based Information Access (InA) service exposure enables ABAP environment developers to create analytical queries that are based on ABAP-CDS analytical data models, and expose them via the InA service protocol. These analytical queries can then be consumed in SAP Analytics Cloud (SAC) to create analytical models, stories, KPIs, multi-dimensional reports, and more. For information on how to integrate SAP Analytics Cloud, see [Integrating SAP Analytics Cloud \[page 2631\]](#).

This guide provides you with all the information you need to get started, explains the concepts and gives detailed step-by-step instructions for the entire process, from start to finish.

## 4.2.8.1 Prerequisites

### ABAP Environment

You have access to ABAP environment.

For more information, see [ABAP Environment](#)

### Development Environment (IDE)

- You have installed ABAP Development Tools (ADT). SAP recommends to use the latest version of the client installation. The ADT download is available on the update site <https://tools.hana.ondemand.com/>.
- You have created an ABAP cloud project to establish a connection between your ABAP back-end system and SAP BTP ABAP environment.

### Authorizations

To create development artifacts described in this guide, you need the developer authorization profile for ABAP environment.

For more information, see [Identity and Access Management \(IAM\) Guide](#).

## 4.2.8.2 Getting Started

### Downloading the ABAP Flight Reference Scenario

The ABAP Flight Scenario contains demo content that you can import into your development environment. It contains a data model consisting of database tables filled with travel data such as customer, flights, or airports. The structure of the complete data model allows you to build simple but also more complex services. That way, it's easy to follow the steps in this development guide while building your own queries based on the same database tables as in the given examples.

To learn more about the ABAP Flight Reference Scenario, see [ABAP Flight Reference Scenario](#).

You can download the complete ABAP Flight Reference Scenario for the ABAP RESTful Application Programming Model from GitHub.

<https://github.com/SAP-samples/abap-platform-refscen-flight/tree/Cloud-Platform> ➔

## 4.2.8.3 Analytical Data Modeling

To be able to consume data, the analytical engine needs a multi-dimensional analytical model (= a star schema), and a query. Let's take a closer look at the star schema and the query that lies on top of it.

### Related Information

[Star Schema \[page 807\]](#)

[Analytical Query \[page 810\]](#)

### 4.2.8.3.1 Star Schema

The structure of the analytical model resembles a star (see graphic below): The cube or fact view at its center is surrounded by and connected to various dimension views. That's why it is also referred to as a star schema.

#### The Star Schema

Analytical models are built on top of CDS views/CDS view entities. Certain CDS views can take over the role of fact views, cube views (= cubes), dimension views (= dimensions) or text views in an analytical model. These different types of views are defined by the following annotations:

- Fact views: `@Analytics.dataCategory: #FACT`  
A fact view contains facts that are suitable for extraction.
- Cube views: `@Analytics.dataCategory: #CUBE`  
The cube view is the analytical interface view that is also used in the respective queries and holds the model together. It selects from facts and can be enriched with additional fields.
- Dimension views: `@Analytics.dataCategory: #DIMENSION`  
The dimension view makes further attributes accessible.
- Text views: `@objectModel.dataCategory: #TEXT`  
Text views bring language-dependent texts into the model.
- Hierarchy views: `@objectModel.dataCategory: #HIERARCHY`  
Hierarchy views map hierarchical structures such as region, country, state, county, city. They can also be recursive (e.g. employee - manager). We will not be using hierarchy views in our example.

### Note

For more information on CDS views and CDS view entities, see [CDS Views](#).

At the center of a star schema lies a **fact** view (annotation `@Analytics.dataCategory: #FACT`) or a **cube** view (annotation `@Analytics.dataCategory: #CUBE`). In our example, we will use a cube view. It will serve as the central data source in our analysis.

The cube view contains dimensional data (= descriptive data such as a carrier ID or a booking date) as well as measurable data (=quantifiable fields that can be calculated, e.g. the number of flight bookings). We refer to these as **dimension fields** and **measures**.

Measures can be aggregated and, if necessary, can have an association to a unit of measure or a currency. Their aggregation behavior is defined via annotation `@Aggregation.default`. If annotation `@Aggregation.default: #SUM` is used, for instance, the measures will be summed in an analysis. If, for instance, a measure refers to a unit like 'sales', the annotations `@Semantics.currencyCode` or `@Semantics.unitOfMeasure` can be used to reference a currency code or a unit of measure. For more information on annotations that can be used in measures, see [CDS Annotations](#).

Dimension fields can be used to filter the results of an analysis and to group the result rows of an analysis according to the values of the dimension fields. The more dimension fields a cube contains, the higher the flexibility of possible analyses as there are more options for filtering and grouping the data. Dimension fields in a cube view or a dimension view can also have an association to a text view. **Text** views (annotation `@objectModel.dataCategory: #TEXT`) provide language-dependent texts for the dimension fields. They are connected to the dimension fields via text association (annotation `@ObjectModel.text.association`).

Aside from dimension fields and measures, cubes may also contain numeric fields that aren't measures, and other special fields.

The cube view at the center of our star schema references **dimension** views (annotation `@Analytics.dataCategory: #DIMENSION`) which provide additional attributes for the dimension fields in the cube view: These dimension fields of the cube are connected to the dimension views via foreign key association (annotation `@ObjectModel.foreignKey.association`). They reference the field which was defined as representative key in a dimension view.

### Note

The representative key is the most specific element of a primary key that represents the entity which the view is based on. In non-text views, it's used as an anchor of sorts when defining foreign key relationships. The representative key is defined via annotation `@ObjectModel.representativeKey`.

For more information on the annotations needed for analytical data modelling, see [CDS Annotations](#).

### Note

#### Fact Views and Cube Views

Although possible, it isn't mandatory to construct a fact view to consume it from inside of a cube. You can expose the table that holds the measures directly in the cube to avoid an extra view and consequently an unnecessary level. Unlike cube views, fact views should not have joins or fields from dimension views, and they must hold only measurable values. If you want to connect your dimensions in the same view, you should therefore use a cube instead of a fact view. The facts and dimensions should be modelled with a normalized representation.

### Flight Booking Model:

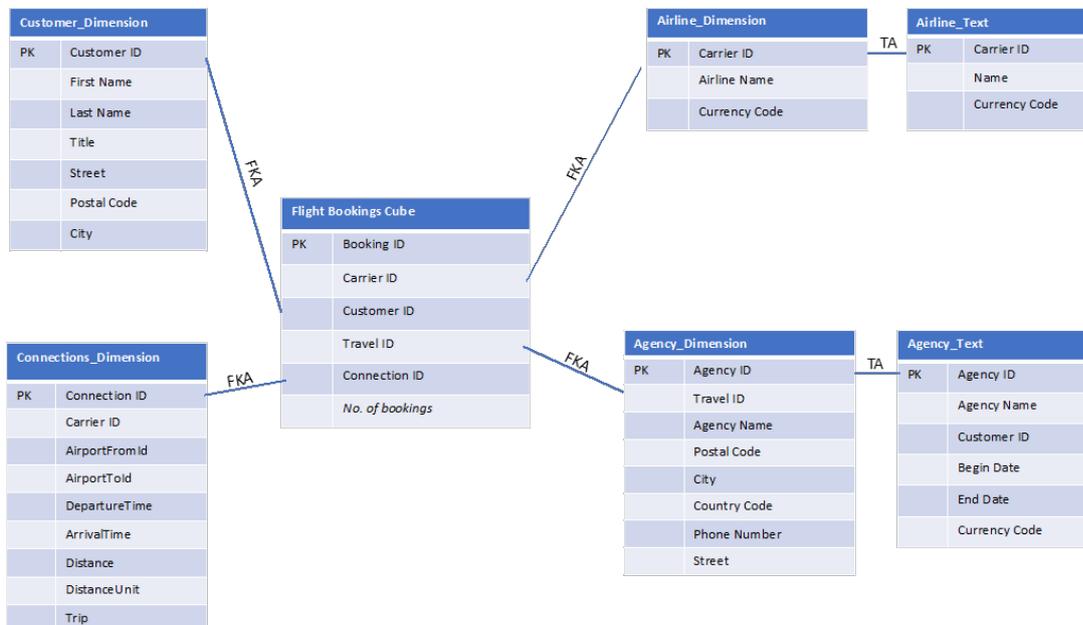

In this guide, you will learn how to implement a simple analytical model that lets you analyze flight bookings based on the /DMO/Flight test database tables. We will create a data model containing measures and dimensions.

#### Measures

- the total number of bookings
- the price of each booking

#### Dimensions:

- Airline
- Connection
- Customer
- Agency

PK: Primary Key; FKA: Foreign Key Association; TA: Text Association

### Note

Note that we will not be associating any text views in our example.

## Related Information

[Analytical Query \[page 810\]](#)

### 4.2.8.3.2 Analytical Query

On top of an analytical model, analytical queries are defined according to your needs to perform different analytical evaluations and calculations. Queries can define the initial layout that is displayed, select the initial data, and can calculate measures that weren't included in the analytical model. Each query will fulfil a specific purpose and can be designed for different applications (e.g. reports, KPIs, etc).

A CDS view that is based on an analytical model (i.e. it selects from a view with analytics data category FACT, CUBE or DIMENSION, and further operations like joins or unions are not allowed) becomes an analytical query with the inclusion of `provider contract analytical_query`. These analytical queries will not be processed by a SQL engine but by an analytical engine, which selects the data via SQL from the views of the underlying analytical model containing cubes, dimensions and text views.

Analytical queries can be exposed to business intelligence (BI) tools such as SAP Analytics Cloud or Design Studio.

In this guide, we will define a query on top of our flight booking model and consume it on SAP Analytics Cloud.

### 4.2.8.4 Business Services Provisioning

#### Business Service

The ABAP development platform can act in the roles of a service provider and a service consumer. In the context of the ABAP RESTful Application Programming Model, a business service is a RESTful service which can be called by a consumer. It is defined by exposing its data model together with the associated behavior. It consists of a service definition and a service binding.

## Mandatory checks to be considered while defining and binding services via InA:

1. An active version of the service definition must exist.
2. An InA service binding can be created on only one service definition that has only one exposed artifact and the exposed artifact must be an analytical query.
3. Only one InA service binding is allowed for one analytical query. This check is performed both during the creation of a new service binding and on the existing InA service.
4. After an InA service has been activated, if the underlying service definition is modified (i.e. the exposed artifact is changed), a warning is thrown for the InA service and the service has to be activated again.

## Service Definition

A service definition represents the service model that is generically derived from the underlying CDS-based data model. You use a service definition to define which data is to be exposed as a business service using one or more business service bindings (short form: service bindings). A service definition itself is independent from the version or type of the protocol that is used for the business service.

## Service Binding

The business service binding (short form: service binding) is used to bind a service definition to a communication protocol. In our case, the protocol that enables web-based data access from ABAP environment systems is the Information Access (InA) protocol.

### Note

For more information, see [Business Service Consumption](#).

## Related Information

[Define a Service Definition and Binding via InA \[page 823\]](#)

## 4.2.8.5 Identity and Access Management

The *Identity and Access Management* apps secure access to the solution for business users.

The main elements of IAM are business catalogs, business roles, and business users. Access to business apps is controlled by role-based authorization management. That means you assign roles to users and these roles provide access to certain business tasks. You can also assign users to roles in the *Maintain Business Roles*

app. The main purpose of the app, however, is to create and adapt business roles. You create business roles by combining pre-defined business catalogs which contain the actual authorizations that allow users to access apps for a specific business area.

## IAM For Our Scenario

By creating an IAM app, the S\_Start authorization is automatically assigned to the query exposed via 'InA' service. This basic authorization is mandatory for users to work with their services. A business catalog needs to be created and added to the developer role using the *Maintain Business Roles* app. This will grant all employees with the same role access to your business catalog.

## Related Information

[Create an IAM App and Assign a Business Catalog \[page 824\]](#)

### 4.2.8.6 Service Consumption

Connecting an ABAP environment system to SAP Analytics Cloud (SAC) using the InA service is only possible via direct connection (Live Data Connection) using communication scenario SAP\_COM\_0065. To find out more about direct connection, see [Live Data Connections to SAP S/4HANA](#).

To use the communication scenario, you need to create a communication system and a communication arrangement using the Fiori launchpad of the ABAP Environment system.

Please note:

- Only one communication arrangement can be created per communication scenario.
- Since the direct connection uses CORS, please verify your end-users' web browser configuration and access. Your end users' web browser has to be configured to:
  - allow pop-up windows from the SAP Analytics Cloud domain: [\*.]sapbusinessobjects.cloud.
  - allow third-party cookies from the SAP S/4HANA server's domain. For example, in Internet Explorer 11, go to *Internet Options > Security > Trusted Sites*, add your domain name, then select *Enable Protected Mode*.

## 4.2.8.7.1 Create Analytical Models Based on CDS View Entities

In this chapter, you will learn how to create analytical models based on CDS view entities.

### 4.2.8.7.1.1 Create Data Definitions using CDS View Entities

All objects in our data model (dimensions, cubes, analytical queries, etc.) will be CDS view entities. In this chapter, you will learn how to create a data definition using CDS view entities. These steps need to be repeated for the implementation of all the other objects, which only differ in the annotations that are used. Find out how to create a data definition using CDS view entities:

#### Create Data Definitions using CDS View Entities

1. Launch the ABAP Development Tools.
2. In your ABAP project, select the relevant package node in the *Project Explorer*.
3. In the context menu, select *File* → *New* → *Other*. This opens a search tool, where you can search for data definition. Click next to launch the creation wizard.
4. Enter a *Name* (taking into account your namespace) and *Description* for the data definition to be created.
5. Click *Next*.
6. Assign a transport request and click *Next*.

7. Select the *Define View Entity* template to speed up the view definition.
8. Click *Finish*.

## Result

In the selected package, the ABAP back-end system creates an inactive version of a data definition and stores it in the ABAP repository. As a result of this creation procedure, the data definition editor will be opened. The generated source code already provides you with the necessary view annotations and adds placeholders for names of the dictionary SQL view, the actual CDS view, and for the data source for query definition.

## 4.2.8.7.1.2 Implement Dimensions

This part of the guide will show you how to implement dimensions needed for the [Star Schema \[page 807\]](#).

You have created a data definition as described in [Create Data Definitions using CDS View Entities \[page 813\]](#)

Dimension views provide additional attributes for the dimension fields in the cube view. See [Star Schema \[page 807\]](#).

In order to avoid the generation of SQL artifacts that are not required by the analytical engine(s) to process the query, a new artifact type in CDS is introduced. This is the `transient (projection) view entity`. These transient view entities support the same functionality as other CDS entity types, with the main difference being that no SQL artifact is generated in the HANA database during activation. The basic CDS syntax looks as follows:

### Sample Code

```
DEFINE TRANSIENT VIEW ENTITY <entity_name>
  PROVIDER CONTRACT analytical_query
  WITH PARAMETERS <param_name> : <param_type> DEFAULT <value>, ...
  AS PROJECTION ON <data_source_name>
{
  ...
} ...;
```

Dimensions consist of several parts. These are:

1. The mandatory header annotations for dimensions:

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@endUserText.label: 'View entity agency'
@Analytics.dataCategory: #DIMENSION
@ObjectModel.representativeKey: 'AgencyId'
```

2. The data source that you would like to select from, as well as associations.

```
define view entity Z_VE_AGENCY_DIM
as select from /dmo/agency as _Agency
association to /DMO/I_Travel_U as _Travel on $projection.AgencyId =
_Travel.AgencyID
```

3. While defining the fields, 'as' must be used to define an alternative element name alias.

### Fields Definition

```
key agency_id as AgencyId,
```

```

name          as Name,
street        as Street,
postal_code   as PostalCode,
city          as City,
country_code  as CountryCode,
phone_number  as PhoneNumber,
/* Associations */
_Travel.TravelID as TravelID,
_Travel

```

## Result

### Z\_VE\_AIRLINE\_DIM

```

@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@endUserText.label: 'View entity agency'
@Analytics.dataCategory: #DIMENSION
@ObjectModel.representativeKey: 'AgencyId'

define view entity Z_VE_AGENCY_DIM
as select from /dmo/agency as _Agency
association to /DMO/I_Travel_U as _Travel on $projection.AgencyId =
_Travel.AgencyID
{
key agency_id    as AgencyId,
name            as Name,
street          as Street,
postal_code     as PostalCode,
city            as City,
country_code    as CountryCode,
phone_number    as PhoneNumber,
/* Associations */
_Travel.TravelID as TravelID,
_Travel
}

```

### Important Notes:

- All dimensions must have an `@Analytics.dataCategory: #DIMENSION` classification in the header of the view entity.
- A correlation of a field with its descriptive language-independent texts and names are established through annotation `@ObjectModel.text.element`. For language-dependent texts, a view of type `@ObjectModel.dataCategory: #TEXT` is needed. This view would then be associated via annotation `@ObjectModel.text.association`.
- Associations of external attributes are determined by foreign keys using annotation **@ObjectModel.foreignKey.association**.
- Dimensions with composite keys need a definition of a single field as a representative key. This configuration is achieved through annotation **@ObjectModel.representativeKey**. The representative key is a key field. If there are multiple key fields, it points to the most specific one.
- Annotation `@Semantics` helps to specify the semantic of a field e.g., text/calendar date/unit/amount.

For more information on the annotations, see [CDS Annotations](#).

## Other dimensions needed for our example:

### Z\_VE\_AIRLINE\_DIM

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@EndUserText.label: 'View entity for Airline'
@Analytics.dataCategory: #DIMENSION
@ObjectModel.representativeKey: 'CarrierId'

define view entity Z_VE_AIRLINE_DIM
as select from /dmo/carrier as _Airline
{

@ObjectModel.text.element: ['AirlineName']
key carrier_id      as CarrierId,
  name              as AirlineName,
  currency_code    as CurrencyCode

}
```

### Z\_VE\_CONNECTION\_DIM

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@EndUserText.label: 'View entity connection'
@Analytics.dataCategory: #DIMENSION
@ObjectModel.representativeKey: 'ConnectionId'

define view entity Z_VE_CONNECTION_DIM
as select from /dmo/connection as _Connection

association to Z_VE_AIRLINE_DIM as _Airline on $projection.CarrierId =
_Airline.CarrierId

{
  @ObjectModel.foreignKey.association: '_Airline'
  key carrier_id      as CarrierId,
  key connection_id  as ConnectionId,
  airport_from_id    as AirportFromId,
  airport_to_id      as AirportToId,
  departure_time     as DepartureTime,
  arrival_time       as ArrivalTime,
  distance            as Distance,
  distance_unit      as DistanceUnit,
  concat(airport_from_id, airport_to_id) as trip,
  /* Associations */
  _Airline
}
```

### Z\_VE\_CUSTOMER\_DIM

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #CHECK
@EndUserText.label: 'View entity customer'
@Analytics.dataCategory: #DIMENSION
@ObjectModel.representativeKey: 'CustomerId'

define view entity Z_VE_CUSTOMER_DIM
as select from /dmo/customer as _Customer
association [0..1] to I_Country as _Country on $projection.CountryCode =
_Country.Country
{
  key customer_id as CustomerId,
  first_name     as FirstName,
  last_name      as LastName,
```

```

title          as Title,
street         as Street,
postal_code   as PostalCode,
city          as City,
@ObjectModel.foreignKey.association: '_Country'
country_code  as CountryCode,
/* Associations */
_Country
}

```

### 4.2.8.7.1.3 Implement Cubes

As we will be using associations and dimensions in our view, we will be implementing cube views instead of a fact views. The cube is the analytical interface view that is also used in the respective queries and holds the model together. It selects from facts and can be enriched with additional fields.

1. Create another data definition as described in [Create Data Definitions using CDS View Entities \[page 813\]](#).
2. Add the mandatory header annotation for cubes:

**Header Annotation:** @Analytics.dataCategory: #CUBE

3. Choose the data source that you would like to select from.

```

define view entity Z_VE_FLTBKS_CUBE
as select from /DMO/I_Booking_U as _Booking

```

4. An association is used to link a view (or table) to the source view (or table) in CDS Views entities. In an association, cardinality is defined. Cardinality is the relationship between the source and associated view entities in the form of [ min .. max ]. Only the target cardinality is stated. The cardinality of associations in a cube has to be [0..1].

#### Associations

```

association to Z_VE_CUSTOMER_DIM          as _Customer  on
_Booking.CustomerID = _Customer.CustomerId
association to Z_VE_AIRLINE_DIM          as _Airline   on
_Booking.AirlineID  = _Airline.CarrierId
association to Z_VE_CONNECTION_DIM       as _Connection on
_Booking.AirlineID  = _Connection.CarrierId

and

_Booking.ConnectionID = _Connection.ConnectionId
association to Z_VE_AGENCY_DIM           as _Agency   on
_Booking.TravelID    = _Agency.TravelID
association to I_Currency                 as _Currency  on
_Currency.Currency = $projection.CurrencyCode
association to /DMO/I_Travel_U           as _Travel    on _Booking.TravelID
= _Travel.TravelID

```

5. All cubes must have at least one measure. For more information on measures, see [Star Schema \[page 807\]](#).

#### Default aggregation

```

@Aggregation.default: #SUM
1                      as TotalNoOfBookings,

```

6. Associations of external attributes are determined by foreign keys using annotation **@ObjectModel.foreignKey.association**. These are the links to the dimensions

#### Foreign key association

```

@ObjectModel.foreignKey.association: '_Customer'

```

```
_Booking.CustomerID      as CustomerID,
```

## Result

### Z\_VE\_FLTBKS\_CUBE

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@EndUserText.label: 'View entity flight bookings cube'
@Analytics.dataCategory: #CUBE

define view entity Z_VE_FLTBKS_CUBE
as select from /DMO/I_Booking_U as _Booking
  association to Z_VE_CUSTOMER_DIM      as _Customer      on
  _Booking.CustomerID      = _Customer.CustomerId
  association to Z_VE_AIRLINE_DIM       as _Airline       on
  _Booking.AirlineID      = _Airline.CarrierId
  association to Z_VE_CONNECTION_DIM    as _Connection on
  _Booking.AirlineID      = _Connection.CarrierId
                                     and
  _Booking.ConnectionID    = _Connection.ConnectionId
  association to Z_VE_AGENCY_DIM        as _Agency      on
  _Booking.TravelID       = _Agency.TravelID
  association to I_Currency              as _Currency    on
  _Currency.Currency = $projection.CurrencyCode
  association to /DMO/I_Travel_U        as _Travel       on _Booking.TravelID =
  _Travel.TravelID
{
  key _Booking.TravelID as TravelID,
  key _Booking.BookingID as BookingID ,
  @ObjectModel.foreignKey.association: '_Customer'
  _Booking.CustomerID as CustomerID,
  @ObjectModel.foreignKey.association: '_Airline'
  _Booking.AirlineID as Airline,
  @ObjectModel.foreignKey.association: '_Connection'
  _Booking.ConnectionID as ConnectionID,
  _Booking.FlightDate as FlightDate,
  _Booking.FlightPrice as FlightPrice,
  _Booking.CurrencyCode as CurrencyCode,
  _Connection.Distance as Distance,
  _Connection.DistanceUnit as DistanceUnit,
  _Travel.BookingFee as BookingFee,
  _Travel.TotalPrice as TotalPrice,

  @Semantics.amount.currencyCode: 'CurrencyCode'
  _Booking.FlightPrice + _Travel.BookingFee as FlightPricePerBooking,

  _Booking.BookingDate as BookingDate,

  @Aggregation.default: #SUM
  1 as TotalNoOfBookings,
  /* Associations */
  _Customer,
  _Airline,
  _Connection,
  _Agency,
  _Currency,
  _Travel
}
```

## Important Notes:

- It isn't mandatory to construct a fact view to consume it from a cube; you can expose the table that holds the measures directly in the cube view to avoid an extra view and consequently an unnecessary level. Fact views cannot have joins or associations and they must hold only measurable values. If you want to connect your dimensions in the same view you should use a cube view instead of a fact view.
- All cubes must have an `@Analytics.dataCategory: #CUBE` classification in the header of the view.
- Associations of external attributes are determined by foreign keys using annotation `@ObjectModel.foreignKey.association`.
- The `@Aggregation.default` annotation should be placed before the fields determined as **measures**.
- The annotation `@Semantics` helps to define the currency and quantity.

## The other cube required for our example

### Sample Code

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_REQUIRED
@EndUserText.label: 'Flight Cube'
@Analytics.dataCategory: #CUBE
define view entity Z_VE_Flight_Cube
  as select from /DMO/I_Flight_R as _Flight
  association to Z_VE_AIRLINE_DIM as _Carrier on _Flight.AirlineID =
  _Carrier.CarrierId
  {
    @ObjectModel.foreignKey.association: '_Carrier'
    key AirlineID,
    key ConnectionID,
    key FlightDate,
    Price,
    CurrencyCode,
    PlaneType,
    MaximumSeats,
    OccupiedSeats,
    @Aggregation.default: #MIN
    MaximumSeats - OccupiedSeats as TotalFreeSeats,
    /* Associations */
    _Carrier
  }
}
```

## 4.2.8.7.1.4 Implement an Analytical Report (Query)

Follow these steps to implement a query on top of your analytical model.

For more information, see [Analytical Query \[page 810\]](#).

### Prerequisites:

You have completed the following steps:

- [Implement Dimensions \[page 814\]](#)

- [Implement Cubes \[page 817\]](#)

1. Create another data definition as described in [Create Data Definitions using CDS View Entities \[page 813\]](#).
2. Choose the underlying cube view.

```
DEFINE TRANSIENT VIEW ENTITY <entity_name>
  PROVIDER CONTRACT analytical_query
  WITH PARAMETERS <param_name> : <param_type> DEFAULT <value>, ...
  AS PROJECTION ON <data_source_name>
{
  ...
} ...;
```

3. Add the query annotations:

- Annotation `@AnalyticsDetails.query.axis: '<VALUE>'`

**Description:** Position elements of a view on a specific axis.

**Possible values:** FREE, ROWS or COLUMNS.

With the annotation `@AnalyticsDetails.query.axis`, the elements of the view can be positioned on multiple axes. The elements can be directly annotated with their axis. All measures (elements which can be aggregated) need to be on the same axis. The annotation of the first measure will therefore be used for all measures of the query. If `@AnalyticsDetails.query.axis` is not found, the system positions the measures on the columns. The default value for elements that are not measures is the free axis. Note that elements in the projection list which belong to the same field in the query will be grouped together.

- Annotation `@AnalyticsDetails.query.display: #KEY_TEXT` is used to display the text of the key.

For more information on all the different query annotations, see [AnalyticsDetails Annotations](#).

#### Query Annotations

```
@AnalyticsDetails.query.display: #KEY_TEXT
@AnalyticsDetails.query.axis: #ROWS
key BookingsCube.TravelID,
```

## Analytical Report 1

### Z\_VE\_ANA\_PROJVIEW\_Q

```
@EndUserText.label: 'Analytical projection view'
@AccessControl.authorizationCheck: #NOT_ALLOWED // No
definition of a DCL
define transient view entity Z_VE_ANA_PROJVIEW_Q //
transient: only a ABAP Server runtime object is generated
  provider contract analytical_query //
  provider contract analytical_query: strict analytical checks are executed inside
  Dictionary Activation

  with parameters //
  Parameters are allowed
  p_preferred_currency : abap.dec(15,2)

  as projection on Z_VE_FLTBKS_CUBE //
  Underlying View needs to be a CUBE view
  {

    @AnalyticsDetails.query.axis: #ROWS
    TravelID,
    @AnalyticsDetails.query.axis: #ROWS
    BookingID,
    @AnalyticsDetails.query.axis: #ROWS
    CustomerID,
```

```

@AnalyticsDetails.query.axis: #ROWS
Airline,
@AnalyticsDetails.query.axis: #ROWS
ConnectionID,
@AnalyticsDetails.query.axis: #ROWS
FlightDate,
@AnalyticsDetails.query.axis: #ROWS
FlightPrice,

CurrencyCode,
@AnalyticsDetails.query.axis: #ROWS
BookingDate,
TotalNoOfBookings,
@AnalyticsDetails.query.axis: #ROWS
Distance,
@AnalyticsDetails.query.axis: #ROWS
DistanceUnit,
@AnalyticsDetails.query.axis: #ROWS
TotalPrice,
@AnalyticsDetails.query.axis: #ROWS
BookingFee,
@AnalyticsDetails.query.axis: #ROWS
FlightPricePerBooking,

@AnalyticsDetails.query.axis: #ROWS //
Typed Literals
@Aggregation.default: #FORMULA //
Calculated Units as references for calculated quantities
@EndUserText.label: 'Discount On Booking'
abap.decfloat34'0.05' as
DiscountOnBooking,

@AnalyticsDetails.query.axis: #ROWS
@Aggregation.default: #FORMULA
@EndUserText.label: 'Tax On Booking'
abap.decfloat34'0.19' as TaxOnBooking,

@AnalyticsDetails.query.axis: #ROWS
virtual CurrencyCode1 : abap.cuky( 5 ), //
Definition of calculated units via virtual

@AnalyticsDetails.query.axis: #ROWS
@Semantics.amount.currencyCode: 'CurrencyCode1'
@Aggregation.default: #FORMULA
@EndUserText.label: 'FliPrice Discounted'
curr_to_decfloat_amount( FlightPricePerBooking ) * ( 1 -
$projection.DiscountOnBooking ) as FlightPriceDiscounted, // Referring to other
expressions via $projection

@AnalyticsDetails.query.axis: #ROWS
@Semantics.amount.currencyCode: 'CurrencyCode'
@Aggregation.default: #FORMULA
@EndUserText.label: 'Final Flight Price'
$projection.FlightPriceDiscounted * ( 1 +
$projection.TaxOnBooking ) as FlightPriceDiscountedTaxed
}

```

## Analytical Report 2

For our example, we will be using two queries. Copy following is the code needed for the second query.

### Sample Code

```

@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #NOT_ALLOWED
@EndUserText.label: 'Flight Analytical Projection Query'

```

```

define transient view entity Z_VE_Flight_AnaProj_Query
provider contract analytical_query

### 4.2.8.7.3 Define a Service Definition and Binding via InA

Define and bind services via the SAP Information Access (InA) service.

#### Service Definition

First, you need to create a service definition on top of your query.

1. In the *Project Explorer*, right-click on your query and select *New Service Definition*.
2. Provide a *Name* (e.g. Z\_BOOKINGS\_SERVICE) and *Description*. The *Exposed Entity* should be your query (Z\_BOOKINGS\_VE\_QUERY). Click *Next*.
3. Select a transport request, then click *Finish*.
4. After the query is exposed as a service, activate the service definition by clicking the wand icon (CTRL+F3).

#### Result

##### Z\_BOOKINGS\_SERVICE

```
@EndUserText.label: 'Bookings Service Definition'
define service Z_Bookings_Service {
  expose Z_BOOKINGS_VE_Query as Bookings;
}
```

## Service Binding

Next, you need to create a service binding on top of your service definition.

1. In the *Project Explorer*, expand *Business Services*. Right-click on your query (Z\_BOOKINGS\_SERVICE) and select *New Service Binding*.
2. Fill in a *Name* (e.g. Z\_BOOKINGS\_INA\_BINDING), *Description* and Service Definition (Z\_BOOKINGS\_SERVICE). Select *InA - UI* as the *Binding Type*. Click *Next*.
3. Select a transport request and click *Finish*.
4. Activate the service binding by clicking the wand icon (CTRL+F3).

### Result

After activation, the external service name for your query is displayed.

Note that the analytical query will be displayed with the external service name as datasource in SAP Analytics Cloud.

## Related Information

[Business Services Provisioning \[page 810\]](#)

## 4.2.8.7.4 Create an IAM App and Assign a Business Catalog

### Create an Identity and Access Management (IAM) App

Follow the steps described in [Creating an App](#) to create an Identity and Access Management (IAM) app. Make sure to choose *EXT - External App* as *Application Type*. In the *Services* tab, select *Service Type InA - UI* and enter the name of your service binding (in our example Z\_BOOKINGS\_INA\_BINDING) in the field *Service Name*. You don't need to make changes to the *Authorizations* tab. Click *Publish Locally*.

### Create a Business Catalog

1. Right-click on *Cloud Identity and Access Management > New > Business Catalog*.
2. Provide a *Name* and *Description* for the Business Catalog. Click *Next*.
3. Select a *Transport Request* and click *Finish*.

## Assign the App to the Business Catalog

1. Go to your business catalog, navigate to the *Apps* tab and click *Add*.
2. Enter the name of the *IAM App* you created, as well as a *Name* (e.g. Z\_EAS\_BUSINESS\_CATALOG\_0001) and *Description*. Click *Next*.
3. Select a *Transport Request* and click *Finish*. Click *Publish Locally* to publish your business catalog.

## Assign the Business Catalog to a Role

1. In the Fiori launchpad, open the *Maintain Business Roles* app.
2. Click the role SAP\_BR\_DEVELOPER to open it.
3. Click *Edit* and navigate to *Assigned Business Catalogs*. Click *Add* and search for the business catalog you created. Select it and click *Apply*.
4. *Save* your changes.

### 4.2.8.7.5 Connect the ABAP Environment System to SAP Analytics Cloud

Connect your ABAP environment system to SAP Analytics Cloud (SAC) using communication scenario SAP\_COM\_0065. Here's how:

#### Create a Communication System and Communication Arrangement

1. Log on to the Fiori Launchpad and open the *Communication Systems* app.
2. Click on the *New* button to create a communication system. Provide a *System ID* and *System Name* and click *Create*.
3. Scroll down to the *Technical Data* section and fill in your *Host Name* for SAP Analytics Cloud (e.g. <xxx>.cloud.sap.) and *Port*: 443. *Save* your changes.
4. Now open the *Communication Arrangements* app.
5. Click the *New* button to create a new communication arrangement. Select SAP\_COM\_0065 as the *Scenario* using the value help and provide an *Arrangement Name*, then click *Create*.
6. In the *Common Data* section, select the *Communication System* you created in step 2.
7. In the *Additional Properties* section, fill in the tenant ID of your SAC tenant.

#### Note

The tenant ID can be found in the main menu of the SAC tenant under *System > About > System Name*.

8. In the *Outbound Services* section, check the *Service Status* for *UI Link Navigation* as active. The *Service Status* for *Retrieve Stories* should be unchecked. Click *Save*.

#### Note

Please note that retrieving stories is not yet supported.

## Connect to SAP Analytics Cloud

1. Login to your SAC tenant. In the main menu, click *Connection*.
2. Click the + icon (*Add Connection*). Under *Connect to Live Data*, select *SAP S/4HANA*.
3. In the *New S/4HANA Live Connection* dialog, maintain the following details:
  - Name and Description
  - Connection Type: Direct Connection
  - Host: <ID>.abap-web.stagingaws.hanavlab.ondemand.com
  - HTTPS Port: 443
  - Client: 100
  - Authentication Method: SAML Single Sign-on (Standard Compliant)

### 4.2.8.7.6 Consume Queries on SAC to Create Models and Stories

Once a successful connection has been established, you can start creating models and stories based on your query.

#### Creating Models

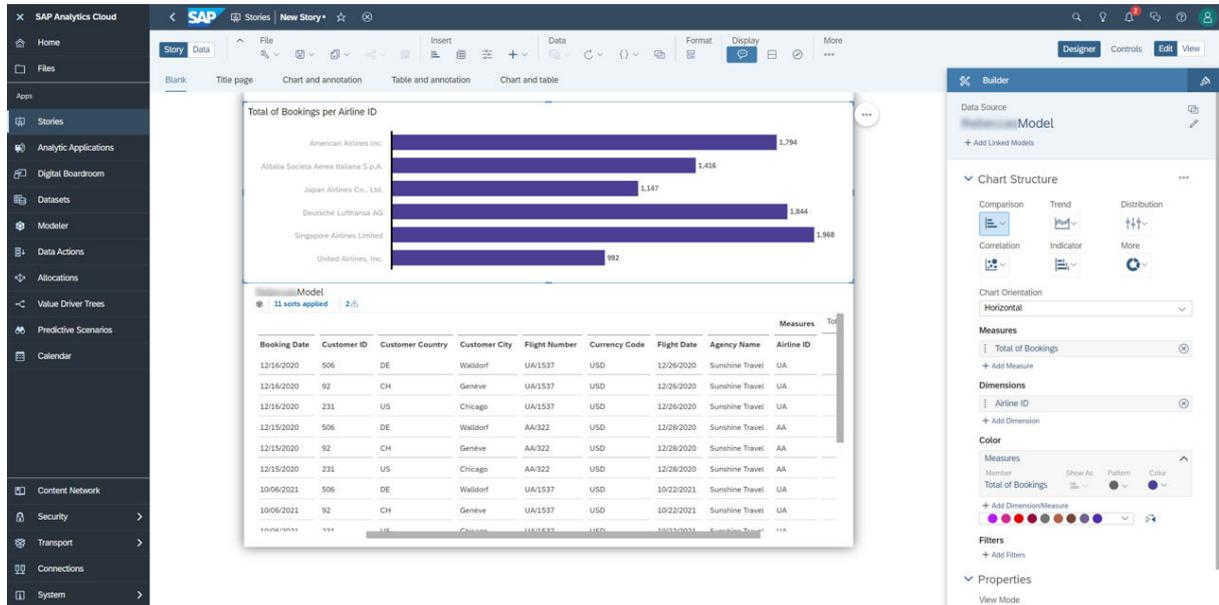

1. Login to your SAP Analytics Cloud (SAC) tenant.
2. In the main menu, select *Modeler*.
3. Click on *Live Data Model*.
4. In the dialog window, provide the following values:
  - *System Type*: SAP BW
  - *Connection*: The name of the connection defined in [Connect the ABAP Environment System to SAP Analytics Cloud \[page 825\]](#).
  - *Data Source*: The technical name of the query. This name can be found in your service binding as *External Service Name*.Click *Ok*.
5. Save your model by clicking the save icon. Select a pre-existing folder or create a new one. Give your model a *Name* and *Description* and click *Ok*.

#### Creating Stories

Now you can create an analytical story.

1. In your SAC tenant, go to the main menu and select *Stories*.
2. Create a new story or select an existing template.
3. Click on *Chart and table* and click the + (Add) button in the graph.
4. Select the model you created.
5. You can insert a table and/or a chart and use the builder on the right to select measures and dimensions.
6. Click the Save icon to export your story.

## Result

## 4.2.9 Business Configuration

Find out how to create custom business configuration objects to enrich your extensibility solutions.

### Context

An important part of a business application is business configuration. Business configuration in enterprise software refers to a predefined set of configuration options that affect its functionality and behavior. You can use your SAP ABAP Environment to create custom business configuration objects. Find out which tasks a developer (business role SAP\_BR\_DEVELOPER) needs to perform to implement business configuration objects. Mind that lifecycle management is usually performed by a separate user. See [Business Configuration Change Logs \[page 2371\]](#) for more information.

### Procedure

Consider the following to implement your custom business configuration objects:

- Business configuration objects are based on database tables with the delivery type C (@AbapCatalog.deliveryClass : #C). This indicates that the content in these tables can be transported between tenants.
- Business configuration content is usually not directly maintained in a productive system but created in a development system and then transported to the test and productive system. As a result, the corresponding transport handling must also be implemented.

- Business users need a way to maintain content. The number of maintenance objects often exceeds the number of master data or transactional apps, yet at the same time, they are used less frequently. This suggests using a highly standardized way of providing business configuration maintenance apps.
- Business configuration administration often involves the maintenance of language-dependent texts.

To enable the maintenance of content, a full business object is built on top of the table and exposed via an OData service, following the [RAP \(Restful ABAP Programming\)](#) model. The resulting service can be consumed by a frontend application, allowing business users to maintain business configuration content.

SAP offers the *Custom Business Configurations* app as a standardized tool for business configuration maintenance. Please refer to [Creating Business Configuration Apps with ABAP RESTful Application Programming Model and Custom Business Configurations App \[page 828\]](#).

As an alternative, you can also enable your business configuration object for upload or download, allowing you to quickly and reliably maintain large amounts of content. In this case, you're not required to develop a full business object. The generic file upload app supports the file format that can be downloaded from SAP ERP or SAP S/4HANA systems, thus supporting an easy migration of data from SAP on-premise systems. For more information, see [here](#).

Should you have special requirements to your maintenance UI, you can also create and deploy your own custom Fiori application. For more information, see [Develop an SAP Fiori Application UI and Deploy it to ABAP Using SAP Business Application Studio \[page 1716\]](#).

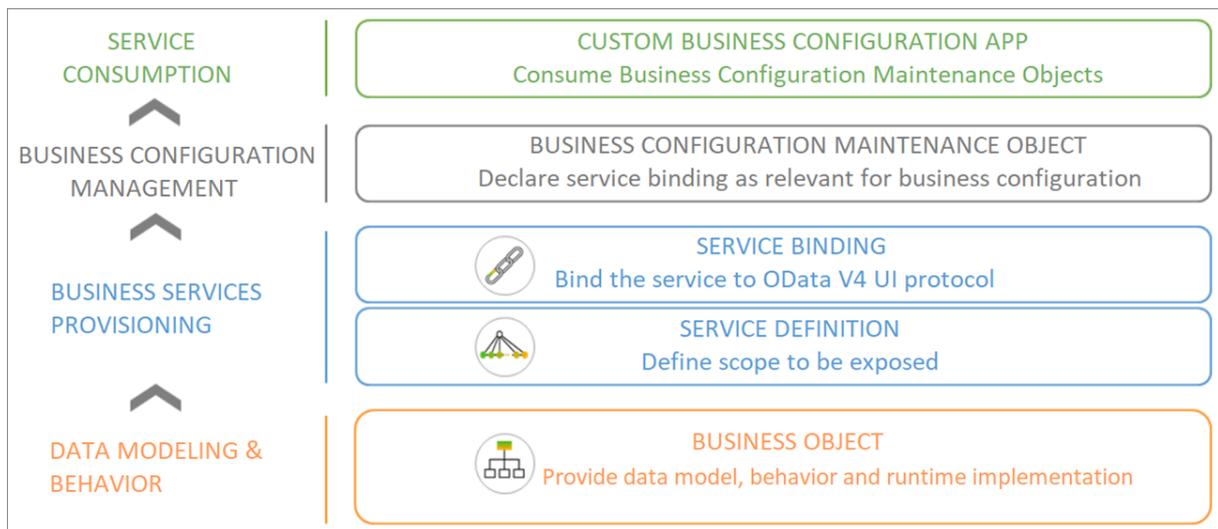

#### Note

Although the management of customizing transport requests is usually done in the *Export Customizing Transports* app by the business process configuration expert, developers can also create such transport requests using the transport organizer view in ABAP Development Tools.

## 4.2.9.1 Creating Business Configuration Apps with ABAP RESTful Application Programming Model and Custom Business Configurations App

As an ABAP Developer you can leverage the *ABAP RESTful Application Programming Model* (RAP) and the *Custom Business Configurations* (CUBCO) app to create a SAP Fiori UI to maintain customizing table data. You don't need to create your own Fiori app. Everything can be implemented with ABAP repository objects.

For more information, see this [tutorial](#) .

The development of a business configuration maintenance Fiori UI requires developers to perform the following fundamental activities:

## 1. Developing Business Object

Based on the customizing tables you define a data model and business object structure. Check the prerequisites of the business configuration maintenance object to see which kind of business object is supported. Using model-driven development approach, you develop actions, validations, and determinations for the entities of the business object to change, maintain and validate configuration entries.

You have the option to use the [Generate ABAP Repository Objects Wizard \[page 833\]](#) to generate all required development objects based on a customizing table. If required, you can then add further functions or enhance the generated business object structure.

For more information, see [Developing a Ready-to-Run Business Object](#) and [Developing Business Logic](#).

## 2. Developing Business Service

Define the scope by exposing the entities of the business object in a service definition and bind the service to OData V4 UI protocol with a service binding. For more information on this, see [Working with Business Services](#).

## 3. Developing Business Configuration Maintenance Object

Declare the service binding as relevant for business configuration by creating a [Business Configuration Maintenance Object \[page 830\]](#).

## 4. Custom Business Configurations App

Based on the Business configuration maintenance object, the custom business configurations app renders a [Fiori Elements List Report Floorplan](#) for the entities exposed by the service binding to maintain the configuration entries. For more information, see [Custom Business Configurations App \[page 2373\]](#).

### 4.2.9.1.1 Business Configuration Maintenance Object

#### Purpose

A business configuration maintenance object declares a service binding as relevant for business configuration. It will be shown on the list of all maintainable business configurations in the Fiori app [Custom Business Configurations App \[page 2373\]](#). The business configuration maintenance object can be maintained via API or ADT. For more information, see also [Creating Business Configuration Apps with ABAP RESTful Application Programming Model and Custom Business Configurations App](#).

#### Prerequisites

- The service binding must be of type OData V4 - UI and exposing CDS root entity with draft enabled behavior definition.
- The following two business object composition tree structures are supported:
  - the height of the tree is less or equal than 2.  
Example: Root entity A has two child entities B and C. Entity C has one child entity D. D cannot have further child entities
  - the height of the tree is less equal than 3 and the option skip root entity list report is enabled. The root entity must be a singleton and have exactly one child entity.  
Example: Root entity S has one child entity A. Entity A has two child entities B and C. Entity C has one child entity D. D cannot have further child entities.
- The data model must consist only of client-dependent tables.

#### Provide Authorizations for a Business Configuration

To grant frontend users the rights to use a business configuration maintenance object, first create an [Identity and Access Management \(IAM\) App](#) and assign it to an [IAM Business Catalog](#). Follow [this user guide](#) but make sure to select the IAM App type [Business Configurations](#) app. In the service tab of the IAM app, select OData V4 as service type and the service binding name of the business configuration maintenance object as service name. In the authorizations tab maintain the authorization object used by the RAP BO for authorization control.

Once you have created the IAM Business Catalog, assign the catalog to a business role on the Fiori Launchpad by following [this user guide](#). Finally, follow [this user guide](#) to assign the business role to business users to grant the rights to use your business configuration inside the *Custom Business Configurations* Fiori app.

## Related Information

[Creating a Business Configuration Maintenance Object in ADT \[page 833\]](#)

[Business Configuration Maintenance Object Cloud Platform API \[page 831\]](#)

[Generating a Business Configuration Maintenance Object with the Generate ABAP Repository Objects Wizard \[page 833\]](#)

### 4.2.9.1.1.1 Business Configuration Maintenance Object Cloud Platform API

Use the ABAP API `mbc_cp_api` to create, update, delete, and read business configuration maintenance objects.

After a business configuration maintenance object has been created, it will be shown on the list of all maintainable business configurations in the Fiori app *Custom Business Configurations* if you have all necessary authorizations regarding the service of the business configuration. You can get the necessary authorizations by following the instructions in [Business Configuration Maintenance Object \[page 830\]](#) > **Provide Authorizations for a Business Configuration**. The end user can then maintain data for the registered business configuration from the frontend.

Before using any of the following methods, first obtain an interface handle by calling `mbc_cp_api=>business_configuration_api` with an identifier for your business configuration.

If an error occurs while calling the following methods, an exception of type `cx_mbc_api_exception` will be raised. Use the method `if_xco_news~get_messages` to retrieve all messages that the exception carries.

#### Create a Business Configuration Maintenance Object

Use the `create` method of the obtained business configuration interface handle to create a new object. Supply the following mandatory parameters, as illustrated in the code sample below.

- A name that is shown on the frontend list of all registered business configurations.
- A description for the business configuration that is shown on the frontend.

#### Note

The name and description are language dependent. The translations can be maintained using the [Maintain Translations](#) app.

- The OData V4 - UI Service Binding that is used to maintain the business configuration data. The service must be draft enabled.
- The name of the service to be used (as defined in the Service Binding).
- The name of an entity set as exposed by the service definition. This entity set is used as the root node for the UI. Only for this root entity set and its associations a UI is shown. Keep in mind that only one level of sub nodes is supported.

- A transport request of type `workbench` to write the business configuration registration to. An entry of type "SMBC" (Business Configuration Object) will be written to that transport request.

### Sample Code

```

CLASS zcl_ys_register_bc DEFINITION PUBLIC FINAL CREATE PUBLIC
  INHERITING FROM cl_xco_cp_adt_simple_classrun.
  PROTECTED SECTION.
  METHODS:
    main REDEFINITION.
ENDCLASS.
CLASS zcl_ys_register_bc IMPLEMENTATION.
  METHOD main.
    DATA(lo_business_configuration) =
mbc_cp_api=>business_configuration_api( '/Y123456/HOLIDAY_CALENDAR' ).
    TRY.
      lo_business_configuration->create(
        iv_name           = 'Holiday Calendar'
        iv_description    = 'A calendar for holidays'
        iv_service_binding = '/Y123456/CAL_I_HOLIDAY_SB'
        iv_service_name   = 'Holiday'
        iv_service_version = 0001
        iv_root_entity_set = 'HolidayRoot'
        iv_transport      = 'X02K900025'
      ).
    CATCH cx_mbc_api_exception INTO DATA(lx_mbc_api_exception).
      DATA(lt_messages) = lx_mbc_api_exception->if_xco_news~get_messages( ).
      LOOP AT lt_messages INTO DATA(lo_message).
        " Use lo_message->get_text( ) to get the error message.
      ENDLOOP.
    ENDTRY.
  ENDMETHOD.
ENDCLASS.

```

The supplied information and an application component are stored in the registration table. The application component is derived from the package that contains the registered service binding. If an error occurs while using the business configuration, it will be shown in an error message on the frontend.

The `create` method also has two optional parameters:

- `skip_root_entity_list_report`: If `abap_true`, the UI automatically navigates to the object page of the root entity skipping the list report. Exactly one root entity must exist.
- `app_configuration`: Configuration of root entity list report and object pages. It is sufficient to maintain only those attributes that should deviate from the standard behavior.

### Update a Business Configuration Maintenance Object

You can only update the name and the description of your business configuration by using the respective methods `update_name` and `update_description`. A transport request of type `Workbench` must be supplied to transport the updated object.

### Delete a Business Configuration Maintenance Object

To delete a business configuration maintenance object, use the method `delete`. A transport request of type `workbench` must be supplied to transport the deletion.

### Check if a Business Configuration Maintenance Object Exists

To check the existence of a business configuration maintenance object, use the method `exists`. The method has no parameters. It returns `abap_true` if the object exists, `abap_false` if it doesn't.

For an overview of business configuration maintenance objects, use CDS view `I_CustABAPObjDirectoryEntry` with `ABAPObjectType = 'SMBC'`.

### Read a Business Configuration Maintenance Object

To retrieve the details of a business configuration maintenance object, use the method `read`. The method has no parameters. The returned structure contains all the metadata of the business configuration maintenance object.

## 4.2.9.1.1.2 Creating a Business Configuration Maintenance Object in ADT

Find out how to create a business configuration maintenance object using the ABAP Development Tools (ADT).

### Procedure

1. In the *Project Explorer*, select the relevant package node.
2. Open the context menu and choose *New>Other ABAP Repository Object>Business Configuration Management>Business Configuration Maintenance Object>Next* to launch the creation wizard.
3. Enter a name and a description and choose *Next*.

### Related Information

[Working with Business Configuration Maintenance Objects](#)

## 4.2.9.1.1.3 Generating a Business Configuration Maintenance Object with the Generate ABAP Repository Objects Wizard

You can create a business configuration maintenance object together with all related development objects on the basis of a database table by using the *Generate ABAP Repository Objects Wizard*.

### Context

Creating a Fiori app to maintain customizing tables involves many different objects that need to be created manually. On the basis of a database table, this wizard creates all the development objects that are required to maintain the content of this table and, optionally, the content of foreign key associated tables and text tables

using the *Custom Business Configurations* app. If required, you can then, for example, add further functions or enhance the generated business object structure. As an alternative to using the app, you can also build your own custom SAP Fiori elements app based on the generated objects. This is described [in this blog entry](#).

For more information, see [Creating Business Configuration Apps with ABAP RESTful Application Programming Model and Custom Business Configurations App](#). A tutorial on how to use this wizard and the *Custom Business Configurations* app is available [here](#).

## Prerequisites

The wizard distinguishes between three types of tables:

- The basis database table in which context the wizard is executed
- (Optional) Additional tables with a foreign key relation of type #KEY to the basis database table
- (Optional) Text tables with a foreign key relationship of type #TEXT\_KEY to one of the tables mentioned above

All tables must fulfill the following requirements:

- have a client key field
- have delivery class C
- allow data maintenance
- (optional) have a timestamp field with data element ABP\_LOCIINST\_LASTCHANGE\_TSTMPL. If the table doesn't contain this field, the concurrency control is not active

The basis database table must also meet the following requirements:

- have a timestamp field with data element ABP\_LASTCHANGE\_TSTMPL. For more information, see [RAP Reuse Data Elements](#). If the table doesn't contain this field, the entire ETag is handled by CDS entity I\_CstmBizConfigLastChgd

The additional tables must also meet the following requirements:

- Have a foreign key of type #KEY that fully matches the primary key of the base table

The text tables must also meet the following requirements:

- have a language key field with type LANG
- have a foreign key of type #TEXT\_KEY that fully matches the primary key of one of the other tables

The software component of the target package and the table package must be changeable.

## Procedure

The wizard can't overwrite existing objects or create only a subset of the objects. The generated objects will have the same ABAP language version as the target package.

1. In your ABAP project, open the context menu for a database table and choose *Generate ABAP Repository Objects*.
2. In the folder *Business Configuration Management*, select *Maintenance Object*. Choose *Next*. Enter the target package and choose *Next* again.

3. In the *Configure Generator* page you can define the names and options for the generated objects. The wizard fills all required fields as a proposal based on the description of the basis table. Select *Next*.
4. In the *Preview Generator Output* page, a preview list is available with the objects to be generated. Choose *Next*.
5. Assign a transport request.
6. Choose *Finish* to start the generation of the objects.
7. After the generation process is complete, the generated *Business Configuration Maintenance Object* is shown.

## Procedure Results

The generated RAP business object has the following properties:

- draft enabled, managed
- authorization control based on authorization object `S_TABU_NAM` and the CDS view entity name of the basis table
- concurrency control based on the table timestamp fields
- integration of the BC transport API to validate and record changes on a customizing transport request
- To enable mass editing and manual transport selection, a singleton root entity is part of the generated data model. For more information, see [here](#).
- internal numbering is used for key fields with ABAP type `raw(16)` (UUID)

## Scenario Options

### Add Copy Action

Select this to include a *Copy* action in the generated app. With this factory action a copy of the selected entry will be created.

### Add Deprecate Actions

Select to include a Deprecate and Invalidate action in the generated app. The table must have a field `CONFIGDEPREICATIONCODE` with the data element `CONFIG_DEPREICATION_CODE`. With this action a selected entry can be deprecated or invalidated. If a foreign key check is executed on a deprecated or invalidated check table entry, the check returns a warning (deprecated) or error (invalidated). If this option is selected, the user can delete a table entry only if it is in draft mode and the entry was never active.

### Add Data Consistency Check

Select this option to include a *Validation* for the *Prepare* draft action in the generated app, which checks the consistency of field inputs with:

- domains with fixed values
- foreign keys where `@AbapCatalog.foreignKey.screenCheck : true`

### Copy Parameter Entity

If the option *Add Copy Action* is selected, an abstract entity for the user input is generated. Provide a name for the abstract entity. This is not necessary if all key fields except the client field of the basis table have type ABAP type `raw(16)`.

## Transport Selection

Select *Manual* to include the action *Select Transport* in the generated app. With this action, you can select an existing customizing transport request before saving the configuration changes.

## BC Management

### BC Maintenance Object

Enter the name of the maintenance object.

### Transport Object

You can specify the name of a transport object. If specified, a transport object of type `IndividualTransaction` is generated. Configuration changes are recorded under this transport object instead of as a `TABU`.

## Data Model

### Tables

This list must contain the basis database table. You can add any additional tables that fulfill the requirements that should be part of the generated RAP business object.

### Text Tables

You can add any text table that fulfills the requirements that are to be part of the generated RAP business object.

## Example

Our example scenario consists of four editable entities with a 1:N cardinality at each level:

- Status Class
- Status Class Text
- Status Code
- Status Code Text

The corresponding database table definitions are as follows:

Status Class:

#### Sample Code

```
@EndUserText.label : 'Status Class'  
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE  
@AbapCatalog.tableCategory : #TRANSPARENT  
@AbapCatalog.deliveryClass : #C
```

```

@AbapCatalog.dataMaintenance : #ALLOWED
define table /dmo/statusclass {
  key client      : abap.clnt not null;
  key status_class_id : /dmo/status_class_id not null;
  last_changed_at : abp_lastchange_tstmpl;
  local_last_changed_at : abp_locinst_lastchange_tstmpl;
}

```

## Status Class Text

### Sample Code

```

@endUserText.label : 'Status Class Text'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #C
@AbapCatalog.dataMaintenance : #ALLOWED
define table /dmo/stclasstext {
  key client      : abap.clnt not null;
  key lang        : abap.lang not null;
  @AbapCatalog.foreignKey.keyType : #TEXT_KEY
  key status_class_id : /dmo/status_class_id not null
  with foreign key /dmo/statusclass where client = /dmo/stclasstext.client
  and status_class_id = /dmo/stclasstext.status_class_id;
  description     : /dmo/description;
  local_last_changed_at : abp_locinst_lastchange_tstmpl;
}

```

## Status Code:

### Sample Code

```

@endUserText.label : 'Status Code'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #C
@AbapCatalog.dataMaintenance : #ALLOWED
define table /dmo/statuscode {
  key client      : abap.clnt not null;
  @AbapCatalog.foreignKey.keyType : #KEY
  key status_class_id : /dmo/status_class_id not null with foreign key /dmo/
  statusclass where client = /dmo/statuscode.client and status_class_id = /dmo/
  statuscode.status_class_id;
  key status_code_id : /dmo/status_code_id not null;
  local_last_changed_at : abp_locinst_lastchange_tstmpl;
}

```

## Status Code Text:

### Sample Code

```

@endUserText.label : 'Status Code Text'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #C
@AbapCatalog.dataMaintenance : #ALLOWED
define table /dmo/stcodetext {
  key client      : abap.clnt not null;
  key lang        : abap.lang not null;
  key status_class_id : /dmo/status_class_id not null;
  @AbapCatalog.foreignKey.keyType : #TEXT_KEY
  key status_code_id : /dmo/status_code_id not null with
  foreign key /dmo/statuscode where client = /dmo/stcodetext.client and

```

```

status_class_id = /dmo/stcodetext.status_class_id and status_code_id = /dmo/
stcodetext.status_code_id;
  description      : /dmo/description;
  local_last_changed_at : abp_locinst_lastchange_tstmpl;
}

```

If you execute the wizard in the context of the table /DMO/STATUSCLASS, the text table /DMO/STCLASSTEXT is automatically added to the list of text tables in the data model section.

Due to the foreign key definition, you can also add the Status Code and Status Code Text table manually.

**Singleton Entity**

Draft Table Name:

Entity Name:

Entity Label:

Interface View:

Projection View:

Key Field Alias:

Table Name	Draft Table Name	Entity Name	Entity Label	Interface View	Projection View
/DMO/STATUSCLASS	/DMO/D_STATUSCLA	StatusClass	Status Class	/DMO/I_StatusClass	/DMO/C_StatusClass
/DMO/STATUSCODE	/DMO/D_STATUSCO	StatusCode	Status Code	/DMO/I_StatusCode	/DMO/C_StatusCode

Text Table Name	Draft Table Name	Entity Name	Entity Label	Interface View	Projection View	Text Field
/DMO/STCLASSTEXT	/DMO/D_STCLASSTE	StatusClassText	Status Class Text	/DMO/I_StatusClassText	/DMO/C_StatusClassText	DESCRIPTION
/DMO/STCODETEXT	/DMO/D_STCODETE	StatusCodeText	Status Code Text	/DMO/I_StatusCodeText	/DMO/C_StatusCodeText	DESCRIPTION

< Back **Next >** Finish Cancel

The resulting table maintenance application then looks like this:

The screenshot shows the SAP Custom Business Configurations table maintenance application for Status Class 4xx. The interface includes a search bar, a search icon, and a search button. The status class is set to 4xx. The application is divided into three sections: Status Code, Status Class Text, and an Apply button at the bottom right.

**Status Class:** 4xx

**Status Code**

**StatusCodes (2)**

Status Code	Description
401	Unauthorized
404	Not found
403	Forbidden

**Status Class Text**

**StatusClassTexts (1)**

Lang	Description
English (EN)	Client Error

**Apply**

## 4.2.9.1.2 Develop Common Capabilities

The guides in this section focus on specific development tasks common to a business configuration application. Whether or not you want to follow these guidelines depends on your initial situation and the desired result of your development.

## 📌 Note

The [Business Configuration Maintenance Object wizard \[page 833\]](#) takes these concepts into account. You can therefore use the wizard to generate an executable example which illustrates the implementation of these concepts.

- [Authorization Control \[page 840\]](#)
- [Transport Handling \[page 841\]](#)

## 4.2.9.1.2.1 Authorization Control

### Context

[Authorization control in RAP](#) protects your business configuration object against unauthorized access to customizing data.

It's recommend to use the authorization `S_TABU_NAM` together with the CDS root entity name of the business object as table name to perform the read and modify operation. However, you can also check against the physical table names or use a different authorization object instead.

### Procedure

The advantage of using the CDS root entity name is that if the business object is extended by a new table you don't need to adjust the authorization check.

See also [Provide Authorization](#) on how to create the IAM app and add the authorization object.

### Example

The business configuration CDS root entity name is `/ITAPC1/I_Status`.

The data control language (DCL) can be defined as follows:

#### 📄 Sample Code

```
@MappingRole: true
define role /ITAPC1/I_Status {
  grant select on /ITAPC1/I_Status
  where ( ) = ASPECT pfcg_auth ( 'S_TABU_NAM', ACTVT = '03', TABLE = '/ITAPC1/
I_STATUS' );
}
```

The global authorization check in the behavior implementation can be defined as follows:

### Sample Code

```
METHOD GET_GLOBAL_AUTHORIZATIONS.  
  AUTHORITY-CHECK OBJECT 'S_TABU_NAM' ID 'TABLE' FIELD '/ITAPC1/I_STATUS'  
  ID 'ACTVT' FIELD '02'.  
  DATA(is_authorized) = COND #( WHEN sy-subrc = 0 THEN if_abap_behv=>auth-  
  allowed  
                                ELSE if_abap_behv=>auth-unauthorized ).  
  result-%UPDATE           = is_authorized.  
  result-%ACTION-Edit     = is_authorized.  
ENDMETHOD.
```

The authorization instance of `S_TABU_NAM` in the IAM app can be defined as follows. Whether or not the user has write or read authorization is finally defined in the General Role Details section of the Business Role the Business Catalog with this IAM app is assigned to.

### Sample Code

```
ACTVT = Change, Display  
TABLE = /ITAPC1/I_STATUS
```

## 4.2.9.1.2.2 Transport Handling

### Context

Business configuration content is usually not directly maintained in a productive system, but created in a development system, and then transported to the test system and productive system. As the developer of a business configuration app, you need to ensure that changes to the business configuration content is recorded onto a transport request of type *Customizing* and the user has the option to select the correct transport request.

### Recording Changes on Transport Request

With the factory class `MBC_CP_API` you can instantiate a transport API to validate and record entity keys of a RAP business object on a transport request.

### Sample Code

```
DATA(api) = mbc_cp_api=>rap_table_cts( table_entity_relations = VALUE  
#( ( entity = '/ITAPC1/I_Status' table = '/ITAPC1/STATUS' )  
  
  ( entity = '/ITAPC1/I_StatusText' table = '/ITAPC1/STATUST' ) ) ).
```

In the behavior implementation define an [Additional Save Implementation](#) in the header directly after the keyword `managed`. In the `save_modified` method you can record the changes on the transport request with the method `record_changes` of this API. Check the ABAP Doc of `record_changes` for more information and example implementation.

For each entity of the RAP BO define a [Validation](#) on save for create, update and delete. In the validation implementation call the method `validate_changes` of the API. Check the ABAP Doc of `validate_changes` for more information and example implementation.

## Transport Selection

The before mentioned API methods require a transport request to be passed. For the transport selection define an action with Abstract CDS Entity `D_SelectCustomizingTransptReqP` as the parameter. This CDS Entity returns all modifiable transport request of type `Customizing` where the user either owns the request or owns at least one open task.

Save the result of the action in a virtual field of the draft entity. When recording or validating the changes the previously selected transport request can then be retrieved from the draft entity.

### Note

When developing custom business configuration objects, you can decide if you want to provide a transport selection screen for change recording. If you are using this transport pattern, we recommend autofilling the transport request based on the software component of the business configuration object.

## 4.2.9.1.3 Develop UI-Specifics

The UI layout of a *Business Configuration Maintenance Object* in the *Custom Business Configurations* app depends on the following layers.

- [CDS Annotations](#)

You can use CDS annotations to define, among other things, the field labels and description, value helps, facets and actions.

- Fiori Elements Settings in the [Business Configuration Maintenance Object definition](#)

You can configure the list report, object pages and table settings of the *Fiori Elements List Report Floor Plan* rendered by the *Custom Business Configurations* app.

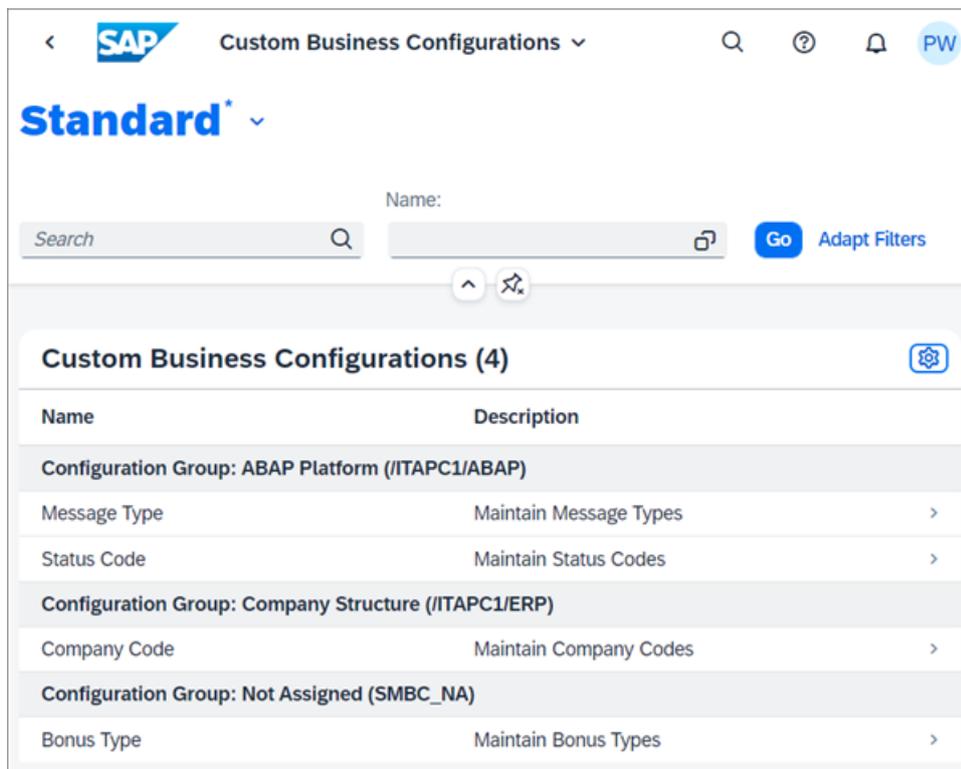

- Generic UI functions of the [Custom Business Configurations App \[page 2373\]](#).

Grouping of business configuration maintenance objects, intent navigation, display change logs and show documentation are generic UI functions of the *Custom Business Configurations* app.

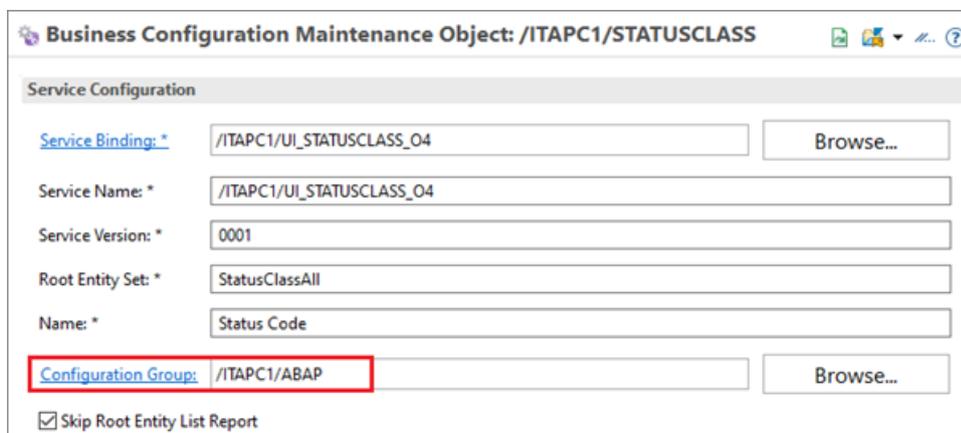

### 4.2.9.1.3.1 Grouping

The standard variant of the *Custom Business Configurations* app shows you the list of business configuration maintenance objects.

If the list needs to be structured in a simple hierarchical manner, you have the option to group the business configuration maintenance objects semantically.

As the developer of the business configuration maintenance object, you specify a data element of the same software component as configuration group.

The name of the data element can then be used by the custom business configurations app user as the *Group By* element in the table settings.

By clicking on settings you can navigate to the *View Settings* window.

The description of the configuration group data element is shown as the group label. Other attributes of the data element are not relevant. If the configuration group of a business configuration maintenance object is not maintained, the object is assigned to the generic group *Not Assigned*.

The *Custom Business Configurations* app user can save and share the variant with grouping in the *My Views* Dialog.

## 4.2.9.1.3.2 Table Creation Mode

If a new entry is added to a table, the *Custom Business Configurations* navigates to the object page of the new entry by default. This can be changed so that a navigation is not triggered.

This configuration is done with the *Table Creation Mode* attribute in the *Table Settings* section of the *definition*.

In the following example the business object consists of five entities:

```
[X11] /ITAPC1/UI_STATUSCLASS x
1 define service /ITAPC1/UI_STATUSCLASS {
2   expose /ITAPC1/C_StatusClass_S as StatusClassAll;
3   expose /ITAPC1/C_StatusClass as StatusClass;
4   expose /ITAPC1/C_StatusClassText as StatusClassText;
5   expose /ITAPC1/C_StatusCodeText as StatusCodeText;
6   expose /ITAPC1/C_StatusCode as StatusCode;
7 }
```

For entity `StatusClass` the app shall navigate to the object page when creating a new table entry because the entity has many attributes which the user must maintain. Therefore *Table Creation Mode* is set to *New Page*.

The app shall not navigate to the object page when creating a new table entry for the entity `StatusClassText` because the user only needs to specify language key and text. Therefore *Table Creation Mode* is set to *Creation Row* and *Table Type* to *Grid Table*.

**Business Configuration Maintenance Object: /ITAPC1/STATUSCLASS**

## 4.2.10.1 Communication Management

Learn more about the basic principles of communication management when integrating your system or solution with other systems to enable data exchange in your ABAP environment.

## 4.2.10.1.1 Communication Scenario

A communication scenario, which is created in the development system using `ABAP Development Tools` and transported to other systems, is a design time description of how two communication partners communicate with each other. It consists of inbound and/or outbound services as well as supported authentication methods.

It provides technical information, such as the used inbound and outbound services and their service type, for example OData or SOAP, and the number of allowed communication arrangement instances. If the scenario exposes inbound services, it specifies the authorizations that are required to run the services.

The following types of communication scenarios are available:

- **Managed by SAP**, where SAP provides a ready-to-use communication scenario and you create and maintain a communication arrangement.
- **Managed by the customer**, where you develop a communication scenario and create and maintain a communication arrangement.

### Related Information

[Display Communication Scenarios \[page 2394\]](#)

[Overview of Communication Scenarios Managed by SAP](#)

[Developing External Service Consumption \(Outbound Communication\) \[page 852\]](#)

[Developing APIs for Inbound Communication \[page 992\]](#)

## 4.2.10.1.2 Communication System

A communication system is a specification of a system that represents a communication partner and the technical information required for the communication, such as the host name, port, users for inbound or outbound communication, certificates, etc.

If the communication system represents an on-premise system that is protected by a firewall, the system can be connected by assigning a cloud connector.

Instead of maintaining the credentials for outbound communication in the communication system itself, the communication system can also refer to a destination from the destination service. This can be a destination on subaccount level, or a destination from a destination service instance.

An administrator user in the ABAP environment has to create the communication system in the [Communication Systems \[page 2397\]](#) app in SAP Fiori launchpad. Note that the communication system is not transported between ABAP systems but created locally. The communication partner can vary for each system.

### 4.2.10.1.3 Communication User

A communication user is a specific type of technical user that is assigned to a communication system. The user can be assigned a password or X.509 certificate.

A communication user is added as a user for inbound communication to communication systems.

An administrator user in the ABAP environment creates the communication user in the [Maintain Communication Users \[page 2391\]](#) app in SAP Fiori launchpad. Note that the communication user is not transported between systems but created locally. The technical users and their credentials can vary for each system.

### 4.2.10.1.4 Communication Arrangement

A communication arrangement is a runtime description of a specific communication scenario. It describes which communication partners communicate with each other in the scenario, and how they communicate.

To describe this runtime behavior, you have to create an arrangement for a scenario, assign the communication system and communication users, and select the authentication method that shall be used.

If the communication scenario exposes inbound services, the communication user is granted the authorizations that have been specified for the communication scenario.

An administrator user in the ABAP environment creates the communication arrangement in the [Communication Arrangements \[page 2394\]](#) app in SAP Fiori launchpad. Note that it is not transported between systems but created locally. For certain SAP-managed scenarios that integrate an SAP BTP service, you can also create a communication arrangement from a service key of the service instance that you would like to connect.

For inbound-only scenarios, you can create a communication arrangement by creating a corresponding service key for the ABAP environment service instance.

## Related Information

[Maintain a Communication Arrangement for Inbound Communication](#) 

### 4.2.10.1.5 Destination Service

Using the SAP destination service, you can retrieve and store technical information about the target resource (destination) that you want to connect with your application to a remote service or a system.

The destination service allows you to read and manage the address of a remote service and the user authentication information for the connection on subaccount and service instance level.

## Related Information

[Destination Service](#)

[Create a Destination \[page 854\]](#)

### 4.2.10.1.6 Destination

A destination is stored in the SAP destinations service and contains the connection details for the communication partner.

You can use a destination to:

- Connect your application to the Internet (via HTTP, RFC, or WebSocket RFC) or to an on-premise system (via HTTP or RFC)
- Send and retrieve emails by configuring a mail destination

#### Note

You can create a destination for a destination service on instance level or subaccount level.

A destination can be referenced in a communication system. To refer a destination from a destination service instance, a communication arrangement for SAP-managed scenario `SAP_COM_0276` needs to be maintained to enable communication with the destination service instance. See [Create a Destination \[page 854\]](#). In this case, the destination name and the service instance name need to be maintained in the communication system.

## Related Information

[Managing Destinations](#)

### 4.2.10.1.7 Cloud Connector

The Cloud Connector serves as a link between cloud applications and on-premise systems.

In the Cloud Connector, the subaccount of the ABAP system is connected so that the Cloud Connector can be used within a communication system or destination in the subaccount.

It provides an easy setup with a clear configuration of the systems that are exposed to SAP BTP.

## Related Information

[Cloud Connector](#)

## 4.2.10.2 Supported Protocols and Authentication Methods

Get an overview about supported protocols and authentication methods in the ABAP environment.

Each communication scenario defines which authentication methods can be used. The tables below gives you an overview of all the authentication methods for communication management.

### Note

- The supported protocols and authentication methods only apply to communication scenarios that are managed by customers.
- Since OData is HTTP-based, the listed authentication methods for HTTP are also valid for OData.

### Outbound Communication

Protocol	Available Authentication Methods via Destination Service	Available Authentication via Outbound Communication User
HTTP (Internet)	No Authentication	No Authentication
	Basic Authentication	Basic Authentication
	Client Certificate Authentication	Client Certificate Authentication
	OAuth 2.0 Client Credentials Grant	OAuth 2.0 Client Credentials Grant
	OAuth 2.0 SAML Bearer Assertion	OAuth 2.0 SAML Bearer Assertion
	OAuth 2.0 User Token Exchange	
HTTP (Cloud Connector)	No Authentication	No Authentication
	Basic Authentication	Basic Authentication
	Principal Propagation	
SOAP (Internet)	No Authentication	No Authentication
	Basic Authentication	Basic Authentication
	Client Certificate Authentication	Client Certificate Authentication
	OAuth 2.0 Client Credentials Grant	OAuth 2.0 Client Credentials Grant
SOAP (Cloud Connector)	No Authentication	No Authentication
	Basic Authentication	Basic Authentication
	Principal Propagation	

Protocol	Available Authentication Methods via Destination Service	Available Authentication via Out-bound Communication User
RFC (Internet)	Basic Authentication	Basic Authentication
	Client Certificate Authentication	Client Certificate Authentication
RFC (Cloud Connector)	Basic Authentication	Basic Authentication
	Principal Propagation	

### Note

The use of Principal Propagation, OAuth 2.0 SAML Bearer Assertion, and OAuth 2.0 User Token Exchange isn't supported in the ADT class runner (`if_oo_adt_classrun`) and application jobs. It can only be used during processing of an OData or HTTP service, and only if you execute the service as a business user.

## Inbound Communication

Protocol	Available Authentication via Inbound Communication User	Available Authentication via Business User
HTTP	Basic Authentication	SAML Assertion Authentication
	Client Certificate Authentication	OpenID Connect Bearer Token
		OAuth 2.0 Authorization Code with Proof Key for Code Exchange (PKCE)
RFC (Internet)	Basic Authentication	
	Client Certificate Authentication	
RFC (Cloud Connector)	Basic Authentication	
SQL service	Basic Authentication	OpenID Connect Bearer Token
	Client Certificate Authentication	

- For more information about the SQL service, see [Accessing ABAP-Managed Data Using SQL Services for Data Integration Scenarios \[page 1096\]](#).
- For more information about SAML Assertion Authentication and OpenID Connect Bearer Token, see [How to Create Communication Systems](#).

## 4.2.10.3 Developing External Service Consumption (Outbound Communication)

Get more information about consuming external services.

To establish outbound communication between two communication partners, you have to implement the call of a service by doing the following:

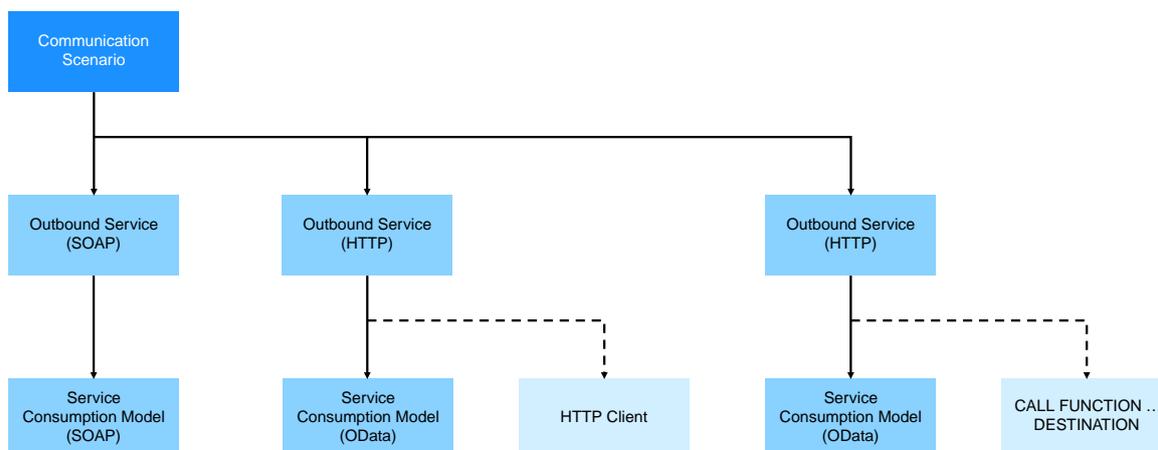

- Create an outbound service  
These outbound services can be HTTP (see [Enable HTTP Communication in Your ABAP Code \[page 951\]](#)), RFC (see [Enable RFC Communication in Your ABAP Code \[page 962\]](#)), or SOAP services (see [Enable SOAP Communication in Your ABAP Code \[page 973\]](#)).
- Create a communication scenario and assign it to the outbound service  
If you enable multiple arrangements, you can add customer-specific properties to the scenario to enable a simple receiver determination.
- Implement the call of the service by using the `create_by_comm_arrangement` method for outbound communication depending on the service protocol, e.g. for HTTP service:

### Sample Code

```
DATA(lo_destination) =  
cl_http_destination_provider=>create_by_comm_arrangement(  
  comm_scenario      = '<SCENARIO ID>'  
  service_id         = '<OUTBOUND SERVICE ID>'  
  comm_system_id     = system_id ).  
  
DATA(lo_http_client) =  
cl_web_http_client_manager=>create_by_http_destination( lo_dest ).
```

If the scenario includes multiple communication arrangements, you have to determine the communication system. You can read the customer-specific properties using class `CL_COM_ARRANGEMENT_FACTORY` to determine the receiver communication system.

ABAP System

### 📌 Note

Alternatively, if you only want to call a remote Web service, use the following method

```
DATA(lv_dest) = cl_http_destination_provider=>create_by_url( i_url = 'https://  
www.example.com' ).
```

Use the URL approach mainly for testing purposes.

### → Recommendation

We recommend using the `create_by_comm_arrangement` method for outbound communication.

## Service Consumption Model

SAP supports various protocols and provides the corresponding clients and functions to handle requests and responses.

HTTP: `CL_WEB_HTTP_CLIENT`

RFC: `CALL FUNCTION`

To simplify the implementation of a remote call, you can create a service consumption model for the external service. The service consumption model creates proxies for the remote service. That way, you can access the service in a strictly typed manner without the need to compile requests and parse responses. The following consumption model types are supported:

- OData
- SOAP
- RFC

## Related Information

[Service Consumption via Communication Arrangements \[page 854\]](#)

### 4.2.10.3.1 Create a Destination

If your business application uses external services, you have to set up a destination for outbound communication either in your subaccount, which is recommended, or in your space.

#### Creating a Destination in Your Subaccount

1. Log on to the SAP BTP cockpit and navigate to your subaccount.
2. In the navigation area, go to ► [Connectivity](#) ► [Destinations](#) and select [New Destination](#).
3. Set up your destination and select [Save](#). See [Set Up HTTP Communication \[page 961\]](#), [Set Up RFC Communication \[page 971\]](#), and [Sending Mails Using SMTP \[page 990\]](#).

#### Creating a Destination in Your Space

##### Prerequisites

- You have created an ABAP service instance. See [Creating an ABAP System](#).
- You have created a destination service instance. See [Creating Service Instances in Cloud Foundry](#).
- You have created a service key. See [Creating Service Keys in Cloud Foundry](#).

1. Log on to the SAP BTP and go to the subaccount that contains the space you'd like to navigate to. See [Navigate in the Cockpit](#).
2. In the navigation area, go to ► [Cloud Foundry](#) ► [Spaces](#) and select the space that contains the ABAP system service instance.
3. Select ► [Services](#) ► [Instances](#) and navigate to your ABAP system service instance.
4. To open the administration launchpad, click on **⋮** and select [View Dashboard](#).
5. If necessary, provide your logon credentials to access the administration launchpad.
6. In the [Communication Management](#) section, select the [Communication Arrangements](#) tile.
7. On the [Communication Arrangements](#) page, select [New](#).
8. In the [New Communication Arrangement](#) dialog, use the value help to select scenario `SAP_COM_0276` and give the arrangement a meaningful name (e.g. the name of the destination service instance).
9. Enter the service key of your destination service instance and select [Create](#).

### 4.2.10.3.2 Service Consumption via Communication Arrangements

You as a developer can create and expose services for external outbound consumption to a communication partner by creating an outbound service of the required type (HTTP, SOAP or RFC) and specifying the

necessary information. To consume these services, you need to create a communication scenario and assign these services to it.

An administrator then creates a communication system and user for the communication partner, maintains a communication arrangement for the scenario using the created communication system, and specifies the authentication method and URLs.

To consume such an external service, you implement the call of the service. Therefore, you need to implement a logical receiver determination in your runtime coding to find the correct target for the outbound call.

The following options are available to establish logical receiver determination provided by communication arrangements:

- *Allowed Scenarios instances: One instance per client*  
Only one active communication arrangement can be maintained for the communication scenario in the system. The generated destination can be retrieved by providing the communication scenario ID and the respective outbound service ID.
- *Allowed Scenarios instances: One instance per scenario & communication system*  
Multiple active communication arrangements for one communication scenario for different communication systems in one system are enabled. To determine the correct receiver, you must use additional information to find the correct target. You can either do this based on:
  - Standard attributes such as *Communication System ID*, or *Business System ID*
  - Your own properties, such as plant, country, or company, which can be derived from the business context during runtime. You can define your own properties for the communication scenario and maintain them in the communication arrangements.

The sample codes below show how to find the correct reference to a destination and how to use it when calling a service.

Find the destination based on the communication scenario only:

### Sample Code

```
data: lr_cscn type if_com_scenario_factory=>ty_query-cscn_id_range.
* Find CA by Scenario ID
  lr_cscn = value #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
  data(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
  lo_factory->query_ca(
    exporting
      is_query          = value #( cscn_id_range = lr_cscn )
    importing
      et_com_arrangement = data(lt_ca) ).
  if lt_ca is initial.
    exit.
  endif.
* take the first one
  read table lt_ca into data(lo_ca) index 1.
* get destination based on Communication Arrangement and the service ID
  try.
    data(lo_dest) =
  cl_http_destination_provider=>create_by_comm_arrangement(
    comm_scenario   = '<Scenario ID>'
    service_id      = '<Outbound Service ID>'
    comm_system_id  = lo_ca->get_comm_system_id( ) ).

    catch cx_http_dest_provider_error into
  data(lx_http_dest_provider_error).
    out->write( lx_http_dest_provider_error->get_text( ) ).
    exit.
  endtry.
```

Find the destination based on the communication scenario and business system:

### Sample Code

```
data: lr_cscn type if_com_scenario_factory=>ty_query-cscn_id_range,
      lr_bs_id type if_com_system_factory=>ty_query-
cs_business_system_id_range.
* Find CA by Scenario ID & Business System ID
  lr_cscn = value #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
  lr_bs_id = value #( ( sign = 'I' option = 'EQ' low = '<Business System
ID>' ) ).
data(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
lo_factory->query_ca(
  exporting
    is_query = value #( cscn_id_range = lr_cscn
                        cs_business_system_id_range = lr_bs_id )

  importing
    et_com_arrangement = data(lt_ca) ).
if lt_ca is initial.
  exit.
endif.
* take the first one
  read table lt_ca into data(lo_ca) index 1.
* get destination based on Communication Arrangement and the service ID
  try.
    data(lo_dest) =
cl_http_destination_provider=>create_by_comm_arrangement(
      comm_scenario = '<Scenario ID>'
      service_id     = '<Outbound Service ID>'
      comm_system_id = lo_ca->get_comm_system_id( ) ).
    catch cx_http_dest_provider_error into
data(lx_http_dest_provider_error).
      out->write( lx_http_dest_provider_error->get_text( ) ).
      exit.
    endtry.
```

Find the destination based on the communication scenario and a customer-defined property:

### Sample Code

```
data: lr_cscn type if_com_scenario_factory=>ty_query-cscn_id_range,
      lt_prpn type if_com_arrangement_factory=>ty_query-ca_property.
* Find CA by Scenario ID & property name/value
  lr_cscn = value #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
  append initial line to lt_prpn assigning field-symbol(<fs_prp>).
  <fs_prp>-name = '<Property Name>'.
  append '<Property Value>' to <fs_prp>-values.

  data(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
  lo_factory->query_ca(
    exporting
      is_query = value #( cscn_id_range = lr_cscn ca_property =
lt_prpn )

    importing
      et_com_arrangement = data(lt_ca) ).
  if lt_ca is initial.
    exit.
  endif.
* take the first one
  read table lt_ca into data(lo_ca) index 1.
* get destination based on Communication Arrangement and the service ID
  try.
    data(lo_dest) =
cl_http_destination_provider=>create_by_comm_arrangement(
```

```

comm_scenario = '<Scenario ID>'
service_id    = '<Outbound Service ID>'
comm_system_id = lo_ca->get_comm_system_id( ).
catch cx_http_dest_provider_error into
data(lx_http_dest_provider_error).
    out->write( lx_http_dest_provider_error->get_text( ) ).
    exit.
endtry.

```

### 4.2.10.3.2.1 Define Specific Properties for Communication Scenarios

For some use cases, such as logical receiver determination based on arbitrary parameters, a communication scenario may require additional parameters that are not part of the standard fields of a communication scenario. Therefore, you can define additional properties in a communication scenario that can be maintained by the administrator in the *Communication Arrangements* app. These properties also support secure storage of data, such as passwords or API keys.

#### Prerequisite

A data element that describes your property is required.

The following definitions are derived from the data element:

- *Data Type*
- *Value Help*
- *Field Label* (long text) for the *Communication Arrangements* app

Enter the name of property in the communication scenario and define the following:

- *Default Value*: This value will be added automatically if you create a communication arrangement
- *Data Element*: Describes the property (please see above)
- *Is Multiple*: Indicates that one can maintain multiple values for the property in the *Communication Arrangements* app
- *Is Secure*: Indicates that this property is stored within the secure store. You can use this to store add. Passwords or API Keys
- *Is Hidden*: Indicates that this property is not displayed on the *Communication Arrangements* app and only used for internal usage
- *Value Help*: Indicates that a value help shall be used in the *Communication Arrangements* app

## 4.2.10.3.3 Service Consumption Model

A Service Consumption Model (SRVC) generates proxy artifacts to consume OData, RFC, or SOAP services.

### Overview

To consume OData, SOAP, or RFC services, you must first create a Service Consumption Model (SRVC). See [Creating Service Consumption Model](#) for more information. An SRVC creates proxy artifacts and a code snippet that you can copy and paste to your code to perform the service call. For RFC, the SRVC is optional.

## Creating a Service Consumption Model

### Overview

A remote client proxy request needs a corresponding SRVC.

The benefits of using an SRVC (instead of manually creating a corresponding model) are:

- Simple creation using XML or EDMX file uploading. You don't need to manually define the model.
- The code generator creates code snippets to use as blueprint on how to write client proxy-related coding.

### Example

Create a Service Consumption Model for remote consumption of your OData service. You have the metadata of the corresponding OData service that you want to consume in an XML or EDMX file.

### Step-by-step

See the following information for how to create your SRVC:

- [Generating Proxies for Remote OData Service](#)
- [Generating Proxies for Remote Function Call \(RFC\)](#)
- [Generating Proxies for Remote Web Service](#)

## Constraints

Not all OData service model features are supported for Service Consumption Models. For example, you might not be able to create a Service Consumption Model for your underlying OData service. This is the case if your Service Model contains Complex Collections, Actions, or Functions.

### 4.2.10.3.4 OData Outbound Communication

The OData Client Proxy is the interface between the client (consumer of a service) and the service implementation (data provisioning) in the OData service consumption in ABAP. This enables ABAP developers to create OData client coding to run OData requests in your ABAP coding.

OData outbound connectivity enables you to consume OData services from other systems. To enable OData outbound communication, there are two different stages that are performed by different roles:

## Development Tasks

Development tasks are performed by developers. Development tasks are all tasks that are performed within ABAP development tools for Eclipse, such as:

- Creating a Communication Scenario
- Creating an outbound service

For more information, see [Enable OData Communication in Your ABAP Code \[page 860\]](#).

## Administrator Tasks

Administrator tasks are performed by administrators. Administrator tasks are all tasks that are performed in SAP Fiori launchpad, such as:

- Creating a communication system
- Creating a communication arrangement
- Creating communication users

For more information, see [Set Up OData Communication \[page 863\]](#).

[Enable OData Communication in Your ABAP Code \[page 860\]](#)

[Set Up OData Communication \[page 863\]](#)

To set up OData communication, use the corresponding communication management apps.

[OData Client Proxies \[page 864\]](#)

There are several consumption types and OData versions for your OData Client Proxy configurations, depending on your use case.

[OData Client Proxy Overview \[page 865\]](#)

Get an overview of some of the most common OData Client Proxy tasks.

[OData Client Proxy User Guide \[page 879\]](#)

See examples and steps for using the Data Client Proxy.

[OData Requests \[page 891\]](#)

Learn how to use OData Requests.

## 4.2.10.3.4.1 Enable OData Communication in Your ABAP Code

### Feature Scope

Based on a service metadata file, you can generate the ABAP code for an OData call by using a Service Consumption Model. See [Service Consumption Model as OData Consumer \[page 860\]](#) for more information.

### 4.2.10.3.4.1.1 Service Consumption Model as OData Consumer

A Service Consumption Model is the main requirement for consuming an OData service in the ABAP environment. To learn how to create a Service Consumption Model with ABAP development tools for Eclipse (ADT), see [Creating Service Consumption Model](#).

#### Note

We recommend to create a new package for the Service Consumption Model. Generated objects are then created within this package. This allows better organization and clarity.

A Service Consumption Model generates ABAP code from the service metadata file (EDMX file) of the OData service you want to consume. For every operation (`Create`, `Read`, `Read List`, `Update`, and `Delete`), a code snippet is generated that indicates how to perform the corresponding operation.

For more information on creating a Service Consumption Model, see [Generating Proxies for Remote OData Service](#).

## 4.2.10.3.4.1.2 OData Communication via Communication Arrangements

OData outbound communication can be established using so-called communication arrangements.

### Prerequisites

- You've created a communication scenario as described in [Defining a Communication Scenario Including Authorization Values \[page 800\]](#).
- You have a service meta data file (EDMX file) for the service you want to consume.
- You have created and activated a service consumption model (SRVC) of type OData. See [Creating Service Consumption Model](#) for more information.

### Procedure

1. Create a corresponding outbound service of type HTTP.
  1. In your ABAP project, select the relevant package node in the Project Explorer.  
Open the context menu and choose **File > New > Other > ABAP Repository Object > Cloud Communication Management > Outbound Service > Next** to launch the creation wizard.
  2. Select *HTTP Service* in the *Service Type* dropdown list.
  3. Choose Next and select a transport request.
  4. Optional: Go to your outbound service and enter the URL in the field *Default Path Prefix*.
  5. Save the outbound service.
2. Add the newly created outbound service to a communication scenario. See [Service Consumption via Communication Arrangements \[page 854\]](#) for more information.
3. Publish the communication scenario. The administrator can then create the required communication management objects as described in [Next Steps \[page 863\]](#).
4. Call the OData service as described in the example. Copy the code snippet from the *Overview* tab in your SRVC and add the `comm_system_id` and `service_id` parameters if necessary. According to your developed communication scenario, add the following:

<code>comm_scenario</code>	mandatory	ID of the developed communication scenario
<code>comm_system_id</code>	optional	ID of the configured communication system
<code>service_id</code>	optional	ID of the developed outbound service

## Example

The following code is generated by the SRVC for the create operation of the OData service `Business User`.

### Sample Code

```
DATA:
  ls_business_data TYPE business_user=>tys_users,
  lo_http_client   TYPE REF TO if_web_http_client,
  lo_client_proxy  TYPE REF TO /iwbsp/if_cp_client_proxy,
  lo_request       TYPE REF TO /iwbsp/if_cp_request_create,
  lo_response      TYPE REF TO /iwbsp/if_cp_response_create.
TRY.
* Create http client
DATA(lo_destination) =
cl_http_destination_provider=>create_by_comm_arrangement(
*                                     comm_scenario = '<Comm
Scenario>'
*                                     comm_system_id = '<Comm System
Id>'
*                                     service_id      = '<Service
Id>' ).
*lo_http_client =
cl_web_http_client_manager=>create_by_http_destination( lo_destination ).
lo_client_proxy = /iwbsp/cl_cp_factory_remote=>create_v4_remote_proxy(
  EXPORTING
    is_proxy_model_key      = VALUE #( repository_id      = 'DEFAULT'
                                       proxy_model_id     = 'BUSINESS_USER'
                                       proxy_model_version = '0001' )
    io_http_client          = lo_http_client
    iv_relative_service_root = '<service_root>' ).
ASSERT lo_http_client IS BOUND.
* Prepare business data
ls_business_data = VALUE #(
  id           = '11112222333344445555666677778888'
  first_name   = 'FirstName'
  last_name    = 'LastName'
  phone        = 'Phone'
  email        = 'Email'
  address      = 'Address' ).
" Navigate to the resource and create a request for the create operation
lo_request = lo_client_proxy->create_resource_for_entity_set( 'USERS' )->
create_request_for_create( ).
" Set the business data for the created entity
lo_request->set_business_data( ls_business_data ).
" Execute the request
lo_response = lo_request->execute( ).
" Get the after image
*lo_response->get_business_data( IMPORTING es_business_data =
ls_business_data ).
CATCH /iwbsp/cx_cp_remote INTO DATA(lx_remote).
" Handle remote Exception
" It contains details about the problems of your http(s) connection
CATCH /iwbsp/cx_gateway INTO DATA(lx_gateway).
" Handle Exception
CATCH cx_web_http_client_error INTO DATA(lx_web_http_client_error).
" Handle Exception
RAISE SHORTDUMP lx_web_http_client_error.
ENDTRY.
```

### Note

We recommend to retrieve the correct destination reference based on the communication scenario and a customer-defined property as described in [Service Consumption via Communication Arrangements \[page 854\]](#).

## Next Steps

To test your outbound call, you have to provide a configuration for the outbound service you want to call in your code.

Create a communication system and communication arrangement for the communication scenario in the Communication Systems and Communication Arrangements apps and maintain the required data.

These tasks are performed by the administrator. For more information, see [Set Up OData Communication \[page 863\]](#).

## 4.2.10.3.4.2 Set Up OData Communication

To set up OData communication, use the corresponding communication management apps.

### Context

The communication management is done by the administrator in SAP Fiori launchpad.

### Procedure

1. Create a communication system. A communication system determines which target system is called and which authentication methods are used. It also provides the user that is required to register at the target system. For more information, see [Communication Systems \[page 2397\]](#).
2. In the communication system, create an outbound communication user.
3. Create a communication arrangement. The communication arrangement is based on the communication scenario, that is created by the developer in ABAP Development Tools for Eclipse. For more information, see [How to Create a Communication Arrangement \[page 2395\]](#).

## Results

The communication management established a connection to the system from which you want to consume the OData service. You can now perform the service call as described in [OData Communication via Communication Arrangements \[page 861\]](#)

### 4.2.10.3.4.3 OData Client Proxies

There are several consumption types and OData versions for your OData Client Proxy configurations, depending on your use case.

#### Consumption Types

The OData Client Proxy can be either local or remote.

##### Local Client Proxy

Use this Client Proxy for the consumption of an OData service on the current server without HTTP.

- No HTTP overhead
- The OData service is processed in the same application session. This allows integration testing, for example, including stubbing.

##### Remote Client Proxy

Use this Client Proxy for the consumption of an OData service that is offered on a remote server.

#### OData Versions

##### OData Version 2 Client Proxy

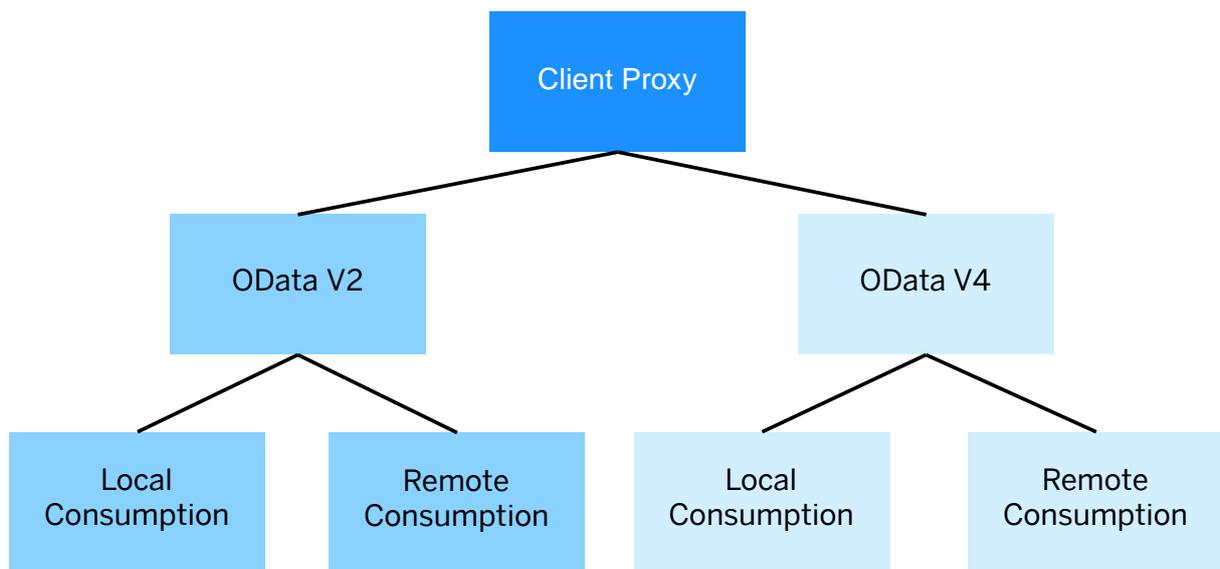

Use this Client Proxy for the consumption of an OData Version 2 service.

##### OData Version 4 Client Proxy

Use this Client Proxy for the consumption of OData Version 4 services.

#### Note

These configurations (the OData version and consumption type) depend on each other. For example, there is a local OData Version 2 Client Proxy or a remote OData Version 4 Client Proxy, but not a local Client Proxy independent of the OData version. The asynchronous Client Proxy is only available for remote consumption of OData Version 4 services.

## Constraints

For Client Proxy known constraints, see SAP Note [2428114 - SAP Gateway Foundation SAP\\_GWFND OData Client Proxy - Known Constraints](#).

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.4.4 OData Client Proxy Overview

Get an overview of some of the most common OData Client Proxy tasks.

OData Client Proxy tasks include:

[Client Proxy Instance Types \[page 866\]](#)

Create remote and local Client Proxy instances in OData Version 2 or Version 4.

[Batch and Change Set Request Instance \[page 869\]](#)

Batch requests group multiple individual requests into a single HTTP request payload.

[Deep Create Data Description Node \[page 870\]](#)

In OData Version 4, deep create requests create an entity that includes related entities.

[Expand Node Instance \[page 871\]](#)

An expand node instance causes related entities to be included inline in the response.

[Resource Instance \[page 872\]](#)

A resource instance represents a resource that is shared between applications and identified using URLs and defined in the data model.

[Filter Node Instance \[page 874\]](#)

A filter node instance filters and returns only the results that match the specified expressions.

[Request Instance \[page 875\]](#)

A request instance describes the action you want to take on a resource.

[Response Instance \[page 877\]](#)

A response instance includes information that the request returns.

[Handling Exceptions \[page 878\]](#)

Handling exceptions when running Client Proxy-related coding.

## 4.2.10.3.4.4.1 Client Proxy Instance Types

Create remote and local Client Proxy instances in OData Version 2 or Version 4.

### Client Proxy Versions

#### Client Proxy Version 2 and Version 4

Depending on the OData service you want to consume (Version 2 or Version 4 service), you'll create a Version 2 or Version 4 Client Proxy instance. The underlying OData protocols differ between Version 2 and Version 4. You can't provide a version-agnostic Client Proxy.

### Consumption Types

The decision of using a local or remote Client Proxy instance depends on the current use case.

#### Remote Client Proxy

A remote Client Proxy is used to consume an OData service offered on a remote server. If you want to create a remote Client Proxy instance, the following is required:

- A configured HTTP client instance
- The relative service root pointing to the service document
- Service Consumption model

If you want to create an HTTP client instance, see [Enable HTTP Communication in Your ABAP Code](#).

**Relative Service Root:** The relative service root (combined with the HTTP destination) should point to the service document for the OData service you want to consume. The service document is the top-level representation of an OData service. It lists the entity sets, singletons, and service functions. It is available at `http(s)://host/service/` base URL. You can access the resources in the service document using a URL that is the concatenation of the base URL and the resource URL.

## ❁ Example

You want to consume the OData Version 4 service **TEA\_BUSI** in version 2, which is part of the `/IWBEP/TEA` OData service group and belongs to the service repository **DEFAULT**.

If the absolute URL to fetch the corresponding service document is `http://xyzialb.rot.sap.corp:1234/sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0002/`, the relative service URL is `/sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0002/`.

The remote Client Proxy needs a model object, which is the runtime representation of a model (compared to the model defined by a model provider class (MPC) for an OData service). The Service Consumption Model is needed since we don't have (for example) statically generated OData service specific proxies. Instead, we have one generic Client Proxy. To handle everything needed to process a client request, the framework needs this information:

- Name and definition of the EDM artifacts
- The mapping from EDM to ABAP names (most importantly for properties)
- ABAP data types
- ABAP conversion exits

A Service Consumption Model defines the characteristics, properties, or parameters (such as, the number or the age of employees).

For detailed examples on how to create a Service Consumption Model, see [Service Consumption Model \[page 858\]](#).

The OData Client Proxy supports SAP Passport to trace and monitor requests between different systems. To send SAP Passport via the header `sap-passport`, you need to take one of the following actions:

- Define the destination type 'H' (ABAP-ABAP communication) if you instantiated the HTTP client object with `CL_HTTP_CLIENT=>CREATE_BY_DESTINATION`.
- Set the attribute `lo_http_client->PROPERTYTYPE_SEND_SAP_PASSPORT = lo_http_client->CO_ENABLED`.

## Local Client Proxy

Use the local Client Proxy when a locally-deployed OData service is consumed. The local Client Proxy delegates a request to the backend component of the corresponding Version 2 or Version 4 runtime without an HTTP overhead. The use case for this scenario is to create Unit Tests, for example, when you want to build an integration test for your service data provider.

## 📌 Note

Since the local Client Proxy is designed for writing tests of your data provider, it skips several layers inside the *SAP Gateway Framework* and directly calls the data provider class. This has following effects:

- Certain tests that are usually executed during OData request processing are skipped.
- For both Version 2 and Version 4, the business data received from the (local consumption) response is not re-converted for outbound processing.
- When using the Version 4 local client proxy, the business data you enter is not converted for inbound processing. The data provider receives the data exactly how you entered in the request.

For creating a local Client Proxy instance, the service key is required. The service key includes the service repository id (for example, **DEFAULT**), the service id (the ODATA service internal name), and the service id version (for example, **0003**). You don't need an HTTP client instance or a Service Consumption model.

## Creating an Instance

You can create an instance of the Client Proxy using class `cl_web_odata_client_factory`, which provides these static methods:

- `create_v2_local_proxy`
- `create_v2_remote_proxy`
- `create_v4_local_proxy`
- `create_v4_remote_proxy`

### Note

All returned instances are from type `/iwbep/if_cp_client_proxy` and offer the same methods. Certain methods are only used by a specific Client Proxy (for example, a remote OData Version 4 proxy) and can raise an exception if the wrong Client Proxy instance is called.

## Functionality

- The Client Proxy instance is the starting point for the OData service consumption with ABAP.
- The Client Proxy instance provides a corresponding [Resource Instance \[page 872\]](#) (for example, an action import or an entity set).
- The Client Proxy instance provides methods for creating `$batch` and delta link requests (with certain delta link-centered utility methods).

## Examples

For examples on how to create and use Client Proxy instances, see [Client Proxy Examples \[page 880\]](#).

## Related Information

[Resource Instance \[page 872\]](#)

[OData Request as Batch Including Changesets \[page 892\]](#)

[OData Request: Delta Link Query Option \[page 927\]](#)

## 4.2.10.3.4.4.2 Batch and Change Set Request Instance

Batch requests group multiple individual requests into a single HTTP request payload.

### OData Version 4 Batch Requests

These individual requests can be included in a batch request:

- Metadata
- Data
- Data Modification
- Action Invocation
- Function Invocation

Batch requests are submitted as a single HTTP POST request to the batch endpoint of a service at the `$batch` URL that is related to the service root. Individual requests in a batch request are evaluated according to the same semantics used with an individual request.

In the *Multipart* format, you can group data modification requests or action invocation requests as part of an atomic change set. Operations outside the change set are executed sequentially. Operations in the change set are executed in any order.

#### Note

In batch requests, *operation* is an individual request in the batch request payload. A change set request is a part of this type of batch request.

### Creating a Batch Request Instance

A batch request instance is created on the Client Proxy instance. It adds individual requests, executes the batch request, and checks the execution. The batch request instance creates a change set request instance.

After you create a batch request instance, you can define the operations and add them to the batch request or to a change set. The change set request instance is created directly on the batch request instance.

### Related Information

[OData Client Proxy Overview \[page 865\]](#)

[OData Request as Batch Including Changesets \[page 892\]](#)

## 4.2.10.3.4.4.3 Deep Create Data Description Node

In OData Version 4, deep create requests create an entity that includes related entities.

### Overview

A **deep create** is also known as **deep insert**). In this example, you want to create a new customer and the first sales order from this customer. You can first create the new customer and then the first sales order or you can use a **deep create** to create both at the same time:

```
POST http://host/service/Customers
```

This request contains the following payload:

```
{ "CustomerName" : "James Bond",
  "CustomerId" : 007,
  "Customer_2_Salesorders" : {
    "Object" : "Walther PPK",
    "Category" : "Pistols"
  }
}
```

You must use a Data Description node to describe the properties and inline navigations for deep business data for a request. The Data Description node is necessary to describe the structure of your deep business data to the Client Proxy.

A Data Description node is always created on the corresponding create [Request Instance \[page 875\]](#).

#### Note

In OData Version 2, complex properties can't have associations, such as navigation properties. You can only define navigation properties in entity types. In OData Version 4, you can define navigation properties for a complex property.

### Creating an Instance

A Data Description node instance is always created in the corresponding [Request Instance \[page 875\]](#).

### Functionality

The Data Description node instances describe the payload for a deep create request to the Client Proxy. This is required to execute any deep create request.

## Example

For examples of how to create and work with Data Description nodes, see [OData Request: Deep Create \[page 923\]](#).

## Related Information

[OData Request: Deep Create \[page 923\]](#)

### 4.2.10.3.4.4.4 Expand Node Instance

An expand node instance causes related entities to be included inline in the response.

## Overview

When reading an entity with a `GET` request, related entities can also be requested using the `$expand` statement on a navigation property. In this example, you want to read the data about customer “Posey” and the open sales orders for this customer (with navigation property “`Customer_2_Salesorders`”). Here is an example of this OData request:

#### Sample Code

```
GET http://host/service/Customers('Posey')?$expand=Customer_2_Salesorders
```

## Creating an Instance

In the Client Proxy Framework, an expand expression is described by an expand node instance. It is created directly in the corresponding read request instance.

#### Note

In OData Version 2, complex properties can't have associations, such as navigation properties. You can only define navigation properties in entity types. In OData Version 4, you can define navigation properties for a complex property.

An expand node instance is always created in the corresponding [Request Instance \[page 875\]](#). These request types can be used to create an expand node:

- read entity

- read entity list
- read entity zero-to-one

## Functionality

The expand node instances add an expand expression into the underlying read request. You can also set the selected properties for each expand node. If not all properties of the expanded entity are returned, compare to `GET http://host/service/Customers('Posey')?$expand=Customer_2_Salesorders($select=Date,Status)`.

## Example

For examples of how to create and work with expand nodes, see [\\$expand Option \[page 934\]](#).

## Related Information

[Request Instance \[page 875\]](#)

### 4.2.10.3.4.4.5 Resource Instance

A resource instance represents a resource that is shared between applications and identified using URLs and defined in the data model.

## Overview

In OData Version 4, a resource is anything in the model that can be addressed (an entity set, entity, property, or operation).

The OData instance creates REST-based data services that allows resources (identified using URLs and defined in an Entity Data Model), to be published and edited by web clients with simple HTTP messages.

For a standard OData request, you must provide a corresponding URL that points to a resource (for example, `entity_list(id='1')` points to a specific resource:

#### Sample Code

```
/sap/opu/odata/sap/srv/entity_list(id='1')/entity
```

## Note

The resources aren't OData protocol-specific (Version 2 or Version 4).

In the Client Proxy, you don't need to provide the URI. But you need to create an instance of the resource you want to access (for example, a function or a single entity).

## Creating an Instance

Depending on the resource type, the instance creation can vary. Some resources (for example, an entity set or action resources) are created at the [Client Proxy Instance Types \[page 866\]](#). Other resources are created on another resource instance (for example, an entity resource, created on the entity set resource). You can't call an entity resource without providing the corresponding entity set resource.

## Examples

- `GET/sap/opu/odata/sap/srv/teams` The target resource is an entity set (**teams**). The resource instance is created at the Client Proxy instance. For more information, see [OData Request: Read Entity List \[page 915\]](#).
- `GET /sap/opu/odata/sap/srv/order(customer='Jane Doe')` The target resource is a single entity (Jane Doe), so the resource instance is created at the parent resource instance (entity set order).

## Resource Types

These resource types are available to users:

- `/IWBEP/IF_CP_RESOURCE_ACTION`: Describes the resource of an **action** that is created on the Client Proxy instance (for action imports) or on an entity (set) resource (for bound actions).
- `/IWBEP/IF_CP_RESOURCE_ENTITY`: Describes the resource of a **single** entity that is created on an entity (set) resource.
- `/IWBEP/IF_CP_RESOURCE_ENTITY01`: Describes the resource of an **optional** entity (the target entity of a zero-to-one navigation) that is created on an entity resource.
- `/IWBEP/IF_CP_RESOURCE_FUNCTION`: Describes the resource of a **function** that is created on the Client Proxy instance (for function imports) or on an entity (set) resource (for bound functions).
- `/IWBEP/IF_CP_RESOURCE_LIST`: Describes the resource of an **entity set** that is created on the Client Proxy instance or an entity resource.

## Functionality

Resource instances are used to create requests (for example, an update request on an entity) or other resource instances (for example, an action resource from an entity list resource). The options that a resource instance offers depends on the different resource types.

## Example

For examples of how to create and work with resources see [Actions and Functions \[page 883\]](#) and [OData Request: Using Navigation \[page 930\]](#).

## Related Information

[OData Request: Read Entity List \[page 915\]](#)

### 4.2.10.3.4.4.6 Filter Node Instance

A filter node instance filters and returns only the results that match the specified expressions.

## Overview

The `$filter` system query option restricts the set of items returned. It allows you to filter a source collection addressed by a request URI. The expression specified with `$filter` is evaluated for each resource in the collection. Only items where the expression is `true` are included in the response.

In this example, you want to read a collection of sales orders and get only the unpaid orders. Here's an example of the OData request:

#### Sample Code

```
GET http://host/service/SalesOrders?$filter=Payment eq 'open'
```

A filter expression is described by a filter node instance that a filter factory instance creates and can be set into the Client Proxy instance.

#### Note

The filter nodes are not OData protocol-specific (Version 2 or Version 4).

## Creating an Instance

A filter node instance is always created by a filter factory instance. You can create a filter factory instance in a read list request instance.

## Functionality

The main functionality of filter node instances is to create a filter expression for a read request on an entity list, which can be integrated into the corresponding request to only show a subset of the complete result.

## Example

For examples of how to create and work with filter nodes, see [\\$filter Option \[page 936\]](#).

## Related Information

[OData Request: Read Entity \[page 908\]](#)

### 4.2.10.3.4.4.7 Request Instance

A request instance describes the action you want to take on a resource.

## Overview

You can read or modify an OData [Resource Instance \[page 872\]](#) by sending an OData request on this resource. This example reads all entities for the entity set "**teams**":

#### Sample Code

```
GET /sap/opu/odata/sap/srv/teams
```

This example deletes the "**order**" entity of customer "**Jane Doe**":

#### Sample Code

```
DELETE /sap/opu/odata/sap/srv/order(customer='Jane Doe')
```

A request instance describes the actual operation you want to perform on the corresponding resource. It includes all relevant information (for example, the request body data for updating an entity) for the operation execution.

#### Note

The requests are not OData protocol-specific (Version 2 or Version 4).

## Creating an Instance

Request instances are created on the resource instance the request will act on (for example, a request to update an entity is created on the corresponding entity resource). The only exceptions are `$batch/changeset requests` (these can contain requests acting on different resources), and delta link requests, that are both created on the Proxy Instance

### Request Examples

- `/IWBEP/IF_CP_REQUEST_ACTION`: A request to execute an **ACTION** (using action import or as a bound action).
- `/IWBEP/IF_CP_REQUEST_BATCH`: A `$batch` request. It can be used to add other requests (for example, a **DELETE** request) and execute them together as part of a `$batch`.
- `/IWBEP/IF_CP_REQUEST_CHANGESET`: A request for a **changeset**. This request can be used to add other requests (for example, **CREATE** request) into one changeset. The changeset request can only be executed as part of a `$batch` request (for example, it must be added to a `$batch` request before executing the request).
- `/IWBEP/IF_CP_REQUEST_CREATE`: A request to **CREATE** an entity.
- `/IWBEP/IF_CP_REQUEST_DELETE` : A request to **DELETE** an entity
- `/IWBEP/IF_CP_REQUEST_FUNCTION`: A request to execute a **FUNCTION** (using function import or as bound function).
- `/IWBEP/IF_CP_REQUEST_READ`: A request to **READ** an entity.
- `/IWBEP/IF_CP_REQUEST_READ_01`: A request to **READ** an entity WITH a zero-to-one navigation.
- `/IWBEP/IF_CP_REQUEST_READ_DELTA`: A request to **READ** the delta of a list of entities
- `/IWBEP/IF_CP_REQUEST_READ_LIST`: A request to **READ** a list of entities.
- `/IWBEP/IF_CP_REQUEST_UPDATE`: A request to **UPDATE** an entity.
- `/IWBEP/IF_CP_REQUEST_UPDATE_L` : A request to **UPDATE** a list of entities.

## Functionality

Request instances create an OData request and a corresponding [Response Instance \[page 877\]](#). The options a request instance offers depend on the different request types.

## Example

For examples of how to create and work with requests, see the [OData Requests \[page 891\]](#).

## 4.2.10.3.4.4.8 Response Instance

A response instance includes information that the request returns.

### Overview

Most OData requests return a corresponding response body after the request is successful (an exception can be a successful `DELETE` request with HTTP return code 204 with no content).

The Client Proxy response instance contains information returned by the request. You can use it to read all relevant response information (for example, the entity business data).

#### Note

The responses aren't OData protocol-specific (Version 2 or Version 4).

### Creating an Instance

A response instance is always created by the corresponding request instance when a request is created.

### Response Types

These response types are available:

- `/IWBEP/IF_CP_RESPONSE_ACTION`: **ACTION** request response.
- `/IWBEP/IF_CP_RESPONSE_CREATE`: **CREATE** request response.
- `/IWBEP/IF_CP_RESPONSE_DELETE`: **DELETE** entity request response.
- `/IWBEP/IF_CP_RESPONSE_FUNCTION`: **FUNCTION** request response.
- `/IWBEP/IF_CP_RESPONSE_READ`: **READ** entity request response.
- `/IWBEP/IF_CP_RESPONSE_READ_01`: **READ** entity (with zero-to-one navigation) request response.
- `/IWBEP/IF_CP_RESPONSE_READ_LST`: **READ** entity list request response.
- `/IWBEP/IF_CP_RESPONSE_UPDATE`: **UPDATE** entity request response.
- `/IWBEP/IF_CP_RESPONSE_UPDATE_L`: **UPDATE** entity list request response.

### Functionality

Response instances return the response business data of a successful OData request execution. The options a response instance offers depend on the different response types.

## Example

For examples of how to create and work with responses, see the [OData Requests \[page 891\]](#).

### 4.2.10.3.4.4.9 Handling Exceptions

Handling exceptions when running Client Proxy-related coding.

#### Overview

There are two types of exceptions in the Client Proxy context:

- `/IWBEF/CX_GATEWAY`: for client issues (for example, if the provided entity set name is unknown or if you try to fetch business data from a response instance that doesn't have any response data).
- `/IWBEF/CX_CP_REMOTE`: for server issues in remote scenarios (for example, the returned HTTP status code is not **2xx** (internal server errors [500] or missing authorizations [401]).

The remote server exception contains this information:

- HTTP Status Code
- HTTP Status Reason Message
- OData Error Details
- HTTP Client Error Details
- HTTP error body
- Content type
- HTTP method

## Handling Exceptions

#### Overview

For the **remote** client proxy: always catch both exceptions (`/IWBEF/CX_GATEWAY` and `/IWBEF/CX_CP_REMOTE`) separately and implement corresponding exception handling.

For the **local** client proxy: catch `/IWBEF/CX_GATEWAY`. The remote exception isn't raised in the local scenario.

#### Example

Use remote client proxy to consume an OData request. Include proper exception handling in your coding:

```
DATA: lv_http_status_code      TYPE /iwbep/cx_gateway=>ty_http_status_code,
      lv_http_status_message  TYPE string,
      lv_error_body           TYPE string,
      ls_odata_error          TYPE /iwbep/cx_cp_remote=>ty_s_odata_error,
      lv_client_error_text    TYPE string,
      lx_remote               TYPE REF TO /iwbep/cx_cp_remote,
      lx_gateway              TYPE REF TO /iwbep/cx_gateway.
```

```

TRY.
  "Your Client Proxy Coding
  catch /iwbeb/cx_cp_remote into lx_remote.
  lv_http_status_code = lx_remote->http_status_code.
  lv_http_status_message = lx_remote->http_status_message.
  lv_error_body = lx_remote->http_error_body.
  ls_odata_error = lx_remote->s_odata_error.
  "Further error handling
  catch /iwbeb/cx_gateway into lx_gateway.
  lv_client_error_text = lx_gateway->get_text( ).
  "Further error handling
  ...

```

## Steps

**Step 1:** Catch the remote exception and fetch the information on the exception (in addition to your own exception handling):

```

DATA: lv_http_status_code      TYPE /iwbeb/cx_gateway=>ty_http_status_code,
      lv_http_status_message  TYPE string,
      lv_error_body           TYPE string,
      ls_odata_error          TYPE /iwbeb/cx_cp_remote=>ty_s_odata_error,
      lx_remote               TYPE REF TO /iwbeb/cx_cp_remote.
CATCH /iwbeb/cx_cp_remote INTO lx_remote.
lv_http_status_code = lx_remote->http_status_code.
lv_http_status_message = lx_remote->http_status_message.
lv_error_body = lx_remote->http_error_body.
ls_odata_error = lx_remote->s_odata_error.
"Further error handling
...

```

**Step 2:** Catch the gateway exception and fetch the corresponding error text (in addition to your own exception handling):

```

DATA: lx_gateway              TYPE REF TO /iwbeb/cx_gateway,
      lv_client_error_text    TYPE string.
CATCH /iwbeb/cx_gateway INTO lx_gateway.
lv_client_error_text = lx_gateway->get_text( ).
"Further error handling
...

```

## 4.2.10.3.4.5 OData Client Proxy User Guide

See examples and steps for using the Data Client Proxy.

The OData Client Proxy User Guide includes:

[Client Proxy Examples \[page 880\]](#)

OData Proxy examples for OData Version 2 and Version 4 for local and remote client proxies.

[Actions and Functions \[page 883\]](#)

Create an OData request to run an operation (an action or function) in the Client Proxy instance.

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.4.5.1 Client Proxy Examples

OData Proxy examples for OData Version 2 and Version 4 for local and remote client proxies.

#### Overview

For information about the Client Proxy Instance, see [Client Proxy Instance Types \[page 866\]](#).

## OData Version 2: Local Client Proxy

### Overview

You can create a Client Proxy instance with class `IWBEP/CL_CP_CLIENT_PROXY_FACTORY`. It offers the static method `CREATE_V2_LOCAL_PROXY` to create a local V2 Client Proxy instance. The service key parameters (`service_id` and `service_version`) are required for the V2 OData service you want to consume. You can also specify if you want to write a workload trace (you can later check in transaction `STAD`).

#### Note

A workload trace is not written by default.

### Example

Create a Client Proxy instance to consume the OData V2 service “`ODATA_V2_TEST_SERVICE`” in version number 1:

#### Sample Code

```
DATA: lo_client_proxy TYPE REF TO /iwbsp/if_cp_client_proxy.  
      lo_client_proxy =  
      cl_web_odata_client_factory=>create_v2_local_proxy( VALUE #( service_id =  
      'ODATA_V2_TEST_SERVICE' service_version = '0001' ) ).
```

## OData Version 2: Remote Client Proxy

### Overview

You can create a Client Proxy instance using class `CL_WEB_ODATA_CLIENT_FACTORY`. It offers the static method `CREATE_V2_REMOTE_PROXY` to create a remote V2 Client Proxy instance. The relative service root parameter (`service_definition_name`) and a configured HTTP web client instance are required.

For more information about how to create a configured HTTP web client instance, see:

- [Enable HTTP Communication in your ABAP Code \[page 951\]](#).
- [HTTP Communication via Communication Arrangements \[page 952\]](#).

The service definition is automatically generated when you create a `Service Consumption Model`.

The concatenated HTTP destination and the relative service root must point to the service document of the OData service. Depending on your HTTP web client instance configuration, the way your relative service root looks can vary. In our example, we assume that your HTTP destination doesn't have a path prefix (for example, doesn't point to a specific OData service). The relative service root follows the general pattern `/sap/opu/odata/<service_id>`.

## Example

Create a Client Proxy instance to consume the OData Version 2 service with the service definition `ODATA_V2_SERVICE_DEFINITION` and the service id `ODATA_V2_SERVICE`.

### Sample Code

```
DATA: lo_client_proxy TYPE REF TO /iwbsp/if_cp_client_proxy,
      lo_web_http_client TYPE REF TO if_web_http_client.
lo_client_proxy = cl_web_odata_client_factory=>create_v2_remote_proxy(
    iv_service_definition_name = 'ODATA_V2_SERVICE_DEFINITION'
    io_http_client = lo_web_http_client
    iv_do_fetch_csrf_token = abap_true

    iv_relative_service_root = '/sap/opu/odata/ODATA_V2_SERVICE' ).
```

### Note

In this example, the Client Proxy automatically fetches a cross-site request forgery (CSRF) token. It does a `HEAD` request to fetch a CSRF token. This token is automatically reused for all requests executed with this Client Proxy instance. If you want to change this behavior, set `iv_do_fetch_csrf_token` to `abap_false`.

## OData Version 4: Local Client Proxy

### Overview

Create a Client Proxy instance using class `CL_WEB_ODATA_CLIENT_FACTORY`. It offers the static method `CREATE_V4_LOCAL_PROXY` to create a local Version 4 Client Proxy instance. The service key parameters (**`service_id`**, **`relative_service_root`**, which is "`SRVD`", and the **`service_version`**) are required for the Version 4 OData service you want to consume.

### Note

The local Version 4 Client Proxy can't be used to consume SAP OData services. You can only use it to consume your own services.

## Example

Create a Client Proxy instance to consume the OData Version 4 service `ODATA_V4_TEST_SERVICE` in version number 1:

### Sample Code

```
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy.  
      lo_client_proxy = /  
cl_web_odata_client_factory=>create_v4_local_proxy( VALUE #( service_id  
='ODATA_V4_TEST_SERVICE'  
  
      service_version = '0001'  
  
      repository_id = 'DEFAULT' ) ).
```

## OData Version 4: Remote Client Proxy

### Overview

You can create a Client Proxy instance using class `CL_WEB_ODATA_CLIENT_FACTORY`. It offers the static method `CREATE_V4_REMOTE_PROXY` to create a remote Version 4 Client Proxy instance. The relative service root parameters (`relative_service_root`) definition and a configured HTTP web client instance are required.

The concatenated HTTP destination and the relative service root must point to the OData service document. Depending on your HTTP web client instance configuration, the way your the relative service root looks can vary. In our example, we assume that your HTTP destination does not contain a path prefix (i.e. does not point to a specific OData service); then, the relative service root follows the general pattern `/sap/opu/odata4/<service group id>/<repository id>/<service id>/<service version>`

### Example

You want to create a Client Proxy instance to consume the OData Version 4 service with the service definition named `ODATA_V4_SERVICE_DEFINITION` and the service id `ODATA_V4_SERVICE` (version 1), stored in service group `ODATA_GROUP` and repository `SRVD`.

### Sample Code

```
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy,  
      lo_web_http_client TYPE REF TO if_web_http_client.  
      lo_client_proxy =  
cl_web_odata_client_factory=>create_v4_remote_proxy( iv_service_definition_name  
= 'ODATA_V4_SERVICE_DEFINITION'                                     io_http_client  
  
= lo_web_http_client  
  
iv_do_fetch_csrf_token = abap_true  
  
iv_relative_service_root = '/sap/opu/odata4/ODATA_GROUP/SRVD/ODATA_V4_SERVICE/  
0001' ).
```

### Note

In this example, the Client Proxy automatically fetches a cross-site request forgery (CSRF) token. It does a `HEAD` request to fetch a CSRF token. This token is automatically reused for all requests executed

with this Client Proxy instance. If you want to change this behavior, set `iv_do_fetch_csrf_token` to `abap_false`.

## Constraints

The local Client Proxy (both Version 2 and Version 4) can't be used to consume SAP OData services.

## Related Information

[Service Consumption Model \[page 858\]](#)

### 4.2.10.3.4.5.2 Actions and Functions

Create an OData request to run an operation (an action or function) in the Client Proxy instance.

## OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

### Function

A Service Operation is represented by a Function Import and can return:

- Primitive type
- A single Entity-Type instance
- A single Complex-Type instance
- Collection of Complex-Type instances
- Collection of Primitive types

The corresponding Function Import can have side effects and can be invoked by any pre-defined HTTP method.

## OData Version 4

See [OData Version 4.01. Part 1: Protocol](#) .

### Function

**Functions** are operations exposed by an OData service that don't have side effects. Functions must return data and can include additional path segments. Functions are invoked using HTTP method `GET`.

## Action

**Actions** are operation exposed by an OData service that can have side effects. Actions can return data but **must not** be composed with additional path segments. Actions are invoked using HTTP method `POST`.

## Operation

Functions and Actions are operations that can return data. Operations are either **bound** to a resource (for example, an entity type), that makes them members of that instance type. Operations can also be **unbound**. Unbound operations are called as static operations (using “action imports” or “function imports”) since a static (unbound) operation can't be called directly.

## Example Requests

### Version 4 Function Import

“**GetEmployeeByManagerId**” with non-binding parameter “**ManagerId**”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/
GetEmployeeByManagerID(ManagerID='0001')
```

### V4 Bound Action

“**AcChangeTeamOfEmployee**” with non-binding parameter “**TeamId**”

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES('2')/
SAP__self.AcChangeTeamOfEmployee
```

Request body JSON:

```
{
  "TeamID" : "TEAM_02"
}
```

### Version 2 Function

“**SetEmployeeSalary**” with non-binding parameter “**Id**” and “**Amount**”

```
PUT /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/SetEmployeeSalary?
Id='0001'&Amount=200
```

For examples and steps for Import and Bound operations, see:

- [Import Operation \[page 885\]](#)
- [Bound Operation \[page 888\]](#)

## Constraints

- If-Match header is only supported for **remote** consumption.
- For function imports, the If-Match header is only supported for OData **Version 2** requests.

- Composable Functions are **not** supported.
- **\$expand** with operations is **not** supported.
- **\$select** is **not** supported for actions.
- **Return-Prefer** header is **not** supported for actions.
- System query options are **not** supported for Version 4 functions.
- If the return type of a Version 2 function is an entity type and this entity type is used by more than one entity set, the Version 2 request context only contains the (EDM) name of the first entity set with the underlying entity type. A precise mapping is currently not possible. For remote consumption, this can be handled in the proxy model by setting the correct entity set via method `. /iwbeb/if_v4_med_func_imp->set_entity_set_name`

## 4.2.10.3.4.5.2.1 Import Operation

### Overview

The starting point for an operation import is the corresponding operation resource that is created directly on the Client Proxy instance. You can use the resource instance to create a request instance. You can use the response instance to retrieve the response business data of the successfully executed request. This is fetched from the request instance.

#### Note

In OData Version 2, all Operation requests must be created as Function Import requests.

### Example

To invoke the Version 2 function **PromoteEmployee** with the non-binding (for example, input) parameters **"Id='0001'"** and **"Level=2"**:

```
POST /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/PromoteEmployee?Id='0001'&Level=2
```

```
TYPES:
BEGIN OF tys_parameter,
id TYPE /iwbeb/tea_employee_id,
level TYPE i,
END OF tys_parameter.
DATA: lo_client_proxy      TYPE REF TO /iwbeb/if_cp_client_proxy,
      lo_function_resource TYPE REF TO /iwbeb/if_cp_resource_function,
      lo_function_request  TYPE REF TO /iwbeb/if_cp_request_function,
      lo_function_response TYPE REF TO /iwbeb/if_cp_response_function,
      ls_parameter         TYPE tys_parameter,
      ls_busi_data         TYPE /iwbeb/tea_employee.
      lo_function_resource = lo_client_proxy->
>create_resource_for_function( 'PROMOTE_EMPLOYEE' ).
      ls_parameter = VALUE #( id = '0001' level = 2 ).
      lo_function_resource->set_parameter( ls_parameter ).
      lo_function_request = lo_function_resource->create_request( ).
      lo_function_request->set_if_match( '2407' ).
      lo_function_response = lo_function_request->execute(/iwbeb/
if_cp_request_function=>gcs_http_method-post ).
      CHECK lo_function_response->has_business_data( ) = abap_true.
      lo_function_response->get_business_data( IMPORTING ea_response_data =
ls_busi_data ).
```

## Steps

**Step 1:** Create the function resource “**PROMOTE\_EMPLOYEE**” with the **internal** name of function “**PromoteEmployee**”:

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_function_resource TYPE REF TO /iwbep/if_cp_resource_function.
lo_function_resource = lo_client_proxy-
>create_resource_for_function( 'PROMOTE_EMPLOYEE' ).
```

**Step 2:** Set the non-binding (for example. input) parameters on the function resource instance. You can do this on the function resource, using method “**SET\_PARAMETER**”:

```
TYPES:
BEGIN OF tys_parameter,
id TYPE /iwbep/tea_employee_id,
level TYPE i,
END OF tys_parameter.
DATA: ls_parameter TYPE tys_parameter.
ls_parameter = VALUE #(id = '0001' level = 2 ).
lo_function_resource->set_parameter( ls_parameter ).
```

**Step 3:** Create a function request in the function resource instance:

```
DATA: lo_function_request TYPE REF TO /iwbep/if_cp_request_function.
lo_function_request = lo_function_resource->create_request( ).
```

**Step 4:** Select the corresponding HTTP method to invoke the function on the request object. In this example, it is **POST**. You must do this in method **SET\_HTTP\_METHOD** or directly in the **EXECUTE** method. You can use the given constants in **GCS\_HTTP\_METHOD** of interface **/IWBEP/IF\_CP\_REQUEST\_FUNCTION**:

```
DATA: lo_function_response TYPE REF TO /iwbep/if_cp_response_function.
"Option one: Set http method on the request
lo_function_request->set_http_method( /iwbep/
if_cp_request_function=>gcs_http_method-post ).
"Option two: Directly set the http method when executing the function
lo_function_response = lo_function_request->execute( /iwbep/
if_cp_request_function=>gcs_http_method-post ).
```

### Note

Setting the HTTP method is only allowed for OData Version 2 requests. In OData Version 4, functions must always be called with **GET** and actions with **POST**. You don't need to set the HTTP method if the function is called with **GET**.

**Step 5:** Set the **If-Match** header to provide an ETag (if needed for this request). For example, if the corresponding request header is **if-match: W/"2407"**, the required input for **SET\_IF\_MATCH** is **'2407'**:

```
lo_function_request->set_if_match( '2407' ).
```

### Note

Only Version 2 remote consumption supports the **If-Match** header.

**Step 6:** Create the Function request:

```
DATA: lo_function_response TYPE REF TO /iwbep/if_cp_response_function.
```

```
lo_function_response = lo_function_request->execute( /iwbep/  
if_cp_request_function=>gcs_http_method-post ).
```

**Step 7:** Check if the response object contains business data. This is especially useful for nullable operations, where the operation might not return data (compare to HTTP return code 204 – No Content):

```
CHECK lo_function_response->has_business_data( ) = abap_true.
```

**Step 8:** Fetch the business data from the response object (if the corresponding function does return business data):

```
DATA: ls_busi_data TYPE /iwbep/tea_employee.  
lo_function_response->get_business_data( IMPORTING ea_response_data =  
ls_busi_data ).
```

### Note

- When using the Version 4 local client proxy, the business data you enter is not converted for inbound processing. The data provider receives the data exactly how you entered it in the request. For both Version 2 and Version 4, the business data received from the (local consumption) response is also not re-converted for outbound processing.
- Using an OData Version 4 action import works the same way. Use method **CREATE\_RESOURCE\_FOR\_ACTION** instead of **CREATE\_RESOURCE\_FOR\_FUNCTION**.

## Constraints

- If-Match header is only supported for **remote** consumption.
- For function imports, the If-Match header is only supported for OData **Version 2** requests.
- Composable Functions are **not** supported.
- **\$expand** with operations is **not** supported.
- **\$select** is **not** supported for actions.
- **Return-Prefer** header is **not** supported for actions.
- System query options are **not** supported for Version 4 functions.
- If the return type of a Version 2 function is an entity type and this entity type is used by more than one entity set, the Version 2 request context only contains the (EDM) name of the first entity set with the underlying entity type. A precise mapping is currently not possible. For remote consumption, this can be handled in the proxy model by setting the correct entity set via method `. /iwbep/  
if_v4_med_func_imp->set_entity_set_name`

[Bound Operation \[page 888\]](#)

## 4.2.10.3.4.5.2.2 Bound Operation

### Bound Operation

#### Overview

The starting point for invoking a bound operation is the corresponding operation resource. This resource is not created directly at the client proxy instance. It is created at the resource object the operation is bound to (for example, an entity resource or an entity list resource). You can use the resource instance to create a request instance. You can use the response instance to retrieve the response business data for the successfully executed request and can be fetched from the request instance.

#### Note

Bound Operations are only available for OData Version 4 requests. All Operation related OData Version 2 requests must be created as Function Import requests.

#### Example

Invoke the Version 4 bound action **'IncreaseSalary'** with the non-binding (for example, input) parameters **"NewSalary=5000"** and **"Currency='EUR'"**. The action is bound to one entity of the entity set **"Employees"**:

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0006') /
com.sap.gateway.default.iwbep.tea_busi.v0003.IncreaseSalary
```

```
WITH the request body
{
  "NewSalary" : 5000, "Currency" : "EUR"
}
```

```
TYPES:
BEGIN OF tys_parameter,
  new_salary TYPE i,
  currency TYPE c LENGTH 3,
END OF tys_parameter,

BEGIN OF tys_key,
  id TYPE /iwbep/v4_tea_employee_id,
END OF tys_key.
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_action_request   TYPE REF TO /iwbep/if_cp_request_action,
      lo_action_resource  TYPE REF TO /iwbep/if_cp_resource_action,
      lo_action_response  TYPE REF TO /iwbep/if_cp_response_action,
      lo_entity_resource  TYPE REF TO /iwbep/if_cp_resource_entity,
      ls_parameter        TYPE tys_parameter,
      ls_employee         TYPE /iwbep/s_v4_tea_employee,
      ls_key              TYPE tys_key.
ls_key = VALUE #( id = '0006' ).
lo_entity_resource = lo_client_proxy-
>create_resource_for_entity_set( 'EMPLOYEES' )->navigate_with_key( ls_key ).
lo_action_resource = lo_entity_resource->bind_action( 'INCREASE_SALARY' ).
lo_action_request = lo_action_resource->create_request( ).
ls_parameter = VALUE #( new_salary = 5000 currency = 'eur' ).
lo_action_request->set_parameter( ls_parameter ).
lo_action_request->set_if_match( '1234' ).
```

```

lo_action_response = lo_action_request->execute( ).
CHECK lo_action_response->has_business_data( ) = abap_true.
lo_action_response->get_business_data( IMPORTING ea_business_data =
ls_employee ).

```

## Steps

**Step 1:** Create the entity resource with the employee **Id** '0006' of the entity set '**Employees**' (with **internal** name '**EMPLOYEES**')

```

TYPES:
  BEGIN OF tys_key,
    id TYPE /iwbep/v4_tea_employee_id,
  END OF tys_key.
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity,
      ls_key TYPE tys_key.
ls_key = VALUE #( id = '0006' ).
lo_entity_resource = lo_client_proxy-
>create_resource_for_entity_set( 'EMPLOYEES')->navigate_with_key( ls_key ).

```

**Step 2:** Create the action resource instance on the instance the action is bound to (In this example, an entity of entity set '**Employees**'). '**INCREASE\_SALARY**' is the **internal** name of action '**IncreaseSalary**'

```

DATA: lo_action_resource TYPE REF TO /iwbep/if_cp_resource_action.
lo_action_resource = lo_entity_resource->bind_action( 'INCREASE_SALARY' ).

```

**Step 3:** Create an action request instance with the action resource:

```

DATA: lo_action_request TYPE REF TO /iwbep/if_cp_request_action.
lo_action_request = lo_action_resource->create_request( ).

```

**Step 4:** Set the non-binding (for example, input) parameters of the bound action on the action request:

```

TYPES:
  BEGIN OF tys_parameter,
    new_salary TYPE i,
    currency TYPE c LENGTH 3,
  END OF tys_parameter,
DATA: ls_parameter TYPE tys_parameter.
ls_parameter = VALUE #( new_salary = 5000 currency = 'eur' ).
lo_action_request->set_parameter( ls_parameter ).

```

**Step 5:** Set the **If-Match** header to provide an ETag (if needed for this request) on the action request. In this example, the corresponding request header is **if-match: W/"2407"**, the required input for **SET\_IF\_MATCH** is '**2407**'

```

Lo_action_request->set_if_match( '2407' )

```

### Note

Only remote consumption supports the **If-Match** header.

**Step 6:** Create the action request and get the action response instance:

```

DATA: lo_action_response TYPE REF TO /iwbep/if_cp_response_action.
lo_action_response = lo_action_request->execute( ).

```

**Step 7:** Check if the response object contains business data. This is especially useful for nullable operations, where the operation might not return data (compare to HTTP return code **204 - No Content**):

```
CHECK lo_action_response->has_business_data( ) = abap_true.
```

**Step 8:** Fetch the business data from the response object (if the corresponding action **does** return business data):

```
DATA: ls_employee TYPE /iwbep/s_v4_tea_employee.  
lo_action_response->get_business_data( IMPORTING ea_business_data = ls_employee
```

### Note

- When using the Version 4 local client proxy, the business data you enter isn't converted for inbound processing. The data provider receives the exact data you entered in the request. The business data received from the (local consumption) response is also not re-converted for outbound processing.
- Invoking an OData Version 4 bound function works the same way. Use method **BIND\_FUNCTION** instead of **BIND\_ACTION**.

## Constraints

- If-Match header is only supported for **remote** consumption.
- For function imports, the If-Match header is only supported for OData **Version 2** requests.
- Composable Functions are **not** supported.
- **\$expand** with operations is **not** supported.
- **\$select** is **not** supported for actions.
- **Return-Prefer** header is **not** supported for actions.
- System query options are **not** supported for Version 4 functions.
- If the return type of a Version 2 function is an entity type and this entity type is used by more than one entity set, the Version 2 request context only contains the (EDM) name of the first entity set with the underlying entity type. A precise mapping is currently not possible. For remote consumption, this can be handled in the proxy model by setting the correct entity set via method `. /iwbep/if_v4_med_func_imp->set_entity_set_name`

## 4.2.10.3.4.6 OData Requests

Learn how to use OData Requests.

OData is a standardized protocol built over existing HTTP and REST protocols supporting CRUD (Create, Read, Update, Delete) operations for creating and consuming data APIs. There are various types of requests (including **Create**, **Update**, **Read**, and more) and system query options you can use for your particular use case.

### [OData Request Terms \[page 892\]](#)

An overview of some OData Request terminology.

### [OData Request as Batch Including Changesets \[page 892\]](#)

Create an \$batch request, including changesets in the Client Proxy instance.

### [OData Request: Create Entity \[page 901\]](#)

Create an entity in the Client Proxy instance with insert entity request.

### [OData Request: Update Entity \[page 905\]](#)

Create an OData request to update an entity in the Client Proxy instance.

### [OData Request: Read Entity \[page 908\]](#)

To create an OData request to read an entity in the Client Proxy instance.

### [OData Request: Read Optional Entity \[page 911\]](#)

Create an OData request to read an optional entity in the Client Proxy instance.

### [OData Request: Delete Entity \[page 913\]](#)

Create an OData request to delete an entity in the Client Proxy instance.

### [OData Request: Read Entity List \[page 915\]](#)

Create an OData request to read an entity list (entity collection) in the Client Proxy instance.

### [OData Request: Update Entity List \[page 917\]](#)

Create an OData request to update an entity list in the Client Proxy instance.

### [OData Request: Custom Query Option \[page 921\]](#)

Create an OData request using a custom query option that isn't one of the OData-defined system query options in the Client Proxy instance.

### [OData Request: Deep Create \[page 923\]](#)

Create an OData request to execute a "deep create" (deep insert) in the Client Proxy instance.

### [OData Request: Delta Link Query Option \[page 927\]](#)

Create an OData request with \$delta token query option in the Client Proxy instance.

### [OData Request: Using Navigation \[page 930\]](#)

Create an OData request using a navigation in the Client Proxy instance.

### [OData Request: Including a Nextlink \[page 932\]](#)

Create an OData request to read an entity list (entity collection) with a next link in the Client Proxy instance.

### [OData Request System Query Options \[page 934\]](#)

### 4.2.10.3.4.6.1 OData Request Terms

An overview of some OData Request terminology.

Here's a list of some common terms you'll see when creating OData Requests.

Term	Definition
Request	OData Protocol enables clients to make requests and retrieve responses from the OData service.
Entity	An entity is an instance of the <b>EntityType</b> element (for example, Customer or Employee) that is a structured record with a key that uniquely identifies it.
Entity Key	Each entity has a key that uniquely identifies it (for example, CustomerId or EmployeeId). The key is defined by a subset of the entity type properties.
Entity Type	An entity type is a collection or category that a particular entity belongs to.
Entity Set	An entity set is a group of all entities (for example, the EntitySet Customers is a set of Customer instances) for a particular entity type at any point in time.
Property	An entity type has one or more properties that define the entity type's structure. Each property has a name and one or more values.

### 4.2.10.3.4.6.2 OData Request as Batch Including Changesets

Create an \$batch request, including changesets in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A **batch** request is a single standard HTTP request that includes multiple application requests. Within that main HTTP request, each of the parts contains a nested HTTP request. \$batch request is useful to group

multiple requests and sends a batch to the data service in a single HTTP request. This section explains how a Batch Request works using ChangeSet syntax to logically group requests into a single value in a batch.

## OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

**Batch** requests group multiple individual requests into a single HTTP request payload. An individual request in a **batch** request is one of the following:

- Metadata request
- Data request
- Data modification request
- Action invocation request
- Function invocation request

**Batch** requests are sent as a single HTTP POST request to the **batch** endpoint of a service in the URL **\$batch** that is relative to the service root.

Individual requests in a batch request are evaluated according to the same semantics that are used when the request isn't part of a **batch** request.

In the Multipart format, data modification or action invocation requests can be grouped as part of an atomic change set. Operations outside the change set are executed sequentially. Operations within the change set are executed in any order.

## Example Requests

### Version 4

Get all entities of entity set "**EMPLOYEES**" with Id = '1' and execute the Action Import "**ChangeTeamBudgetByID**":

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/$batch
```

With request body

```
--batch
Content-Type: application/http
Content-Transfer-Encoding: binary
GET EMPLOYEES?$filter=ID%20eq%20%271%27 HTTP/1.1
--batch
Content-Type: multipart/mixed;boundary=change_set_1
--change_set_1
Content-Type: application/http
Content-Transfer-Encoding: binary
Content-ID: 1
POST ChangeTeamBudgetByID HTTP/1.1
Content-Type: application/json
{
  "TeamID" : "TEAM_01",
  "Budget" : 700.00
}
--change_set_1--
--batch--
```

## Version 2

Update two entities of entity set '**Conversions**'

```
POST /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/$batch
```

With request body

```
--batch
Content-Type: multipart/mixed; boundary=changeset
--changeset Content-Type: application/http
Content-Transfer-Encoding: binary
PUT Conversions(Id='0001') HTTP/1.1
Content-Type: application/json
{
  "Id" : "1",
  "price_1" : "-180.59",
  "currency_1" : "EUR",
  "price_2" : "1.706",
  "currency_2" : "KWD",
  "amount_1" : "1.1235",
  "unit_1" : "D",
  "amount_2" : "1.123",
  "unit_2" : "CMS",
  "oSQL_Where_Cl" : "",
  "Is_Boolean" : true
}
--changeset--
--batch
Content-Type: multipart/mixed; boundary=changeset
--changeset
Content-Type: application/http
Content-Transfer-Encoding: binary
PUT Conversions(Id='0001') HTTP/1.1
Content-Type: application/json
{
  "Id" : "1",
  "price_1" : "-000.00",
  "currency_1" : "EUR",
  "price_2" : "1.706",
  "currency_2" : "KWD",
  "amount_1" : "1.1235",
  "unit_1" : "D",
  "amount_2" : "1.123",
  "unit_2" : "CMS",
  "oSQL_Where_Cl" : "",
  "Is_Boolean" : true
}
--changeset--
--batch--
```

## Batch with Changesets Request

### Overview

#### 📌 Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **BATCH** request on an entity.

The starting point for a `$batch` request is the Client Proxy instance. It's possible to create a `$batch` request that you can use to create a changeset request.

## Example

Get all entities of entity set "`Employees`" and create a new entity in entity set "`Teams`":

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/$batch
```

With request body

```
--batch
Content-Type: application/http
Content-Transfer-Encoding: binary
GET Employees HTTP/1.1
--batch
Content-Type: multipart/mixed;boundary=change_set_1
--change_set_1
Content-Type: application/http
Content-Transfer-Encoding: binary
Content-ID: 1
POST Teams HTTP/1.1
Content-Type: application/json
{
    "Id" : "TEAM_04",
    "Name" : "Test Team"
}
--change_set_1--
--batch--
```

```
DATA:      lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
          lo_read_request      TYPE REF TO /iwbep/if_cp_request_read_list,
          lo_read_response     TYPE REF TO /iwbep/if_cp_response_read_lst,
          lo_create_request    TYPE REF TO /iwbep/if_cp_request_create,
          lo_create_response   TYPE REF TO /iwbep/if_cp_response_create,
          lo_batch_request     TYPE REF TO /iwbep/if_cp_request_batch,
          lo_changeset_request TYPE REF TO /iwbep/if_cp_request_changeset,
          lt_employee         TYPE STANDARD TABLE OF /iwbep/
s_v4_tea_employee,ls_team
          TYPE /iwbep/s_v4_tea_team.
lo_batch_request = lo_client_proxy->create_request_for_batch( ).
lo_changeset_request = lo_batch_request->create_request_for_changeset( ).
lo_changeset_request->add_request( lo_create_request ).

lo_batch_request->add_request( lo_read_request ).
lo_batch_request->add_request( lo_changeset_request ).
lo_batch_request->execute( ).
lo_batch_request->check_execution( ).
lo_changeset_request->check_execution( ).
lo_read_request->check_execution( ).
lo_create_request->check_execution( ).
lo_read_response = lo_read_request->get_response( ).
lo_read_response->get_business_data( IMPORTING et_business_data =
lt_employee ).

lo_create_response = lo_create_request->get_response( ).
lo_create_response->get_business_data( IMPORTING es_business_data = ls_team ).
```

## Steps

**Step 1:** Create the `$batch` request at the client proxy instance:

```
DATA:      lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
```

```
lo_batch_request TYPE REF TO /iwbsp/if_cp_request_batch.
lo_batch_request = lo_client_proxy->create_request_for_batch( ).
```

**Step 2:** Create the changeset request using the `$batch` request instance:

```
DATA: lo_batch_request TYPE REF TO /iwbsp/if_cp_request_batch,
      lo_changeset_request TYPE REF TO /iwbsp/if_cp_request_changeset.
      lo_changeset_request = lo_batch_request->
>create_request_for_changeset( ).
```

**Step 3:** Add the `CREATE` request to the changeset request:

```
DATA: lo_create_request TYPE REF TO /iwbsp/if_cp_request_create,
      lo_changeset_request TYPE REF TO /iwbsp/if_cp_request_changeset.
      lo_changeset_request->add_request( lo_create_request ).
```

**Step 4:** Add both the `READ` and the `change_set` request into the `$batch` request. Run the `$batch` request:

```
DATA: lo_read_request TYPE REF TO /iwbsp/if_cp_request_read_list,
      lo_batch_request TYPE REF TO /iwbsp/if_cp_request_batch,
      lo_changeset_request TYPE REF TO /iwbsp/if_cp_request_changeset.
      lo_batch_request->add_request( lo_read_request ).
      lo_batch_request->add_request( lo_changeset_request ).
      lo_batch_request->execute( ).
```

**Step 5:** Check that the four requests ran successfully. (optional):

```
DATA: lo_read_request TYPE REF TO /iwbsp/if_cp_request_read_list,
      lo_create_request TYPE REF TO /iwbsp/if_cp_request_create,
      lo_batch_request TYPE REF TO /iwbsp/if_cp_request_batch,
      lo_changeset_request TYPE REF TO /iwbsp/if_cp_request_changeset.
      lo_batch_request->check_execution( ).
      lo_changeset_request->check_execution( ).
      lo_read_request->check_execution( ).
      lo_create_request->check_execution( ).
```

### Note

If the exception didn't run successfully, `CHECK_EXECUTION` raises an exception. See [Handling Exceptions \[page 878\]](#) for more information.

**Step 6:** Get the `READ` response instance using the `READ` request instance and use it to fetch the corresponding business data:

```
DATA: lo_read_request TYPE REF TO /iwbsp/if_cp_request_read_list,
      lo_read_response TYPE REF TO /iwbsp/if_cp_response_read_lst,
      lt_employee
      TYPE STANDARD TABLE OF /iwbsp/s_v4_tea_employee.
      lo_read_response = lo_read_request->get_response( ).
      lo_read_response->get_business_data( IMPORTING et_business_data =
      lt_employee ).
```

**Step 7:** Get the `CREATE` response instance using the `CREATE` request instance and use it to fetch the corresponding business data:

```
DATA: lo_create_request TYPE REF TO /iwbsp/if_cp_request_create,
      lo_create_response TYPE REF TO /iwbsp/if_cp_response_create,
      ls_team
      TYPE /iwbsp/s_v4_tea_team.
      lo_create_response = lo_create_request->get_response( ).
```

```
lo_create_response->get_business_data( IMPORTING es_business_data =
ls_team ).
```

### Note

When you're using the Version 4 local client proxy, the business data you receive from the local consumption response isn't converted again for outbound processing.

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.4.6.2.1 Content ID Referencing

Create an OData \$batch request using Content ID Referencing in the Client Proxy instance.

## OData Specification

### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#).

Multipurpose Internet Mail Extensions (MIME) is set of extensions that redefines and expands support for various types of content in email messages. Each MIME part that represents a request in a Change Set can include a Content-ID MIME header. See [\[RFC2045 Section 7: Content-ID Header Field\]](#) for more information.

If a MIME part defines an **InsertEntity** request and includes a **Content-ID** header, the new entity is defined by the **InsertEntity** request. You can reference the new entity in future requests in the Change Set using the "\$<Content-ID value of your previous request>" token in place of a Resource Path that identifies the new resource. The token acts as an alias for the Resource Path that identifies the new entity. Requests in different Change Sets can't reference one another, even if they are in the same Batch.

### OData Version 4

See [OData Version 4.01. Part 1: Protocol](#).

Each request in a batch request can have an assigned request identifier. The request identifier:

- is case-sensitive.
- Must be unique within the batch request.
- Must satisfy the rule request-id in [\[OData-ABNF\]](#).

The body part contents that represent a change set must be a multipart document with one body part for each operation in the change set. See [\[RFC2046\]](#). Each body part that represents an operation in the change set must specify a **Content-ID** header with a unique request identifier in the batch request.

## Example Requests

### Version 4

Create new entity in entity set "**TEAMS**" and update it afterwards:

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/$batch
```

With request body

```
--batch
content-type: multipart/mixed; boundary=changeset
--changeset
content-type: application/http
content-id: 111
POST TEAMS HTTP/1.1
Content-Type: application/json
{
  "Name": "Unit Test Task Force",
  "MANAGER_ID": "3",
  "BudgetCurrency": "JPY",
  "Budget": 111100
}
--changeset
content-type: application/http
content-id: 222
PATCH $111 HTTP/1.1
Content-Type: application/json
{
  "MEMBER_COUNT": 66
}
--changeset--
--batch--
```

### Version 2

Create a new entity in entity set "**Decimals**", then read it:

```
POST /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/$batch
```

With request body

```
--batch
Content-Type: multipart/mixed; boundary=changeset
--changeset
Content-Type: application/http
Content-Transfer-Encoding: binary
POST Decimals HTTP/1.1
Content-Type: application/json
Accept: application/json
Content-Id: 1
{
  "Id" : 1,
  "Name" : "Decimal 10",
  "Decimal1" : "1.1000000000"
}
--changeset---
--batch
Content-Type: application/http
Content-Transfer-Encoding: binary
Accept: application/json
GET $1?$format=json HTTP/1.1
--batch--
```

## Create a \$batch request using Content ID Referencing

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to create an OData \$batch request using Content ID Referencing.

The starting point for a using Content ID Referencing is a create request instance and create an entity resource with a Content ID reference.

### Example

Create a new entity in entity set "**Teams**", then update the member count:

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/$batch
```

With request body

```
--batch
content-type: multipart/mixed; boundary=changeset
--changeset
content-type: application/http
content-id: 111
POST Teams HTTP/1.1
Content-Type: application/json
{
  "Name": "Unit Test Task Force"
}
--changeset
content-type: application/http
content-id: 222
PATCH $111 HTTP/1.1
Content-Type: application/json
{
  "MemberCount": 42
}
--changeset--
--batch--
```

```
DATA:   lo_create_request      TYPE REF TO /iwbep/if_cp_request_create,
        lo_batch_request     TYPE REF TO /iwbep/if_cp_request_batch,
        lo_changeset_request TYPE REF TO /iwbep/if_cp_request_changeset,
        lo_update_request    TYPE REF TO /iwbep/if_cp_request_update,
        lo_entity_resource_w_cir TYPE REF TO /iwbep/if_cp_resource_entity,
        ls_patch_data        TYPE /iwbep/s_v4_tea_team.
        lo_entity_resource_w_cir = lo_create_request-
>create_res_w_content_id_ref( ).
        lo_update_request
= lo_entity_resource_w_cir->create_request_for_update( /iwbep/
if_cp_request_update=>gcs_update_semantic-patch ).
        ls_patch_data = VALUE #( member_count = 42 ).
        lo_update_request->set_business_data( is_business_data = ls_patch_data
It_provided_property = VALUE #( ( `MEMBER_COUNT` ) ) ).
        lo_changeset_request->add_request( lo_create_request ).
        lo_changeset_request->add_request( lo_update_request ).
        lo_batch_request->add_request( lo_changeset_request ).
        lo_batch_request->execute( ).
```

## Steps

**Step 1:** Create the entity resource with a Content ID reference in the create request instance:

```
DATA:    lo_create_request TYPE REF TO /iwbep/if_cp_request_create,
        lo_entity_resource_w_cir TYPE REF TO /iwbep/if_cp_resource_entity.
        lo_entity_resource_w_cir = lo_create_request->
>create_res_w_content_id_ref( ).
```

**Step 2:** Create the update request instance at the entity resource instance:

```
DATA:    lo_update_request TYPE REF TO /iwbep/if_cp_request_update,
        lo_entity_resource_w_cir TYPE REF TO /iwbep/if_cp_resource_entity.
        lo_update_request
= lo_entity_resource_w_cir->create_request_for_update( /iwbep/
if_cp_request_update=>gcs_update_semantic_patch ).
```

**Step 3:** Define the corresponding update data and set it into the update request:

```
DATA:    lo_update_request TYPE REF TO /iwbep/if_cp_request_update,
        ls_patch_data TYPE /iwbep/s_v4_tea_team.
        ls_patch_data = value #( member_count = 42 ).
        lo_update_request->set_business_data( is_business_data = ls_patch_data

        It_provided_property = VALUE #( ( `MEMBER_COUNT` ) ).
```

**Step 4:** Add the **CREATE** and **UPDATE** requests into the changeset request. Then add the changeset request into the **\$batch** request:

```
DATA:    lo_create_request      TYPE REF TO /iwbep/if_cp_request_create,
        lo_batch_request        TYPE REF TO /iwbep/if_cp_request_batch,
        lo_changeset_request    TYPE REF TO /iwbep/if_cp_request_changeset,
        lo_update_request        TYPE REF TO /iwbep/if_cp_request_update.

        lo_changeset_request->add_request( lo_create_request ).
        lo_changeset_request->add_request( lo_update_request ).
        lo_batch_request->add_request( lo_changeset_request ).
```

**Step 5:** Run the **\$batch** request:

```
DATA:    lo_batch_request TYPE REF TO /iwbep/if_cp_request_batch.
        lo_batch_request->execute( ).
```

## Constraints

- You can't use Content ID Referencing with navigation (for example, **POST \$1/NavigationProperty**).

## Related Information

[OData Request as Batch Including Changesets \[page 892\]](#)

## 4.2.10.3.4.6.3 OData Request: Create Entity

Create an entity in the Client Proxy instance with insert entity request.

### OData Specification

#### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

The **InsertEntity** request enables a new Entity Type instance with new related entities you add to an EntitySet.

#### OData Version 4

See [OData Version 4.01. Part 1: Protocol](#) .

To create an entity in a collection, the client sends a **POST** request to the collection's URL. The **POST** body MUST contain a single valid entity representation.

### Example Requests

#### Version 4

Create the employee with id '007' in the entity set "**Employees**"

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees
```

With request body

```
{
  "Id" : "007",
  "Name" : "James Bond",
  "Gun" : "Walther PPK",
  "Car" : "Aston Martin DB5"
}
```

#### Version 2

Create the employee with id '007' in the entity set "**Employees**"

```
POST /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees
```

With request body

```
{
  "Id" : "007",
  "Name" : "James Bond",
  "Gun" : "Walther PPK",
  "Car" : "Aston Martin DB5"
}
```

## Create Entity Request

### Overview

#### 📘 Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **CREATE** request on an entity..

The starting point for a **POST** request on an entity list is the Client Proxy instance. It's possible to create an entity list resource, which can then be used to create a create request.

Running the create request provides the create response instance, which can return the business data for the **CREATE** entity request.

### Example

Create the employee with key id = '007' of the Version 4 entity set '**Employees**':

```
POST /sap/opus/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees
```

With request body

```
{
  "Id" : "007",
  "Name" : "James Bond",
  "Age" : 38,
  "Entrydate" : "1962-10-05",
  "ManagerId" : "001",
  "RoomId" : "1",
  "TeamId" : "TEAM_BRITANIA",
  "IsManager" : false,
  "Status" : "Available"
}
TYPES: BEGIN OF tys_entity_data,
       Id          TYPE i,
       Name        TYPE string,
       age         TYPE i,
       entry_date  TYPE dats,
       manager_id  TYPE i,
       room_id     TYPE i,
       team_id     TYPE string,
       is_manager  TYPE abap_bool,
       status      TYPE string,
END OF tys_entity_data.
```

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_create_request    TYPE REF TO /iwbep/if_cp_request_create,
      lo_create_response   TYPE REF TO /iwbep/if_cp_response_create,
      lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list,
      ls_entity_data       TYPE tys_entity_data, ls_employee
      TYPE /iwbep/s_v4_tea_employee.
      lo_entity_list_resource = lo_client_proxy-
>create_resource_for_entity_set( 'EMPLOYEES' ).
      lo_create_request = lo_entity_list_resource-
>create_request_for_create( ).
      ls_entity_data = VALUE #( id = 007
```

```

name = 'James Bond'
age = 38
entry_date = '19621005'
manager_id = 001
room_id = 1
team_id = 'team_britania'
is_manager = abap_false
status = 'Available' ).
lo_create_request->set_business_data( is_business_data = ls_entity_data
It_provided_property = VALUE #( ( |ID| )
( |NAME| )
( |AGE| )
( |ENTRY_DATE| )
( |MANAGER_ID| )
( |ROOM_ID| )
( |TEAM_ID| )
( |IS_MANAGER| )
( |STATUS| ) ).
lo_create_response = lo_create_request->execute( ).
lo_create_response->get_business_data( IMPORTING es_business_data =
ls_employee ).

```

## Steps

**Step 1:** Create the entity list resource for entity set '**Employees**' (with **internal** name '**EMPLOYEES**')

```

DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy,
lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
lo_entity_list_resource = lo_client_proxy-
>create_resource_for_entity_set( 'EMPLOYEES' ).

```

**Step 2:** Run the create request instance on the entity list resource.

```

DATA: lo_update_request TYPE REF TO /iwbep/if_cp_request_create,
lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
lo_create_request = lo_entity_list_resource-
>create_request_for_create( ).

```

**Step 3:** Set the business data for your create request. In our example, the create request properties are:

Properties	Internal Names
Id	<b>ID</b>
Name	<b>NAME</b>
Age	<b>AGE</b>
EntryDate	<b>ENTRY_DATE</b>
ManagerId	<b>MANAGER_ID</b>
RoomId	<b>ROOM_ID</b>
TeamId	<b>TEAM_ID</b>
Status	<b>STATUS</b>
IsManager	<b>IS_MANAGER</b>

Define the values and set the business data into the create request:

```

TYPES: BEGIN OF tys_entity_data,
Id TYPE i,
Name TYPE string,

```

```

        age          TYPE i,
        entry_date   TYPE dats,
        manager_id   TYPE i,
        room_id      TYPE i,
        team_id      TYPE string,
        is_manager   TYPE abap_bool,
        status       TYPE string,
        END OF tys_entity_data.
DATA: lo_update_request TYPE REF TO /iwbep/if_cp_request_create,
      ls_entity_data    TYPE tys_entity_data,
      ls_employee       TYPE /iwbep/s_v4_tea_employee.
ls_entity_data = VALUE #( id = 007
                          name = 'James Bond'
                          age = 38
                          entry_date = '19621005'
                          manager_id = 001
                          room_id = 1
                          team_id = 'team_britania'
                          is_manager = abap_false
                          status = 'Available' ).
lo_create_request->set_business_data( is_business_data = ls_entity_data
it_provided_property = VALUE #( ( |ID| )
                                ( |NAME| )
                                ( |AGE| )
                                ( |ENTRY_DATE| )
                                ( |MANAGER_ID| )
                                ( |ROOM_ID| )
                                ( |TEAM_ID| )
                                ( |IS_MANAGER| )
                                ( |STATUS| ) ).

```

#### ⓘ Note

(Optional) Provide the properties when calling **SET\_BUSINESS\_DATA**. If you provide properties, only the properties you set are considered. If you don't provide properties, all properties are considered for the **CREATE** request.

#### ⓘ Note

If the entity has value control or VCS properties, these properties **should** also be part of the provided data container (**ls\_entity\_data** in this example). If the value control/VCS properties are not provided, the behavior (for example: conversion exits) is undefined and can cause unexpected side-effects.

**Step 4:** Run the **create** request and get the create response instance:

```

DATA: lo_update_request TYPE REF TO /iwbep/if_cp_request_create,
      lo_update_response TYPE REF TO /iwbep/if_cp_response_create.
lo_create_response = lo_create_request->execute( ).

```

**Step 5:** You fetch the business data from the response object:

```

DATA: lo_update_response TYPE REF TO /iwbep/
if_cp_response_create, ls_employee
      TYPE /iwbep/s_v4_tea_employee.
lo_create_response->get_business_data( IMPORTING es_business_data =
ls_employee ).

```

#### ⓘ Note

When you're using the Version 4 local client proxy, the business data you receive from the local consumption response isn't converted again for outbound processing.

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.4.6.4 OData Request: Update Entity

Create an OData request to update an entity in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

An **UpdateEntity** Request is used by a client to update an existing AtomPub Entry Resource, as specified in [RFC5023](#) , that maps to an EntityType instance in the abstract data model.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

To update an individual entity, the client makes a **PATCH** or **PUT** request to a URL that identifies the entity. Services can be restricted to only request updates addressing the edit URL of the entity.

## Example Requests

### Version 4

Update the employee with id '007' of entity set "**Employees**

```
PATCH /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
```

With request body

```
{
  "Car" : "Aston Martin DB5"
}
```

### Version 2

Update the employee with id '007' of entity set "**Employees**":

```
PUT /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees('007')
```

With request body

```
{ "Id" : "007",
```

```

    "Name" : "James Bond",
    "Gun" : "Walther PPK",
    "Car" : "Aston Martin DB5"
  }

```

## Update Entity Request

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **UPDATE** request on an entity.

The starting point for a **PUT/PATCH** entity request is the Client Proxy instance. You can create an **entity resource** based on an **entity list resource**, and use it to create an update request.

Running the update request provides the update response, which can return the business data of the **UPDATE** entity request.

### Example

Update the employee with key "id = '007'" of the Version 4 entity set '**Employees**':

```
PATCH /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
```

With request body

```

{
  "Age" : 38,
  "IsManager" : true,
  "Status" : "Available"
}

```

```

TYPES:
  BEGIN OF tys_patch_data,
  types: BEGIN OF tys_patch_data,
    age      TYPE i,
    is_manager TYPE abap_bool,
    status   TYPE string,
  END OF tys_patch_data.
DATA:
  lo_client_proxy      TYPE REF TO /iwbe/if_cp_client_proxy,
  lo_update_request   TYPE REF TO /iwbe/if_cp_request_update,
  lo_update_response  TYPE REF TO /iwbe/if_cp_response_update,
  lo_entity_resource  TYPE REF TO /iwbe/if_cp_resource_entity,
  ls_patch_data       TYPE tys_patch_data,
  ls_employee         TYPE /iwbe/s_v4_tea_employee.
  lo_entity_resource
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-
>navigate_with_key(value /iwbe/if_v4_tea_busi_types=>ty_s_employee_key( id =
'007' ) ).
  lo_update_request = lo_entity_resource->create_request_for_update( /
iwbe/if_cp_request_update=>gcs_update_semantic_patch ).
  ls_patch_data = VALUE #( age = 38
    is_manager = abap_true
    status = 'Available' ).
  lo_update_request->set_business_data( is_business_data = ls_patch_data
it_provided_property = VALUE #( ( |AGE| )
( |IS_MANAGER| )

```

```

        ( |STATUS| ) ).

    lo_update_request->set_if_match( '1234' ).
    lo_update_response = lo_update_request->execute( ).
    lo_update_response->get_business_data( IMPORTING es_business_data =
ls_employee ).

```

## Steps

**Step 1:** Create the entity resource for the employee with the following:

- key "Id='007'" in the entity set '**Employees**' (internal name '**EMPLOYEES**')
- type "**ty\_s\_employee\_key**" in the interface **/iwbep/if\_v4\_tea\_busi\_types**"

```

DATA      lo_client_proxy    TYPE REF TO /iwbep/if_cp_client_proxy,
          lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
          lo_entity_resource
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-
>navigate_with_key(value /iwbep/if_v4_tea_busi_types=>ty_s_employee_key( id =
'007' ) ).

```

**Step 2:** Create the update request instance on the entity resource. You need to provide the correct semantic (either **PATCH** or **PUT**). **PUT** creates a full new resource representation. If some attributes are not provided, these attributes should be removed (set to null) or set to their default value. **PATCH** also updates a resource, but unlike **PUT**, it applies a delta rather than replacing the entire resource. The **PATCH** payload is a different content-type than the entity that it is modifying. Instead of being a full resource, it is a resource that describes modifications that be made to a resource.

In our example, we use **PATCH** semantic. You can use the constants in structure **gcs\_update\_semantic** of interface **/iwbep/if\_cp\_request\_update** as input:

```

DATA:      lo_update_request TYPE REF TO /iwbep/if_cp_request_update,
          lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
          lo_update_request = lo_entity_resource->create_request_for_update( /
iwbep/if_cp_request_update=>gcs_update_semantic-patch ).

```

**Step 3:** Set the business (for example, update) data for your update request. In our example, we want to update three properties. We define the new values and set the business data into the update request:

Properties	Internal Names
Age	<b>AGE</b>
Status	<b>STATUS</b>
IsManager	<b>IS_MANAGER</b>

```

TYPES:      BEGIN OF tys_patch_data,
          age      TYPE i,
          is_manager TYPE abap_bool,
          status   TYPE string,
          END OF tys_patch_data.
DATA:      lo_update_request TYPE REF TO /iwbep/if_cp_request_update,
          ls_patch_data     TYPE tys_patch_data.
          ls_patch_data = VALUE #( age = 38
is_manager = abap_true
status = 'Available' ).
lo_update_request->set_business_data( is_business_data = ls_patch_data
it_provided_property = VALUE #( ( |AGE| )
( |IS_MANAGER| )
( |STATUS| ) ) ).

```

### Note

Providing the properties is required when calling `SET_BUSINESS_DATA` for a `PATCH` request.

**Step 4:** Set the `If-Match` header to provide a ETag (if needed for this request). For example, if the corresponding request header is `if-match: W/"1234"`, the required input for `SET_IF_MATCH` is `'1234'`:

```
DATA:      lo_update_request TYPE REF TO /iwbep/if_cp_request_update.  
          lo_update_request->set_if_match( '1234' ).
```

**Step 5:** Run the update request and get the update response instance:

```
DATA:      lo_update_request TYPE REF TO /iwbep/if_cp_request_update,  
          lo_update_response TYPE REF TO /iwbep/if_cp_response_update.  
  
          lo_update_response = lo_update_request->execute( ).
```

**Step 6:** Fetch the business data from the response object:

```
DATA:      lo_update_response TYPE REF TO /iwbep/if_cp_response_update,  
          ls_employee         TYPE /iwbep/s_v4_tea_employee.  
          lo_update_response->get_business_data( IMPORTING es_business_data =  
          ls_employee ).
```

### Note

When you're using the Version 4 local client proxy, the business data you receive from the local consumption response isn't converted again for outbound processing.

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.5 OData Request: Read Entity

To create an OData request to read an entity in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A client uses a RetrieveEntity request to retrieve an AtomPub Entry Resource. See [RFC5023: Atom Publishing Protocol](#) for more information on the Atom Publishing Protocol.

## OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

OData services support requests for data using HTTP GET requests. The URL path includes the request target (for example, the collection of entities, entity, navigation property, structural property, or operation).

## Example Requests

### Version 4

Get the employee with id '007' from the "Employees" entity set.

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
```

### Version 2

Get the employee with id '007' from the "Employees" entity set.

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees('007')
```

## OData Request: Read Entity

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **READ** request on an entity.

The starting point for a **GET** entity request is the Client Proxy instance. You can create an entity resource based on an entity list resource, which can use create an entity resource based on an entity list resource. Use the entity resource to create a read request.

Running the read request provides a response, which can return the business data of the **READ** entity request.

### Example

From the Version 4 entity set 'Employees', fetch the employee with key id '007':

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
```

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,  
      lo_read_request     TYPE REF TO /iwbep/if_cp_request_read,  
      lo_read_response    TYPE REF TO /iwbep/if_cp_response_read,  
      lo_entity_resource  TYPE REF TO /iwbep/if_cp_resource_entity,  
      ls_employee        TYPE /iwbep/s_v4_tea_employee.  
      lo_entity_resource  
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-  
>navigate_with_key( VALUE /iwbep/if_v4_tea_busi_types=>ty_s_employee_key( id =  
'007') ).  
      lo_read_request = lo_entity_resource->create_request( ).
```

```

lo_read_response = lo_read_request->execute( ).
lo_read_response->get_business_data( IMPORTING es_business_data =
ls_employee ).

```

## Steps

To run an OData request to read an entity:

**Step 1:** Create the entity resource for the employee with the key `id='007'` from the entity set 'Employees' (with internal name '`EMPLOYEES`'). Use type `ty_s_employee_key` in interface `/iwbep/if_v4_tea_busi_types` that includes the key property `id`:

```

DATA: lo_client_proxy    TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
lo_entity_resource
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-
>navigate_with_key( VALUE /iwbep/if_v4_tea_busi_types=>ty_s_employee_key( id =
'007' ) ).

```

**Step 2:** Create the read request instance on the entity resource:

```

DATA: lo_read_request    TYPE REF TO /iwbep/if_cp_request_read,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
lo_read_request = lo_entity_resource->create_request( ).

```

**Step 3:** Execute the read request and get the read response instance:

```

DATA: lo_read_request    TYPE REF TO /iwbep/if_cp_request_read,
      lo_read_response   TYPE REF TO /iwbep/if_cp_response_read.
lo_read_response = lo_read_request->execute( ).

```

**Step 4:** Fetch the business data from the response object:

```

DATA: lo_read_response TYPE REF TO /iwbep/if_cp_response_read,
      ls_employee      TYPE /iwbep/s_v4_tea_employee.
lo_read_response->get_business_data( IMPORTING es_business_data =
ls_employee ).

```

### Note

When you're using the Version 4 local client proxy, the business data you receive from the local consumption response isn't converted again for outbound processing.

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.6 OData Request: Read Optional Entity

Create an OData request to read an optional entity in the Client Proxy instance.

An optional entity is accessed using navigation with cardinality (for example, the measure of the number of elements in a set) zero-to-one (for example, the accessed entity has either zero or one entry).

### OData Specification

#### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

The client uses a **RetrieveEntity** Request to retrieve an AtomPub Entry Resource, as specified in [RFC5023](#) , and potentially related entities that map to EntityType instances.

#### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

OData services support requests for data with HTTP GET requests. The URL path specifies the target of the request (for example, the collection of entities, entity, navigation property, structural property, or operation).

### Example Requests

#### Version 4

Get the manager of the Employee with Id '0004' via zero-to-one navigation property '**Employee2Manager**':

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0004')/Employee2Manager
```

#### Version 2

Get the technical info of the Team '**TEAM\_02**' via zero-to-one navigation property "**Technical\_Info**"

```
GET/sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Teams('TEAM_02')/Technical_Info
```

### Read Optional Entity Request

#### Overview

##### 📌 Note

As the coding is independent of the OData version, we're presenting a general example on how to read an optional entity .

The starting point for a **\$read** optional entity request is an optional entity in the Client Proxy instance. It's possible to create a **\$read** request with a corresponding zero-to-one navigation.

On the optional entity resource, it's possible to create an optional read request instance.

Running the zero-to-one read request provides the zero-to-one read response, which can return the business data of the optional READ entity request.

## Example

Get the manager of the Employee with Id '0004' via zero-to-one navigation property '**Employee2Manager**':

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0004')/Employee2Manager
```

## Steps

```
DATA: lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity01,  
      lo_read_request    TYPE REF TO /iwbep/if_cp_request_read_01,  
      lo_read_response   TYPE REF TO /iwbep/if_cp_response_read_01,  
      lt_manager         TYPE STANDARD TABLE OF /iwbep/s_v4_tea_manager.  
lo_read_request = lo_entity_resource->create_request_for_read( ).  
lo_read_response = lo_read_request->execute( ).  
lo_read_response->get_business_data( IMPORTING et_business_data = lt_manager ).
```

**Step 1:** Create the read request instance using the entity resource instance:

```
DATA: lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity01,  
      lo_read_request    TYPE REF TO /iwbep/if_cp_request_read_01.  
lo_read_request = lo_entity_resource->create_request_for_read( ).
```

### Note

See [OData Request: Using Navigation \[page 930\]](#) for more information about how to create an optional entity resource instance.

### Note

Instead of a **READ** request, you can also to set up an **UPDATE** or **DELETE** request for the optional entity.

**Step 2:** Execute the **read** request and fetch the corresponding read response instance:

```
DATA: lo_read_request  TYPE REF TO /iwbep/if_cp_request_read_01,  
      lo_read_response TYPE REF TO /iwbep/if_cp_response_read_01.  
lo_read_response = lo_read_request->execute( ).
```

**Step 3:** Retrieve the business data from the read response instance:

```
DATA: lo_read_response TYPE REF TO /iwbep/if_cp_response_read_01,  
      lt_manager       TYPE STANDARD TABLE OF /iwbep/s_v4_tea_manager.  
lo_read_response->get_business_data( IMPORTING et_business_data = lt_manager ).
```

### Note

The zero-to-one read request response is always a table that contains either zero or one entry.

## Related Information

[OData Request Terms \[page 892\]](#)

[OData Request: Using Navigation \[page 930\]](#)

### 4.2.10.3.4.6.7 OData Request: Delete Entity

Create an OData request to delete an entity in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

The **DeleteEntity Request** enables an **EntityType** instance to be deleted from a data service. The base rules and semantics of this request type are defined by AtomPub, as specified in [RFC5023](#) section 9.4 -- Deleting Resources with **DELETE**.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

To delete an individual entity, the client makes a **DELETE** request to a URL that identifies the entity.

When the delete is successfully completed, the response MUST be `<response code and name>` and contain an empty body.

## Example Requests

### Version 4

Delete the employee with id '007' of entity set "**Employees**"

```
DELETE /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
```

### Version 2

Delete the employee with id '007' of entity set "**Employees**"

```
DELETE /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees('007')
```

# Delete Entity Request

## Overview

### Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **DELETE** entity request.

The starting point for a **DELETE** entity request is the Client Proxy instance. You can create an entity resource based on an entity list resource, which you can use to create a delete request.

## Example

Delete the employee with key "id = '007'" of the Version 4 entity set '**Employees**':

```
DELETE /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('007')
with IF-MATCH header W/"MI6".
```

```
DATA: lo_client_proxy    TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_delete_request  TYPE REF TO /iwbep/if_cp_request_delete,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
lo_entity_resource
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-
>navigate_with_key(value /iwbep/if_v4_tea_busi_types=>ty_s_employee_key( id =
'007') ).
lo_delete_request = lo_entity_resource->create_request_for_delete( ).
lo_delete_request->set_if_match( 'mi6' ).
lo_delete_request->execute( ).
lo_delete_request->check_execution( ).
```

## Steps

**Step 1:** Create the entity resource for the employee with the key "Id='007'" of entity set '**Employees**' (with internal name '**EMPLOYEES**'). Type "**ty\_s\_employee\_key**" in interface "**/iwbep/if\_v4\_tea\_busi\_types**" is a structure containing the key property "id":

```
DATA: lo_client_proxy    TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
lo_entity_resource
= lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES')-
>navigate_with_key(value /iwbep/if_v4_tea_busi_types=>ty_s_employee_key( id =
'007') ).
```

**Step 2:** Create the delete request instance on the entity resource:

```
DATA: lo_delete_request TYPE REF TO /iwbep/if_cp_request_delete,
      lo_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
lo_delete_request = lo_entity_resource->create_request_for_delete( ).
```

**Step 3:** Set the If-Match header to provide an ETag (if needed for this request). If the corresponding request header is, for example, **if-match: W/"MI6"**, the required input for **SET\_IF\_MATCH** is '**MI6**':

```
DATA: lo_delete_request TYPE REF TO /iwbep/if_cp_request_delete.
lo_delete_request->set_if_match( 'mi6' ).
```

**Step 4:** Run the delete request:

```
DATA: lo_delete_request TYPE REF TO /iwbeb/if_cp_request_delete.  
lo_delete_request->execute( ).
```

#### Note

A successful delete request doesn't have response data, which means that the **EXECUTE** method doesn't return a delete response object.

**Step 5:** Check if the execution was successful:

```
DATA: lo_delete_request TYPE REF TO /iwbeb/if_cp_request_delete.  
lo_delete_request->check_execution( ).
```

#### Note

Normally, any issues during the request execution raises an exception in method **EXECUTE**. This method call is optional.

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.8 OData Request: Read Entity List

Create an OData request to read an entity list (entity collection) in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A **RetrieveEntitySet** Request is used by a client to update the entries in an AtomPub Collection, as specified in [RFC5023](#) , that maps to an **EntitySet** in the abstract data model.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

OData services support data requests for using HTTP GET requests. The URL path specifies the target of the request (for example, the collection of entities, entity, navigation property, structural property, or operation).

## Example Requests

### Version 4

Get all entities of entity set “**Employees**”

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees
```

### Version 2

Get all entities of entity set “**Employees**”

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees
```

## Read Entity List Request

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to create a **READ** request on an entity list.

The starting point for a **GET** entity request is the [Client Proxy Examples \[page 880\]](#). You can create a **read list request** based on an **entity list resource**.

Running the **read list request** provides the read list response that can provide the business data of the **READ** entity list request.

### Example

Fetch all entities of the Version 4 entity set '**Employees**':

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees
```

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst,
      lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list,
      lt_employee          TYPE STANDARD TABLE OF /iwbep/s_v4_tea_employee.
lo_entity_list_resource = lo_client_proxy-
>create_resource_for_entity_set( 'EMPLOYEES' ).
lo_read_list_request = lo_entity_list_resource->create_request_for_read( ).
lo_read_list_response = lo_read_list_request->execute( ).
lo_read_list_response->get_business_data( IMPORTING et_business_data =
lt_employee ).
```

### Steps

**Step 1:** Create the entity list resource for entity set '**Employees**' (with **internal** name '**EMPLOYEES**'):

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
```

```
lo_entity_list_resource = lo_client_proxy->create_resource_for_entity_set( 'EMPLOYEES' ).
```

**Step 2:** Create the read list request instance on the entity resource:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,  
      lo_entity_list_resource TYPE REF TO /iwbep/if_cp_resource_list.  
lo_read_list_request = lo_entity_list_resource->create_request_for_read( ).
```

**Step 3:** Run the read list request and get the read list response instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,  
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.  
lo_read_list_response = lo_read_list_request->execute( ).
```

**Step 4: Fetch the business data from the response object:**

```
DATA: lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst,  
      lt_employee TYPE STANDARD TABLE OF /iwbep/s_v4_tea_employee.  
lo_read_list_response->get_business_data( IMPORTING et_business_data =  
lt_employee ).
```

#### Note

When you're using the Version 4 local client proxy, the business data you receive from the local consumption response isn't converted again for outbound processing.

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.9 OData Request: Update Entity List

Create an OData request to update an entity list in the Client Proxy instance.

You want

## OData Specification

### OData Version 2

An update request for an entity list is not supported in OData Version 2.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

You can update entity collections by submitting a **PATCH** request to the collection's resource path. The body of the request:

- **MUST** be a **delta payload**.
- the resource path of the collection **MUST NOT** include type cast or filter segments.
- **MUST NOT** include any system query options that affect the shape of the result.

Added/changed entities are applied as upserts. Deleted entities are applied as deletions.

## Example Requests

### Version 4

Update the complete entity set "**Teams**":

```
PATCH /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams
```

With request body

```
{
  "@context" : "#$delta",
  "value" : [
    {
      "Id" : "NEW 1",
      "Name" : "Created",
      "MemberCount" : 2,
      "ManagerId" : "3",
      "BudgetCurrency" : "USD",
      "Budget" : 555.55
    },
    {
      "Id" : "TEAM_02",
      "Name" : "Update?"
    },
    {
      "Id" : "New 3",
      "Name" : "Created"
    }
  ]
}
```

## Update Entity List Request

### Overview

The starting point for a **PATCH** entity request is the Client Proxy instance. You can create an **entity resource** based on an **update list** request, and use it to create an update request.

Running the **update list** provides the update list response, which can return the business data of the **UPDATE** entity list request.

## Example

Update the entity set "**Teams**":

```
PATCH /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams
```

With request body

```
{
  "@context" : "#$delta",
  "value" : [
    {
      "Id" : "New Team",
      "Name" : "Created",
      "BudgetCurrency" : "USD",
      "Budget" : 555
    },
    {
      "Id" : "TEAM_02",
      "Name" : "New Team Name"
    }
  ]
}
```

```
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_update_list_request TYPE REF TO /iwbep/if_cp_request_update_l,
      lo_update_list_response TYPE REF TO /iwbep/if_cp_response_update_l,
      lo_list_resource TYPE REF TO /iwbep/if_cp_resource_list,
      lt_response_data TYPE STANDARD TABLE OF /iwbep/s_v4_tea_team,
      lt_request_data TYPE STANDARD TABLE OF /iwbep/s_v4_tea_team.
      lo_list_resource = lo_client_proxy-
>create_resource_for_entity_set( 'TEAMS' ).
      lo_update_list_request = lo_list_resource->create_request_for_update( ).
      lt_request_data = value #( ( id = 'New team' name = 'Created' budget = 555
      budget_currency = 'USD' )
      ( id = 'TEAM_02' name = 'New Team Name' ) ) .
      lo_update_list_request->set_business_data( it_business_data =
      lt_request_data ).
      lo_update_list_request->request_continue_on_error( ).
      lo_update_list_response = lo_update_list_request->execute( ).
      lo_update_list_response->get_business_data( IMPORTING et_business_data
      = lt_response_data )
```

## Steps

**Step 1:** Create the entity list resource for entity set '**Teams**' (with internal name '**TEAMS**')

```
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
      lo_list_resource = lo_client_proxy-
>create_resource_for_entity_set( 'TEAMS' ).
```

**Step 2:** Create the update list request instance on the entity list resource:

```
DATA: lo_update_list_request TYPE REF TO /iwbep/if_cp_request_update_l,
      lo_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
      lo_update_list_request = lo_list_resource->create_request_for_update( ).
```

**Step 3:** Set the business data (for example, update) for your update list request. Define the corresponding business data and set it into the update list request:

```
DATA: lo_update_list_request TYPE REF TO /iwbep/if_cp_request_update_l,
      lt_request_data TYPE STANDARD TABLE OF /iwbep/s_v4_tea_team.
```

```

lt_request_data = VALUE #( ( id = 'New team' name = 'Created' budget =
555 budget_currency = 'usd' )
( id = 'team_02' name = 'New Team Name' ) ) .
lo_update_list_request->set_business_data( it_business_data =
lt_request_data ).

```

**Step 4:** (Optional) Request that the request processing continues even when there is an error (if supported).

If the server supports this setting, a failed operation for one entity doesn't cause the complete request to fail. The failed entity is marked with the instance annotation `Core.DataModificationException`:

```

DATA:    lo_update_list_request TYPE REF TO /iwbsp/if_cp_request_update_l.
        lo_update_list_request->request_continue_on_error( ).

```

### Note

This information is mapped into the request header `prefer:odata.continue-on-error`. This preference is optional. The consumed OData service does **not** have to follow this preference.

**Step 5:** Run the update list request and get the update list response instance:

```

DATA:    lo_update_list_request TYPE REF TO /iwbsp/if_cp_request_update_l,
        lo_update_list_response TYPE REF TO /iwbsp/if_cp_response_update_l.
        lo_update_list_response = lo_update_list_request->execute( ).

```

**Step 6:** Fetch the business data from the response list object:

```

DATA:    lo_update_list_response TYPE REF TO /iwbsp/if_cp_response_update_l,
        lt_response_data        TYPE STANDARD TABLE OF /iwbsp/s_v4_tea_team.
        lo_update_list_response->get_business_data( IMPORTING et_business_data
= lt_response_data ).

```

## Constraints

- Updating an entity list is only supported for OData Version 4
- This feature is not supported for local consumption
- Only **PATCH** is supported. **PUT** is not supported.
- **IF-MATCH** handling is not supported
- Query options are not supported
- Updating an entity list within a \$batch is not supported

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.10 OData Request: Custom Query Option

Create an OData request using a custom query option that isn't one of the OData-defined system query options in the Client Proxy instance.

### OData Specification

#### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

Custom Query Options enable you to include data service-specific information in a data service URI query string.

#### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

Services can support additional custom query options that are not defined in the OData specification. The custom query options:

- can't begin with the "\$" or "@" character
- can't conflict with any OData-defined system query options defined in the OData version that the service supports

### Example Requests

#### Version 4

Use custom query option "**sap-statistics**":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams?sap-statistics=true
```

#### Version 2

Use custom query option "**sap-statistics**":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Prices?sap-statistics=true
```

# Custom Query Option Request

## Overview

### Note

As the coding is independent of the OData version, we're presenting a general example on how to use `$count`.

The starting point for a custom query option request is an entity list read request. You can set a custom query option on the entity list read request.

## Example

Use custom query option "`sap-statistics`"

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams?sap-
statistics=true
```

```
DATA: lo_read_list_request      TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_http_client           TYPE REF TO if_http_client,
      lv_sap_statistics_result TYPE string.
lo_read_list_request->set_custom_query_options( VALUE #( ( name = 'sap-
statistics' value = 'true' ) ) ).
lo_read_list_request->execute( ).
lv_sap_statistics_result = lo_http_client->response->get_header_field( name =
'sap-statistics' ).
```

## Steps

**Step 1:** Set the custom query option directly at the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list.
lo_read_list_request->set_custom_query_options( VALUE #( ( name = 'sap-
statistics' value = 'true' ) ) ).
```

**Step 2:** Run the read request and fetch the sap statistics result from the HTTP client instance:

```
DATA: lo_read_list_request      TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_http_client           TYPE REF TO if_http_client,
      lv_sap_statistics_result TYPE string.
lo_read_list_request->execute( ).
lv_sap_statistics_result = lo_http_client->response->get_header_field( name =
'sap-statistics' ).
```

### Note

`lo_http_client` must be the **same** HTTP client instance as the one used for creating the Client Proxy.

## Constraints

- Regardless of the Client Proxy OData version, input MUST conform with the more stricter OData Version 4 specification.

- You can only use custom query options for remote consumption. Custom query options are not supported in local consumption scenarios.

## Related Information

[OData Request Terms \[page 892\]](#)

[Client Proxy Instance Types \[page 866\]](#)

### 4.2.10.3.4.6.11 OData Request: Deep Create

Create an OData request to execute a "deep create" (deep insert) in the Client Proxy instance.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

In the Deep Create request, you can insert a new Entity Type instance (E1) into an Entity Set and insert new entities related to E1. This is described by a Navigation Property on the Entity Type associated with E1) in a single InsertEntity Request. For example, in a customer relationship management-focused data service, you can insert a new customer entity and new related order entities in a single **InsertEntity** Request. This type of an InsertEntity Request is also known as a "deep insert".

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

A "deep insert" request creates an entity that includes related entities using the appropriate inline representation

## Example Requests

### Version 4

Create a new team (entity set "**TEAMS**") and a new manager (entity set "**MANAGERS**") via navigation property "**TEAM\_2\_MANAGER**":

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/TEAMS
```

With request body

```
{  
  "Name" : "Business Suite",
```

```

    "MEMBER_COUNT" : 2,
    "MANAGER_ID" : "8",
    "BudgetCurrency" : "USD",
    "Budget" : 555.55,
    "TEAM_2_MANAGER" : {
      "ID" : "8",
      "TEAM_ID" : ""
    }
  }
}

```

## Version 2

Create the employee with id '1' (entity set "**EMPLOYEES**") and the corresponding team (entity set "**TEAMS**") with navigation property "**My\_Team**":

```
POST /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees
```

With request body

```

{
  "Location" : {
    "Country" : "Germany",
    "City" : {
      "PostalCode" : "69124",
      "CityName" : "Heidelberg",
      "VeryLongPropertyNameForOrderBy" : ""
    }
  },
  "Id" : "1",
  "Name" : "Walter Winter",
  "Age" : " 52",
  "EntryDate" : "\/Date(91514880000)\/",
  "Manager_ID" : "1",
  "Room_ID" : "1",
  "Team_ID" : "TEAM_01",
  "My_Team" : {
    "Team_Identifier" : "TEAM_01",
    "Name" : "Business Suite"
  }
}

```

## Deep Create Request

### Overview

#### 📌 Note

As the coding itself is independent of the OData version, we will just present one general example on how to create a execute a deep create request.

As the coding is independent of the OData version, we're presenting a general example on how to create a **deep create** request on an entity.

The main difference between a **create** and a **deep create** request in the Client Proxyinstance is that the **deep create** request requires a data description node. You create a data description node at the create request instance and it is used later when setting the deep business data.

## Note

See [OData Request: Create Entity \[page 901\]](#) for more information.

## Example

Create a new team (entity set "**Teams**") and a new manager (entity set "**Managers**"):

```
POST /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Team
```

With request body

```
{
  "Id" : "TEAM_04",
  "MemberCount" : 2,
  "Team2Manager" : {
    "Id" : "0009"
  }
}
```

```
DATA: lo_create_request      TYPE REF TO /iwbep/if_cp_request_create,
      lo_create_response     TYPE REF TO /iwbep/if_cp_response_create,
      lo_data_desc_node_root TYPE REF TO /iwbep/if_cp_data_desc_node,
      lo_data_desc_node_child TYPE REF TO /iwbep/if_cp_data_desc_node,
      ls_deep_busi_data      TYPE /iwbep/
if_v4_tea_busi_types=>ty_s_team_and_manager,
      ls_response_data      TYPE /iwbep/
if_v4_tea_busi_types=>ty_s_team_and_manager.
      lo_data_desc_node_root = lo_create_request-
>create_data_description_node( ).
      lo_data_desc_node_root->set_properties( VALUE #( ( |ID| ) ( |
MEMBER_COUNT| ) ) ).
      lo_data_desc_node_child = lo_data_desc_node_root-
>add_child( 'team_2_manager' ).
      lo_data_desc_node_child->set_properties( VALUE #( ( |ID| ) ) ).
      ls_deep_busi_data = VALUE #( id = 'team_04'
      member_count = 2
      team_2_manager = VALUE #( id = '0009' ) ).
      lo_create_request->set_deep_business_data( is_business_data =
ls_deep_busi_data
      io_data_description_node = lo_data_desc_node_root ).
      lo_create_response = lo_create_request->execute( ).
      lo_create_response->get_business_data( IMPORTING es_business_data =
ls_response_data ).
      lo_create_response->get_business_data( IMPORTING es_business_data =
ls_response_data ).
```

## Steps

**Step 1:** Creation of the data description node for the root entity (here: "Teams") on the create request instance:

```
DATA: lo_create_request      TYPE REF TO /iwbep/if_cp_request_create,
      lo_data_desc_node_root TYPE REF TO /iwbep/if_cp_data_desc_node.
      lo_data_desc_node_root = lo_create_request-
>create_data_description_node( ).
```

## Note

See [OData Request: Create Entity \[page 901\]](#) for more information.

**Step 2:** Set the properties for the root entity. In our example, the properties are “**Id**” (internal name “**ID**”) and “**MemberCount**” (internal name “**MEMBER\_COUNT**”):

```
DATA: lo_data_des_node_root TYPE REF TO /iwbep/if_cp_data_desc_node.
      lo_data_desc_node_root->set_properties( VALUE #( ( |ID| ) ( |
MEMBER_COUNT| ) ) ).
```

**Step 3:** Create the data description node for the child entity (in this example, “**Managers**”) on the root data description node. “**TEAM\_2\_MANAGER**” is the **internal** name of navigation property “**Team2Manager**”:

```
DATA: lo_data_des_node_root TYPE REF TO /iwbep/if_cp_data_desc_node,
      lo_data_desc_node_child TYPE REF TO /iwbep/if_cp_data_desc_node.
      lo_data_desc_node_child = lo_data_desc_node_root-
>add_child( 'team_2_manager' ).
```

**Step 4:** Set the properties for the child entity (in this example, “**Managers**”). Only property “**Id**” (with internal name “**ID**”) is included:

```
DATA: lo_data_desc_node_child TYPE REF TO /iwbep/if_cp_data_desc_node.
      lo_data_desc_node_child->set_properties( VALUE #( ( |ID| ) ) ).
```

**Step 5:** Define the request data for the deep create and set the deep business data into the request instance (in the root data description node):

```
DATA: lo_create_request TYPE REF TO /iwbep/if_cp_request_create,
      lo_data_des_node_root TYPE REF TO /iwbep/if_cp_data_desc_node,
      ls_deep_busi_data TYPE /iwbep/
if_v4_tea_busi_types=>ty_s_team_and_manager.
      ls_deep_busi_data = VALUE #( id = 'team_04'
member_count = 2
team_2_manager = VALUE #( id = '0009' ) ).
      lo_create_request->set_deep_business_data( is_business_data =
ls_deep_busi_data
io_data_description_node = lo_data_desc_node_root ).
      ENDCLASS.
```

### 📌 Note

The property that references the child entity business data **MUST** be named using the **internal** name of the corresponding navigation property (in this example, the property is “**TEAM\_2\_MANAGER**”, which describes the business data for the child entity “**Managers**”).

### 📌 Note

If the underlying entity has value control or VCS properties. The VCS properties **should** also be part of the provided data container (in this example, `ls_deep_busi_data`). If the properties aren't part of the data container, the behavior (for example conversion exits) is undefined and can cause unexpected errors.

**Step 6:** Run the deep create request and fetch the response business data from the create response instance:

```
DATA: lo_create_request TYPE REF TO /iwbep/if_cp_request_create,
      lo_create_response TYPE REF TO /iwbep/if_cp_response_create,
      ls_response_data TYPE /iwbep/
if_v4_tea_busi_types=>ty_s_team_and_manager.
      lo_create_response = lo_create_request->execute( ).
      lo_create_response->get_business_data( IMPORTING es_business_data =
ls_response_data ).
```

## Note

This part is identical to handling a typical create request in the Client Proxy instance.

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.12 OData Request: Delta Link Query Option

Create an OData request with \$delta token query option in the Client Proxy instance.

## OData Specification

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

Delta links are service-generated links the client uses to access newly created, updated, or deleted entities without a full read of the target resource with every request.

Delta links are based on a defining query that tracks the changes of the set of results. For example, the request that generated the results containing the delta link. The delta link encodes the entity collection that tracks the changes. Also, it includes a starting point to begin track changes.

## Example Requests

### Version 4

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_tech/0001/PagedDeltaEntities?  
$deltatoken=20170612000000
```

## Delta Link Query Request

### Overview

The starting point for a delta link in the Client Proxy instance is either a Client Proxy instance or a read list request instance (depending on your use case).

## Example 1: Create a new delta link

You run a read list request in the Client Proxy instance and you want to save a delta link for this response, so you can track future changes to the current response:

**Step 1:** Save the current response as delta link (in this example under the name '**DELTA\_LINK\_NAME**');

```
DATA: lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.  
lo_read_list_response->save_delta_link ( 'delta_link_name' ).
```

## Example 2: Create a delta request from an existing delta link

You have an existing delta link and want to use it to create a delta request:

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,  
      lo_delta_read_request TYPE REF TO /iwbep/if_cp_request_read_dlt,  
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.  
CHECK lo_client_proxy->does_delta_link_exist( 'delta_link_name' ) = abap_true.  
CHECK lo_client_proxy->can_delta_request_be_created( 'delta_link_name' ) =  
abap_true.  
lo_delta_read_request = lo_client_proxy->  
>create_request_for_delta( 'delta_link_name' ).  
lo_read_list_response = lo_delta_read_request->execute( ).
```

## Steps

**Step 1:** Check that the delta link:

- does exist (in this example, '**DELTA\_LINK\_NAME**').
- can be used to create a delta request. If the stored delta link was manually changed, the delta link can't be used).

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,  
      lo_delta_read_request TYPE REF TO /iwbep/if_cp_request_read_dlt,  
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.  
CHECK lo_client_proxy->does_delta_link_exist( 'delta_link_name' ) = abap_true.  
CHECK lo_client_proxy->can_delta_request_be_created( 'delta_link_name' ) =  
abap_true.
```

### Note

You can only find and use delta links that you created.

**Step 2:** Use the stored delta link to create a delta link request instance:

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,  
      lo_delta_read_request TYPE REF TO /iwbep/if_cp_request_read_dlt.  
lo_delta_read_request = lo_client_proxy->  
>create_request_for_delta( 'delta_link_name' ).
```

**Step 3:** Run the delta link request and fetch the corresponding response instance:

```
DATA: lo_delta_read_request TYPE REF TO /iwbep/if_cp_request_read_dlt,  
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.  
lo_read_list_response = lo_delta_read_request->execute( ).
```

### Example 3: Insert an existing delta link into an existing request

You have an existing request and want to use it in combination with an existing delta link:

```
DATA: lo_client_proxy      TYPE REF TO /iwbep/if_cp_client_proxy,
      lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.
CHECK lo_client_proxy->does_delta_link_exist( 'delta_link_name' ) = abap_true.
CHECK lo_client_proxy->can_delta_request_be_created( 'delta_link_name' ) =
abap_false.
lo_read_list_request->use_delta_link( 'delta_link_name' ).
lo_read_list_response = lo_read_list_request->execute( ).
```

### Steps

**Step 1:** Check that the delta link:

- does exist (in this example, '**DELTA\_LINK\_NAME**').
- can be used to create a delta request. If it can be used to create a delta request, you use method **CREATE\_REQUEST\_FOR\_DELTA**, in example 2.

```
DATA: lo_client_proxy TYPE REF TO /iwbep/if_cp_client_proxy.
CHECK lo_client_proxy->does_delta_link_exist( 'DELTA_LINK_NAME' ) = abap_true.
CHECK lo_client_proxy->can_delta_request_be_created( 'DELTA_LINK_NAME' ) =
abap_false.
```

#### Note

You can only find and use delta links that you created.

**Step 2:** Insert the delta link into the existing read list request:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list.
lo_read_list_request->use_delta_link( 'delta_link_name' ).
```

**Step 3:** Get the read list response instance using the read list request

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst.
lo_read_list_response = lo_read_list_request->execute( ).
```

[Client Proxy Instance Types \[page 866\]](#)

## 4.2.10.3.4.6.13 OData Request: Using Navigation

Create an OData request using a navigation in the Client Proxy instance.

### OData Specification

#### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A unidirectional (one-way) relationship (for example, a Link) is when two entity types are related by association, but only one of the entity types defines a **NavigationProperty** that binds to the association.

#### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

Relationships from one entity to another are represented as navigation properties. Navigation properties are defined as part of an entity type, but can also appear on entity instances as undeclared dynamic navigation properties. Each relationship has a cardinality.

### Example Requests

#### Version 4

Get all employees associated with Team 'TEAM\_01' via navigation property 'Team2Employees':

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams('TEAM_01')/Team2Employees
```

#### Version 2

Get the team of the employee with Id '0005' via navigation property "My\_Team":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees(Id='0005')/My_Team
```

### Using Navigation Request

#### Overview

##### Note

As the coding is independent of the OData version, we're presenting a general example on how to use navigations.

The starting point for a request using a navigation is an entity resource. On the entity resource, you can create a resource for the corresponding navigation target.

## Example 1

Navigate to an entity list with Navigation Property “**Department2Teams**”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/
Departments(Id='1',Sector='Consulting')/Department2Teams
```

### Steps

**Step 1:** Create the target resource on the entity resource using the **internal** name of the navigation property (“**DEPARTMENT\_2\_TEAMS**”):

```
DATA: lo_entity_resource      TYPE REF TO /iwbep/if_cp_resource_entity,
      lo_target_list_resource TYPE REF TO /iwbep/if_cp_resource_list.
      lo_target_list_resource = lo_entity_resource->
>navigate_to_many( 'department_2_teams' ).
```

#### Note

You can use the target resource to create a READ request.

## Example 2

Navigate to a single entity using the Navigation Property “**Team2Manager**”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams('TEAM_01')/
Team2Manager
```

### Steps

**Step 1:** Create the target resource on the entity resource using the **internal** name of the navigation property (“**TEAM\_2\_MANAGER**”):

```
DATA: lo_entity_resource      TYPE REF TO /iwbep/if_cp_resource_entity,
      lo_target_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity.
      lo_target_entity_resource = lo_entity_resource->
navigate_to_single( 'team_2_manager' ).
```

#### Note

You can use the target resource to create a READ request.

## Example 3

Navigate to an optional (for example. zero-to-one navigation) entity using the Navigation Property “**Employee2Manager**”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0004')/
Employee2Manager
```

### Step-by-step

**Step 1:** Create the target resource on the entity resource using the **internal** name of the navigation property (“**EMPLOYEE\_2\_MANAGER**”):

```
DATA: lo_entity_resource      TYPE REF TO /iwbep/if_cp_resource_entity,
      lo_target_entity_resource TYPE REF TO /iwbep/if_cp_resource_entity01.
```

```
lo_target_entity_resource = lo_entity_resource->
navigate_to_optional( 'employee_2_manager' ).
```

### Note

You can use the target resource to create an optional READ request.

## Related Information

[OData Request: Read Entity \[page 908\]](#)

## 4.2.10.3.4.6.14 OData Request: Including a Nextlink

Create an OData request to read an entity list (entity collection) with a next link in the Client Proxy instance.

## OData Specification

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

In responses that include a partial set of the items identified by the request, the URL MUST include a link (a next link) that allows retrieving the next partial set of items. A next link representation is format-specific. The final partial set of items MUST NOT contain a next link.

## Nextlink Request

### Overview

The starting point for a **next link** request is the Client Proxy instance, is **read list** response instance.

### Example

You created a read list request in the Client Prox instance and want to manage potential next links:

```
DATA: lo_read_list_response TYPE REF TO /iwbsp/if_cp_response_read_lst,
      lt_employee           TYPE STANDARD TABLE OF /iwbsp/s_v4_tea_employee.
lo_read_list_response->get_business_data( IMPORTING et_business_data =
lt_employee ).
WHILE lo_read_list_response->has_next( ).
  lo_read_response = lo_read_response->get_next( ).
  lo_read_list_response->get_business_data( IMPORTING et_business_data =
lt_employee ).
ENDWHILE.
```

## Steps

**Step 1:** Fetch the first batch of entities from the read list response instance:

```
DATA: lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst,  
      lt_employee           TYPE STANDARD TABLE OF /iwbep/s_v4_tea_employee.  
lo_read_list_response->get_business_data( IMPORTING et_business_data =  
lt_employee ).
```

**Step 2:** Check that there are still next links using the **HAS\_NEXT** method on the response instance). Then you can fetch the next batch of entities. Get the corresponding response instance by using the **GET\_NEXT** method on the previous response instance. Then get the business data from this new instance:

```
DATA: lo_read_list_response TYPE REF TO /iwbep/if_cp_response_read_lst,  
      lt_employee           TYPE STANDARD TABLE OF /iwbep/s_v4_tea_employee.  
WHILE lo_read_list_response->has_next( ).  
  lo_read_response = lo_read_response->get_next( ).  
  lo_read_list_response->get_business_data( IMPORTING et_business_data =  
lt_employee ).  
ENDWHILE.
```

## Constraints

- Next links are only supported for OData Version 4 requests.
- Next links are only supported for remote consumption.

## Related Information

[OData Request Terms \[page 892\]](#)

[OData Request: Read Entity List \[page 915\]](#)

## 4.2.10.3.4.6.15 OData Request System Query Options

Learn how to use OData system query options. System query options include:

### 4.2.10.3.4.6.15.1 \$expand Option

Use the \$expand system query option to represent associated EntityType instance or EntitySet inline.

## OData Specification

### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

The **\$expand** System Query Option indicates that entities associated with the EntityType instance or EntitySet (identified by the Resource Path section of the URI) must be represented inline.

### OData Version 4

See [OData Version 4.01. Part 1: Protocol](#) .

The **\$expand** system query option indicates the related entities and stream values that MUST be represented inline. The service MUST return the specified content and can choose to return additional information.

The value of the **\$expand** query option is a comma-separated list of navigation property names, stream property names, or **\$value** that indicate the stream content of a media-entity.

## Example Requests

### Version 4

Get the team '**TEAM\_03**' and its manager with navigation property "**Team2Manager**":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams('TEAM_03')?
$expand=Team2Manager
```

### Version 2

Get the manager with id '**0004**' and the information about his team with navigation property "**My\_Team**":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Managers('0001')?$expand=My_Team
```

# \$expand System Query Option

## Overview

### Note

As the coding is independent of the OData version, we're presenting a general example on how to use the **\$expand** option.

The starting point for a request with the **\$expand** option is an entity list read request. On the entity list read request, you can set the **\$expand** option.

## Example

Get all entities from the entity set "Teams". For each term, fetch the corresponding manager using the navigation property "Team2Manager". You want to retrieve only the Id of each manager:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams?
$expand=Team2Manager($select=Id)
```

## Steps

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_expand_node_root TYPE REF TO /iwbep/if_cp_expand_node,
      lo_expand_node      TYPE REF TO /iwbep/if_cp_expand_node.
lo_expand_node_root = lo_read_list_request->create_expand_node( ).
lo_expand_node      = lo_expand_node_root->add_expand( 'team_2_manager' ).
lo_expand_node->set_select_properties( VALUE #( ( CONV #( 'id' ) ) ) ).
```

### Note

The **SET\_EXPAND** method is obsolete. It's not necessary to explicitly set the expand node in the request.

**Step 1:** Create the root expand node on the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_expand_node_root TYPE REF TO /iwbep/if_cp_expand_node.
lo_expand_node_root = lo_read_list_request->create_expand_node( ).
```

**Step 2:** Add the expand path by using the **internal** name of the navigation property ("**TEAM\_2\_MANAGER**"). This step creates a new expand node:

```
DATA: lo_expand_node_root TYPE REF TO /iwbep/if_cp_expand_node,
      lo_expand_node      TYPE REF TO /iwbep/if_cp_expand_node.
lo_expand_node = lo_expand_node_root->add_expand( 'team_2_manager' ).
```

**Step 3:** Set the selected properties (using **internal** names) on the select node. "**ID**" is the internal name of property "**Id**":

```
DATA: lo_expand_node TYPE REF TO /iwbep/if_cp_expand_node.
lo_expand_node->set_select_properties( VALUE #( ( CONV #( 'id' ) ) ) ).
```

## Related Information

[OData Request: Read Entity \[page 908\]](#)

[OData Request: Read Entity List \[page 915\]](#)

### 4.2.10.3.4.6.15.2 \$filter Option

Use the \$filter system query option to restrict the returned set of items.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A data service URI with a **\$filter** System Query Option identifies a subset of the entities in the EntitySet (identified by the Resource Path section of the URI) by only selecting the entities that meet the predicate expression the query option specifies.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

The `$filter` system query option restricts the set of items that are returned.

## Example Requests

### Version 4

Get the entities in entity set “**Employees**” that have the Id “**0006**” and the Postalcode “**69190**”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees?
$filter=Location/City/Postalcode eq '69190' and Id eq '0006'
```

### Version 2

Get the entities in entity set “**Employees**” with the Id “**0006**” and the PostalCode “**69190**”:

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees?$filter=Location/City/
PostalCode eq '69190' and Id eq '0006'
```

# \$filter System Query Option

## Overview

### Note

As the coding is independent of the OData version, we're presenting a general example on how to use the `$filter` option.

The starting point for a request with the `$filter` option is an entity list read request.

## Example

Get all entities from the entity set "Buildings" with the BuildingID "ROT05" and Cityname is not "Walldorf":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Buildings?
$filter=Location/City/Cityname ne 'Walldorf' and BuildingID eq 'ROT05'
```

## Steps

```
DATA: lo_read_list_request TYPE REF TO /iwbe/if_cp_request_read_list,
      lt_range             TYPE RANGE OF string,
      lo_filter_factory    TYPE REF TO /iwbe/if_cp_filter_factory,
      lo_filter_node_1     TYPE REF TO /iwbe/if_cp_filter_node,
      lo_filter_node_2     TYPE REF TO /iwbe/if_cp_filter_node,
      lo_filter_node_final TYPE REF TO /iwbe/if_cp_filter_node.
lo_filter_factory = lo_read_list_request->create_filter_factory( ).
lt_range = VALUE #( ( option = 'ne' sign = 'i' low = 'Walldorf' ) ).
lo_filter_node_1 = lo_filter_factory->create_by_range( iv_property_path =
'location-city-cityname'
                                                    it_range = lt_range ).
lo_filter_node_2 = lo_filter_factory->create_by_range( iv_property_path =
'building_id'
                                                    it_range = lt_range ).
lo_filter_node_final = lo_filter_node_1->and( lo_filter_node_2 ).
lo_read_list_request->set_filter( lo_filter_node_final ).
.
```

**Step 1:** Create an instance of the filter factory at the read list request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbe/if_cp_request_read_list,
      lo_filter_factory    TYPE REF TO /iwbe/if_cp_filter_factory.
lo_filter_factory = lo_read_list_request->create_filter_factory( ).
```

**Step 2:** Create a filter node for the first filter expression (Location/City/Cityname ne 'Walldorf'). We define the new values and set the business data to the request:

Properties	Internal Names
Cityname	CITYNAME
Location	LOCATION
City	CITY

The filter expression must be expressed in a range:

```
DATA: lt_range             TYPE RANGE OF string,
      lo_filter_factory    TYPE REF TO /iwbe/if_cp_filter_factory,
```

```

        lo_filter_node_1 TYPE REF TO /iwbeb/if_cp_filter_node.
        lo_filter_factory = lo_read_list_request->create_filter_factory( ).
        lt_range = VALUE #( ( option = 'ne' sign = 'i' low = 'Walldorf' ) ).
        lo_filter_node_1 = lo_filter_factory->create_by_range( iv_property_path =
'location-city-cityname'
                                                                it_range =
lt_range
                                                                ).

```

**Step 3:** Create a filter node for the second filter expression **BuildingID' ROT05'**. The internal name of the primitive property "**BuildingID**" is "**BUILDING\_ID**". The filter expression must be expressed in a range:

```

DATA: lt_range          TYPE RANGE OF string,
      lo_filter_factory TYPE REF TO /iwbeb/if_cp_filter_factory,
      lo_filter_node_2  TYPE REF TO /iwbeb/if_cp_filter_node.
lt_range = VALUE #( ( option = 'eq' sign = 'i' low = 'rot05' ) ).
lo_filter_node_2 = lo_filter_factory->create_by_range( iv_property_path =
'building_id'
                                                                it_range =
lt_range
                                                                ).

```

**Step 4:** Connect the two filter nodes with **"and"** in the final filter node:

```

DATA: lo_filter_node_1 TYPE REF TO /iwbeb/if_cp_filter_node,
      lo_filter_node_2 TYPE REF TO /iwbeb/if_cp_filter_node,
      lo_filter_node_final TYPE REF TO /iwbeb/if_cp_filter_node.
lo_filter_node_final = lo_filter_node_1->and( lo_filter_node_2 ).

```

**Step 5:** Set the final **filter** node in the request instance:

```

DATA: lo_read_list_request TYPE REF TO /iwbeb/if_cp_request_read_list,
      lo_filter_node_final TYPE REF TO /iwbeb/if_cp_filter_node.
lo_read_list_request->set_filter( lo_filter_node_final ).

```

## Negation

To use negation call the **NOT** method on a **filter** node instance (for example, **\$filter=not(BuildingID is 'WDF03')**). This step creates a new filter node (the negated filter node):

```

DATA: lo_filter_node      TYPE REF TO /iwbeb/if_cp_filter_node,
      lo_filter_node_not TYPE REF TO /iwbeb/if_cp_filter_node.
lo_filter_node_not = lo_filter_node->not( ).

```

## Constraints

- **\$filter** is only supported for primitive and complex properties.
- Only these range options are allowed: **EQ**, **NE**, **GT**, **GE**, **LT**, and **LE**.
- Only range signs **"I"** and **"E"** are allowed.
- Conversions with range option **"CP"** are not allowed.
- Only these functions can be used with **CP**: **startswith**, **endswith**, and **substringof** (for OData Version 2), **contains** (for OData Version 4).
- Not all filter expression are supported for local consumption.
- The currency code must be provided when the addressed property has a reference to a currency property.
- The unit of measurement must be provided when the addressed property has a reference to a unit property.

- You can't set a **\$filter** for an **\$expand**.

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/TEAMS?
$expand=TEAM_2_EMPLOYEES($filter=AGE eq 56)
```

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.4.6.15.3 \$count Option

Use the **\$count** or **\$inlinecount** system query option to indicate a certain number or total count of entities in the EntitySet.

## OData Specification

### OData Version 2

See also: [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

**\$inlinecount**: For a value of "allpages", the **\$inlinecount** option indicates the response to the request must include the number of entities count in the EntitySet. The number of entities count is identified by the Resource Path section of the URI after all **\$filter** System Query Options are applied.

If the value is "none", this option indicates the response to the request MUST NOT include the count value.

### OData Version 4

See also: [OData Version 4.01. Part 1: Protocol](#) .

The **\$count** system query option with a value of **true** specifies that the total item count in a collection that matches the request is returned with the result.

The **\$count** system query option ignores **\$stop**, **\$skip**, or **\$expand** query options, and returns the total results count across all pages (including only the results that match any specified **\$filter** and **\$search**). The count returned inline might not equal the actual number of items returned. This happens due to latency between calculating the count and enumerating the last value or due to inexact calculations on the service.

## Example Requests

### Version 4

Get the number of entities in entity set "TEAMS":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/TEAMS/$count
```

Get all Equipment entities associated with "**Employee 1**" and the total count of associated items:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES('1')/
EMPLOYEE_2_EQUIPMENTS?$count=true
```

## Version 2

Get the number of entities in entity set "**EquipmentSet**":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/EquipmentSet/$count
```

Get all Team Member entities associated with Team "**TEAM\_01**" and the total count of associated members:

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Teams('TEAM_01')/Team_Members?
$inlinecount=allpages
```

## \$count System Query Option

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to use the **\$count** option.

The starting point for a request with the **\$count** option is an entity list read request. You can set the **\$count** on the entity list read request.

You can fetch the **\$count** result from the entity list read response instance.

#### Note

The actual "flavor" of the **\$count** that the Client Proxy sets depends on the request type:

- **\$count** if no business data is requested.
- **\$count=true** for OData Version 4 requests if business data is requested.
- **\$inlinecount=allpages** for OData Version 2 if business data is requested.

### Example 1

Get the number of entities in entity set "**TEAMS**":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/TEAMS/$count
```

### Steps

```
DATA: lo_read_list_request TYPE REF TO /iwbe/if_cp_request_read_list,
      lo_read_list_response TYPE REF TO /iwbe/if_cp_response_read_lst,
      lv_count              TYPE REF TO int8.
lo_read_list_request-> request_no_business_data( ).
lo_read_list_request->request_count( ).
lo_read_list_response = lo_read_list_request->execute( ).
lv_count = lo_read_list_response->get_count( ).
```

**Step 1:** Set the request to NOT fetch the entity list (for example, `request_no_business_data`):

```
DATA: lo_read_list_request TYPE REF TO /iwbsp/if_cp_request_read_list.  
lo_read_list_request-> request_no_business_data( ).
```

**Step 2:** Request the `$count` at the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbsp/if_cp_request_read_list.  
lo_read_list_request->request_count( ).
```

**Step 3:** Run the request and fetch the count value from the read list response instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbsp/if_cp_request_read_list,  
      lo_read_list_response TYPE REF TO /iwbsp/if_cp_response_read_list,  
      lv_count TYPE REF TO int8.  
lo_read_list_response = lo_read_list_request->execute( ).  
lv_count = lo_read_list_response->get_count( ).
```

## Example 2

Get all `Equipment` entities associated with "Employee 1" and the total count of associated items:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES('1')/  
EMPLOYEE_2_EQUIPMENTS?$count=true
```

## Steps

```
DATA: lo_read_list_request TYPE REF TO /iwbsp/if_cp_request_read_list,  
      lo_read_list_response TYPE REF TO /iwbsp/if_cp_response_read_list,  
      lv_count TYPE REF TO int8.  
lo_read_list_request->request_count( ).  
lo_read_list_response = lo_read_list_request->execute( ).  
lv_count = lo_read_list_response->get_count( ).
```

### Note

The steps for this example are identical to the first example, except that you do **NOT** request to not return any business data (you skip step 1 in the first example).

See example one for a the steps.

## Related Information

[OData Request Terms \[page 892\]](#)

[OData Request: Read Entity \[page 908\]](#)

[OData Request: Read Entity List \[page 915\]](#)

## 4.2.10.3.4.6.15.4 \$orderby Option

Use the \$orderby system query option to determine what values are used to order the entities in the EntitySet.

### OData Specification

#### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A data service URI with the **\$orderby** System Query Option specifies an expression for determining what values are used to order the entities in the EntitySet (identified by the Resource Path section of the URI).

#### OData Version 4

See [OData Version 4.01. Part 1: Protocol](#) .

The **\$orderby** System Query option specifies the order that items are returned from the service. The value of the **\$orderby** System Query option is a comma-separated list of expressions that use the primitive result values to sort the items. The expression can include the suffix **asc** for ascending or **desc** for descending that you separate from the property name by one or more spaces.

### Example Requests

#### Version 4

Get all entities of entity set "**Employees**" and sort the response descending to property "**Cityname**" and ascending to property "**Age**":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees?$orderby=Location/City/Cityname desc, Age
```

#### Version 2

Get all entities of entity set "**Employees**" and sort the response ascending to property "**Id**" and descending to property "**Name**":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Employees?$orderby=Id, Name asc
```

## \$orderby System Query Option

### Overview

#### 📌 Note

As the coding is independent of the OData version, we're presenting a general example on how to use the **\$orderby** option.

The starting point for a request with the `$orderby` option is an entity list read request. You can set the `$orderby` on the entity list read request.

## Example

Get all entities of entity set "**Employees**" and sort the response descending to property "**Cityname**" (in complex property "**City**", which is part of complex property "**Location**") and ascending to property "**Age**":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees?
$orderby=Location/City/Cityname desc, Age
```

## Steps

**Step 1:** Set the `$orderby` values at the request instance:

Properties	Internal Names
Age	<b>AGE</b>
Location	<b>LOCATION</b>
City	<b>CITY</b>
Cityname	<b>CITYNAME</b>

```
DATA: lo_read_list_request TYPE REF TO /iwbsp/if_cp_request_read_list.
      lo_read_list_request-> set_orderby( value #( ( property_path = 'LOCATION-
CITY-CITYNAME'
                                                    descending = abap_true )
      ( property_path =
'AGE'
                                                    descending =
abap_false ) ) ).
```

## Related Information

[OData Request Terms \[page 892\]](#)

[OData Request: Read Entity \[page 908\]](#)

[OData Request: Read Entity List \[page 915\]](#)

## 4.2.10.3.4.6.15.5 \$select Option

Use the \$select system query option to return a subset for the returned properties of the URI without a \$select query option.

### OData Specification

#### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A data service URI **with** a \$select System Query Option identifies the same set of entities as a URI **without** a \$select query option. If you have a \$select query option, the data service response returns a subset (identified by the \$select query option) for the returned properties of the URI that didn't include a \$select query option.

#### OData Version 4

See [OData Version 4.01. Part 1: Protocol](#) .

The \$select system query option requests that the service return only the properties, dynamic properties, actions, and functions explicitly requested by the client. The service returns the specified content (if available) and any available expanded navigation or stream properties. It can also return additional information.

### Example Requests

#### Version 4

Get the employee with Id '0002' of entity set "Employees" and return only properties "Name" and "Age":

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0002')?
$select=Name, Age
```

#### Version 2

Get all entities of entity set "Managers" and return only properties "Name" and "Age":

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Managers?$select=Name, Age
```

## \$select System Query Option

### Overview

#### Note

As the coding is independent of the OData version, we're presenting a general example on how to use the \$select option.

The starting point for a request with `$select` is a read request on an entity list. You can set the selected properties on the entity list read request.

## Example

Set the properties “Age”, “Name” and “Cityname” for the employee with Id ‘0002’ for the entity set “Employees”. “Cityname” is in the complex property “City”, which is of the complex property “Location”:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Employees('0002')?
$select=Name,Age,Location/City/Cityname
```

## Steps

**Step 1:** Set the properties you want to select at the read request instance:

Properties	Internal Names
Age	AGE
Location	LOCATION
City	CITY
Cityname	CITYNAME
Name	NAME

```
DATA: lo_read_request TYPE REF TO /iwbep/if_cp_request_read.
      lo_read_request->set_select_properties( VALUE #( ( CONV #('AGE') )
                                                    ( CONV #('LOCATION-CITY-CITYNAME') )
                                                    ( CONV #('NAME') ) ) ).
```

## Related Information

[OData Request Terms \[page 892\]](#)

[OData Request: Create Entity \[page 901\]](#)

[OData Request: Read Entity \[page 908\]](#)

## 4.2.10.3.4.6.15.6 \$skip and \$top Options

Use the `$skip` or `$top` system query options to identify a subset of the entities in an entity collection.

## OData Specification

### OData Version 2

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

A data service URI with:

### **\$skip System Query Option**

identifies a subset of the entities in an entity collection (identified by the Resource Path section of the URI)

the subset is defined by searching **N** entities in an collection and selecting **only the remaining entities** (starting with entity **N+1**).

**N** is a positive integer specified by this query option.

### **\$top System Query Option**

identifies a subset of the entities in an entity collection (identified by the Resource Path section of the URI)

the subset is formed by selecting **only the first N** items of the set.

**N** is a positive integer specified by this query option.

## **OData Version 4**

See [OData Version 4.01. Part 1: Protocol](#) .

A data service URI with:

### **\$skip System Query Option**

specifies a non-negative integer **n** that **excludes** the first **n** items of the queried collection.

the service returns items starting at position **n+1**.

### **\$top System Query Option**

specifies a non-negative integer **n** that **limits** the number of items returned from a collection.

the service returns the number of available items up to but not greater than the specified value **n**.

## **Example Requests**

### **Version 4**

Skip the first entity in entity set "TEAMS" and get the following two ones:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams?$skip=1&$top=2
```

### **Version 2**

Skip the first entity in entity set "Managers" and get the following two ones:

```
GET /sap/opu/odata/IWBEP/TEA_TEST_APPLICATION/Managers?$skip=1&$top=2
```

## **\$skip and \$top Query Options**

### **Overview**

#### **Note**

As the coding is independent of the OData version, we're presenting a general example on how to use the **\$count** option.

The starting point for a request with **\$skip** or **\$top** option is an entity list read request. You can set both the **\$skip** and the **\$top** on the entity list read request.

## Example

Skip the first entity in entity set "**TEAMS**" and get these entities:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0003/Teams?$skip=1&$top=2
```

## Steps

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list.  
      lo_read_list_request->set_skip( 1 ).  
      lo_read_list_request->set_top( 2 ).
```

**Step 1:** Set the **\$skip** value at the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list.  
      lo_read_list_request->set_skip( 1 ).
```

**Step 2:** Set the **\$top** value at the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list.  
      lo_read_list_request->set_top( 2 ).
```

## Related Information

[OData Request Terms \[page 892\]](#)

## 4.2.10.3.4.6.15.7 \$search Option

Use the **\$search** system query option to restrict results to include items you specify in the expression..

## OData Specification

### OData Version 4

See [\[MS-ODATA\]: Open Data Protocol \(OData\)](#) .

The **\$search** system query option restricts the result to include only the items that match the specified search expression. The type of match depends on your implementation.

## Example Requests

### Version 4

Get all entities of Entity Set “**Employees**” with “**Peter**” or “**Smith**” in their name:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES?$search=Peter OR Smith
```

## \$search System Query Option

### Overview

The starting point for a request with the `$search` option is an entity list read request. You can set the `$search` expression on the entity list read request.

#### Note

Depending on your implementation, the result of the `$search` option on a property can vary. In our example, `$search` acts on property “**Name**”.

### Example

Search all entities of Entity Set “**Employees**” with “**Peter**” or “**Smith**” in their name:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES?$search=Peter OR Smith
```

### Steps: Option 1

**Step 1:** Set the search expression at the request instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbp/if_cp_request_read_list.  
lo_read_list_request->set_search( 'Peter OR Smith' ).
```

#### Note

This approach is only supported for remote consumption, not for local consumption

### Steps: Option 2

```
DATA: lo_read_list_request TYPE REF TO /iwbp/if_cp_request_read_list,  
      lo_search_node      TYPE REF TO /iwbp/if_cp_search_node.  
lo_search_node = lo_read_list_request->create_search_node( 'Peter' ).  
lo_search_node->or( 'Smith' ).  
lo_read_list_request->set_search_node( lo_search_node ).
```

**Step 1:** Create the search node on the request instance. For this step, you already provided the first part of your `$search` expression (“**Peter**” from “**Peter OR Smith**”):

```
DATA: lo_read_list_request TYPE REF TO /iwbp/if_cp_request_read_list,  
      lo_search_node      TYPE REF TO /iwbp/if_cp_search_node.
```

```
lo_search_node = lo_read_list_request->create_search_node( 'Peter' ).
```

**Step 2:** Insert the second expression (“**Smith**”) and connect it with “**OR**” to the first expression:

```
DATA: lo_search_node TYPE REF TO /iwbep/if_cp_search_node.
lo_search_node->or( 'Smith' ).
```

**Step 3:** Set the search node in the request:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_search_node       TYPE REF TO /iwbep/if_cp_search_node.
lo_read_list_request->set_search_node( lo_search_node ).
```

## Negation

Negate the previous expression. For example, this request:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES?$search=NOT
(Peter OR Smith)
```

Call the method “**NOT**” on the search node instance:

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_search_node       TYPE REF TO /iwbep/if_cp_search_node.
lo_search_node = lo_read_list_request->create_search_node( 'Peter' ).
lo_search_node->or( 'Smith' ).
lo_search_node->not( ).
lo_read_list_request->set_search_node( lo_search_node ).
```

## Connect Two Search Nodes

You can connect two search nodes. For example, this request:

```
GET /sap/opu/odata4/iwbep/tea/default/iwbep/tea_busi/0001/EMPLOYEES?
$search=(Peter OR Smith) AND (John AND Mary)
```

```
DATA: lo_read_list_request TYPE REF TO /iwbep/if_cp_request_read_list,
      lo_search_node_1     TYPE REF TO /iwbep/if_cp_search_node,
      lo_search_node_2     TYPE REF TO /iwbep/if_cp_search_node.
lo_search_node_1 = lo_read_list_request->create_search_node( 'Peter' ).
lo_search_node_1->or( 'Smith' ).
lo_search_node_2 = lo_read_list_request->create_search_node( 'John' ).
lo_search_node_2->and( 'Mary' ).
lo_search_node_1->and_node( lo_search_node_2 ).
lo_read_list_request->set_search_node( lo_search_node_1 ).
```

## Constraints

- **\$search** is only available for OData Version 4 requests.
- **SET\_SEARCH** is not supported for local consumption.

## Related Information

[OData Request Terms \[page 892\]](#)

### 4.2.10.3.5 HTTP Outbound Communication

Learn how to set up and enable HTTP outbound communication.

HTTP outbound connectivity enables you to consume HTTP services from other systems. To enable HTTP outbound communication, there are two different stages that are performed by different roles:

#### Development Tasks

Development tasks are performed by developers. Development tasks are all tasks that are performed within ABAP development tools for Eclipse, such as:

- Creating a Communication Scenario
- Creating an outbound service

For more information, see [Enable HTTP Communication in Your ABAP Code \[page 951\]](#).

#### Administrator Tasks

Administrator tasks are performed by administrators. Administrator tasks are all tasks that are performed in SAP Fiori launchpad, such as:

- Creating a communication system
- Creating a communication arrangement
- Creating communication users

For more information, see [Set Up HTTP Communication \[page 961\]](#).

[Enable HTTP Communication in Your ABAP Code \[page 951\]](#)

The HTTP client allows to connect to HTTP endpoints.

[Set Up HTTP Communication \[page 961\]](#)

To set up HTTP communication, use the corresponding communication management apps.

## 4.2.10.3.5.1 Enable HTTP Communication in Your ABAP Code

The HTTP client allows to connect to HTTP endpoints.

### Feature Scope

- Communication arrangement
  - Provides APIs for receiver determination based on arbitrary properties (see [Define Specific Properties for Communication Scenarios \[page 857\]](#)).
  - Local configuration via communication management UIs or central configuration in SAP BTP cockpit via SAP BTP destination service reference in the communication system (not relevant for Developer Extensibility, see [Developer Extensibility](#)). See [Create HTTP Destinations](#) and [Communication Systems \[page 2397\]](#).
  - Requires development of communication scenario artifacts.
- Destination service (not relevant for Developer Extensibility, see [Developer Extensibility](#)).
  - Provides APIs to fetch connection information for a given destination name from the SAP BTP destination service.
  - No additional development artifacts required.
  - Central configuration in SAP BTP cockpit.
  - Comparable to `create_by_destination` in on-premise ABAP.
- Static configuration in code (only recommended for public services and test purposes).

We recommend using the communication arrangement approach for the following reasons:

- There are no hardcoded values/assumptions for a destination name in the destination service or destination service integration (for example, only default integration).
- The communication system can also refer to a destination service. The destination name and destination service instance are then configured instead of hardcoded.

#### 📌 Note

When using on-premise connectivity, make sure the called ICF service is exposed in Cloud Connector.

[HTTP Communication via Communication Arrangements \[page 952\]](#)

HTTP outbound communication can be established using so-called communication arrangements.

[HTTP Communication via Destination Service \(Deprecated\) \[page 954\]](#)

[HTTP Communication via URL \[page 956\]](#)

[Example: HTTP Multipart Request \[page 957\]](#)

[Example: Enable Path Prefix \[page 958\]](#)

[Example: Retry Design Pattern \[page 959\]](#)

## 4.2.10.3.5.1.1 HTTP Communication via Communication Arrangements

HTTP outbound communication can be established using so-called communication arrangements.

### Prerequisites

You've created a communication scenario as described in [Defining a Communication Scenario Including Authorization Values \[page 800\]](#).

### Procedure

1. Create a corresponding outbound service of type HTTP.
  1. In your ABAP project, select the relevant package node in the Project Explorer.
  2. Open the context menu and choose **File > New > Other ABAP Repository Object > Cloud Communication Management > Outbound Service > Next**.
  3. Enter the name of the outbound service.
  4. Select *HTTP Service* in the *Service Type* dropdown list.
  5. Choose *Next* and select a transport request.
  6. Optional: Go to your outbound service and enter the URL in the field *Default Path Prefix*.
  7. Save the outbound service.
2. Add the newly created outbound service to your scenario.
3. Publish the communication scenario. The administrator can then create the required communication management objects as described in [Test Your Outbound Call \[page 953\]](#).
4. Adapt the communication arrangement call according to your needs as described in the example. See [Service Consumption via Communication Arrangements \[page 854\]](#) for more information. According to your developed communication scenario, add the following:

<code>comm_scenario</code>	mandatory	ID of the developed communication scenario.
<code>comm_system_id</code>	optional	ID of the configured communication system. Use method <code>query_ca</code> of class <code>cl_com_arrangement_factor</code> to derive it dynamically.
<code>service_id</code>	optional	ID of the developed outbound service.

#### Note

You can't use the `create_by_comm_arrangement` method for SAP-delivered scenarios.

## Example

### Sample Code

```
DATA: lr_cscn type if_com_scenario_factory=>ty_query-cscn_id_range.

" find CA by scenario
  lr_cscn = value #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
  DATA(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
  lo_factory->query_ca(
    EXPORTING
      is_query          = value #( cscn_id_range = lr_cscn )
    IMPORTING
      et_com_arrangement = data(lt_ca) ).

  IF lt_ca is initial.
    EXIT.
  ENDIF.

" take the first one
  READ TABLE lt_ca INTO DATA(lo_ca) INDEX 1.

" get destination based to Communication Arrangement
  TRY.
    DATA(lo_dest) =
      cl_http_destination_provider=>create_by_comm_arrangement(
        comm_scenario   = '<Scenario ID>'
        service_id      = '<Outbound Service ID>'
        comm_system_id = lo_ca->get_comm_system_id( ) ).

    DATA(lo_http_client) =
      cl_web_http_client_manager=>create_by_http_destination( lo_dest ).

    " execute the request
    DATA(lo_request) = lo_http_client->get_http_request( ).
    DATA(lo_response) = lo_http_client->execute( if_web_http_client=>get ).

    CATCH cx_http_dest_provider_error.
      " handle exception here

    CATCH cx_web_http_client_error.
      " handle exception here
  ENDTRY.
```

### Note

We recommend to retrieve the correct destination reference based on the communication scenario and a customer-defined property as described in [Service Consumption via Communication Arrangements \[page 854\]](#).

## Test Your Outbound Call

To test your outbound call, you have to provide a configuration for the outbound service you want to call in your code.

Create a communication system and communication arrangement for the communication scenario and maintain the required data, such as host name and credentials in the Communication Systems and Communication Arrangements apps. For more information, see [Communication Management \[page 846\]](#).

These tasks are performed by the administrator. For more information, see [Set Up HTTP Communication \[page 961\]](#).

## Related Information

[Set Up HTTP Communication \[page 961\]](#)

### 4.2.10.3.5.1.2 HTTP Communication via Destination Service (Deprecated)

## Context

Use the destination service in SAP BTP to store destination information that can be reused by applications deployed in one of the BTP environments.

#### Note

You can use the destination service. However, this approach is deprecated. We recommend using the communication arrangement approach instead. See [HTTP Communication via Communication Arrangements \[page 952\]](#) for more information.

You've the following options to consume a destination service:

- Dynamic by using a communication arrangement and a communication system
- Static by using the method `create_by_cloud_destination` in the code

## Procedure

When using `create_by_cloud_destination`, proceed as follows:

Create a destination object using class `cl_http_destination_provider` and method `create_by_cloud_destination` with the following parameters:

- `i_name`: the name of the destination
- Optional: `i_service_instance_name`: Typically, you use the destinations of the subaccount in which the ABAP instance resides or, in case of a SaaS solution based on the ABAP environment, the destinations of the consumer subaccount. However, you can add more destinations using your own destination service

instance and communication scenario SAP\_COM\_0276, for example, to achieve separation of concerns (see also [Create a Destination \[page 854\]](#)). In this case, specify the value of the service instance name property of the communication arrangement for SAP\_COM\_0276.

- `i_authn_mode`: Set the value of this parameter according to the authentication method configured in your destination. If the authentication method uses user propagation, the value is `if_a4c_cp_service=>user_propagation`, if it doesn't, set `if_a4c_cp_service=>service_specific`:

#### Authentication Methods

Value	Proxy Type <i>Internet</i>	Proxy Type <i>OnPremise</i>
<code>if_a4c_cp_service=&gt;user_propagation</code>	<ul style="list-style-type: none"> <li>• <a href="#">OAuth User Token Exchange Authentication</a></li> <li>• <a href="#">OAuth SAML Bearer Assertion Authentication</a></li> <li>• <a href="#">OAuth JWT Bearer Authentication</a></li> </ul>	<a href="#">Principal Propagation SSO Authentication for HTTP</a>
<code>if_a4c_cp_service=&gt;service_specific</code>	<ul style="list-style-type: none"> <li>• No Authentication</li> <li>• Basic Authentication</li> <li>• <a href="#">Client Authentication Types for HTTP Destinations</a></li> <li>• <a href="#">OAuth Client Credentials Authentication</a></li> <li>• <a href="#">OAuth Password Authentication</a></li> </ul>	<ul style="list-style-type: none"> <li>• No Authentication</li> <li>• Basic Authentication</li> </ul>

Other authentication methods are currently not supported by the SAP BTP, ABAP environment.

## Example

The actual processing of an HTTP request and its response is shown in the following code example:

### Sample Code

```
DATA lo_http_destination TYPE REF TO if_http_destination.
DATA lo_http_client      TYPE REF TO if_web_http_client.
DATA lo_http_response    TYPE REF TO if_web_http_response.

TRY.
  " create HTTP destination by cloud destination
  lo_http_destination =
cl_http_destination_provider=>create_by_cloud_destination( i_name =
'DestinationName' i_authn_mode = if_a4c_cp_service=>service_specific ).

  " create HTTP client by HTTP destination
  lo_http_client =
cl_web_http_client_manager=>create_by_http_destination( lo_http_destination ).

  " adding header fields
  lo_http_client->get_http_request( )->set_header_fields( VALUE
#( ( name = if_web_http_header=>content_type value =
if_web_http_header=>accept_application_json )
```

```

( name = if_web_http_header=>accept          value =
if_web_http_header=>accept_application_json ) ).

" execute HTTP GET-request and store response
lo_http_response = lo_http_client->execute( if_web_http_client=>get ).

" print response text to console
DATA(ls_status) = lo_http_response->get_status( ).
out->write( |Response is: { ls_status-code } { ls_status-reason }.| ).
out->write( lo_http_response->get_text( ) ).

CATCH cx_http_dest_provider_error cx_web_http_client_error INTO
DATA(lx_error).
" display error details
out->write( lx_error->get_text( ) ).
ENDTRY.

```

## Test Your Outbound Call

To test your outbound call, configure an HTTP destination as described in [Create HTTP Destinations](#).

### Authentication Methods

- Only the authentication methods listed in table *Authentication Methods* are available.
- If you're using Client Certificate Authentication as authentication method, activate *Use client provided certificate*. This flag is only visible if the URL field contains a URL string starting with *https://... .*
- For proxy type **Internet** and the use of authentication type **client certificate**, you must upload the X.509 client certificate in P12 format on the client side in the SAP BTP, ABAP environment using the Maintain Client Certificates application. For more information, see [Maintain Client Certificates \[page 2564\]](#). Uploading the client certificate via destination service isn't supported.
- The use of `if_a4c_cp_service=>user_propagation` isn't supported in the ADT class runner. It can only be tested when a business user context is available, for example, during processing of OData services or HTTP services.

## Related Information

[Destination Service \[page 848\]](#)

### 4.2.10.3.5.1.3 HTTP Communication via URL

You can configure the URL static in the code:

#### Sample Code

```
DATA(lo_url_destination) = cl_http_destination_provider=>create_by_url(
```

```
'https://  
<host>/sap/bc/srt/xip/sap/<provider>/000/<service>/<binding>').
```

### Note

Using `create_by_url` is only suitable for public services or test purposes, because credentials should be stored in the destination service, or using communication arrangements (`create_by_comm_arrangement`, `create_by_cloud_destination`).

## Related Information

[Set Up HTTP Communication \[page 961\]](#)

### 4.2.10.3.5.1.4 Example: HTTP Multipart Request

Using multipart requests for HTTP communication from the ABAP environment.

The code examples below show an **HTTP multipart request**:

#### Client Side

##### Sample Code

```
DATA: http_client TYPE REF TO if_web_http_client,  
      lo_response TYPE REF TO if_web_http_response,  
      iv_url TYPE string.  
  
iv_url = 'https://...'. "Enter a correct url  
  
TRY.  
  http_client =  
  cl_web_http_client_manager=>create_by_http_destination( i_destination =  
  cl_http_destination_provider=>create_by_url( i_url = iv_url ) ).  
  
  DATA(lo_request) = http_client->get_http_request( ).  
  lo_request->set_header_field( i_name = 'Content-type'  
                              i_value = 'multipart/mixed' ).  
  
  DATA(part_1) = lo_request->add_multipart( ).  
  part_1->set_header_field( i_name = 'Content-type'  
                          i_value = 'text/html; charset=UTF-8' ).  
  
  part_1->set_text( 'This is part one.' ).  
  
  DATA(part_2) = lo_request->add_multipart( ).  
  part_2->set_header_field( i_name = 'Content-type'  
                          i_value = 'text/html; charset=UTF-8' ).  
  part_2->set_text( 'This is part two.' ).
```

```

lo_response = http_client->execute( if_web_http_client=>post ).

DATA(status) = lo_response->get_status( ).
IF status-code NE 200.
  "Error handling here
ENDIF.

CATCH cx_web_http_client_error cx_http_dest_provider_error.
  "Handle exception here.
ENDTRY.

```

## Server Side

### Sample Code

```

CLASS ZCL_TEST_MULTIPART IMPLEMENTATION.
  method IF_HTTP_SERVICE_EXTENSION~HANDLE_REQUEST.
    DATA: answer TYPE string,
           num_part TYPE i.

    num_part = request->num_multipart( ).
    IF num_part = 0.
      answer = '<html><body>No multipart found in request!!</body></html>'.
      response->set_text( answer ).
    ELSE.
      DO num_part TIMES.
        DATA(lo_part_request) = request->get_multipart( index = sy-index ).
        IF lo_part_request IS BOUND.
          "Do something here with this part.
          ENDIF.
        ENDDO.
      ENDIF.
    ENDMETHOD.
  ENDMETHOD.
ENDCLASS.

```

### 4.2.10.3.5.1.5 Example: Enable Path Prefix

Enable a path prefix for HTTP calls in ABAP.

Interface `IF_WEB_HTTP_CLIENT` provides a method `enable_path_prefix` to extend a URL set by the method `set_uri_path`.

Calling only `set_uri_path` overwrites the URL used to instantiate the client:

### Sample Code

```

DATA: http_client TYPE REF TO if_web_http_client,
      lo_response TYPE REF TO if_web_http_response,
      iv_url TYPE string.

```

```

iv_url = 'https://hostfoobar:port/fool/bar1'. "Enter a correct url

TRY.
  http_client =
cl_web_http_client_manager=>create_by_http_destination( i_destination =
cl_http_destination_provider=>create_by_url( i_url = iv_url ) ).

  DATA(lo_request) = http_client->get_http_request(   ).

  lo_request->set_uri_path( EXPORTING i_uri_path = '/foo2/bar2' ).
  "the request will be send to /foo2/bar2
  lo_response = http_client->execute( if_web_http_client=>post ).

  DATA(status) = lo_response->get_status(   ).
  IF status-code NE 200.
    "Error handling here
  ENDIF.

CATCH cx_web_http_client_error cx_http_dest_provider_error.
  " handle exception here
ENDTRY.

```

If you call the method `enable_path_prefix` before calling `set_uri_path`, the path passed by `set_uri_path` is appended to the initial path:

#### Sample Code

```

DATA: http_client TYPE REF TO if_web_http_client,
      lo_response TYPE REF TO if_web_http_response,
      iv_url TYPE string.

iv_url = 'https://hostfoobar:port/fool/bar1'. "Enter a correct url

TRY.
  http_client =
cl_web_http_client_manager=>create_by_http_destination( i_destination =
cl_http_destination_provider=>create_by_url( i_url = iv_url ) ).

  DATA(lo_request) = http_client->get_http_request(   ).

  http_client->enable_path_prefix(   ).
  lo_request->set_uri_path( EXPORTING i_uri_path = '/foo2/bar2' ).
  "the request will be send to /fool/bar1/foo2/bar2
  lo_response = http_client->execute( if_web_http_client=>post ).

  DATA(status) = lo_response->get_status(   ).
  IF status-code NE 200.
    "Error handling here
  ENDIF.

CATCH cx_web_http_client_error cx_http_dest_provider_error.
  " handle exception here
ENDTRY.

```

## 4.2.10.3.5.1.6 Example: Retry Design Pattern

Repeat an HTTP request automatically in ABAP.

Using this feature, you can repeat a request automatically up to 3 times, as long as the status code from the response has an appropriate value.

You can provide a set of response codes upon which the request is supposed to be repeated, if the corresponding response returns a status code from this set.

If you do not provide this set of codes, a default set is drawn depending on the idempotence of a request. You can control the idempotence of a request via parameter.

The default set for a non-idempotent request is 408, 429 and 503. For an idempotent request, the default set is 308, 429, 500, 502, 503, 504, 507, 509.

All other parameters correspond to the known `execute` method.

### ↔ Sample Code

```
DATA: http_client          TYPE REF TO if_web_http_client,
      lo_response         TYPE REF TO if_web_http_response,
      lt_retry_status_codes TYPE http_status_codes,
      iv_url              TYPE string.
iv_url = 'https://hostfoobar:port/foo/bar'. "Enter a correct url
TRY.
  http_client =
cl_web_http_client_manager=>create_by_http_destination( i_destination =
cl_http_destination_provider=>create_by_url( i_url = iv_url ) ).

  "select for which numbers the execution should be retried
  lt_retry_status_codes = VALUE http_status_codes( ( '111' )
                                                  ( '222' )
                                                  ( '333' ) ).

  lo_response = http_client->retry_execute(
    i_retry_status_codes = lt_retry_status_codes      " Table
for HTTP status codes for whose entries retry is done
    i_method              = if_web_http_client=>post  " HTTP
Method (GET, POST etc.)
    i_idempotent_method  = abap_true                  "
Idempotent request method
  ).
  DATA(status) = lo_response->get_status( ).
  IF status-code NE 200.
    "Error handling here
  ENDIF.
  CATCH cx_web_http_client_error cx_http_dest_provider_error.
    " handle exception here
ENDTRY. has occurred!'.
ENDTRY.
```

## 4.2.10.3.5.2 Set Up HTTP Communication

To set up HTTP communication, use the corresponding communication management apps.

### Context

The communication management is done by the administrator in SAP Fiori launchpad.

### Procedure

1. Create a communication system. A communication system determines which target system is called and which authentication methods are used. It also provides the user that is required to register at the target system. For more information, see [Communication Systems \[page 2397\]](#).
2. In the communication system, create an outbound communication user.
3. Create a communication arrangement. The communication arrangement is based on the communication scenario, that is created by the developer in ABAP Development Tools for Eclipse. For more information, see [How to Create a Communication Arrangement \[page 2395\]](#).

### Result

The communication management established a connection to the system from which you want to consume the HTTP service. You can now perform the service call as described in [HTTP Communication via Communication Arrangements \[page 952\]](#).

## 4.2.10.3.6 RFC Outbound Communication

RFC outbound connectivity enables you to consume RFC services from other systems. To enable RFC outbound communication, there are two different stages that are performed by different roles:

### Development Tasks

Development tasks are performed by developers. Development tasks are all tasks that are performed within ABAP development tools for Eclipse, such as:

- Creating a Communication Scenario
- Creating a Service Consumption Model (optional, recommended)

- Creating an outbound service

For more information, see [Enable RFC Communication in Your ABAP Code \[page 962\]](#).

## Administrator Tasks

Administrator tasks are performed by administrators. Administrator tasks are all tasks that are performed in SAP Fiori launchpad, such as:

- Creating a communication system
- Creating a communication arrangement
- Creating communication users

For more information, see [Set Up RFC Communication \[page 971\]](#).

[Enable RFC Communication in Your ABAP Code \[page 962\]](#)

[Set Up RFC Communication \[page 971\]](#)

To set up RFC communication, use the corresponding communication management apps.

### 4.2.10.3.6.1 Enable RFC Communication in Your ABAP Code

#### Overview

The RFC client allows to connect to RFC-enabled function modules in remote systems.

##### Note

Only synchronous RFC calls are supported.

#### Feature Scope

There are two development approaches to provide configuration for RFC communication. Each development approach has different setup options:

- Communication arrangement
  - Provides APIs for receiver determination based on arbitrary properties (see [Define Specific Properties for Communication Scenarios \[page 857\]](#)).
  - Local configuration via communication management UIs or central configuration in SAP BTP cockpit via SAP BTP destination service reference in the communication system (not relevant for Developer Extensibility, see [Developer Extensibility](#)). For more information, see [Create RFC Destinations and Communication Systems \[page 2397\]](#).
  - Requires the development of communication scenario artifacts.
- Destination service (not relevant for Developer Extensibility, see [Developer Extensibility](#)).

- Provides APIs to fetch connection information for a given destination name from the SAP BTP destination service. No additional development artifacts required.
- Central configuration in SAP BTP cockpit.

### **Note**

When using on-premise connectivity, make sure the called RFC function module is exposed in Cloud Connector.

We recommend using the communication arrangement approach for the following reasons:

- There are no hardcoded values/assumptions for a destination name in the destination service or destination service integration (for example, only default integration).
- The communication system can also refer to a destination service. The destination name and destination service instance are then configured instead of hardcoded.

### **Note**

The communication arrangement approach requires an existing communication scenario and outbound service. See [Communication Systems \[page 2397\]](#) and [RFC Communication via Communication Arrangements \[page 965\]](#) for more information.

## **Service Consumption Model**

Other than with OData, SOAP, or HTTP communication, you can either configure an RFC connection with a Service Consumption Model (SRVC) or without SRVC using the standard `CALL FUNCTION ... DESTINATION` statement. For more information, see [Service Consumption Model as RFC Consumer \[page 964\]](#).

### [Service Consumption Model as RFC Consumer \[page 964\]](#)

Instead of using the `CALL FUNCTION ... DESTINATION` statement, you can configure an RFC connection with a Service Consumption Model (SRVC).

### [RFC Communication via Communication Arrangements \[page 965\]](#)

### [RFC Communication via Destination Service \(Deprecated\) \[page 968\]](#)

## 4.2.10.3.6.1.1 Service Consumption Model as RFC Consumer

Instead of using the `CALL FUNCTION . . . DESTINATION` statement, you can configure an RFC connection with a Service Consumption Model (SRVC).

### Concept

Based on tool support in ABAP development tools for Eclipse (ADT), you can generate an ABAP proxy for calling one or more remote-enabled function modules (RFMs) using the SRVC. To learn how to create a Service Consumption Model with ADT, see [Creating Service Consumption Model](#).

The proxy class contains a specific method for each called RFM. The main benefit of using an SRVC for RFC is that in this class, all data types required for the RFM parameters are generated automatically.

The best way to define an RFC proxy class is to use it for calling only one RFM, or a few RFMs that belong together semantically.

For more information on generating an RFC proxy class based on an SRVC, see [Generating Proxies for Remote Function Call \(RFC\)](#).

In ADT, you can find an example code snippet in the SRVC object of the corresponding RFM.

#### Note

We recommend to create a new package for the Service Consumption Model. Generated objects are then created within this package. This allows better organization and clarity.

### Advantages

In many cases, you can reduce development efforts for synchronous RFC calls to other systems significantly by generating an RFC proxy via the SRVC.

The SRVC generates data types required for a typed access to the RFC response.

When using the `CALL FUNCTION . . . DESTINATION` statement in these cases, you would have to generate all affected data types manually.

The effort increases with the number and complexity of the required data types. For example, in ABAP applications containing tables with a large number of columns, manual data type generation would be time-consuming. This effort is reduced significantly when using an SRVC.

You can save even more time if you're calling the same RFM in different releases and some of the required data types have different characteristics in each release. In this case, you wouldn't only have to generate the different data types for each release separately, but also in different versions. Note that for each release, one proxy is required.

You can also benefit from RFC calls via SRVC if you want to perform object-oriented development in a consistent manner.

## 4.2.10.3.6.1.2 RFC Communication via Communication Arrangements

To establish communication via RFC, you need to create an outbound service of type RFC and use a Service Consumption Model (SRVC) or the `CALL FUNCTION ... DESTINATION` statement to call other systems from the ABAP environment.

### Prerequisites

- You've created a communication scenario as described in [Defining a Communication Scenario Including Authorization Values \[page 800\]](#).
- If you want to call other systems via SRVC, you must have created an SRVC of type RFC as described in [Generating Proxies for Remote Function Call \(RFC\)](#).

### Procedure

1. Create a corresponding outbound service of type RFC.
  1. In your ABAP project, select the relevant package node in the Project Explorer.
  2. Open the context menu and choose **File > New > Other ABAP Repository Object > Cloud Communication Management > Outbound Service > Next** to launch the creation wizard.
  3. Enter the name of the outbound service.
  4. Select RFC in the *Service Type* dropdown list.
  5. Choose *Next* and select a transport request.
  6. Optional: In field *RFC Function Module*, enter the name of the relevant RFC function module.
2. Add the newly created outbound service to a communication scenario. See [Service Consumption via Communication Arrangements \[page 854\]](#) for more information. According to your developed communication scenario, pass the ID of you developed communication scenario to the `comm_scenario` parameter.

#### Note

You can use this field to document a used RFC function module.

7. Save the outbound service.

#### Note

You can't use the `create_by_comm_arrangement` method for SAP-delivered scenarios.

To call an RFC function module in your communication scenario, it's sufficient to define one outbound service of type RFC that can be used to call multiple RFC function modules. For this outbound service, go to the corresponding communication scenario. On the *Outbound* tab in the *Outbound Service* section, select *Generate Destination*.

To document which RFC function modules are called by a communication scenario, you can define separate outbound services and define the name of the function modules without selecting *Generate Destination*.

3. Call the RFC service as described in the example. Copy the code from the *Overview* tab in your SRVC and add the `comm_system_id` and `service_id` parameters if necessary.

## Example

### Using a Service Consumption Model

This example shows how to use RFC communication with an SRVC.

#### Sample Code

```
DATA: lr_cscn TYPE if_com_scenario_factory=>ty_query-cscn_id_range.

" find Communication Arrangement by scenario ID
lr_cscn = VALUE #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
DATA(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
lo_factory->query_ca(
  EXPORTING
    is_query = VALUE #( cscn_id_range = lr_cscn )
  IMPORTING
    et_com_arrangement = DATA(lt_ca) ).

IF lt_ca IS INITIAL.
  EXIT.
ENDIF.

" take the first one
READ TABLE lt_ca INTO DATA(lo_ca) INDEX 1.

" get destination based on Communication Arrangement
TRY.
  DATA(lo_dest) = cl_rfc_destination_provider=>create_by_comm_arrangement(
    EXPORTING
      comm_scenario = '<Scenario ID>'
    ).
  CATCH cx_rfc_dest_provider_error.
    " handle CX_RFC_DEST_PROVIDER_ERROR
ENDTRY.

" Service Consumption Model:
TRY.
  CREATE OBJECT myobj
  EXPORTING
    destination = lo_dest.
  myobj->bapi_activitytype_getlist(
    IMPORTING
      return          = lt_return
    CHANGING
      activitytype_list = lt_acttype_list.
  ).
  CATCH cx_aco_communication_failure INTO DATA(lcx_comm).
    " handle CX_ACO_COMMUNICATION_FAILURE (sy-msg* in lcx_comm-
>IF_T100_MESSAGE~T100KEY)
    CATCH cx_aco_system_failure INTO DATA(lcx_sys).
      " handle CX_ACO_SYSTEM_FAILURE (sy-msg* in lcx_sys-
>IF_T100_MESSAGE~T100KEY)
```

```

CATCH cx_aco_application_exception INTO DATA(lcx_appl).
  " handle APPLICATION_EXCEPTIONS (sy-msg* in lcx_appl-
>IF_T100_MESSAGE~T100KEY)
ENDTRY.

```

## Note

We recommend to retrieve the correct destination reference based on the communication scenario and a customer-defined property as described in [Service Consumption via Communication Arrangements \[page 854\]](#).

## Using CALL FUNCTION ... DESTINATION

To use the CALL FUNCTION ... DESTINATION statement, use the following code:

### Sample Code

```

DATA: lr_cscn TYPE if_com_scenario_factory=>ty_query-cscn_id_range.
  " find Communication Arrangement by scenario ID
  lr_cscn = VALUE #( ( sign = 'I' option = 'EQ' low = '<Scenario ID>' ) ).
  DATA(lo_factory) = cl_com_arrangement_factory=>create_instance( ).
  lo_factory->query_ca(
    EXPORTING
      is_query = VALUE #( cscn_id_range = lr_cscn )
    IMPORTING
      et_com_arrangement = DATA(lt_ca) ).
  IF lt_ca IS INITIAL.
    EXIT.
  ENDIF.
  " take the first one
  READ TABLE lt_ca INTO DATA(lo_ca) INDEX 1.
  " get destination based on Communication Arrangement
  TRY.
    DATA(lo_dest) =
cl_rfc_destination_provider=>create_by_comm_arrangement(
    EXPORTING
      comm_scenario = '<Scenario ID>'
      service_id = '<Outbound Service ID>'
      comm_system_id = lo_ca->get_comm_system_id( )
    ).
    DATA(destination_name) = lo_dest->get_destination_name( ).
  CATCH cx_rfc_dest_provider_error.
    " handle CX RFC_DEST_PROVIDER_ERROR
  ENDTRY.
  " CALL FUNCTION
  DATA msg TYPE c LENGTH 255.
  CALL FUNCTION 'BAPI_ACTIVITYTYPE_GETLIST' DESTINATION destination_name
  IMPORTING
    return = lt_return
  TABLES
    activitytype_list = lt_acttype_list
  EXCEPTIONS
    system_failure = 1 MESSAGE msg
    communication_failure = 2 MESSAGE msg
    OTHERS = 3.
  CASE sy-subrc.
    WHEN 1.
      " handle system failure
    WHEN 2.
      " handle communication failure
    WHEN 3.
      " handle application failure
  ENDCASE.

```

## Test Your Outbound Call

To test your outbound call, you have to provide a configuration for the outbound service you want to call in your code.

Create a communication system and communication arrangement for the communication scenario in the Communication Systems and Communication Arrangements apps and maintain the required data.

## Related Information

[Service Consumption via Communication Arrangements \[page 854\]](#)

[Call a Remote Function Module \(RFC\) From SAP BTP, ABAP Environment](#) 

### 4.2.10.3.6.1.3 RFC Communication via Destination Service (Deprecated)

## Context

Use the destination service in SAP BTP to store destination information that can be reused by SAP BTP app services.

#### Note

You can use the destination service. However, this approach is deprecated. We recommend using the communication arrangement approach instead. See [RFC Communication via Communication Arrangements \[page 965\]](#) for more information.

You've the following options to consume a destination service:

- Dynamic by using a communication arrangement and a communication system
- Static by using the method `create_by_cloud_destination` in the code

## Prerequisites

If you want to call other systems via SRVC, you must have created an SRVC of type RFC as described in [Generating Proxies for Remote Function Call \(RFC\)](#).

## Procedure

When using `create_by_cloud_destination`, proceed as follows:

Create a destination object using class `cl_http_destination_provider` and method `create_by_cloud_destination` with the following parameters:

- `i_name`: the name of the destination.
- Optional: `i_service_instance_name`: Typically, you use the destinations of the subaccount in which the ABAP instance resides or, in case of a SaaS solution based on the ABAP environment, the destinations of the consumer subaccount. However, you can add more destinations using your own destination service instance and communication scenario `SAP_COM_0276`, for example, to achieve separation of concerns (see also [Create a Destination \[page 854\]](#)). In this case, specify the value of the service instance name property of the communication arrangement for `SAP_COM_0276`.

## Example

### Using a Service Consumption Model

You can consume your service using a Service Consumption Model (SRVC). Create an SRVC and replace the call of the method `cl_rfc_destination_provider=>create_by_comm_arrangement( )` that is proposed in the SRVC with `cl_rfc_destination_provider=>create_by_cloud_destination( )`:

#### Sample Code

```
TRY.  
  
    " replace Method create_by_comm_arrangement( ).  
    " dest = cl_rfc_destination_provider=>create_by_comm_arrangement(  
    " comm_scenario = 'MY_COMM_SCENARIO'  
    " ).  
  
    " replacement  
    DATA(dest) = cl_rfc_destination_provider=>create_by_cloud_destination(  
    EXPORTING  
        i_name          = 'name of destination'  
    ).  
  
    CREATE OBJECT myobj  
        EXPORTING  
            destination = dest.  
  
    myobj->bapi_activitytype_getlist(  
    IMPORTING  
        return          = lt_return  
    CHANGING  
        activitytype_list = lt_acttype_list.  
    ).  
    CATCH cx_aco_communication_failure INTO DATA(lcx_comm).  
    " handle CX_ACO_COMMUNICATION_FAILURE (sy-msg* in lcx_comm-  
>IF_T100_MESSAGE~T100KEY)  
    CATCH cx_aco_system_failure INTO DATA(lcx_sys).  
    " handle CX_ACO_SYSTEM_FAILURE (sy-msg* in lcx_sys-  
>IF_T100_MESSAGE~T100KEY)  
    CATCH cx_aco_application_exception INTO DATA(lcx_appl).  
    " handle APPLICATION_EXCEPTIONS (sy-msg* in lcx_appl-  
>IF_T100_MESSAGE~T100KEY)
```

```

CATCH cx_rfc_dest_provider_error.
  " handle CX RFC_DEST_PROVIDER_ERROR

ENDTRY.

```

### Using CALL FUNCTION ... DESTINATION

The sample code below shows how to get a reference to a destination and how to use it when calling a remote-enabled function module.

#### Sample Code

```

" getting the reference to the relevant destination
TRY.
DATA(lr_dest) = cl_rfc_destination_provider=>create_by_cloud_destination(
  EXPORTING
    i_name      = 'name_of_destination'
  ).
CATCH cx_rfc_dest_provider_error.
  " handle CX RFC_DEST_PROVIDER_ERROR
ENDTRY.

DATA(lo_dest) = lr_dest->get_destination_name( ).
" using the destination in RFC

DATA msg TYPE c LENGTH 255.
CALL FUNCTION 'BAPI_ACTIVITYTYPE_GETLIST' DESTINATION lo_dest->
get_destination_name( )
  IMPORTING
    return      = lt_return
  TABLES
    activitytype_list = lt_acttype_list.
EXCEPTIONS
  system_failure      = 1 MESSAGE msg
  communication_failure = 2 MESSAGE msg
  OTHERS              = 3.
CASE sy-subrc.
  WHEN 1.
    " handle system failure
  WHEN 2.
    " handle communication failure
  WHEN 3.
    " handle application failure
ENDCASE.

```

#### Note

When using on-premise connectivity, make sure the called RFC function module is exposed in Cloud Connector. See [Configure Access Control \(RFC\)](#).

## Test Your Outbound Call

To test your outbound call, configure an RFC destination as described in [Create RFC Destinations](#). The following authentication methods are supported in the SAP BTP, ABAP environment:

#### Internet:

- Basic Authentication: Fill the *User* and *Password* fields. If an alias logon is required, use the field *Alias User*.
- Client Certificate Authentication: Use the additional property `jco.client.tls_client_certificate_logon` with value `1` to enable Client Certificate Authentication.

#### OnPremise:

- Basic Authentication: Fill the *User* and *Password* fields.
- Principal Propagation: Use the additional property `jco.destination.auth_type` with value **PrincipalPropagation** to enable Principal Propagation.

#### Note

- For proxy type *Internet* and the use of authentication type client certificate, you must upload the X.509 client certificate in P12 format on the client side in the SAP BTP, ABAP environment, using the Maintain Client Certificates application. For more information, see [Maintain Client Certificates \[page 2564\]](#). Uploading the client certificate via destination service isn't supported.
- For proxy type *OnPremise*, the use of authentication type **PrincipalPropagation** for a destination isn't supported in the ADT class runner.

## Related Information

[Destination Service \[page 848\]](#)

### 4.2.10.3.6.2 Set Up RFC Communication

To set up RFC communication, use the corresponding communication management apps.

## Context

The communication management is done by the administrator in SAP Fiori launchpad.

#### Note

If you've configured on-premise connectivity (via Cloud Connector) in the RFC settings of your communication system or destination service, use fast serialization. See SAP Note [2418683](#) for more information. For example, if you use a Service Consumption Model, data and structures containing includes can be transferred incorrectly because of displaced offsets. Fast serialization is set by default.

## Procedure

1. Create a communication system. A communication system determines which target system is called and which authentication methods are used. It also provides the user that is required to register at the target system. For more information, see [Communication Systems \[page 2397\]](#).
2. In the communication system, create an outbound communication user.
3. Create a communication arrangement. The communication arrangement is based on the communication scenario, that is created by the developer in ABAP Development Tools for Eclipse. For more information, see [How to Create a Communication Arrangement \[page 2395\]](#).

## Result

The communication management established a connection to the system from which you want to consume the RFC service. You can now perform the service call as described in [RFC Communication via Communication Arrangements \[page 965\]](#).

### 4.2.10.3.7 SOAP Outbound Communication

Learn how to set up and enable SOAP outbound communication.

SOAP outbound connectivity enables you to consume web services from other systems. To enable SOAP outbound communication, there are three different stages that are performed by different roles:

## Development Tasks

Development tasks are performed by developers. Development tasks are all tasks that are performed within ABAP development tools for Eclipse, such as:

- Creating a Communication Scenario
- Creating a Service Consumption Model
- Creating an outbound service

For more information, see [Enable SOAP Communication in Your ABAP Code \[page 973\]](#).

## Administrator Tasks

Administrator tasks are performed by administrators. Administrator tasks are all tasks that are performed in SAP Fiori launchpad, such as:

- Creating a communication system

- Creating a communication arrangement
- Creating communication users

For more information, see [Set Up SOAP Communication \[page 988\]](#).

## Monitoring Tasks

Monitoring tasks are performed by administrators. Monitoring tasks are all tasks that are performed in the respective monitoring apps in SAP Fiori launchpad, such as:

- SOAP error log
- Message Monitoring

For more information, see [SOAP Monitoring \[page 989\]](#).

[Enable SOAP Communication in Your ABAP Code \[page 973\]](#)

[Set Up SOAP Communication \[page 988\]](#)

To set up SOAP communication, use the corresponding communication management apps.

[SOAP Monitoring \[page 989\]](#)

### 4.2.10.3.7.1 Enable SOAP Communication in Your ABAP Code

## Feature Scope

SOAP-based web services cover the following features:

- Synchronous and asynchronous outbound web service communication
- Self-contained WSDL (single file with no import or include statements)
- gCTS Support (not relevant for Developer Extensibility, see [Developer Extensibility](#))
- Web service protocols, e.g. to add custom XML elements to the SOAP request header, add the Application Interface Key, or enable EOIO processing. For more information, see [SOAP Protocols \[page 982\]](#).

To enable SOAP communication, there are three different approaches:

- Communication arrangement
  - Provides APIs for receiver determination based on arbitrary properties (see [Define Specific Properties for Communication Scenarios \[page 857\]](#)).
  - Local configuration via communication management UIs or central configuration in SAP BTP cockpit via SAP BTP destination service reference in the communication system (not relevant for Developer Extensibility, see [Developer Extensibility](#)). For more information, see [Communication Systems \[page 2397\]](#).
- Requires the development of communication scenario artifacts.

- Destination service (not relevant for Developer Extensibility, see [Developer Extensibility](#)).
  - Provides APIs to fetch connection information for a given destination name from the SAP BTP destination service. No additional development artifacts required.
  - Central configuration in SAP BTP cockpit.
- URL approach: By using a plain URL and setter methods to provide the needed configuration directly in the coding.

All of the listed approaches above require a Service Consumption Model. For more information, see [Service Consumption Model as SOAP Consumer \[page 976\]](#).

### 4.2.10.3.7.1.1 Enhanced WSDL Document

The enhanced Web Services Description Language (WSDL) document is a WSDL document enhanced by ABAP information that is relevant for design time.

When you use a regular WSDL as input to create a Service Consumption Model (SRVC), the design time relevant information, such as the types, messages, and port type sections, are analyzed and interpreted by the ABAP Web service framework. For all the ABAP properties like the names and types, it will make suggestions and generate a WSDL similar to the input WSDL enhanced with this ABAP information. If needed, you can change these ABAP properties within the enhanced WSDL document to adjust the ABAP artifacts accordingly (upon activation). The mapping between XSD and ABAP types in particular can be adjusted this way. Of course, an enhanced WSDL document can be used as input as well.

To encode ABAP properties into the WSDL, the namespace `http://sap.com/abap/proxy` with the prefix `abap` was introduced: `xmlns:abap=http://sap.com/abap/proxy`. For any applicable node of a WSDL, the corresponding enhanced WSDL document contains additional nodes within this namespace to accommodate its ABAP properties. Wherever you see the `abap` prefix in the WSDL, you can adjust the ABAP property. These additional nodes can be XSD attributes or elements, depending on where the node to be enhanced is located. This is necessary to maintain WSDL validity. Schema nodes such as `xmlns:xsd=http://www.w3.org/2001/XMLSchema` are enhanced via additional XSD attributes. WSDL nodes `xmlns:wSDL=http://schemas.xmlsoap.org/wSDL/`, on the other hand, are enhanced via additional XSD (sub)elements. Regular ABAP properties of any node contain the following:

- Prefix
- Name
- Description
- ABAP type

With the ABAP type, you can control the mapping between XSD and ABAP types. The property `availableTypes` displays all applicable ABAP types in this case. To change the ABAP type, copy and paste one of the listed types into the type attribute of the given element. Afterwards, reactivate the SRVC to apply the changes.

## Summary of Additional Nodes and Their Technical Types

Node name	Technical Type	Description
<code>abap:prefix</code>	Up to 20 characters, case insensitive	ABAP prefix (only used if the object is represented by an ABAP object such as CLAS, INTF, TABL, DTEL)
<code>abap:name</code>	Up to 30 characters, case insensitive	ABAP name
<code>abap:type</code>	String	Default or set ABAP type
<code>abap:availableTypes</code>	Comma-separated list of 30 characters	List of all available ABAP types
<code>abap:description</code>	Up to 60 characters	Description
<code>abap:prefixT</code>	See <code>abap:prefix</code>	Prefix for corresponding table type (if <code>maxOccurs &gt; 1</code> and additional table type is generated and a prefix is required)
<code>abap:nameT</code>	See <code>abap:name</code>	Name for corresponding table type (if <code>maxOccurs &gt; 1</code> and additional table type is generated)
<code>abap:descriptionT</code>	See <code>abap:description</code>	Description for corresponding table type (if <code>maxOccurs &gt; 1</code> and additional table type is generated)

### Example

The following code snippet displays a types section of an enhanced WSDL with a schema node (prefix `xsd`), where all ABAP properties are encoded as XSD attributes:

#### Sample Code

```
<xsd:element name="NumberToWords">
  <xsd:complexType abap:prefix="ZZZ_"
  abap:name="ZZZ_NUMBER_TO_WORDS_SOAP_REQUE" abap:description="Proxy
  Structure (generated)">
    <xsd:sequence>
      <xsd:element name="ubiNum" form="qualified" type="xsd:unsignedLong"
  abap:name="UBI_NUM" abap:type="INT8" abap:availableTypes="INT8, INT4,
  DEC-20"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:element>
```

The element `NumberToWords` being a `complexType` is represented by the dictionary structure `ZZZ_NUMBER_TO_WORDS_SOAP_REQUE` in ABAP. The element within this `complexType` `ubiNum` of XSD type `xsd:unsignedLong` corresponds to structure entry `UBI_NUM` of ABAP type `INT8`, which you could change to `INT4` or `DEC-20` (`availableTypes`).

The second snippet represents an exemplary `portType` section, where all ABAP properties are encoded as additional XSD elements (prefix `wsdl`) rather than attributes:

#### Sample Code

```
<wsdl:portType name="NumberConversionSoapType">
  <abap:prefix>ZZZ_</abap:prefix>
```

```

<abap:name>ZZZ_CO_NUMBER_CONVERSION_SOAP</abap:name>
<abap:description>Proxy Class (generated)</abap:description>
<wsdl:operation name="NumberToWords">
  <abap:name>NUMBER_TO_WORDS</abap:name>
  <abap:description>Returns the word corresponding to the positive number
  passed</abap:description>
  <wsdl:input message="tns:NumberToWordsSoapRequest" />
  <wsdl:output message="tns:NumberToWordsSoapResponse" />
</wsdl:operation>
</wsdl:portType>

```

In this code snippet, the generated ABAP class is called `ZZZ_CO_NUMBER_CONVERSION_SOAP` and its method is `NUMBER_TO_WORDS`, which corresponds to the operation `NumberToWords` of the service.

## 4.2.10.3.7.1.2 Service Consumption Model as SOAP Consumer

A Service Consumption Model is the main requirement for consuming a web service in the ABAP environment. To learn how to create a Service Consumption Model with ABAP development tools for Eclipse (ADT), see [Creating Service Consumption Model](#).

### Note

We recommend to create a new package for the Service Consumption Model. Generated objects are then created within this package. This allows better organization and clarity.

For the consumption type web service, you need to upload the WSDL of the service you want to consume. See [Generating Proxies for Remote Web Service](#). Upon successful activation, all the dependent objects are created and displayed in the ADT project explorer, such as:

- The enterprise service
- Corresponding dictionary objects
- The generated ABAP class

For any operation of the web service, a code snippet is displayed in ADT that indicates how to call the service via the corresponding method of the generated class. It is instantiated using a destination object that refers to a communication arrangement and scenario.

An enhanced WSDL document has been introduced that describes how schema/WSDL entities are mapped to ABAP. In the WSDL, any schema element is enhanced by ABAP properties such as ABAP name and type. You can change all these ABAP properties by editing the enhanced WSDL and reactivating the Service Consumption Model. To learn more about the enhanced WSDL, see [Enhanced WSDL Document \[page 974\]](#).

### Note

The Service Consumption Model is initially saved in an inactive state. Therefore, not all dependent objects are immediately visible in the project explorer. Upon activation, all dependent objects are created according to the enhanced WSDL. They are then visible in the project explorer.

## 4.2.10.3.7.1.3 SOAP Communication via Communication Arrangements

### Prerequisites

- You have created a communication scenario as described in [Defining a Communication Scenario Including Authorization Values \[page 800\]](#).
- You have a service meta data file (WSDL file) for the service you want to consume.
- You have created and activated a service consumption model (SRVC) of type `web Service`. See [Generating Proxies for Remote Web Service](#) for more information.

### Procedure

1. Create a corresponding outbound service of type `SOAP`.
  1. In your ABAP project, select the relevant package node in the Project Explorer.
  2. Open the context menu and choose **File > New > Other ABAP Repository Object > Cloud Communication Management > Outbound Service > Next** to launch the creation wizard.
  3. Enter the name of the outbound service.
  4. Select `SOAP` in the *Service Type* dropdown list.
  5. Choose *Next* and select a transport request.
  6. In field *Service Interface*, enter the name of the relevant consumer proxy. You can choose the consumer proxy from the list of the value help.
  7. Save the outbound service.
2. Add the newly created outbound service to the communication scenario. See [Service Consumption via Communication Arrangements \[page 854\]](#) for more information.

#### Note

You can't use the `create_by_comm_arrangement` method for SAP-delivered scenarios.

3. Publish the communication scenario. The administrator can then create the required communication management objects as described in [Test Your Outbound Call \[page 979\]](#).
4. Call the SOAP service as described in the example. Copy the code snippet from the *Overview* tab in your SRVC and add the `comm_system_id` and `service_id` parameters if necessary. Note the difference between synchronous and asynchronous services. According to your developed communication scenario, add the following:

<code>comm_scenario</code>	mandatory	ID of the developed communication scenario
----------------------------	-----------	--

---

comm_system_id	optional	ID of the configured communication system
service_id	optional	ID of the developed outbound service

## Example

### Synchronous Services

#### Sample Code

```

TRY.
  DATA(soap_destination) =
  cl_soap_destination_provider=>create_by_comm_arrangement(
                                comm_scenario = '<demo scenario>'
                                service_id     = '<service id>'
                                comm_system_id  = '<comm system>' ).

  DATA(proxy) = NEW zsc_co_epm_product_soap( destination =
  soap_destination ).

  DATA(request) = VALUE zsc_req_msg_type( req_msg_type-product = '<product
  name>' ).
  proxy->get_price(
    EXPORTING
      input = request
    IMPORTING
      output = DATA(response) ).

  "handle response
  CATCH cx_soap_destination_error.
  "handle error
  CATCH cx_ai_system_fault.
  "handle error
  CATCH zsc_cx_fault_msg_type.
  "handle error

ENDTRY.

```

#### Note

We recommend to retrieve the correct destination reference based on the communication scenario and a customer-defined property as described in [Service Consumption via Communication Arrangements \[page 854\]](#).

### Asynchronous Services

For asynchronous services, follow the same procedure as for synchronous services. The only differences in the code are the following:

- The `IMPORTING` parameter is missing since the service doesn't return any value.
- A `COMMIT WORK` triggers the SOAP call.

#### Sample Code

```

TRY.

```

```

DATA(destination) =
cl_soap_destination_provider=>create_by_comm_arrangement(
                                comm_scenario = '<demo scenario>'
*                                service_id     = '<service id>'
*                                comm_system_id = '<comm system>'
                                ).
DATA(proxy) = NEW zco_appointment_activity_reque(
                                destination = destination
                                ).
DATA(request) = VALUE zappointment_activity_request1( ).
proxy->appointment_activity_request_i(
    EXPORTING
        input = request
    ).
COMMIT WORK. "to trigger async call
CATCH cx_soap_destination_error.
    "handle error
CATCH cx_ai_system_fault.
    "handle error
ENDTRY.

```

## Test Your Outbound Call

To test your outbound call, you have to provide a configuration for the outbound service you want to call in your code.

Create a communication system and communication arrangement for the communication scenario in the Communication Systems and Communication Arrangements apps and maintain the required data.

To check if an asynchronous call was successfully sent to the provider system, see [SOAP Monitoring \[page 989\]](#).

These tasks are performed by the administrator. For more information, see [Set Up SOAP Communication \[page 988\]](#) and [SOAP Monitoring \[page 989\]](#).

## Related Information

[Enable SOAP Communication in Your ABAP Code \[page 973\]](#)

[Communication Management \[page 846\]](#)

[Communication Arrangement \[page 848\]](#)

[Developing External Service Consumption \(Outbound Communication\) \[page 852\]](#)

### 4.2.10.3.71.4 SOAP Communication via Destination Service (Deprecated)

To configure a SOAP-specific destination, create an HTTP destination as described in [Set Up HTTP Communication \[page 961\]](#).

## Note

You can use the destination service. However, this approach is deprecated. We recommend using the communication arrangement approach instead. See [SOAP Communication via Communication Arrangements \[page 977\]](#) for more information.

You can set Web service-specific properties by maintaining the following *Additional Properties* in the destination:

- `ws.soapVersion`: Sets the SOAP version.
- `ws.maxWaitTime`: Sets the maximum waiting time for the consumer (in seconds).
- `ws.compressMessage`: Enables compression of the message.
- `ws.soapAction.<operationName>`: Sets the SOAP action for a given operation with name `<operationName>`.

## Sample Code

```
TRY.
  DATA(lo_soap_dest) =
  cl_soap_destination_provider=>create_by_cloud_destination(
                                i_name           = '<destination name>'
                                i_service_instance_name = '<destination service
instance name>').
  DATA(proxy) = NEW zco_appointment_activity_reque(
                    destination = destination ).
  DATA(request) = VALUE zsc_req_msg_type(
                    req_msg_type-product = '<product name>' ).
  proxy->get_price(
    EXPORTING
      input = request
    IMPORTING
      output = DATA(response) ).

  "handle response
CATCH cx_soap_destination_error.
  "handle error
CATCH cx_ai_system_fault.
  "handle error
CATCH zsc_cx_fault_msg_type.
  "handle error

ENDTRY.
```

## Related Information

[Enable SOAP Communication in Your ABAP Code \[page 973\]](#)

### 4.2.10.3.71.5 SOAP Communication via URL

Instead of setting the *Additional Properties* as in the destination service approach, you can set them programmatically:

- `set_soap_version( )`: Sets the SOAP version. Valid values for the SOAP version are provided by the constants `if_soap_destination=>soap_version_11` and `if_soap_destination=>soap_version_12`.
- `set_max_wait_time( )`: Sets the maximum waiting time for the consumer (in seconds).
- `set_compress_message( )`: Enables compression of messages if parameter `i_compress_message` is set to `true`. Disables compression if the parameter is set to `false`.
- `set_soap_action( )`: Sets the SOAP action for a given operation. Parameters are the name of the operation and the value of the SOAP action.
- `set_url( )`: Sets the URL of the endpoint.
- `set_basic_authentication( )`: Sets the authentication method to basic authentication and sets user and password.
- `use_client_certificate( )`: Sets the authentication method to client certificate authentication. The default client certificate is used.

### Note

An existing service consumption model (SRVC) is required.

### Note

Use the URL approach mainly for testing purposes.

Call the SOAP service as described in the example. As described in [SOAP Communication via Communication Arrangements \[page 977\]](#), copy the code snippet from the *Overview* tab in your SRVC. Replace the `CREATE_BY_COMM_ARRANGEMENT` method with the `CREATE_BY_URL` method and pass the required URL to the method.

### Sample Code

```
TRY.
"replace create_by_comm_arrangement with create_by_url
  DATA(soap_destination) = cl_soap_destination_provider=>create_by_url(
    'https://<host>/sap/bc/srt/xip/sap/<provider>/000/
<service>/<binding>').

  soap_destination->use_client_certificate( ).
"generated code snippet
  DATA(proxy) = NEW zsc_co_service( destination = soap_destination ).

  DATA(request) = VALUE zsc_req_msg_type( req_msg_type-product = '<product
name>' ).
  proxy->get_price(
    EXPORTING
      input = request
    IMPORTING
      output = DATA(response) ).

  "handle response
  CATCH cx_soap_destination_error.
    "handle error
  CATCH cx_ai_system_fault.
    "handle error
  CATCH zsc_cx_fault_msg_type.
    "handle error

ENDTRY.
```

## Related Information

[Enable SOAP Communication in Your ABAP Code \[page 973\]](#)

[Tutorial: Consume SOAP-Based Web Services with SAP BTP ABAP Environment](#)

### 4.2.10.3.7.1.6 SOAP Protocols

Protocols allow you to use additional SOAP runtime features.

Class `CL_WS_PROTOCOL_FACTORY` provides factory methods that return an interface specific to each protocol that you want to use.

The exception `CX_WS_PROTOCOL_ERROR` is raised whenever a protocol error occurs.

The following protocols are available:

#### [Add Custom SOAP Header Elements \[page 982\]](#)

With the web services SOAP header protocol, you can programmatically add custom XML elements to the SOAP request header.

#### [Add the AIR Key to a SOAP Request in the HTTP Header \[page 985\]](#)

With the web services HTTP header protocol, you can programmatically add the Application Interface Key (AIR key) field to the HTTP header of a SOAP request.

#### [Enable EOIO Processing \[page 986\]](#)

With the web services sequence protocol, you can enable exactly once in order (EOIO) processing for asynchronous web services.

### 4.2.10.3.7.1.6.1 Add Custom SOAP Header Elements

With the web services SOAP header protocol, you can programmatically add custom XML elements to the SOAP request header.

## Context

Some services can require setting specific XML elements in the SOAP header. To add such custom elements, you can use the method `ADD_SOAP_HEADER_ELEMENT`.

## Procedure

1. Create a consumer proxy by instantiating the generated class with a SOAP destination object. See [Enable SOAP Communication in Your ABAP Code \[page 973\]](#) for more information.

2. Pass the proxy object to the factory method  
`cl_ws_protocol_factory=>get_soap_header_protocol( )`. The factory method returns a (proxy-specific) WS protocol object to adjust the SOAP header.
3. Pass the custom XML element as string to the method `add_soap_header_element`.

```
DATA(ws_soap_header_facade) =
cl_ws_protocol_factory=>get_soap_header_protocol( proxy ).
ws_soap_header_facade->add_soap_header_element( '<XML element>' ).
```

### Note

To add multiple XML elements, call the method for each element separately.

## Exception Handling

The API raises the exception `CX_WS_PROTOCOL_ERROR`, for example, if the code snippet is syntactically incorrect or if one of the following reserved namespaces is used:

- `http://schemas.xmlsoap.org/ws/2004/08/addressing`
- `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd`
- `http://www.w3.org/2005/08/addressing`
- `http://www.sap.com/webas/640/soap/features/messageId`
- `http://schemas.xmlsoap.org/ws/2005/02/rm`
- `http://docs.oasis-open.org/ws-rx/wsrn/200702`
- `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512`
- `http://schemas.xmlsoap.org/ws/2005/02/sc`
- `http://www.sap.com/webas/630/soap/runtime/session/protocol`

## Example

The following example shows how to adjust the SOAP request header followed by the web service call.

### Note

First, you must get a SOAP destination object according to your SAP product as described in [Enable SOAP Communication in Your ABAP Code \[page 973\]](#).

### Sample Code

```
" Get destination object
TRY.
  DATA(proxy) = NEW example_consumer( destination = soap_destination ).

  DATA xml_element TYPE string VALUE
    '<n0:CustomHeaderElement xmlns:n0="http://ws.example.org/ws/">' &
    '<n0:CustomElement>' &
```

```

        '<n0:value>specific info</n0:value>' &
        '</n0:CustomElement>' &
        '</n0:CustomHeaderElement>' .

    TRY.
        " Pass the proxy object to factory method and add XML element to the
        SOAP request header.
        DATA(ws_header_facade) =
        cl_ws_protocol_factory=>get_soap_header_protocol( proxy ).
        ws_header_facade->add_soap_header_element( xml_element ).

        CATCH cx_ws_protocol_error.
            " Handle error.
        ENDTRY.

    " Call server
    DATA(request) = VALUE example_req_msg_type( ).
    proxy->example_operation(
    EXPORTING
        input = request
    IMPORTING
        output = DATA(response) ).

    CATCH cx_ai_system_fault.
        " Handle error.

    ENDTRY.

```

The resulting SOAP request looks like this:

```

<?xml version="1.0" encoding="UTF-8"?>
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    ...
    <n0:CustomHeaderElement xmlns:n0="http://ws.example.org/ws/">
      <n0:CustomElement>
        <n0:value>specific info</n0:value>
      </n0:CustomElement>
    </n0:CustomHeaderElement>
    ...
  </env:Header>
  <env:Body>
    ...
  </env:Body>
</env:Envelope>

```

## Related Information

[Set Up SOAP Communication \[page 988\]](#)

## 4.2.10.3.7.1.6.2 Add the AIR Key to a SOAP Request in the HTTP Header

With the web services HTTP header protocol, you can programmatically add the Application Interface Key (AIR key) field to the HTTP header of a SOAP request.

### Context

If your application calls an SAP SOAP API, the Application Interface Key must be part of the request. The Application Interface Key is passed in the HTTP header. For SOAP requests, you can do this with the HTTP header protocol. To add this field, you can use the method `SET_FIELD` of the interface `IF_WS_HTTP_HEADER_FACADE`.

#### Note

- It isn't possible to add a field other than the Application Interface Key field.
- Only synchronous web service calls are supported.

### Procedure

1. Create a consumer proxy by instantiating the generated class with a SOAP destination object. See [Enable SOAP Communication in Your ABAP Code \[page 973\]](#) for more information.
2. Pass the proxy object to the factory method `cl_ws_protocol_factory=>get_http_header_protocol( )`. The factory method returns a (proxy-specific) WS protocol object to adjust the HTTP header.
3. Pass the name of the HTTP header field and value as string to the method `set_field`.

#### Sample Code

```
DATA(header) = cl_ws_protocol_factory=>get_http_header_protocol( io_proxy
= proxy ).
header->set_field( iv_name =
if_ws_http_header_facade=>co_field_appl_interface_key iv_value =
'0123abcd' ).
```

### Example

#### Note

After executing a service call, the field value is initialized by the SOAP runtime. Therefore, you have to set the HTTP field values for each service call with the `SET_FIELD` method.

## Sample Code

```
" Get destination object
TRY.
  DATA(destination) =
cl_soap_destination_provider=>create_by_comm_arrangement(
  comm_scenario = 'HTTP_HEADER' ).
  DATA(proxy) = NEW zco_srt_test_provider( destination = destination ).
  " Pass the proxy object to factory method to obtain an instance of the HTTP
header protocol
  DATA(header) = cl_ws_protocol_factory=>get_http_header_protocol( io_proxy
= proxy ).
  " First service call
  " Add HTTP field to the SOAP request.
  header->set_field( iv_name =
if_ws_http_header_facade=>co_field_appl_interface_key iv_value = '0123abcd' ).
  " Call service
  DATA(request) = VALUE zrfc_system_info( ).
  proxy->rfc_system_info( EXPORTING input = request IMPORTING output =
DATA(response) ).
  " Second service call
  " Add HTTP field to the SOAP request.
  header->set_field( iv_name =
if_ws_http_header_facade=>co_field_appl_interface_key iv_value = '9876wxyz' ).
  " Call service
  DATA(request) = VALUE zrfc_system_info( ).
  proxy->rfc_system_info( EXPORTING input = request IMPORTING output =
DATA(response) ).
  CATCH cx_ws_protocol_error INTO DATA(lx_protocol_error).
  " Handle protocol error
  CATCH cx_soap_destination_error INTO DATA(lx_error).
  " Handle destination error
  CATCH cx_ai_system_fault INTO DATA(lx_fault).
  " Handle system fault
ENDTRY.
```

### 4.2.10.3.7.1.6.3 Enable EOIO Processing

With the web services sequence protocol, you can enable exactly once in order (EOIO) processing for asynchronous web services.

#### Context

It can sometimes be important that service requests arrive at the provider side in the correct order. This is the case when database entries that depend on a previous write process are being written. If a database entry is changed that has not yet even been created, errors occur.

To ensure that calls are processed in the correct order, calls that belong together are given a sequence and then are evaluated by the provider.

If proxy object methods are called as part of a sequence, these calls are processed 'exactly once in order' (EOIO). If the proxy object methods are called without sequence, the methods are called 'exactly once' without a particular order.

To enable EOIO processing, proceed as follows.

## Procedure

1. Create a consumer proxy by instantiating the generated class with a SOAP destination object. See [Enable SOAP Communication in Your ABAP Code \[page 973\]](#) for more information.
2. Pass the proxy object to the factory method `cl_ws_protocol_factory=>get_sequence_protocol( )`. The factory method returns a (proxy-specific) WS protocol object.
3. To enable EOIO processing, use the methods `ws_sequence_facade->begin_eoio_sequence( )` and `ws_sequence_facade->end_eoio_sequence( )`. The proxy calls in between these two methods are processed EOIO.
4. Use `COMMIT WORK` to trigger web service calls in the EOIO sequence block.

### Sample Code

```
DATA(ws_sequence_facade) =
cl_ws_protocol_factory=>get_sequence_protocol( proxy ).
ws_sequence_facade->begin_eoio_sequence( ).
    <WS calls to be executed EOIO>
ws_sequence_facade->end_eoio_sequence( ).
```

### Note

If there are multiple `begin/end_eoio_sequence` blocks, the corresponding sequences are executed independently of each other. All messages within a sequence are still executed exactly once in order.

## Example

### Note

First, you must get a SOAP destination object according to your SAP product as described in [Enable SOAP Communication in Your ABAP Code \[page 973\]](#).

### Sample Code

```
" Get destination object
TRY.
    DATA(proxy) = NEW zco_appointment_activity_reque(
        destination = destination
    ).

    DATA(ws_sequence_facade) =
cl_ws_protocol_factory=>get_sequence_protocol( proxy ).

" Begin EOIO sequence
ws_sequence_facade->begin_eoio_sequence( ).
DATA(request1) = VALUE zco_appointment_activity_reque( ).
    proxy->check_operation(
        EXPORTING
            input = request1
    ).
DATA(request2) = VALUE zco_appointment_activity_reque( ).
```

```

        proxy->check_operation(
            EXPORTING
                input = request2
        ).
" End EOIO sequence.
ws_sequence_facade->end_eoio_sequence( ).

COMMIT WORK.

CATCH cx_ws_protocol_error
    "handle response
CATCH cx_ai_system_fault.
    "handle error
CATCH cx_srt_check_oper_fault.
    "handle error
ENDTRY.

```

### 4.2.10.3.7.2 Set Up SOAP Communication

To set up SOAP communication, use the corresponding communication management apps.

#### Context

The communication management is done by the administrator in SAP Fiori launchpad.

#### Procedure

1. Create a communication system. A communication system determines which target system is called and which authentication methods are used. It also provides the user that is required to register at the target system. For more information, see [Communication Systems \[page 2397\]](#).
2. In the communication system, create an outbound communication user.
3. Create a communication arrangement. The communication arrangement is based on the communication scenario, that is created by the developer in ABAP Development Tools for Eclipse. For more information, see [How to Create a Communication Arrangement \[page 2395\]](#).

#### Result

The communication management established a connection to the system from which you want to consume the SOAP service. You can now perform the service call as described in [SOAP Communication via Communication Arrangements \[page 977\]](#).

## 4.2.10.3.73 SOAP Monitoring

### Prerequisites

You can find error logs related to SOAP services in the SOAP Error Log application. For more information, see [SOAP Error Log, OData Error Log, and Event Error Log \[page 2517\]](#)

To monitor asynchronous SOAP calls, use the Message Monitoring Overview app. To use the app, the following is required.

- Roles based on the following business catalogs are assigned to your user in SAP Fiori launchpad:
  - `SAP_CA_BC_COM_ERR_PC`
  - `SAP_CA_BC_COM_CONF_PC`

See [How to Define Authorizations Based on Restrictions \[page 2478\]](#) and [Business Catalogs \[page 2504\]](#) for more information.

- The user is a recipient of the `/SPRX` namespace. You can manage this in the Assign Recipients to Users app. See [Assign Recipients to Users \[page 2516\]](#) for more information.

### Context

**Asynchronous SOAP services:** When calling asynchronous SOAP services as described in [SOAP Communication via Communication Arrangements \[page 977\]](#), you can check if the call has been sent to the receiver using the Message Monitor Overview app. See [Message Monitoring Overview \[page 2513\]](#) for more information.

### Procedure

1. Create a Service Consumption Model (SRVC) of type `web_service` as described in [Creating Service Consumption Model](#).
2. Activate the SRVC. This creates a so-called AIF interface in the Message Monitor Overview app.

#### Note

For every operation in your Web service, a new AIF interface is generated.

3. Open the Message Monitoring Overview app.
4. Select the relevant AIF interface.

### Results

You've created an AIF interface for each operation in your asynchronous Web service. When you call an operation, you can monitor it in the Message Monitor Overview app.

## Related Information

[Set Up SOAP Communication \[page 988\]](#)

### 4.2.10.3.8 Mail Communication

Create a mail destination and enable mail communication from SAP BTP, ABAP environment

[Sending Mails Using SMTP \[page 990\]](#)

Send mails with the *Simple Message Transfer Protocol* (SMTP), using a mail server that is connected via the Cloud Connector.

#### 4.2.10.3.8.1 Sending Mails Using SMTP

Send mails using the Simple Message Transfer Protocol (SMTP).

You can send mails with the Simple Message Transfer Protocol (SMTP) using a mail server connected via the *SAP Business Technology Platform (SAP BTP), Cloud Connector* or use a publicly available SMTP server.

For more information, see [Configure Access Control \(TCP\)](#)

## Prerequisites

You must define the following configurations in a communication system. See [How to Create Communication Systems](#) for more information.

- Host
- Port
- Enable *Cloud Connector* to access your customer owned SMTP server
- Disable *Cloud Connector* when the communication is done directly to a publicly available SMTP server
- *SCC Location ID* of the SAP BTP Cloud Connector (only needed when the Cloud connector is enabled)

### Note

This parameter is only required if several SAP BTP, Cloud connectors are used in one subaccount (to define the target SAP BTP, Cloud Connector with the same *SCC Location ID*).

- A referenced outbound communication user with authentication method *User and Password*

### Note

- Instead of maintaining the information directly in the communication system, it's also possible to enter a referenced destination of type *MAIL* in the destination service. For more information, see [Create Mail Destinations](#).

Afterwards, create a communication arrangement for the SAP\_COM\_0548 communication scenario using this communication system.

## Application Programming Interface (API)

Use the `CL_BCS_MAIL_MESSAGE` class to create and send mails. You can specify sender and recipient. Furthermore, you can add textual body parts using class `CL_BCS_MAIL_TEXTPART` or binary attachments (e.g. PDF documents) represented by class `CL_BCS_MAIL_BINARYPART`, respectively.

With the send method of the API, the mail is sent via the mail server configured in the destination using the cloud connector. Sending is performed synchronously.

### Sample Code

```
try.
  data(lo_mail) = cl_bcs_mail_message=>create_instance( ).
  lo_mail->set_sender( 'noreply@yourcompany.com' ).
  lo_mail->add_recipient( 'recipient1@yourcompany.com' ).
  lo_mail->add_recipient( iv_address = 'recipient2@yourcompany.com' iv_copy
= cl_bcs_mail_message=>cc ).
  lo_mail->set_subject( 'Test Mail' ).
  lo_mail->set_main( cl_bcs_mail_textpart=>create_instance(
    iv_content      = '<h1>Hello</h1><p>This is a test mail.</p>'
    iv_content_type = 'text/html'
  ) ).
  lo_mail->add_attachment( cl_bcs_mail_textpart=>create_instance(
    iv_content      = 'This is a text attachment'
    iv_content_type = 'text/plain'
    iv_filename     = 'Text_Attachment.txt'
  ) ).
  lo_mail->send( importing et_status = data(lt_status) ).
catch cx_bcs_mail into data(lx_mail).
  "handle exceptions here
endtry.
```

## Bodyparts in a Message

Each mail message consists of one or more body parts (MIME parts). A body part consists of the text or binary content, the type and additional attributes like the filename for an attachment. A main body part (`SET_MAIN`) must be set and additional body parts can be set as attachments (`ADD_ATTACHMENT`) or alternatives (`ADD_MAIN_ALTERNATIVE`). Attachments are usually files that are attached to the mail. Alternative body parts are different representations of the main part of the email. For example, a mail can have an HTML representation and clients that can only display text or plain text will see this alternative body part.

The factory methods `CREATE_TEXT_PLAIN`, `CREATE_TEXT_HTML` of class `CL_BCS_MAIL_TEXTPART` can be used for the most common body parts. If a body part is to be sent with a different content-type, the `CREATE_INSTANCE` method can be used and a content-type can be passed.

For more information, see

- [Create Mail Destinations](#)

- [Communication Systems \[page 2397\]](#)
- [How to Create a Communication Arrangement \[page 2395\]](#)
- [Integrating On-Premise Systems \[page 1070\]](#)
- [Configure Access Control \(TCP\)](#)

## 4.2.10.4 Developing APIs for Inbound Communication

Learn more about developing APIs for inbound communication.

You can create and expose services for external consumption to a communication partner. To create and expose services for external consumption, you create a communication scenario and assign the required services.

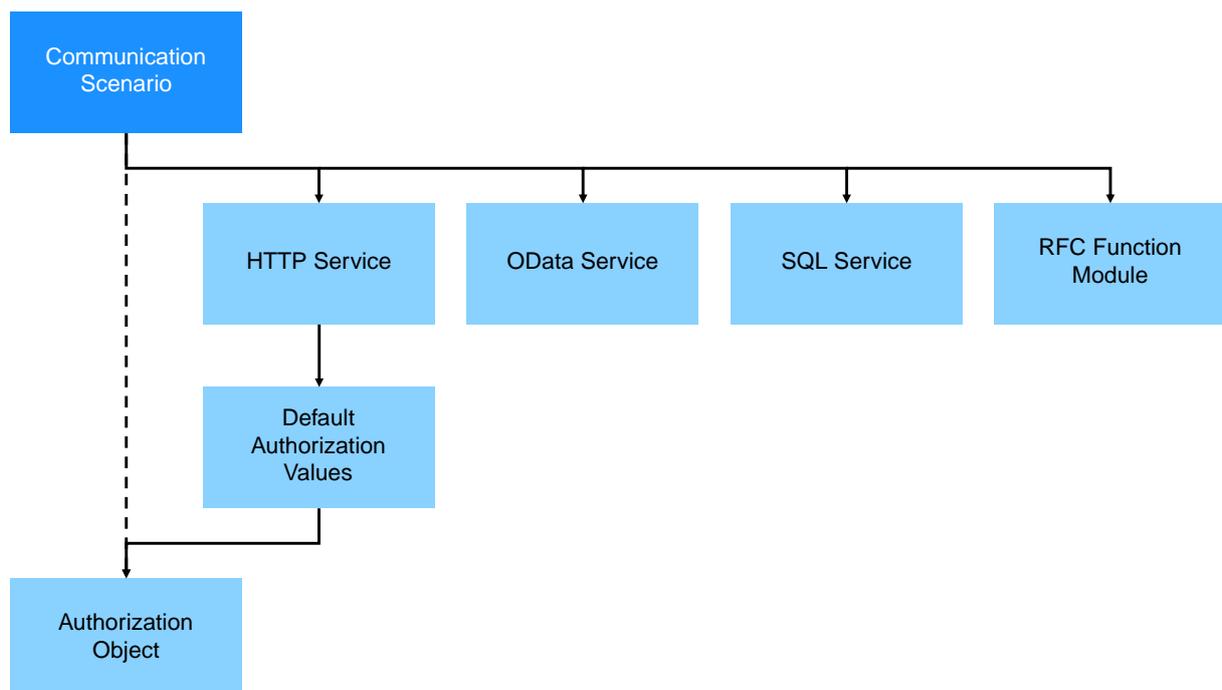

These inbound services can be:

- HTTP services, see [HTTP Service Development \[page 995\]](#)
- Remote-enabled function modules, see [Develop a Remote-Enabled Function Module \(RFM\) \[page 997\]](#)
- Services published via service bindings, such as OData or SQL services, see [Developing and Exposing an SQL Service in the ABAP System \[page 1106\]](#)

See also [Supported Protocols and Authentication Methods \[page 850\]](#).

Inbound services can be protected with an authorization object and protection against unauthorized activities. For each inbound service, authorization default values are defined that can later be used in the authorizations defined in the communication scenario. See [Granting Access Based on Activities for Communication Users \[page 794\]](#).

### ABAP System

## Related Information

[Communication Management \[page 846\]](#)

### 4.2.10.4.1 Create a Communication Arrangement for Inbound Communication with Service Key Type Basic

Learn how to quickly create a communication user and communication arrangement for an inbound communication scenario by using a service key of type basic.

#### Prerequisites

- You have created a communication scenario.
- You have created a space. See [Create Spaces](#).
- You have the space developer role. See [Assigning the Space Developer Role to the Developer Users](#).

#### Procedure

1. Log on to the cockpit and go to the subaccount that contains the space you'd like to navigate to. See [Navigate in the Cockpit](#).
2. In the navigation area, go to **Cloud Foundry** > **Spaces** and choose your space.
3. Select **Services** > **Instances** from the navigation area and find your ABAP system service instance.
4. Click on **...** and select [Create Service Key](#).
5. In the [New Service Key](#) dialog, enter a name for your service key and specify the parameters in JSON format as follows:

```
{
  "scenario_id": "SAP_COM_XYZ",
  "type": "basic"
}
```

#### Note

SAP\_COM\_XYZ is the ID of the communication scenario in your ABAP system.

basic is the type of service key that is needed to generate a communication user and communication arrangement for an inbound communication scenario.

## Results

The communication user is generated and the credentials, depending on the selected type, are returned in the service key. The communication user receives authorizations for all services included in the communication scenario.

### 4.2.10.4.2 Configure Timeout of @sap/approuter Component of a Communication Arrangement for Inbound Communication with Service Key OAuth

By default, communication between the approuter and connected services is timed out after 30 seconds. This default value is suitable for most applications. However, for long-lasting data transfer, communication lasts longer. If you experience timeouts, you can set the service key parameter `abap_endpoint_timeout` to a value higher than 30 seconds.

## Prerequisites

- You have created a space. See [Create Spaces](#).
- You have the space developer role. See [Assigning the Space Developer Role to the Developer Users](#).

## Procedure

1. Log on to the cockpit and go to the subaccount that contains the space you'd like to navigate to. See [Navigate in the Cockpit](#).
2. In the navigation area, go to ► [Cloud Foundry](#) ► [Spaces](#) ► and choose your space.
3. Select ► [Services](#) ► [Instances](#) ► from the navigation area and navigate to your ABAP system service instance.
4. Click on **•••** and select [Create Service Key](#).
5. In the [New Service Key](#) dialog, enter a name for your service key and specify the parameter in JSON format as follows:

```
{
  "abap_endpoint_timeout": 600000
}
```

#### Note

You can use s (seconds) or m (minutes) to define the value.

If no unit is defined, the value is interpreted as seconds.

The maximum value is 600s or 10m.

Learn how to set up and enable HTTP inbound communication.

[HTTP Service Development \[page 995\]](#)

#### 4.2.10.4.3.1 HTTP Service Development

With the ABAP environment, you can develop HTTP services in your ABAP Development Tools (ADT) in Eclipse.

For the implementation of your HTTP service, we provide the interface `IF_HTTP_SERVICE_EXTENSION` with HTTP request/response parameters, giving you the full flexibility to build an HTTP service of your choice. See [Working with the HTTP Service Editor](#) and [Tutorial: Create an HTTP Service](#).

## Related Information

[ABAP Development User Guide](#)

[Protection Against CSRF Attacks \[page 995\]](#)

#### 4.2.10.4.3.1.1 Protection Against CSRF Attacks

Protect against cross-side request forgery (CSRF) attacks by enabling CSRF token handling in the HTTP service.

To protect an HTTP service against CSRF attacks, you must implement the method `HANDLE_REQUEST` in the interface `IF_HTTP_SERVICE_EXTENSION` of the service. If this method is implemented, within a session each caller of the service must :

- Request a CSRF token by setting the header `X-CSRF-Token` with value `fetch`.
- Provide the specific CSRF token with each request of this session in header `X-CSRF-Token`, which is validated by the server.

The method `HANDLE_REQUEST`:

- Provides a CSRF token and adds it to the HTTP response, if the value `fetch` is present in the corresponding header field.
- Validates the CSRF token, if it is present in the header field of the request.
- Returns an error with the HTTP response, if validation fails.

### ⚠ Caution

If you have implemented the method `IF_HTTP_SERVICE_EXTENSION` for an HTTP service, all calls that do not request a CSRF token and provide it in the respective session are rejected. Only clients enabled for CSRF token handling can perform successful calls to the service in this case.

### Example

The code below shows an example for implementing the method `HANDLE_REQUEST` of the interface `IF_HTTP_SERVICE_EXTENSION` to enable correct CSRF token handling:

### 📄 Sample Code

```
method IF_HTTP_SERVICE_EXTENSION~HANDLE_REQUEST.
    data(lv_valid) = cl_http_service_utility=>handle_csrf(
        EXPORTING
            request = request
            response = response
        ).
    check lv_valid = abap_true.
    //Start der Implementierung des HTTP Services
    //Beginn der Anwendungslogik
endmethod.
```

## 4.2.10.4.4 RFC Inbound Communication

Learn how to set up and enable RFC inbound communication.

### [Develop a Remote-Enabled Function Module \(RFM\) \[page 997\]](#)

Develop RFMs in ABAP Development Tools (ADT).

### [Set Up the Cloud Connector for Inbound RFC from On-Premise Systems \(Deprecated\) \[page 998\]](#)

Configure inbound connectivity to the ABAP environment to consume a remote-enabled function module (RFM) from an on-premise ABAP system through the Cloud Connector.

### [Set Up Inbound RFC from On-Premise Systems Using WebSocket RFC \[page 1000\]](#)

Learn how to set up an inbound RFC connection from an on-premise system to the ABAP environment using WebSocket RFC. Get instructions on creating a communication scenario and arrangement, as well as the necessary settings in the on-premise system.

## 4.2.10.4.4.1 Develop a Remote-Enabled Function Module (RFM)

Develop RFMs in ABAP Development Tools (ADT).

You can develop RFMs in ABAP Development Tools (ADT) for Eclipse. For more information, see [Creating an ABAP Function Module](#).

In this tool, you create the respective RFM as you are used to in an on-premise system. Objects that are required to consume the RFM remotely are created automatically, such as authorization default values and the respective inbound service.

### Note

To enable automatic object creation for an RFM in ADT, choose *Properties* and select RFC as *<Processing Type>*. The default processing type is `Normal`. When activating an RFM of type `Normal`, no objects are generated.

For detailed information on consuming an RFM in an inbound communication scenario, see [Set Up the Cloud Connector for Inbound RFC from On-Premise Systems \(Deprecated\)](#) [page 998].

## RFC Metadata Integration (Communication Scenario SAP\_COM\_0636)

Instead of using classic RFC via CPI-C, you can also use RFC via WebSocket with SAP Java Connector (JCo) or other RFC connectors.

Optionally, you can configure these external RFC connectors to use a dedicated user to retrieve the metadata.

### Note

This scenario also applies for calls routed through the Cloud Connector.

Communication scenario `SAP_COM_0636` lets you separate metadata access for RFC calls by RFC client libraries from the actual RFC application call.

It provides access to the following function modules:

- `RFC_METADATA_GET`
- `RFC_FUNCTION_SEARCH`
- `RFC_GET_FUNCTION_INTERFACE`
- `DDIF_FIELDINFO_GET`

### Note

When using WebSocket RFC, you must use a host name that follows the pattern `<myTenantHost>.abap.hana.ondemand.com`.

## 4.2.10.4.4.2 Set Up the Cloud Connector for Inbound RFC from On-Premise Systems (Deprecated)

Configure inbound connectivity to the ABAP environment to consume a remote-enabled function module (RFM) from an on-premise ABAP system through the Cloud Connector.

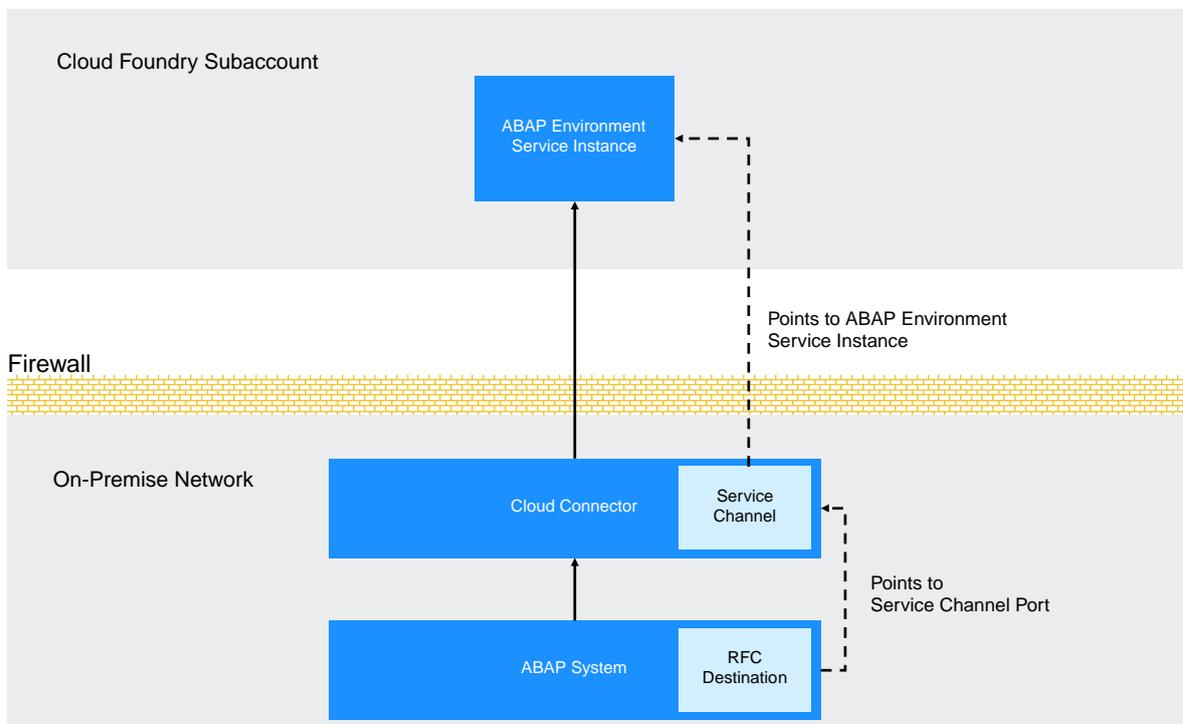

### Context

RFC connections from on-premise systems to the ABAP environment can be performed through a so called Cloud Connector *service channel*.

#### Note

Using Cloud Connector service channels is deprecated. Use WebSocket RFC instead. HTTP(S) or WebSocket RFC connections do not require the Cloud Connector because they can be opened directly on the Internet.

To establish an RFC connection from an on-premise system to the ABAP environment, the Cloud Connector opens an RFC port just like an RFC gateway and acts as a local proxy for the cloud system. Connections to this port are routed through a secure tunnel to SAP BTP.

In the Cloud Connector, you create a service channel with a local instance number. In the on-premise ABAP system, you correspondingly create an RFC destination in transaction SM59 with the hostname of the Cloud Connector in your on-premise network and the same instance number.

### 📘 Note

If you are using different ABAP instances on SAP BTP, create a service channel for each instance, choose an arbitrary instance number in the service channel settings of the Cloud Connector configuration, and use the same instance number in the RFC destination of your on-premise system (transaction SM59) to identify the called ABAP instance. Since the instance number is defined as a two-digit number, the number of target systems you can configure in the Cloud Connector is limited to 99.

## Prerequisites

- You have developed a communication scenario that contains the RFM to be called.
- You have created a communication arrangement of that scenario with a communication system and communication user.

### 📘 Note

To define authorizations for the communication user, use the authorization default values on inbound service level. These authorizations are automatically assigned to the respective communication user.

## Restrictions

- Only remote function modules that are part of a communication scenario can be called from an on-premise system. Most others are blocked, except for the system function module RFCPING.
- An inbound RFC connection supports only *basic authentication* as authentication type.
- The user used for authentication must be a *communication* user, a *business* user is not allowed.
- The user name you can enter in an RFC destination of an on-premise ABAP system is limited to 12 characters.

## Procedure

1. To establish a service channel, configure it in the Cloud Connector as described in [Configure a Service Channel for RFC](#).

### 📘 Note

When creating a service channel for the ABAP environment, the URL of the ABAP instance (tenant host) follows the pattern `<myTenantHost>.abap.hana.ondemand.com` (not `<myTenantHost>-api...`, which is valid only for connections to S/4HANA Cloud). Make sure you create the service channel for the correct subaccount.

2. Create an RFC destination in the on-premise system:
  - Use connection type 3 (RFC connection to an ABAP system).

- Do not configure your destination in the ABAP system as a load-balanced destination. Specify one target host. If you want to use load balancing, this must be the host of the TCP load balancer.
- Provide logon credentials for a communication user, including the client information. The ABAP environment always uses client 100.
- Use the connection test in transaction SM59 to verify that the service channel works correctly.

#### ⓘ Note

When calling an RFM, you must write its name in *upper case*.

### 4.2.10.4.4.3 Set Up Inbound RFC from On-Premise Systems Using WebSocket RFC

Learn how to set up an inbound RFC connection from an on-premise system to the ABAP environment using WebSocket RFC. Get instructions on creating a communication scenario and arrangement, as well as the necessary settings in the on-premise system.

#### Context

Use WebSocket RFC to establish an RFC connection from an on-premise system to the ABAP environment. WebSocket RFC makes it possible to call RFC function modules of the ABAP environment using the API URL of the cloud system using TLS-encrypted WebSocket connections.

#### ⓘ Note

All WebSocket-RFC-connections are TLS-encrypted. WebSocket RFC always uses HTTPS.

#### Procedure

1. Create a Communication Scenario that defines all RFMs to be called on the server side (inbound scenario). See [Communication Scenario \[page 847\]](#) for more information.
2. Create a Communication Arrangement with a Communication System and a Communication User. See the following for more information:
  - [Communication Arrangement \[page 848\]](#)
  - [Communication System \[page 847\]](#)
  - [Communication User \[page 848\]](#)

## Settings in the On-Premise System

In the on-premise system, the following parameters must be set in transaction SM59.

Create a destination of connection type w:

### Technical Settings

Host	The API-URL defined in the Communication Arrangement without the <b>https://</b> prefix
Port	<b>443</b>

### Logon & Security

Explicit Client	by Hostname
Authentication Method	by User/Password
	by X.509 Certificate

#### Note

If you choose user/password authentication, activate *Alias User*.

#### Note

These settings are available with SAP S/4HANA 1909. For older releases, you need to transform from a CPIC-based RFC to WebSocket RFC via Business Connector. See [SAP Business Connector](#) for more information.

## 4.2.10.4.5 SOAP Inbound Communication

Learn how to set up and enable SOAP inbound communication.

## 4.2.10.4.5.1 Generate Provider Proxies From WSDL Files

SOAP-based provider proxies are generated using a so-called SOAP Provider Model (SPRV).

### Prerequisites

You have created a communication scenario as described in [Defining a Communication Scenario Including Authorization Values](#) [page 800].

### Context

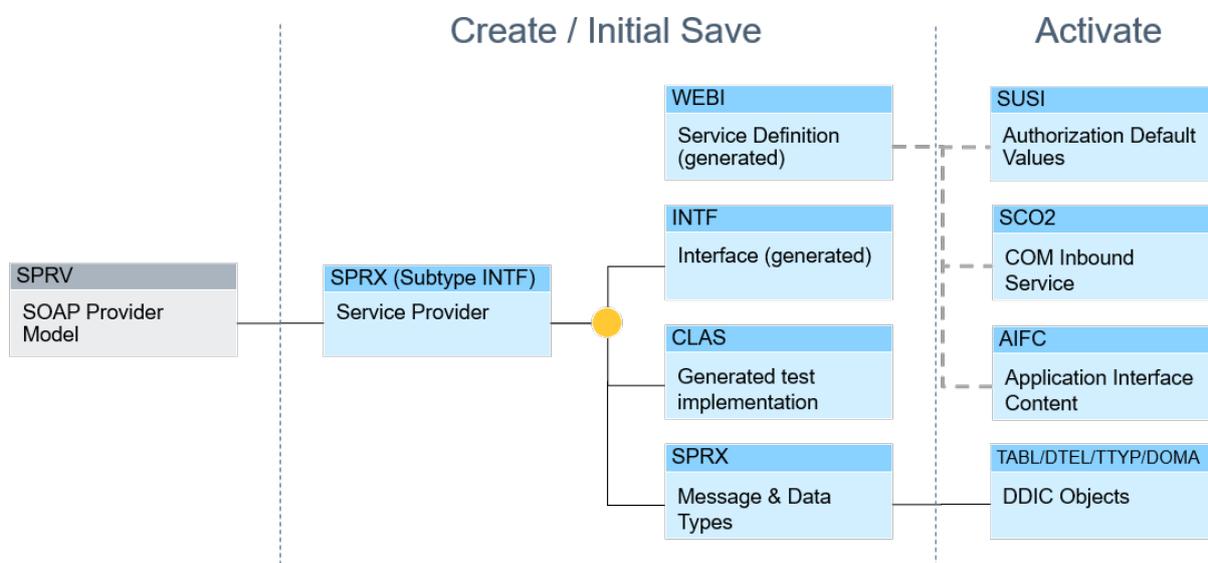

With the SOAP Provider Model (SPRV), you can generate the proxy objects that are required for providing SOAP services, based on a WSDL file that describe your service. The SPRV is mainly used to provide a corresponding inbound service for an exposed outbound service.

#### ❁ Example

An external system triggers a confirmation in your system to inform the external system about the creation of an appointment activity. To receive this information, a provider proxy for this service must be implemented in your system. This provider proxy is generated by the SPRV.

During and after activation, the following objects are generated:

- Proxy objects
- DDIC-objects, e.g. the required data elements
- The service definition
- Application Interface Framework objects for monitoring
- The required inbound services for the communication scenario
- The authorization default values

### ⚠ Restriction

It is not possible to model web services in ABAP development tools for Eclipse. To use the SPRV, you must use a WSDL file that describes the service interface.

## Procedure

1. Based on the WSDL file of the service you want to provide, create an SPRV as described in [Creating SOAP Service Providers](#).
2. Activate the SPRV.
3. Add the generated inbound service to the relevant communication scenario.
4. Publish the communication scenario locally to make it available for the administrator in SAP Fiori launchpad.

## Next Steps

The SPRV generates an implementing class of the service you want to provide. To provide the functionality of your service, add the required application logic to the generated implementing class. Afterwards, activate the implementing class.

### 📘 Note

When deleting the SPRV, the implementing class is not deleted to avoid data loss. All other generated objects that depend on the SPRV are deleted with the SPRV.

Based on the communication scenario, the administrator can create a communication system, inbound user, and communication arrangement, to make the service available for consumption. For more information, see [Communication Management \[page 846\]](#), and [SOAP Outbound Communication \[page 972\]](#)

## 4.2.10.5 SAP-Provided APIs

[Inbound Service: Business User \[page 1004\]](#)

[Inbound Service: Business User - Read \[page 1021\]](#)

[Business User - Read Metadata \[page 1036\]](#)

[Manage Git Repository \[page 1043\]](#)

The Manage Git Repository API allows you to manage software components (Git repositories) on an SAP BTP ABAP Environment system.

## 4.2.10.5.1 Inbound Service: Business User

Technical name: `MANAGEBUSINESSUSERIN`

This synchronous inbound SOAP service enables you to create, update, and delete business users from your external data sources, such as an identity management system. Deleting business users doesn't mean you've actually deleted them yet. The user assigned to the business user is deleted and the `MarkedForArchivingIndicator` has been set. Only during the ILM process the business user is physically deleted.

You can assign business role IDs to the users at the node `Role`.

We recommend processing blocks of 10 users to a maximum of 100 users. Otherwise, the target system may time out.

This service supports the business users Employee (BUP003).

### ⚠ Caution

This service directly influences the data and authorizations of business users. Changes are effective immediately in the target system.

Make sure to maintain only those authorizations that are intended for what a user needs to do in the system. Not doing so can cause security issues.

## Service Request

The service is structured into the following two top-level nodes:

### Message Header (`MessageHeader`)

The service message header is not in use in this service.

### Business User (`BusinessUser`)

The service nodes contain the service's business data.

### 📌 Note

In the following table, attributes are marked in blue.

Nodes and Fields for the BusinessUser Node

Node or Field	Description	Maximum Field Length	Cardinality	Necessity
PersonExternalID	The Person External ID is the ID of the employee.	60	0..1	Mandatory for create for business partner category (BUP003 - Employee).  Optional for update (at least one of the person IDs is mandatory.)
PersonID	Person ID is the ID of the business partner.	10	0..1	Optional  (At least one of the person IDs is mandatory.)
PersonUUID	Person UUID is the unique ID of the business partner.	36	0..1	Optional  (At least one of the person IDs is mandatory.)
BusinessPartnerRoleCode	Business Partner Role Code	6	0..1	Mandatory for create for Business partner category (BUP003 - Employee).  Optional for update.

Node or Field	Description	Maximum Field Length	Cardinality	Necessity
MarkedForArchivingIndicator	<p>Mark for Archiving</p> <p>Set to <b>True</b>:</p> <ul style="list-style-type: none"> <li>The business user will be archived</li> <li>The actionCode [1] for User must be set to 02</li> </ul> <p>Set to <b>False</b>:</p> <ul style="list-style-type: none"> <li>The business user will be reactivated (Undo Archive)</li> <li>The actionCode [1] for User must be set to 02</li> </ul>		0..1	Optional
ValidityPeriod	<p>StartDate</p> <p>Format: YYYY-MM-DD</p> <p>By default, the system date is set.</p>		0..1	Optional
	<p>EndDate</p> <p>Format: YYYY-MM-DD</p> <p>By default, 9999-12-31 is set.</p>		0..1	Optional
PersonalInformation	<p>FormOfAddress</p> <p>Form of address</p>	4	0..1	Optional

Node or Field	Description	Maximum Field Length	Cardinality	Necessity	
Cardinality: 0..1	FirstName	First name	40	0..1	Optional
	LastName	Last name This field is mandatory.	40	0..1	Mandatory
	PersonFullName	Person full name	80	0..1	Optional
	AcademicTitle	Academic title	4	0..1	Optional
	CorrespondenceLanguage	Correspondence language	9	0..1	Optional
	MiddleName	Middle name	40	0..1	Optional
	AdditionalLastName	Additional last name	40	0..1	Optional
	BirthName	Birth name	40	0..1	Optional
	NickName	Nick name	40	0..1	Optional
	Initials	Initials	10	0..1	Optional
	AcademicSecondTitle	Academic second title	4	0..1	Optional
	LastNamePrefix	Last name prefix	4	0..1	Optional
	LastNameSecondPrefix	Last name second prefix	4	0..1	Optional
	NameSupplement	Name supplement	4	0..1	Optional

Node or Field	Description	Maximum Field Length	Cardinality	Necessity	
actionCode	<p>You can use the following values:</p> <ul style="list-style-type: none"> <li>• 01 - Create</li> <li>• 02 - Update</li> <li>• 03 - Delete</li> </ul> <p>Mandatory if [2] is not set and personal information data are given.</p>	2	optional	Optional	
User (only for Cloud)	UserName	User name/ Alias	40	0..1	Optional
Cardinality: 0..1	LogonLanguageCode	Logon language	9	0..1	Optional

**Note**

For more information about default values, see [Defaulting of User Attributes](#).

Node or Field	Description	Maximum Field Length	Cardinality	Necessity
DateFormatCode	<p>You can use the following values:</p> <ul style="list-style-type: none"> <li>• 1 - DD.MM.YY YY (Gregorian Date)</li> <li>• 2 - MM/DD/YYYY (Gregorian Date)</li> <li>• 3 - MM-DD-YYYY (Gregorian Date)</li> <li>• 4 - YYYY.MM.DD (Gregorian Date)</li> <li>• 5 - YYYY/MM/DD (Gregorian Date)</li> <li>• 6 - YYYY-MM-DD (Gregorian Date, ISO 8601)</li> <li>• 7 - GYY.MM.D (Japanese Date)</li> <li>• 8 - GYY/MM/DD (Japanese Date)</li> <li>• 9 - GYY-MM-DD</li> </ul>	2	0..1	Optional

Node or Field	Description	Maximum Field Length	Cardinality	Necessity
	(Japanese Date) <ul style="list-style-type: none"> <li>A - YYYY/MM/DD (Islamic Date 1)</li> <li>B - YYYY/MM/DD (Islamic Date 2)</li> <li>C - YYYY/MM/DD (Iranian Date)</li> </ul>			
DecimalFormatCode	You can use the following values: <ul style="list-style-type: none"> <li>1.234.567,89</li> <li>X - 1,234,567.89</li> <li>Y - 1234567,89</li> </ul>	2	0..1	Optional
TimeZoneCode	Time zone	10	0..1	Optional

Node or Field	Description	Maximum Field Length	Cardinality	Necessity
TimeFormatCode	<p>You can use the following values:</p> <ul style="list-style-type: none"> <li>• 0 - 24 Hour Format (Example: 12:05:10)</li> <li>• 1 - 12 Hour Format (Example: 12:05:10 PM)</li> <li>• 2 - 12 Hour Format (Example: 12:05:10 pm)</li> <li>• 3 - Hours from 0 to 11 (Example: 00:05:10 PM)</li> <li>• 4 - Hours from 0 to 11 (Example: 00:05:10 pm)</li> </ul>	2	0..1	Optional
LockedIndicator	Locked indicator	5	0..1	Optional
ValidityPeriod	<p>Format: YYYY-MM-DD</p> <p>If the start date is not maintained for the User, the StartDate for the BusinessUser is entered.</p>		1	Optional

Node or Field		Description	Maximum Field Length	Cardinality	Necessity
	EndDate	Format: YYYY-MM-DD  If the EndDate is not maintained, it is set to 9999-12-31.		1	Optional
Role	RoleName	Role name	40	1	Optional
Cardinality: 0..unbounded	actionCode	You can use the following values: <ul style="list-style-type: none"><li>• 01 - Create</li><li>• 03 - Delete</li></ul> Mandatory if [6] is not set and role name data is given.	2	Optional	Optional
GlobalUserID		Used to uniquely identify your business user across different systems.	36		Optional
UserGroupCode		Assign a business user to an existing user group.	12	0..1	Optional

Node or Field	Description	Maximum Field Length	Cardinality	Necessity	
	actionCode You can use the following values: <ul style="list-style-type: none"> <li>01 - Create</li> <li>02 - Update</li> <li>03 - Delete</li> </ul> Mandatory if [3] is not set and user data (UserName and Role) are given.	2	Optional	Optional	
	[6] roleListCompleteTransmissionIndicator CTI for the Role node See <a href="#">CTI note [page 1017]</a> for more information.		Optional	Optional	
UserAssignment (only for on-premise)	UserID	User ID	12	1	N/A
Cardinality: 0..1	actionCode You can use the following values: <ul style="list-style-type: none"> <li>01 - Create</li> <li>02 - Update</li> <li>03 - Delete</li> </ul> Mandatory if [4] is not set and User ID data are given.	2	Optional	N/A	
WorkplaceInformation	EmailAddress	Email address	241	0..1	N/A
	PhoneInformation PhoneType Cardinality: 0..2 One set of phone informa-	Phone type <ul style="list-style-type: none"> <li>B - Business</li> <li>C - Cell</li> </ul>	1	1	N/A

Node or Field	Description	Maximum Field Length	Cardinality	Necessity

[5] relationshipListCompleteTransmissionIndicator			Optional	Optional

### Note

#### Complete Transmission Indicator (CTI)

The complete transmission indicator represents the state of the data in the inbound XML. There are multiple transmission indicators that represent the state of the corresponding segment. The transmission indicator is interpreted by the web service:

- If a complete transmission indicator is set to true, the existing data is overwritten by the newly entered data.
- If a complete transmission indicator is set to false, the value of the action code of the corresponding node applies.
- If an action code and the complete transmission indicator are set, then the action code of the corresponding node applies.

## Service Response

You receive a confirmation message response for each bundle of business users you send. If the service request is processed, a confirmation message is sent. This contain crucial information provided by the fields `PersonExternalID`, `PersonID`, and `PersonUUID` for each business user of the bundle.

The following table provides an overview of the response structure for the `BusinessUser` service node.

Field or Node	Description	Maximum Field Length	Cardinality
<code>PersonExternalID</code>	Person External ID	60	0..1
<code>PersonID</code>	Person ID	10	0..1
<code>PersonUUID</code>	Person UUID	36	0..1
Log Cardinality: 1	<code>BusinessDocumentProcessingResu ltCode</code> Not in use	2	0..1

Field or Node		Description	Maximum Field Length	Cardinality
MaximumLogItemSeverityCode		If several messages are stored for a business user, the maximum of all received severity codes the most severe level will be shown.	1	0..1
Item Cardinality: 0..unbounded	TypeID	Message number	40	0..1
	CategoryCode	Not in use	15	0..1
	SeverityCode	Severity code definition: <ul style="list-style-type: none"> <li>1 - Information</li> <li>2 - Warning</li> <li>3 - Error</li> </ul>	1	0..1
	Note	Contains the message texts.	200	1
	WebURI	Not in use		0..1

## Error Codes

Error Code	Description
104	<p>Combination of Ext. ID &amp;1 and ID &amp;2 inconsistent. Processing cancelled.</p> <p>PersonExternalID and PersonID have a 1:1 relationship. Enter thePersonID that corresponds with the PersonExternalID.</p>
105	<p>Combination of Ext. ID &amp;1 and UUID &amp;2 inconsistent.</p> <p>Person ExternalID and PersonUUID have a 1:1 relationship.</p> <p>Enter thePersonUUID that corresponds with the PersonExternalID</p>

## Constraints

This service does not support:

- Freelancer (BBP010) business users

## Additional Information

### Note

For more details about Communication Management, see [Communication Management \[page 2390\]](#).

## 4.2.10.5.2 Inbound Service: Business User - Read

Technical name: QUERYBUSINESSUSERIN

This synchronous inbound SOAP service enables you to read users from your external data source such as an identity management system in SAP S/4HANA Cloud.

## Service Request

The service is structured into the following two top-level nodes:

### Business User (BusinessUser)

The service node contains the search parameters.

Nodes and Fields for the BusinessUser Node

Field or Node	Description	Maximum Field Length	Cardinality
PersonExternalIDInterval	IntervalBoundaryTypeCode  The following values exist:  <ul style="list-style-type: none"> <li>1- Equal No upper boundary value must be set.</li> <li>3 - Between Upper boundary value is mandatory.</li> <li>6 - Lower than Upper boundary value is optional.</li> <li>7 - Lower equal Upper boundary value is optional.</li> <li>8 - Greater than Upper boundary value is optional.</li> <li>9 - Greater equal Upper boundary value is optional.</li> </ul> This field is mandatory if LowerBoundaryPersonExtID is set.	1	1
LowerBoundaryPersonExtID	Employee name	60	0..1
UpperBoundaryPersonExtID		60	0..1

Field or Node	Description	Maximum Field Length	Cardinality
PersonIDInterval Cardinality: 0..un- bounded	IntervalBoundaryT ypeCode  The following values exist: <ul style="list-style-type: none"> <li>1- Equal No upper boundary value must be set.</li> <li>3 - Between Upper boundary value is mandatory.</li> <li>6 - Lower than Upper boundary value is optional.</li> <li>7 - Lower equal Upper boundary value is optional.</li> <li>8 - Greater than Upper boundary value is optional.</li> <li>9 - Greater equal Upper boundary value is optional.</li> </ul> This field is mandatory if LowerBoundaryPersonID is set.	1	1
	LowerBoundaryPersonID	10	0..1
	UpperBoundaryPersonID	10	0..1

Field or Node		Description	Maximum Field Length	Cardinality
BusinessPartnerRoleCodeInterval	IntervalBoundaryTypeCode	The following values exist: <ul style="list-style-type: none"> <li>1- Equal No upper boundary value must be set.</li> <li>3 - Between Upper boundary value is mandatory.</li> <li>6 - Lower than Upper boundary value is optional.</li> <li>7 - Lower equal Upper boundary value is optional.</li> <li>8 - Greater than Upper boundary value is optional.</li> <li>9 - Greater equal Upper boundary value is optional.</li> </ul> <p>This field is mandatory if LowerBoundaryBusinessPartnerRoleCode is set.</p>	1	1
	LowerBoundaryBusinessPartnerRoleCode	Only business partner role code BUP003 (Employee) is supported.	6	0..1
MarkedForArchivingIndicator	IntervalBoundaryTypeCode	The following values exist: <ul style="list-style-type: none"> <li>True</li> <li>False</li> </ul>		1
	LowerBoundaryMarkedForArchivingIndicator		1	0..1

Field or Node		Description	Maximum Field Length	Cardinality
UserIDInterval Cardinality: 0..un- bounded	IntervalBoundaryT ypeCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>• 1- Equal No upper boundary value must be set.</li> <li>• 3 - Between Upper boundary value is mandatory.</li> <li>• 6 - Lower than Upper boundary value is optional.</li> <li>• 7 - Lower equal Upper boundary value is optional.</li> <li>• 8 - Greater than Upper boundary value is optional.</li> <li>• 9 - Greater equal Upper boundary value is optional.</li> </ul> <p>This field is mandatory if LowerBoundaryUser ID is set.</p>	1	1
	LowerBoundaryUser ID		12	0..1
	UpperBoundaryUser ID		12	0..1

Field or Node		Description	Maximum Field Length	Cardinality
UserNameInterval Cardinality: 0..un- bounded	IntervalBoundaryT ypeCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>• 1- Equal No upper boundary value must be set.</li> <li>• 3 - Between Upper boundary value is mandatory.</li> <li>• 6 - Lower than Upper boundary value is optional.</li> <li>• 7 - Lower equal Upper boundary value is optional.</li> <li>• 8 - Greater than Upper boundary value is optional.</li> <li>• 9 - Greater equal Upper boundary value is optional.</li> </ul> <p>This field is mandatory if LowerBoundaryUser Name is set.</p>	1	1
	LowerBoundaryUser Name		40	0..1
	UpperBoundaryUser Name		40	0..1

Field or Node		Description	Maximum Field Length	Cardinality
FirstNameInterval	IntervalBoundaryTypeCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>1- Equal No upper boundary value must be set.</li> <li>3 - Between Upper boundary value is mandatory.</li> <li>6 - Lower than Upper boundary value is optional.</li> <li>7 - Lower equal Upper boundary value is optional.</li> <li>8 - Greater than Upper boundary value is optional.</li> <li>9 - Greater equal Upper boundary value is optional.</li> </ul> <p>This field is mandatory if LowerBoundaryFirstName is set.</p>	1	1
	LowerBoundaryFirstName		35	0..1
	UpperBoundaryFirstName		35	0..1

Field or Node		Description	Maximum Field Length	Cardinality
LastNameInterval Cardinality: 0..un- bounded	IntervalBoundaryT ypeCode	The following values exist: <ul style="list-style-type: none"> <li>• 1- Equal No upper boundary value must be set.</li> <li>• 3 - Between Upper boundary value is mandatory.</li> <li>• 6 - Lower than Upper boundary value is optional.</li> <li>• 7 - Lower equal Upper boundary value is optional.</li> <li>• 8 - Greater than Upper boundary value is optional.</li> <li>• 9 - Greater equal Upper boundary value is optional.</li> </ul> <p>This field is mandatory if LowerBoundaryLast Name is set.</p>	1	1
	LowerBoundaryLast Name		40	0..1
	UpperBoundaryLast Name		40	0..1
	EmailAddressInter val	IntervalBoundaryT ypeCode		1
Cardinality: 0..un- bounded	LowerBoundaryEmai lAddress		241	0..1
	UpperBoundaryEmai lAddress		241	0..1

### Query Processing Conditions (QueryProcessingConditions)

The service nodes contain the service's business data.

## Fields for the QueryProcessingConditions Node

Field	Description	Maximum Field Length	Cardinality
QueryHitsTotalNumberIndicator	The following values exist: <ul style="list-style-type: none"> <li>• True</li> <li>• False (default)</li> </ul>		1
QueryHitsMaximumNumberValue	Enter the maximum number of hits. If no value is entered, the default is automatically set to 1000.	999999999	0..1
QueryHitsUnlimitedIndicator	The following values exist: <ul style="list-style-type: none"> <li>• True</li> <li>• False (default)</li> </ul> Set <b>True</b> to get all data based on selection criteria.		1
QueryLastReturnedObjectID	The following values exist: <ul style="list-style-type: none"> <li>• True</li> <li>• False (default)</li> </ul> If QueryHitsMaximumNumberValue is set and more data is available, you can set this value to <b>True</b> .		0..1

## Sample Payload

### Sample Code

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:aba="http://sap.com/xi/ABA">
  <soapenv:Header/>
  <soapenv:Body>
    <aba:BusinessUserSimpleByElementsQuery_sync>
      <BusinessUser>
        <PersonIDInterval>
          <IntervalBoundaryTypeCode>1</IntervalBoundaryTypeCode>
          <!--Optional:-->
          <LowerBoundaryPersonID>9980035943</LowerBoundaryPersonID>
          <!--Optional:-->
        </PersonIDInterval>
        <BusinessPartnerRoleCodeInterval>
          <IntervalBoundaryTypeCode>1</IntervalBoundaryTypeCode>
          <!--Optional:-->
          <LowerBoundaryBusinessPartnerRoleCode>bup003</
LowerBoundaryBusinessPartnerRoleCode>
        </BusinessPartnerRoleCodeInterval>
      </BusinessUser>
      <QueryProcessingConditions>
        <!--Optional:-->
        <QueryHitsMaximumNumberValue>1</QueryHitsMaximumNumberValue>
        <QueryHitsUnlimitedIndicator>>false</QueryHitsUnlimitedIndicator>
      </QueryProcessingConditions>
    </aba:BusinessUserSimpleByElementsQuery_sync>
```

```
</soapenv:Body>
</soapenv:Envelope>
```

## Service Response

### Business User (BusinessUser)

#### Note

The fields below the node `User` will be filled.

Node or Field	Description	Maximum Field Length	Cardinality
PersonExternalID	Person External ID	60	0..1
PersonID	Person ID	10	1
PersonUUID	Person UUID	36	1
BusinessPartnerRoleCode	Business Partner Role Code	6	1
MarkedForArchivingIndicator	<ul style="list-style-type: none"> <li>True</li> <li>False</li> </ul>		1
ValidityPeriod	StartDate	Format: YYYY-MM-DD	1
Cardinality: 0..1	EndDate	Format: YYYY-MM-DD	1
PersonalInformation	FormOfAddress	Form of address	4
Cardinality: 0..1	FirstName	First name	40
	LastName	Last name	40
	PersonFullName	Person full name	80
	AcademicTitle	Academic title	4
	CorrespondenceLanguage	Correspondence language	9
	MiddleName	Middle name	40

Node or Field		Description	Maximum Field Length	Cardinality
	AdditionalLastName	Additional last name	40	0..1
	BirthName	Birth name	40	0..1
	NickName	Nick name	40	0..1
	Initials	Initials	10	0..1
	AcademicSecondTitle	Academic second title	4	0..1
	LastNamePrefix	Last name prefix	4	0..1
	LastNameSecondPrefix	Last name second prefix	4	0..1
	NameSupplement	Name supplement	4	0..1
User (only for Cloud) Cardinality: 0..1	UserID	User ID	12	1
	UserName	User name/Alias	40	1
	LogonLanguageCode	Logon language	9	0..1

Node or Field	Description	Maximum Field Length	Cardinality
DateFormatCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>• 1 - DD.MM.YYYY (Gregorian Date)</li> <li>• 2 - MM/DD/YYYY (Gregorian Date)</li> <li>• 3 - MM-DD-YYYY (Gregorian Date)</li> <li>• 4 - YYYY.MM.DD (Gregorian Date)</li> <li>• 5 - YYYY/MM/D (Gregorian Date)</li> <li>• 6 - YYYY-MM-DD (Gregorian Date, ISO 8601)</li> <li>• 7 - GYY.MM.DD (Japanese Date)</li> <li>• 8 - GYY/MM/DD (Japanese Date)</li> <li>• 9 - GYY-MM-DD (Japanese Date)</li> <li>• A - YYYY/MM/D (Islamic Date 1)</li> <li>• B - YYYY/MM/D (Islamic Date 2)</li> </ul>	2	0..1

Node or Field	Description	Maximum Field Length	Cardinality
	<ul style="list-style-type: none"> <li>C - YYYY/MM/D D (Iranian Date)</li> </ul>		
DecimalFormatCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>1.234.567,89</li> <li>X - 1,234,567.89</li> <li>Y - 1 234 567,89</li> </ul>	2	0..1
TimeZoneCode	Time zone	10	0..1
TimeFormatCode	<p>The following values exist:</p> <ul style="list-style-type: none"> <li>0 - 24 Hour Format (Example: 12:05:10)</li> <li>1 - 12 Hour Format (Example: 12:05:10 PM)</li> <li>2 - 12 Hour Format (Example: 12:05:10 pm)</li> <li>3 - Hours from 0 to 11 (Example: 00:05:10 PM)</li> <li>4 - Hours from 0 to 11 (Example: 00:05:10 pm)</li> </ul>	2	0..1
LockedIndicator	Locked indicator	5	0..1

Node or Field			Description	Maximum Field Length	Cardinality
ValidityPeriod	StartDate		Format: YYYY-MM-DD  If no start date is maintained for the User, the StartDate for the BusinessUser is entered.		1
	EndDate		Format: YYYY-MM-DD  If no EndDate is maintained, it is set to 9999-12-31.		1
Role	RoleName		Role name	40	1
Cardinality: 0..unbounded					
UserAssignment (only for on-premise)	UserID		User ID	12	1
	UserName			40	0..1
	UserAssignmentStatusCode		The following values exist: <ul style="list-style-type: none"><li>1 - is reserved</li><li>2 - is assigned</li></ul>	1	1
Cardinality: 0..1					
WorkplaceInformation	EmailAddress		Email address	241	0..1
	PhoneInformation	PhoneType	Phone type	1	1
		CountryDialingCode	Country dialing code	10	0..1
		PhoneNumberAreaID	Phone number area code	10	0..1
		PhoneNumberSubscriberID	Phone number subscriber ID	30	0..1
		PhoneNumberExtension	Phone number extension	10	0..1
Cardinality: 0..1 One set of phone information per phone type supported.					

Node or Field	Description	Maximum Field Length	Cardinality
FunctionalTitleName	Functional title name	40	0..1
Department	Department name	40	0..1
RoomNumber	Room number	10	0..1
Building	Building name	10	0..1

### Response Processing Conditions (ResponseProcessingConditions)

Field	Description	Maximum Field Length	Cardinality
HitsTotalNumberValue	Contains the number of users based on given criteria.	999999999	1
ReturnedQueryHitsNumberValue	Contains the number of found data sets for business users.	999999999	1
MoreHitsAvailableIndicator	The indicator is set if the query was limited to a number of hits, but more business user data sets are available based on the query.		1
LastReturnedObjectID	Displays the last row of the results list limited by the found hits or by the value given for QueryHitsMaximumNumberValue.	999999999	0..1

### Log (Log)

If errors occur, the log contains the information shown in the table below:

Field or Node	Description	Maximum Field Length	Cardinality
BusinessDocumentProcessingResultCode		2	0..1
MaximumLogItemSeverityCode	If several messages are stored for a business user, the most severe level is shown from the maximum of all received severity codes.	1	0..1

Field or Node		Description	Maximum Field Length	Cardinality
Item  Cardinality: 0..unbounded	TypeID	Message number	40	0..1
	CategoryCode	Not in use	15	0..1
	SeverityCode	Severity code definition: <ul style="list-style-type: none"> <li>• 1 - Information</li> <li>• 2 - Warning</li> <li>• 3 - Error</li> </ul>	1	0..1
	Note	Contains the message texts.	200	1
	WebURI	Not in use		0..1

## Constraints

This service does not support:

- Freelancer (BBP010) business users

## Additional Information

### ⓘ Note

For more details about Communication Management, see [Communication Management \[page 2390\]](#).

## 4.2.10.5.3 Business User - Read Metadata

Technical name: `QueryBusinessUserMetadataIn`

This service enables you to read metadata information from your external data source such as an identity management system for service Business User with this synchronous inbound service.

This service provides the search parameter `RoleCategory`, which restricts the result set of the metadata information of the service. The response includes the metadata information based on the given criteria. If errors occur, the log contains information about the severity code, the message number and message texts.

This service is available on the SAP Business Accelerator Hub, for more information see [APIs on SAP Business Accelerator Hub](#).

## Service Request

### Service Nodes

The service nodes contain the service's business data.

Node or Field	Description	Cardinality
BusinessPartnerRoleCategoryInterval	IntervalBoundaryTypeCode You can only use the following value:	1..1
Cardinality: 0..unbounded	<ul style="list-style-type: none"> <li>1 - Equal</li> </ul>	
	LowerBoundaryBusinessPartnerRoleCategoryCode For example: BUP003	0..1

### Sample Payload

#### Sample Code

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:aba="http://sap.com/xi/ABA">
  <soapenv:Header/>
  <soapenv:Body>
    <aba:BusinessUserMetaDataQuery_sync>
      <!--Zero or more repetitions!-->
      <BusinessPartnerRoleCategoryInterval>
        <IntervalBoundaryTypeCode>1</IntervalBoundaryTypeCode>
        <LowerBoundaryBusinessPartnerRoleCategoryCode>BUP003</
LowerBoundaryBusinessPartnerRoleCategoryCode>
      </BusinessPartnerRoleCategoryInterval>
    </aba:BusinessUserMetaDataQuery_sync>
  </soapenv:Body>
</soapenv:Envelope>
```

## Service Response

Service Node	Description	Link to Details
BusinessUserMetaData	RoleCategoryDependentMetaData This node contains all meta-data, which depends on the role category of a business user, such as the role category with its role, external ID category with its external ID type or relationship category.	<a href="#">RoleCategoryDependentMetaData [page 1039]</a>

Service Node	Description	Link to Details
CodeList	This node provides the available code lists for SAP specific codes. For example country/region code, academic title.	<a href="#">CodeList [page 1041]</a>
Log	This nodes displays occurred messages.	<a href="#">Log [page 1042]</a>

## Error Codes

Error Code	Message	Description
112	Interval Boundary Type Code &1 is not supported for BusinessPartnerRoleCategoryInterval.	You can only use the following value: <ul style="list-style-type: none"> <li>1 - Equal</li> </ul>
118	No data found by given search criteria.	To display all data, don't enter any value.

## Authentication Method

You can use the following authentication methods: User ID/password (Username Token), X.509 certificate (X509 Token) or Single Sign On using SAML (SAML Token).

## Constraints

Currently this SOAP service is only enabled for English.

## Additional Information

If you have any issues, report an incident for component CA-GTF-BUM.

### Note

For more information about the API, choose the [Details](#) tab on the SAP Business Accelerator Hub.

## 4.2.10.5.3.1 RoleCategoryDependentMetaData

### Nodes and Fields

#### Note

In the following table, field attributes are marked in blue.

RoleCategoryDependentMetaData

Node or Field	Description	Cardinality
BusinessPartnerRoleCategory	BusinessPartnerRoleCategoryCode For example: BUP003	1..1
Cardinality: 1..1	Description languageCode For example: Employee	0..unbounded
BusinessPartnerRole	BusinessPartnerRoleCode For example: BBP005	1..1
Cardinality: 1..1	Description languageCode DefaultIndicator Can be <i>true</i> or <i>false</i>	0..unbounded
BusinessPartnerExternalIDCategory	BusinessPartnerExternalIDCategoryCode For example: HCM030	1..1
Cardinality: 0..1	Description languageCode	0..unbounded
BusinessPartnerExternalID	BusinessPartnerExternalIDCode For example: HCM030	1..1
Cardinality: 0..unbounded	Description languageCode DefaultIndicator The value can be either <i>true</i> or <i>false</i>	0..unbounded
BusinessPartnerRelationshipCategory	BusinessPartnerRelationshipCategoryCode For example: BUR025	1..1
Cardinality: 0..1	Description languageCode	0..unbounded
Partner1_BusinessPartnerCategory	BusinessPartnerCategoryCode Can be: 1..1 • 2 - Organization • 3 - Group	1..1
Cardinality: 0..unbounded	Description languageCode	0..unbounded
Partner2_BusinessPartnerCategory	BusinessPartnerCategoryCode Can be: 1..1 • 1 - Person	1..1

Node or Field		Description	languageCode	Description	Cardinality
	Cardinality: 0..unbounded	Description	languageCode		0..unbounded
NodeProperties	NodePath			For example: BUSINESS_USER	1.1
Cardinality:	0..unbounded	NodeProperty	NodePropertyCode	Node property codes are:	1.1
	Cardinality: 0..unbounded	Description	languageCode	<ul style="list-style-type: none"> <li>• 01 - enabled</li> <li>• 02 - disabled</li> <li>• 03 - read only</li> </ul>	0..unbounded
FieldProperties	NodePath			For example:	1.1
Cardinality:	0..unbounded			<ul style="list-style-type: none"> <li>• BUSINESS_USER-USER-ROLE</li> <li>• BUSINESS_USER-USER-VALIDITY_PERIOD</li> <li>• BUSINESS_USER-USER_ASSIGNMENT</li> </ul>	
	Fieldname			Name of a field.	1.1

Node or Field	Description	Cardinality
FieldProperty Cardinality: 0..unbounded	FieldPropertyCode Node property codes are: <ul style="list-style-type: none"> <li>• 01 - enabled</li> <li>• 02 - disabled</li> <li>• 03 - read only</li> <li>• 04 - mandatory</li> <li>• 05 - enabled, read only for update</li> <li>• 06 - mandatory, read only for update</li> </ul>	1..1
	Description languageCode	0..unbounded

#### Note

To display more information about the service nodes on the SAP Business Accelerator Hub, select the [API Reference](#) tab and choose the [View Details](#) button in the table.

## 4.2.10.5.3.2 CodeList

### Nodes and Fields

#### Note

In the following table, field attributes are marked in blue.

#### CodeList

Node or Field	Description	Cardinality
FieldName	Name of the field.	1..1
FieldCodeList Cardinality: 0..unbounded	FieldValue This node provides the available code lists for SAP specific codes. For example coun-	1..1

Node or Field		Description	Cardinality
	FieldDescription	languageCode	try/region code, academic title.
			0..unbounded

#### Note

To display more information about the service node on the SAP Business Accelerator Hub, select the operation.

## 4.2.10.5.3.3 Log

### Nodes and Fields

#### Note

In the following table, field attributes are marked in blue.

Log

Node or Field		Description	Cardinality
	BusinessDocumentProcessingResultCode		0..1
	MaximumLogItemSeverityCode	If several messages are stored for a business user, the most severe level is shown from the maximum of all received severity codes.	0..1
Item	TypeID	Message number.	0..1
Cardinality: 0..unbounded	CategoryCode	Not in use.	0..1
	SeverityCode	Severity code definition: <ul style="list-style-type: none"> <li>1 - Information</li> <li>2 - Warning</li> <li>3 - Error</li> </ul>	0..1
	Note	Contains the message texts.	1..1
	WebURI	Not in use.	0..1

#### Note

To display more information about the service node on the SAP Business Accelerator Hub, select the operation.

## 4.2.10.5.4 Manage Git Repository

The Manage Git Repository API allows you to manage software components (Git repositories) on an SAP BTP ABAP Environment system.

### Overview

On an ABAP Environment system, software components, which represent Git repositories, can be controlled with Git operations. This includes cloning to an ABAP Environment system, pulling updates and working with branches (create, delete, checkout). These operations can be used with this API.

**Technical Name:** MANAGE\_GIT\_REPOSITORY

**OData Version:** 2.0

**Root URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY

### Permissions

In order to access this service, you need to:

- Create a *Communication User* as described in [How to Create Communication Users \[page 2393\]](#).
- Create a *Communication System* as described in [How to Create Communication Systems](#).
- Create a *Communication Arrangement* as described in [How to Create a Communication Arrangement \[page 2395\]](#).
- Select the communication scenario **SAP\_COM\_0510** for your communication arrangement and have mapped it to your communication system.

### Service Structure

**Service Metadata URI:** sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/\$metadata

### Service Entities

Service Entity	Description
<a href="#">Branches [page 1043]</a>	Branches of a software component
<a href="#">Clones [page 1051]</a>	Clone job of a software component
<a href="#">Execution Log [page 1055]</a>	Execution Log of a software component
<a href="#">Pull [page 1057]</a>	Pull job of a software component
<a href="#">Transport Log [page 1061]</a>	Transport log of an imported transport

### 4.2.10.5.4.1 Branches

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Branches

## Operations

### CRUD Operations

HTTP Method	Operation
GET	<a href="#">Read Branches [page 1044]</a>
POST	<a href="#">Create Branch [page 1046]</a>
DELETE	<a href="#">Delete Branches [page 1048]</a>

### Custom Operations

HTTP Method	Operation Type	Operation	URI
POST	Action	<a href="#">Checkout Branches [page 1049]</a>	/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/checkout_branch

### Parameters

Property	Description
branch_name	name of the branch
sc_name	name of the software component
is_active	indicates if the branch is active in the system
criticality	
derived_from	name of the original branch from which the branch was derived
created_by	user who created the branch
created_on	date when the branch was created
commit_id	latest commit ID on the branch
commit_message	commit message of the latest commit
last_commit_by	user who committed the last commit
last_commit_on	date of the latest commit

## 4.2.10.5.4.1.1 Read Branches

Read one or multiple branches .

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Branches

**Operation Type:** CRUD

**HTTP Method:** GET

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
branch_name	yes	string	name of the branch	query string

### Request Example

#### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/  
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY' HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication  
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Branch was read successfully
404	Not found	Could not read branch; software component or branch may not exist..

### Request Payload Example

#### Sample Code

```
{
```

```

    "d": {
      "__metadata": {
        "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
        "type": "cds_sd_a4c_a2g_gha_sc_web_api.BranchesType"
      },
      "branch_name": "newBranch",
      "sc_name": "/DMO/GIT_REPOSITORY",
      "is_active": false,
      "criticality": 0,
      "derived_from": "main",
      "created_by": "CC0000000001",
      "created_on": "/Date(1584967657000+0000)/",
      "last_commit_on": "/Date(1584634658000+0000)/"
    }
  }
}

```

## 4.2.10.5.4.1.2 Create Branch

Create a new branch.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Branches

**Operation Type:** CRUD

**HTTP Method:** POST

### Request Headers

Header	Required	Values
Accept	no	application/json
		application/xml
Content-Type	no	application/json
		application/xml
x-csrf-token	yes	Value of x-csrf-token

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	Request body

Parameter	Required	Data Type	Description	Parameter Type
branch_name	yes	string	name of the branch	Request body
derived_from	yes	string	name of the original branch from which the branch was derived	Request body

## Request Example

### Sample Code

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
{
  "sc_name" : "/DMO/GIT_REPOSITORY",
  "derived_from" : "main",
  "branch_name" : "newBranch"
}
```

## Response

### Response Status and Error Codes

Code	Reason	Description
201	Created	Branch was created successfully
400	Bad Request	Could not create a branch due to the values passed in the request body.

## Request Payload Example

### Sample Code

```
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches(branch_name='newBranch',sc_name='/DMO/GIT_REPOSITORY')",
      "type": "cds_sd_a4c_a2g_gha_sc_web_api.BranchesType"
    },
    "branch_name": "newBranch",
    "sc_name": "/DMO/GIT_REPOSITORY",
    "is_active": false,
    "criticality": 0,
    "derived_from": "master",
    "created_by": "CC0000000001",
    "created_on": "/Date(1584967657000+0000)/",
    "last_commit_on": "/Date(1584634658000+0000)/"
  }
}
```

```
}
```

## 4.2.10.5.4.1.3 Delete Branches

Delete a branch.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Branches

**Operation Type:** CRUD

**HTTP Method:** DELETE

### Request Headers

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
branch_name	yes	string	name of the branch	query string

### Request Example

#### Sample Code

```
DELETE /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches(branch_name='my-to-be-deleted-branch',sc_name='/DMO/GIT_REPOSITORY') HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

### Response

### Response Headers

#### Sample Code

```
HTTP/1.1 204 No Content
```

## Response Status and Error Codes

Code	Reason	Description
204	No content	Branch was deleted successfully
400	Bad Request	Could not delete branch due to the values passed in the request body.

## 4.2.10.5.4.1.4 Checkout Branches

Checkout a branch.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Branches

**Operation Type:** CRUD

**HTTP Method:** POST

### Request Headers

Header	Required	Values
Content-Type	no	application/json application/xml
Accept	no	application/json application/xml
x-csrf-token	yes	Value of x-csrf-token

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
branch_name	yes	string	name of the branch	query string

### Request Example

#### Sample Code

```
POST /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/checkout_branch?  
branch_name='newBranch' &sc_name=' /DMO/GIT_REPOSITORY' HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication
```

```
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
```

## Response

### Response Status and Error Codes

Code	Reason	Description
200	OK	Branch was checked out successfully
400	Bad Request	Could not check out a branch due to the values passed in the request body

### Response Payload Example

#### Sample Code

```
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Pull(guid'UUID')",
      "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Pull(guid'UUID')",
      "type": "cds_sd_a4c_a2g_gha_sc_web_api.PullType"
    },
    "uuid": "UUID ",
    "sc_name": "/DMO/GIT_REPOSITORY ",
    "namespace": "",
    "status": "R",
    "status_descr": "Running",
    "start_time": "/Date(1571227437000+0000)/",
    "change_time": "/Date(1571227472000+0000)/",
    "criticality": 2,
    "user_name": "CC0000000001",
    "to_Execution_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/

      }
    },
    "to_Transport_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/
MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Transport_log"
      }
    }
  }
}
```

## 4.2.10.5.4.2 Clones

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Clones

### Operations

#### CRUD Operations

HTTP Method	Description
GET	<a href="#">Read Clones [page 1051]</a>
POST	<a href="#">Create Clone [page 1053]</a>

#### Parameterss

Property	Description
uuid	ID of the job
sc_name	Name of the software component
branch_name	Name of the branch
commit_id	Commit ID
import_type	Type of import
status	Status of the job
status_descr	Status description
user_name	Name of the user who triggered the action
start_time	Start time of the job
change_time	Last update of the job

### 4.2.10.5.4.2.1 Read Clones

Read a clone job. The entity is only available after the job has finished. To track the status of the job, you can use the GET /Pull(guid'UUID') request.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Clones

**Operation Type:** CRUD

**HTTP Method:** GET

## Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

## Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
branch_name	yes	string	name of the branch	query string
uuid	yes	string	ID of the job	query string

## Request Example

### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones(uuid=02409ac8-  
dc6a-1edb-908e-31e4b44596d4',branch_name='main',sc_name='/DMO/  
GIT_REPOSITORY') HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication  
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Read clone successfully
400	Bad Request	Could not read the clone entity. Please check the parameters.

### Request Payload Example

#### Sample Code

```
{  
  "d": {  
    "__metadata": {
```

```

      "id": "https://4c7c0f11-
da7c-43cf-b60c-e6e308144458.abap.stagingaws.hanavlab.ondemand.com/sap/opu/

    "user_name": "CC0000000001",
    "start_time": "/Date(1608214205000+0000)/",
    "change_time": "/Date(1608214243000+0000)/"
  }
}

```

## 4.2.10.5.4.2.2 Create Clone

Create a clone job.

### Request

URI: /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Clones

Operation Type: CRUD

HTTP Method: POST

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
Contentt-Type	no	application/json application/xml
x-csrf-token	no	fetch

## Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	Request body
branch_name	no	string	name of the branch	Request body
commit_id	no	string	commit ID	Request body

## Request Example

### Sample Code

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json

{
  "sc_name" : "/DMO/GIT_REPOSITORY"
  "branch_name" : "main"
}
```

## Response

### Response Status and Error Codes

Code	Reason	Description
201	Created	Created a clone job
400	Bad Request	Could not read the clone job. Please check the parameters.

## Request Payload Example

### Sample Code

```
{
  "d": {
    {
      "__metadata": {
        "id":
        "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Clones(uuid=guid'02ceab7d-ff04-1eda-blea-eb7fdbf28bc4',sc_name='ZHM_INITIAL_TEST',branch_name='')",
        "uri":

        "type": "cds_sd_a4c_a2g_gha_sc_web_api.ClonesType"
      },
      "uuid": "02ceab7d-ff04-1eda-blea-eb7fdbf28bc4",
      "sc_name": "/DMO/GIT_REPOSITORY",
      "branch_name": "",
      "import_type": "Clone",
    }
  }
}
```

```

    "namespace": "",
    "status": "S",
    "status_descr": "Success",
    "criticality": 3,
    "user_name": "administrator@example.com",
    "start_time": "/Date(1594898863000+0000)/",
    "change_time": "/Date(1594898891000+0000)/"
  }
}
}

```

## 4.2.10.5.4.3 Execution Log

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/ExecutionLogs

### Operations

#### CRUD Operations

HTTP Method	Description
GET	<a href="#">Read Execution Log [page 1055]</a>

#### Parameters

Property	Description
uuid	ID of the job
index_no	Index number of the log entry
type	Type of the log (information, warning, etc...)
descry	Description text of this log entry
timestamp	Timestamp of the log entry

### 4.2.10.5.4.3.1 Read Execution Log

Read the execution log of a specific job.

#### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/to\_Execution\_log

Operation Type: CRUD

HTTP Method: GET

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
uuid	yes	string	ID of the job	query string

### Request Example

#### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(uuid=02409ac8-  
dc6a-1edb-908e-31e4b44596d4')/to_Execution_log HTTP/1.1  
Host: host.com  
Authentication: basicAuthentication  
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Read execution log successfully
400	Bad Request	Could not find an execution log with the specified UUID.

### Request Payload Example

#### Sample Code

```
{  
  "d": {  
    "results": [ {  
      "__metadata": {
```

```

        "id": "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
ExecutionLogs(index_no=1m,uuid=guid'UUID')", "uri": "host.com/sap/opu/
odata/sap/MANAGE_GIT_REPOSITORY/ExecutionLogs(index_no=1m,uuid=guid'UUID')",
"type": "cds_sd_a4c_a2g_gha_sc_web_api.ExecutionLogsType"
    }
    ,
    "index_no": "1",
    "uuid": "UUID",
    "type": "Information",
    "descr": "Step X: MESSAGE",
    "timestamp": "/Date(1571227438000+0000)/",
    "criticality": 0,
    }
    ]
}

```

## 4.2.10.5.4.4 Pull

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Pull

### Operations

#### CRUD Operations

HTTP Method	Description	Operation
GET	Read pull	
POST	Trigger a pull job	

#### Custom Operations

HTTP Method	Description	Operation	URI
GET	Associationl		/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY /Pull(guid'UUID')/to_Executiong_log
GET	Associationl		/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY /Pull(guid'UUID')/to_Transport_log

#### Parameters

Property	Description
uuid	ID of the job
sc_name	Name of the software component

Property	Description
branch_name	Name of the branch
commit_id	Commit ID
import_type	Type of import
status	Status of the job
status_descr	Status description
user_name	Name of the user who triggered the action
start_time	Start time of the job
change_time	Last update of the job

## 4.2.10.5.4.4.1 Read Pull

Read a pull job.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Pull

**Operation Type:** CRUD

**HTTP Method:** GET

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
uuid	yes	string	ID of the job	query string

### Request Example

#### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(uuid=02409ac8-
dc6a-1edb-908e-31e4b44596d4') HTTP/1.1
Host: host.com
```

```
Authentication: basicAuthentication
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Read pull successfully
400	Bad Request	Could not find a pull entity with the specified UUID.

### Request Payload Example

#### Sample Code

```
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "type": "cds_sd_a4c_a2g_gha_sc_web_api.PullType"
    },
    "uuid": "UUID ",
    "sc_name": "/DMO/GIT_REPOSITORY ",
    "namespace": "",
    "status": "R",
    "status_descr": "Running",
    "start_time": "/Date(1571227437000+0000)/",
    "change_time": "/Date(1571227472000+0000)/",
    "criticality": 2,
    "user_name": "CC0000000001",
    "to_Execution_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Execution_log"
      }
    },
    "to_Transport_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Transport_log"
      }
    }
  }
}
```

## 4.2.10.5.4.4.2 Create Pull

Create a pull job.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Pull

**Operation Type:** CRUD

**HTTP Method:** POST

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
Content-Type	no	application/json application/xml
x-csrf-token	yes	Value of x-csrf-token

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	Request body
commit_id	no	string	commit ID	Request body

### Request Example

#### Sample Code

```
POST/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
{
  "sc_name" : "/DMO/GIT_REPOSITORY"
}
```

## Response

### Response Status and Error Codes

Code	Reason	Description
201	Created	Created a pull job
400	Bad Request	Could not read the pull job. Please check the parameters.

### Request Payload Example

#### Sample Code

```
{
  "d": {
    "__metadata": {
      "id": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')", "type": "cds_sd_a4c_a2g_gha_sc_web_api.PullType"
    },
    "uuid": "UUID ",
    "sc_name": "/DMO/GIT_REPOSITORY ",
    "namespace": "",
    "status": "R",
    "status_descr": "Running",
    "start_time": "/Date(1571227437000+0000)/",
    "change_time": "/Date(1571227472000+0000)/",
    "criticality": 2,
    "user_name": "CC0000000001",
    "to_Execution_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Execution_log"
      }
    },
    "to_Transport_log": {
      "__deferred": {
        "uri": "https://host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(guid'UUID')/to_Transport_log"
      }
    }
  }
}
```

## 4.2.10.5.4.5 Transport Log

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/TransportLogs

## Operations

### CRUD Operations

HTTP Method	Operation
GET	<a href="#">Read Transport Log [page 1062]</a>

### Parameters

Property	Description
uuid	ID of the job
index_no	Index number of the log entry
type	Type of the log (information, warning, etc...)
descry	Description text of this log entry
timestamp	Timestamp of the log entry

## 4.2.10.5.4.5.1 Read Transport Log

### Request

URI: /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/to\_Transport\_log

Operation Type: CRUD

HTTP Method: GET

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
uuid	yes	string	ID of the job	query string

## Request Example

### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Pull(uuid=02409ac8-
dc6a-1edb-908e-31e4b44596d4')/to_Transport_log HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Read transport log successfully
400	Bad Request	Could not find a transport log with the specified UUID.

## Request Payload Example

### Sample Code

```
{ {
  "d": {
    "results": [ {
      "__metadata": {
        "id": "host.com/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
ExecutionLogs(index_no=1m,uuid=guid'UUID')", "uri": "host.com/sap/opu/
odata/sap/MANAGE_GIT_REPOSITORY/ExecutionLogs(index_no=1m,uuid=guid'UUID')",
"type": "cds_sd_a4c_a2g_gha_sc_web_api.ExecutionLogsType"
      }
    },
    "index_no": "1",
    "uuid": "UUID",
    "type": "Information",
    "descr": "Step X: Message",
    "timestamp": "/Date(1571227438000+0000)/",
    "criticality": 0,
  }
}
}
```

## 4.2.10.5.4.6 Tags

**Resource path:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Tags

### Operations

#### CRUD Operations

HTTP Method	Operation
GET	<a href="#">Read Entities from Tag [page 1064]</a>
POST	<a href="#">Create Tag [page 1065]</a>
DELETE	<a href="#">Delete Tag [page 1068]</a>

#### Custom Operations

HTTP Method	Operation Type	Operation	URI
POST	Action	<a href="#">Read Tags by Key [page 1067]</a>	/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Tags(sc_name='{sc_name}',commit_id='{commit_id}',tag_name='{tag_name}')

### 4.2.10.5.4.6.1 Read Entities from Tag

Read entities from tags.

#### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Tags

**Operation Type:** CRUD

**HTTP Method:** GET

## Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

## Request Parameters

No parameters.

## Request Example

### Sample Code

```
GET /sap/opu/odata/sap/Tags
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Branch was read successfully
404	Not found	Could not read branch; software component or branch may not exist..

### Request Payload Example

#### Sample Code

## 4.2.10.5.4.6.2 Create Tag

Create a new tag.

## Request

URI: /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/Tags

Operation Type: CRUD

HTTP Method: POST

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
Content-Type	no	application/json application/xml
x-csrf-token	yes	Value of x-csrf-token

### Request Parameters

No parameters.

### Request Body

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	Request body
commit_id	yes	string	long commit id	Request body
tag_name	yes	string	name of the tag	Request body

### Sample Code

```
POST /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Tags
HTTP/1.1
Host: host.com
Authentication: basicAuthentication
X-csrf-token: xCsrfToken
Content-Type: application/json
Accept: application/json
{
  "sc_name": "string",
  "commit_id": "string",
  "tag_name": "string",
  "tag_description": "string",
  "tag_created_by": "string",
  "tag_created_on": "/Date(1492098664000)/",
  "short_commit_id": "string",
  "message": "string",
  "author": "string",
  "author_mail": "string"
}
```

## Response

### Response Status and Error Codes

Code	Reason	Description
201	Created	Tag was created successfully
400	Bad Request	Could not create a tag due to the values passed in the request body.

### Request Payload Example

Sample Code

## 4.2.10.5.4.6.3 Read Tags by Key

Read entities from tags.

## Request

URI: `/sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Tags(sc_name='{sc_name}',commit_id='{commit_id}',tag_name='{tag_name}')`

Operation Type: CRUD

HTTP Method: GET

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	no	fetch

### Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
commit_id	yes	string	long commit id	query string

Parameter	Required	Data Type	Description	Parameter Type
tag_name	yes	string	name of the tag	query string

### Request Example

#### Sample Code

```
GET /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/
Tags(sc_name='{sc_name}',commit_id='{commit_id}',tag_name='{tag_name}')
HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

### Response Headers

Header	Description
x-csrf-token	Token, which can be used for POST requests

### Response Status and Error Codes

Code	Reason	Description
200	OK	Tag was read successfully
404	Not found	Could not read tag; software component or commit id may not exist..

### Request Payload Example

#### Sample Code

## 4.2.10.5.4.6.4 Delete Tag

Delete a branch.

### Request

**URI:** /sap/opu/odata/sap/MANAGE\_GIT\_REPOSITORY/  
Tags(sc\_name='{sc\_name}',commit\_id='{commit\_id}',tag\_name='{tag\_name}')

**Operation Type:** CRUD

**HTTP Method:** DELETE

### Request Headers

Header	Required	Values
Accept	no	application/json application/xml
x-csrf-token	yes	Value of x-csrf-token

### Request Body

Parameter	Required	Data Type	Description	Parameter Type
sc_name	yes	string	name of the software component	query string
commid_id	yes	string	long commit id	query string
tag_name	yes	string	name of the branch	query string

### Request Example

#### Sample Code

```
DELETE /sap/opu/odata/sap/MANAGE_GIT_REPOSITORY/Branches(branch_name='my-to-be-deleted-branch',sc_name='/DMO/GIT_REPOSITORY') HTTP/1.1
Host: host.com
Authentication: basicAuthentication
Accept: application/json
```

## Response

### Response Headers

#### Sample Code

```
HTTP/1.1 204 No Content
```

### Response Status and Error Codes

Code	Reason	Description
204	No content	Tag was deleted successfully
400	Bad Request	Could not delete tag due to the values passed in the request body.

## 4.2.10.6 Integrating On-Premise Systems

Set up the Cloud Connector to enable communication from the ABAP environment to your on-premise systems using Remote Function Calls (RFC) and HTTP calls.

### Concept

For each subaccount, both a default Connectivity and Destination service instance are set up automatically in the SAP provider account. Using these default instances, you only need to configure the required destinations on subaccount level to enable communication to your on-premise systems.

In this default scenario, you must connect the Cloud Connector to and configure trust for your Cloud Foundry subaccount as described in [SAP BTP Connectivity: Cloud Connector](#).

#### ⚠ Restriction

This scenario requires a Cloud Connector as of version 2.12.3.

The host name of the Cloud Connector is not needed because the Cloud Connector itself connects **to the Cloud**, but it is **never connected from the Cloud**.

#### 📘 Note

For more information on the deprecated scenario that uses the Connectivity service in the Neo environment, see [Create a Communication Arrangement for Cloud Connector Integration \(Deprecated\) \[page 1071\]](#).

After you have completed the setup, a connection from the ABAP environment tenant to an on-premise system is established in the following order:

1. The ABAP environment tenant fetches the destination from the Destination service instance.
2. The ABAP environment tenant requests to open the tunnel connection through the Connectivity service.
3. The Connectivity service tells the Cloud Connector to open the connection to this specific ABAP environment tenant using the admin connection.
4. The Cloud Connector opens a tunnel connection to the ABAP environment tenant using its public tenant URL.
5. After the tunnel is established, it can be used for actual data connection using RFC and HTTP(S) protocols.

### Next Steps

To set up your actual data connections between your ABAP environment and on-premise systems, you must configure the required destinations. See [Enable On-Premise Connectivity \[page 1073\]](#).

## Troubleshooting

In case of issues using the Cloud Connector, see [Cloud Connector Troubleshooting](#) for a troubleshooting guide.

### 4.2.10.6.1 Create a Communication Arrangement for Cloud Connector Integration (Deprecated)

Learn how to create a communication arrangement for communication scenario SAP\_COM\_0200 to integrate the Cloud Connector.

#### Prerequisites

##### Note

This procedure is deprecated and is only available for systems provisioned before May 2022. It was replaced with a scenario that does not require a Neo subaccount. To learn about the steps to migrate to a Cloud Foundry-only usage, see section **Next Steps** below.

To set up your ABAP environment, you have to create a communication arrangement for communication scenario SAP\_COM\_0200 - Cloud Connector Integration, that requires the following:

- An administrative user in the ABAP environment tenant.
- Increased quota for the ABAP runtime.
- An ABAP service instance set up in Cloud Foundry.
- Your Neo subaccount name.
- The name of the region host of your Neo subaccount

##### Note

Please check out the supported Neo subaccounts for on-premise connectivity of the ABAP environment. See SAP Note [2765161](#).

- Installation of Cloud Connector version 2.11 or higher. See [Cloud Connector: Installation](#)
- Initial configuration for Cloud Connector and the Neo subaccount. See [Cloud Connector: Initial Configuration](#)

##### Note

The Cloud Connector is connected to the Neo subaccount and is displayed in the Cloud Cockpit, section [Connectivity](#) under [Cloud Connectors](#).

- User credentials for the Cloud Connector admin role in the Neo subaccount

## Procedure

1. To create a communication system that represents your Neo subaccount, open the *Communication Systems* app from the SAP Fiori launchpad in your Cloud Foundry subaccount and select *New*.
2. Provide a meaningful system name and choose *Create* to proceed.

### Note

You have to disable the destination service first by using the *on/off* slider button.

Enter the following information:

Field	Action
<i>Host Name</i>	Enter the name of the region host of your Neo subaccount. If your Neo URL is <a href="https://account.xyz.hanacloud.sap">https://account.xyz.hanacloud.sap</a> , the host name is <i>account</i> . For more information, see <a href="#">Regions and Hosts Available for the Neo Subaccount</a> .
<i>HTTPS Port</i>	Enter <b>443</b> .
Checkbox <i>Use Cloud Connector</i>	Make sure this checkbox is <b>not checked</b> .
User for Outbound Communication	a) Scroll down to this section. b) Add a new user. c) In the dropdown list for <i>Authentication Method</i> , select <i>Basic</i> . d) Enter the user name and password of the user.

For more information on how to create a communication system, see [How to Create Communication Systems](#).

3. Save the communication system to activate it.
4. To create a communication arrangement that activates the connection to the Neo subaccount, open the *Maintain Communication Arrangements* app from the SAP Fiori Launchpad and click *New*.
5. Select scenario *SAP\_COM\_0200* and enter a meaningful arrangement name.
6. Click *Create* to proceed.

Enter the following information:

Field	Action
<i>Communication System</i>	Enter the name of the communication system.
▶ <i>Additional Properties</i> ▶ <i>Account Name</i> ▶	Enter the name of your Neo subaccount.
▶ <i>Outbound Communication</i> ▶ <i>User Name</i> ▶	

For more information on how to create a communication arrangement, see [How to Create a Communication Arrangement \[page 2395\]](#).

7. Save the communication arrangement to activate it.
8. Carry out the initial configuration for Cloud Connector and the Neo subaccount to make it operational for connections between your Neo subaccount and the on-premise systems.

## Results

You have associated the ABAP environment tenant with the Neo subaccount. This enables the ABAP environment tenant to request the Neo environment to open a tunnel connection.

## Next Steps

After completing the setup of communication scenario `SAP_COM_0200`, you are ready to set up your actual data connections between your ABAP environment and on-premise systems. This requires the configuration of other communication systems and communication arrangements in the ABAP environment tenant as well as the configuration of Cloud Connector. See [Enable On-Premise Connectivity \[page 1073\]](#).

To **migrate** to the usage of the **Cloud Foundry Connectivity service**, proceed as follows:

1. Configure trust in the Cloud Connector for the Cloud Foundry subaccount in which the ABAP instance resides.
2. Delete communication arrangement `SAP_COM_0200`.
3. Destinations do not need to be modified if the same `LocationID` is used.

### 4.2.10.6.2 Enable On-Premise Connectivity

Create an HTTP and an RFC destination to enable communication from the ABAP environment to your on-premise systems.

## Prerequisites

- You have installed Cloud Connector version 2.12.3 or higher, see [Cloud Connector: Installation](#).
- You have done the initial configuration for the Cloud Connector, see [Cloud Connector: Initial Configuration](#).
- If you want to use principal propagation as authentication type, the Cloud Connector must be configured to support this authentication type. See [Cloud Connector: Configuring Principal Propagation](#). Also, make sure that no communication arrangement to the deprecated communication scenario `SAP_COM_0200` exists.
- If you use more than one Cloud Connector in your subaccount, you have assigned a location ID to each of these Cloud Connectors. See [Managing Subaccounts](#) (section **Procedure**, step 4).

## Procedure

To enable on-premise connectivity, you must set up or reuse an HTTP destination or an RFC destination with `<Proxy Type> OnPremise`:

- [Set Up HTTP Communication \[page 961\]](#)
- [Service Consumption Model as RFC Consumer \[page 964\]](#)

### 4.2.10.7 Integrating the ABAP Environment with SAP S/4HANA Cloud

You can integrate the SAP BTP, ABAP environment with an SAP S/4HANA Cloud system for ABAP developers. After you have completed the steps in this documentation, developers can implement outbound service calls from the ABAP environment to the SAP S4/HANA Cloud system.

## Context

Developers in your ABAP environment would like to access data from business services in SAP S/4HANA Cloud as part of their applications.

This documentation provides you with a step-by-step instruction on how to get the integration of the ABAP environment with SAP S/4HANA Cloud up and running, based on an example.

## Example Scenario Used in This Documentation

As an example scenario in this documentation, we'll assume that developers want to use a service that creates, reads, updates, and deletes master data related to business partners, suppliers, and customers in an SAP S/4HANA system. To achieve this, the developer makes an outbound service call from SAP Business Technology Platform to this SAP S/4HANA Cloud service, using this service to create a business partner.

For more information about this example and an overview of the required administration activities, see [Overview of Administration Activities \[page 1075\]](#).

## 4.2.10.7.1 Overview of Administration Activities

Get an overview of the example used in this documentation and what kind of administration activities you need to expect and why.

### Example Scenario Used in This Documentation

In the example scenario used in this documentation, developers want to make an outbound service call from the ABAP environment to SAP S/4HANA Cloud, using an SAP S/4HANA service to create a business partner.

When an outbound service call in the ABAP environment is implemented, the following authentication methods can be used to authenticate at the SAP S4/HANA cloud system:

- User ID and password (basic authentication)
- OAuth 2.0

In this example scenario, OAuth 2.0 authentication is used.

### Overview of Administration Activities

As an administrator, your main task is to establish a trust relationship between the communication partners, the ABAP environment and SAP S/4HANA Cloud. You establish this trust relationship by creating several communication management artifacts in SAP S/4HANA Cloud. At the same time, you have to configure a destination on SAP BTP.

Most of the administrative steps can be performed automatically by using the SAP S/4HANA Cloud Extensibility service on SAP BTP. This is the recommended option, as it simplifies the process and reduces the possibility of human error. However, you can also perform all the steps manually. In the following sections, both options are described.

### Next Step for Developers

After you have completed the integration of the ABAP environment with SAP S/4HANA Cloud, developers can start implementing their services. For more information about the next steps of the developers and additional resources, see [Implementing an Outbound Service Call to SAP S/4HANA Cloud \[page 1084\]](#).

### More Information

To learn more about how to use communication management apps in SAP S4/HANA systems to integrate with other systems, see [Communication Management](#).

For more information about available services in SAP S/4HANA Cloud that can be consumed by external systems, search for services on the SAP API Business Hub at <http://api.sap.com> or follow this [direct link](#).

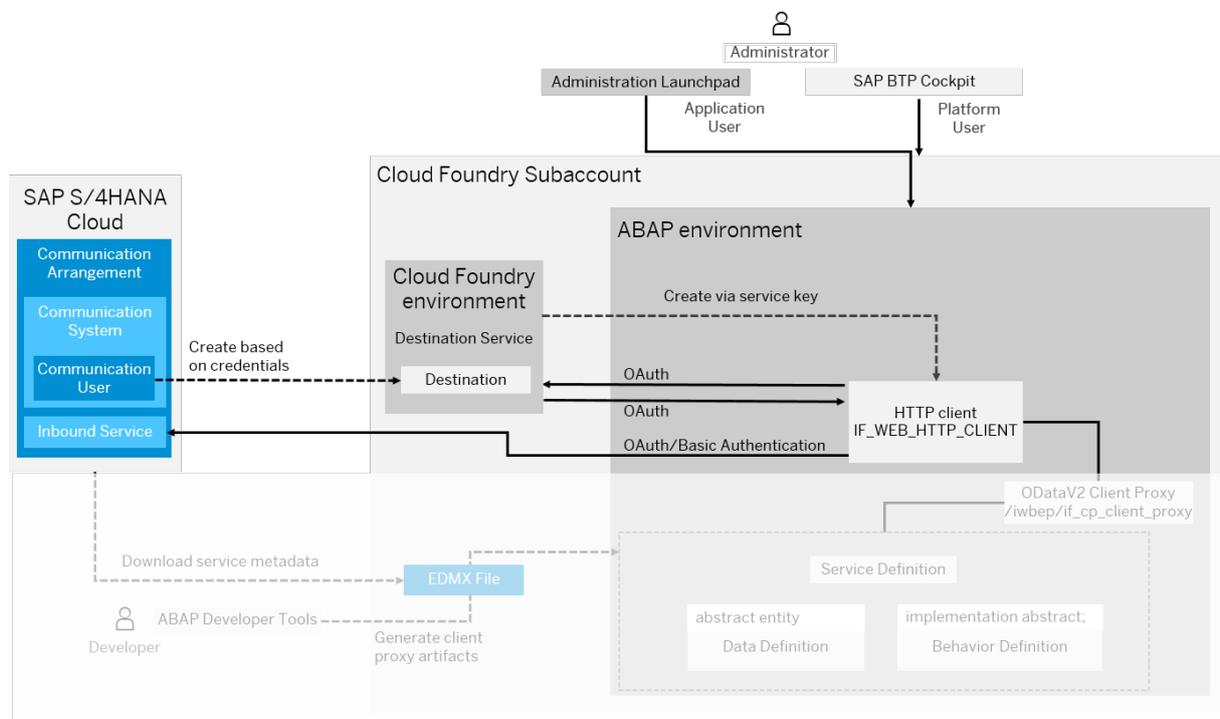

To find out how to consume services offered as part of SAP S/4HANA Cloud or other SAP products, see [API Management](#).

## 4.2.10.7.2 Manually Integrating the ABAP Environment and the SAP S/4HANA Cloud System

In this section, you'll find a step-by-step instruction on how to integrate the ABAP environment and the SAP S/4HANA Cloud system.

### Prerequisites

You have a business user in SAP S/4HANA Cloud that is assigned to a business role in business catalog SAP\_CORE\_BC\_COM - Communication Management. See [How to Create a Business Role from Scratch](#) and [Maintain Business Users](#).

Administration Activities for Establishing Trust Between SAP S/4HANA Cloud and Cloud Foundry (Developer Activities Grayed Out)

### Note

Some of the steps are only relevant if your developers are supposed to expose business services using the OAuth 2.0 authentication method. If you only want to use basic authentication (user ID and password), some of the steps for setting up a trust relationship are not necessary.

Such optional steps are indicated. Note that if you want to use the example service used in this documentation, you must follow all steps.

## Related Information

[Downloading the Trust Certificate from Cloud Foundry \[page 1077\]](#)

[Creating a Role for Communication Management \(Optional\) \[page 1078\]](#)

[Creating a Communication Arrangement in SAP S/4HANA Cloud \[page 1079\]](#)

[Copying the Inbound Service URL and Other Communication Details \[page 1082\]](#)

[Creating the OAuth2SAMLBearerAssertion Destination to SAP S/4HANA Cloud \[page 1083\]](#)

### 4.2.10.7.2.1 Downloading the Trust Certificate from Cloud Foundry

Download the trust certificate from the Cloud Foundry subaccount. You will need the certificate to set up OAuth 2.0 authentication to remote systems such as SAP S/4HANA Cloud.

## Prerequisites

You are a member of the corresponding global account. In addition, you are at least a subaccount viewer and destination admin (or a subaccount admin, which covers both).

## Context

As a first step to set up OAuth authentication for business services, you must establish a trust relationship between SAP S/4HANA Cloud and the Cloud Foundry subaccount containing your ABAP system. Therefore, you must download the certificate that uniquely identifies the Cloud Foundry subaccount as a trusted communication partner for remote systems such as SAP S/4HANA Cloud.

## Procedure

1. As an administrator user, log on to the SAP BTP cockpit.
2. Navigate to the subaccount containing your ABAP system in the Cloud Foundry environment.
3. In the navigation area of the SAP BTP cockpit, choose ► [Connectivity](#) ► [Destinations](#) ▾.
4. Choose [Download Trust](#).
5. Save the trust certificate locally to your hard drive for later use.

### 4.2.10.7.2.2 Creating a Role for Communication Management (Optional)

Optionally, you can create a business role in S/4HANA Cloud that you can assign to a dedicated user who takes care of setting up communication arrangements, systems, and users, including the trusted communication to SAP BTP.

## Context

By default, the administrator user has the required authorizations to create communication arrangements because he has the business catalog [Communication Management](#) (SAP\_CORE\_BC\_COM) assigned. You might want to assign the possibility to create communication arrangements to additional business users.

## Procedure

1. Log on to the S/4HANA Cloud system as administrator.
2. In the launchpad, navigate to the [Identity and Access Management](#) group and choose the [Maintain Business Roles](#) tile.
3. Choose [New](#) to create a new business role or edit an existing business role.
4. Choose the [Assigned Business Catalogs](#) tab and assign the business catalog [Communication Management](#) (SAP\_CORE\_BC\_COM).
5. Choose [Assigned Business Users](#) tab and assign the business users who should create and change communication arrangements.

## 4.2.10.7.2.3 Creating a Communication Arrangement in SAP S/4HANA Cloud

Create a communication arrangement in SAP S/4HANA Cloud to establish trust to the ABAP environment in SAP BTP.

### Prerequisites

Depending on your system (development or production), you might have a different role when you create a communication arrangement. While it might be acceptable that a developer creates communication arrangements in development systems, you'll need an administration user for a production system, or you have a dedicated user who takes care of communication arrangements. Your user needs a business role with the business catalog *Communication Management* (SAP\_CORE\_BC\_COM) assigned (see [Creating a Role for Communication Management \(Optional\)](#) [page 1078]).

### Retrieving the System URL of the ABAP System

As a preparatory step for creating a communication system later, you need to retrieve the system URL of your ABAP system as host name

### Procedure

Retrieve the host name from the service key of the service instance for the ABAP environment in your Cloud Foundry subaccount (`property=url`), for example, `xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx.abap.eu10.hana.ondemand.com`.

## Creating a Communication Arrangement for SAP\_COM\_0008

### Procedure

1. Log on to the SAP S/4HANA Cloud system as administrator.
2. In the launchpad, navigate to the *Communication Management* group and choose the *Communication Arrangements* tile.
3. In the *Communication Arrangements* dialog, choose *New*.

4. Select communication scenario SAP\_COM\_0008 (*Business Partner, Customer, and Supplier Integration*).  
SAP\_COM\_0008 is the communication scenario that we need to set up communication with SAP BTP as business partner.
5. Enter an arrangement name, for example, **ZSAP\_COM\_0008\_OAUTH**.
6. Choose *Create*.

## Creating a Communication System

### Procedure

1. In the following dialog, choose *New* to create a new communication system.
2. Enter a system ID and system name, for example, **ZABAP\_CP\_OAUTH**.
3. Under **Technical Data** > **General**, enter the system URL of the ABAP environment instance as host name.
4. Enter, for example, **DUMMY** as logical system and **DUMMY** as business system. The business system must be unique for all communication systems in the SAP S/4HANA cloud system.

#### Note

Even though outbound communication is not needed to integrate SAP S/4HANA Cloud with SAP BTP, you must enter data for outbound communication. (Logical system and business system are mandatory.) The reason why you need to enter data for outbound communication is because the predefined communication scenario SAP\_COM\_0008 contains outbound communication services (which you can deactivate later).

5. Don't save yet, but continue with uploading the trust certificate.

## Uploading the Trust Certificate

### Context

This procedure is only relevant if you want to ensure that developers can use business services that should be exposed using the OAuth 2.0 authentication method. For the basic authentication with user ID and password, the trust setup that is required for OAuth 2.0 is not needed.

As we are using OAuth as authentication method in this example, uploading the trust certificate is mandatory in this case.

## Procedure

1. In the *OAuth 2.0 Identity Provider* screen area, select the *Enable* checkbox.
2. Choose *Upload Signing Certificate*.
3. Choose *Browse...* to upload the signing certificate that you have downloaded from Cloud Foundry (see [Downloading the Trust Certificate from Cloud Foundry \[page 1077\]](#)).
4. From the *Signing Certificate Subject* field, copy the common name (the string after *CN=*) and paste it into the *Provider Name* field.
5. Don't save the communication arrangement yet, but continue with creating communication users.

## Creating an Inbound and Outbound Communication User

Create an inbound and outbound communication user for your communication scenario.

### Context

The communication scenario `SAP_COM_0008` that is used as an example in this documentation consists of inbound and outbound services, so you need to create inbound and outbound communication users. If you use another communication scenario, you might or might not need to create an outbound communication user.

As outbound communication is not relevant in this documentation, a communication user for the authentication method SSL client certificate is used here as an example.

### Procedure

1. In the *User for Inbound Communication* screen area, to create a communication user for inbound communication in SAP S/4HANA Cloud, choose **+**.
2. In the following popup, choose *New User*.
3. As user name, enter the same name as for the communication system, for example, `ZABAP_CP_OAUTH` and a description.

With this name, you indicate that the user is intended as a communication user for OAuth communication.

4. To generate a password, choose *Propose Password* and copy and save it securely for later use.
5. Choose *Create* and *OK* in the following popup.

A new inbound communication user has now been created and is shown under *User for Inbound Communication*.

#### Note

Instead of using the inbound communication user with authentication method OAuth, you could also use the communication user for authentication with user ID and password.

6. To create an outbound communication user, choose + under *User for Outbound Communication*.
7. Select *SSL Client Certificate* as authentication method and *Default Client Certificate* as certificate type.
8. Choose *Create*.
9. To save your communication arrangement, choose *Save*.

## Deactivating Outbound Services

Deactivate the outbound services of the communication arrangement. The outbound services are not relevant for outbound communication from the ABAP environment to SAP S/4HANA Cloud.

### Context

Depending on the communication scenario that you want to use on the SAP S/4HANA Cloud side, you might or might not have to deactivate outbound services. In this example, we use a communication scenario that has outbound services that are not needed.

### Procedure

1. In the *Inbound Communication* screen area of your communication arrangement, double-check that it is set to OAuth 2.0.
2. To deactivate all outbound services, deselect the *Active* checkbox for the service status of all outbound services.
3. To save the communication arrangement, choose *Save*.

## 4.2.10.7.2.4 Copying the Inbound Service URL and Other Communication Details

Copy the URL and other communication details of the inbound service from the communication arrangement that you have just created. You will need the information later.

### Prerequisites

You have created a communication arrangement in SAP S/4HANA Cloud for the inbound communication from the ABAP environment (see [Creating a Communication Arrangement in SAP S/4HANA Cloud \[page 1079\]](#)).

## Procedure

1. Log on to the SAP S/4HANA Cloud system as administrator.
2. In the launchpad, navigate to the *Communication Management* group and choose the *Communication Arrangements* tile.
3. In the *Communication Arrangements* dialog, choose the communication arrangement that you have created.
4. In the *Inbound Services* screen area, find the inbound service relevant to your use case (here, the ODataV2 service *Business Partner Integration*) and copy the host name of the service URL for later use.
5. In the *Inbound Communication* screen area, choose *OAuth 2.0 Details*.
6. From the following popup, copy the client ID, user name, token service URL, and SAML2 audience for later use.

### 4.2.10.7.2.5 Creating the OAuth2SAMLBearerAssertion Destination to SAP S/4HANA Cloud

## Procedure

1. Log on to the SAP BTP cockpit as administrator.
2. Navigate to your global account and to your ABAP subaccount.
3. From the navigation area, choose *Destinations*.
4. Choose *New Destination*.
5. Enter the following data:

Field	User Input
Name	<b>S4BusinessPartnerOAuth2</b>
Type	<i>HTTP</i>
Description	<i>S/4HANA Cloud Business Partner OAuth2</i>
URL	<Host name of the service URL from the communication arrangement>, for example, <b>https://my303291-api.s4hana.ondemand.com</b> (see <a href="#">Copying the Inbound Service URL and Other Communication Details [page 1082]</a> )
Proxy Type	<i>Internet</i>
Authentication	<i>OAuth2SAMLBearerAssertion</i>
Audience	<SAML2 Audience from Oauth 2.0 Details> (see <a href="#">Copying the Inbound Service URL and Other Communication Details [page 1082]</a> )
authnContextClassRef	<b>urn:oasis:names:tc:SAML:2.0:ac:classes:X509</b>

Field	User Input
Client Key	<Client ID from OAuth 2.0 Details> (see <a href="#">Copying the Inbound Service URL and Other Communication Details [page 1082]</a> )
Token Service URL	<Token Service URL from OAuth 2.0 Details> (see <a href="#">Copying the Inbound Service URL and Other Communication Details [page 1082]</a> )
Token Service User	<Communication user name from OAuth 2.0 Details> (see <a href="#">Copying the Inbound Service URL and Other Communication Details [page 1082]</a> )
Token Service Password	<Password of communication user> (see <a href="#">Creating a Communication Arrangement in SAP S/4HANA Cloud [page 1079]</a> )

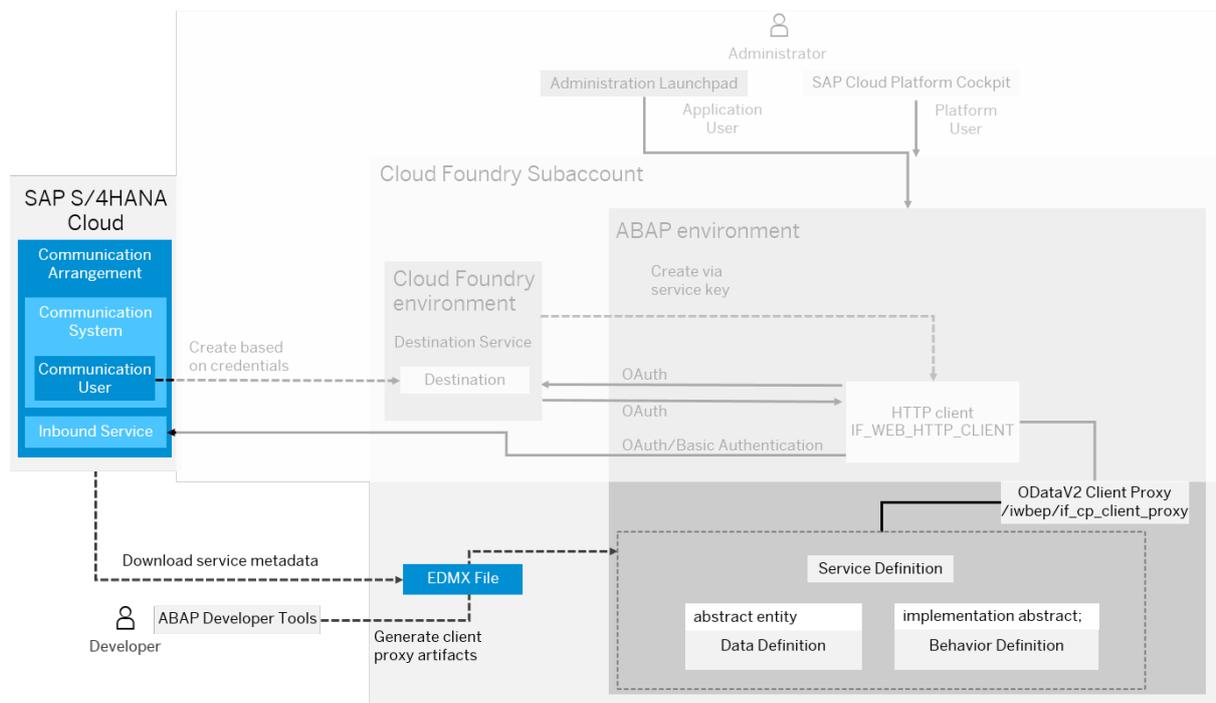

6. Choose *New Property* and add the following property:

Property	Value
nameIdFormat	<code>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</code>

7. Choose *Save*.

### 4.2.10.73 Implementing an Outbound Service Call to SAP S/4HANA Cloud

After an administrator has created an OAuth2SAMLBearerAssertion destination to integrate SAP S/4HANA Cloud and the ABAP environment, as a developer user, you can now implement applications in the ABAP environment that call external services in SAP S/4HANA Cloud.

Outbound Service Call Using Client Proxy: Developer Activities (Administration Activities Grayed Out)

The next steps of the developers would be the following:

1. The developer downloads the service metadata from the business service in SAP S/4HANA Cloud.
2. The developer creates a client proxy from the metadata in the ABAP environment.
3. The developer creates an HTTP service in the ABAP environment.
4. The developer implements an outbound service call from the ABAP environment to the inbound service in SAP S/4HANA Cloud.
5. The business user opens the HTTP service in the ABAP environment.

## Related Information

[Tutorial: Create Business Partner in SAP S/4HANA Cloud using ABAP Environment Data](#)

### 4.2.10.7.4 Using SAP S/4HANA Extensibility Service

Learn how to use the SAP S/4HANA Extensibility service to integrate the ABAP environment and the SAP S/4HANA Cloud system.

## Prerequisites

If you want to use the SAP S/4HANA Cloud Extensibility service, you should assign the corresponding entitlement to the SAP BTP subaccount that you plan to use. The required service plan for this use case is `api-access`. See [Configure the Entitlements for the SAP S/4HANA Cloud Extensibility Service](#).

## Procedure

1. Register the SAP S/4HANA Cloud system in your global account. See [Register an SAP S/4HANA Cloud System in a Global Account in SAP BTP](#).
2. Navigate to your SAP BTP subaccount and create an SAP S/4HANA Cloud Extensibility service instance. See [Create an SAP S/4HANA Cloud Extensibility Service Instance in the Cloud Foundry Environment](#).

During the creation of the service instance, you have to define the communication arrangement and authentication type for the SAP S/4HANA Cloud API access in a JSON file:

#### Note

```
{
  "systemName": "EXAMPLE",
  "communicationArrangement": {
    "communicationArrangementName":
      "INBOUND_COMMUNICATION_ARRANGEMENT",
    "scenarioId": "SAP_COM_0008",
    "inboundAuthentication": "OAuth2SAMLBearerAssertion",
```

```

    "outboundAuthentication": "BasicAuthentication",
    "outboundServices": [
      {
        "name": "Replicate Customers from S/4 System to Client",
        "isServiceActive": false
      },
      {
        "name": "Replicate Suppliers from S/4 System to Client",
        "isServiceActive": false
      },
      {
        "name": "Replicate Company Addresses from S/4 System to
Client",
        "isServiceActive": false
      },
      {
        "name": "Replicate Workplace Addresses from S/4 System to
Client",
        "isServiceActive": false
      },
      {
        "name": "Replicate Personal Addresses from S/4 System to
Client",
        "isServiceActive": false
      },
      {
        "name": "Business Partner - Replicate from SAP S/4HANA
Cloud to Client",
        "isServiceActive": false
      },
      {
        "name": "Business Partner Relationship - Replicate from
SAP S/4HANA Cloud to Client",
        "isServiceActive": false
      },
      {
        "name": "Business Partner - Send Confirmation from SAP S/
4HANA Cloud to Client",
        "isServiceActive": false
      },
      {
        "name": "BP Relationship - Send Confirmation from SAP S/
4HANA Cloud to Client",
        "isServiceActive": false
      }
    ],
    "communicationSystem": {
      "communicationSystemHostname": "default.com",
      "outboundCommunicationUser": {
        "username": "DefaultUser",
        "password": "DefaultPassword"
      }
    }
  }
}

```

During the creation of the service instance, you have to define the communication arrangement and authentication type for the SAP S/4HANA Cloud API access in a JSON file.

For scenarioId use **SAP\_COM\_0008** and for inboundAuthentication use **OAuth2SAMLBearerAssertion**. See [Communication Arrangement JSON File - Properties](#).

## Results

The successful creation of the service instance automatically triggers the creation of the following:

- Destination in your SAP BTP subaccount with the same name as your service instance
- Communication arrangement
- Communication system
- Inbound communication user in your SAP S/4HANA Cloud system

The communication arrangement is based on the communication scenario specified during the service instance creation and uses the generated communication system and inbound communication user. A default user is automatically configured for outbound communication.

Once you specify OAUTH SAML Bearer Assertion as your authentication method during service instance creation, the OAUTH SAML Bearer Assertion Identity Provider section gets automatically configured in your communication system.

### Note

When using OAUTH SAML Bearer Assertion, you have to manually add a property to the generated destination. To do so, navigate to ► [Connectivity](#) ► [Destinations](#) ► in your subaccount, select the corresponding destination, and add the additional property `nameIdFormat` with the value `urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress`.

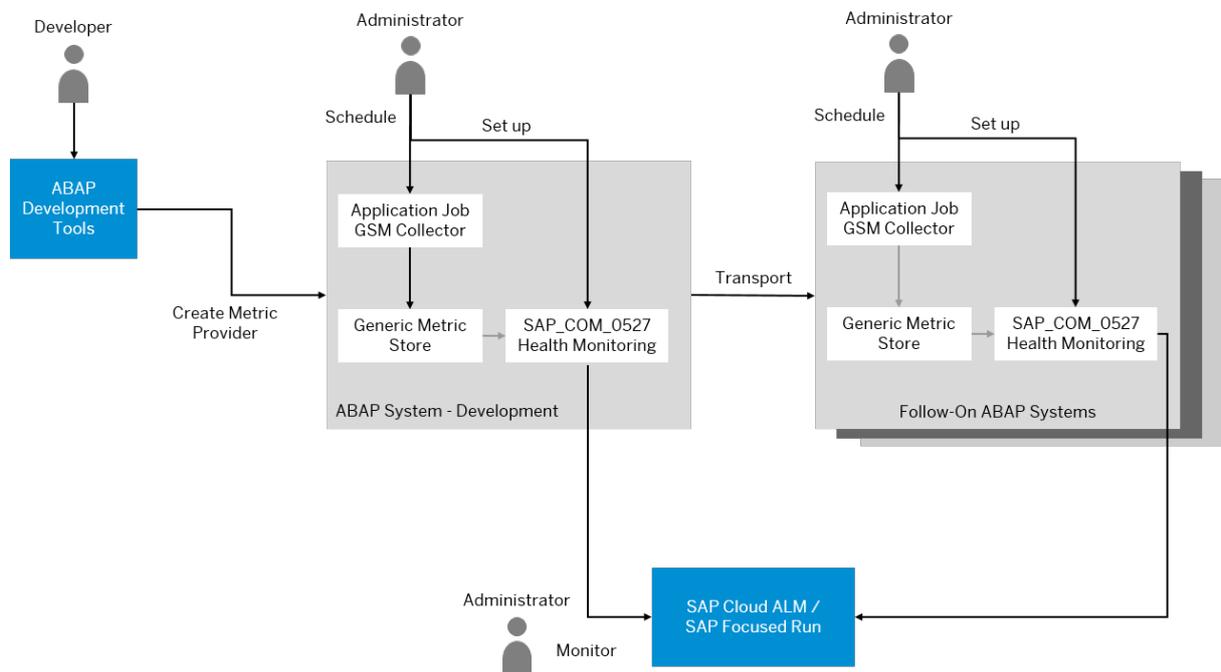

## 4.2.10.8 Developing Metrics for Health Monitoring

Learn how you can add your own metrics to Health Monitoring in SAP Cloud ALM or SAP Focused Run.

### Use Case

SAP Cloud ALM provides you with insights regarding the health of Cloud services. In the overview dashboard, all health monitoring metrics are exposed, and for each metric, a detailed history is available. While a number of metrics defined by SAP are available for checking customer-initiated operational issues, you might want to add your own application-specific metrics. These metrics serve to monitor the health of your own customer or partner solutions running on the ABAP environment. Similarly, you might want to have your own metrics in Health Monitoring of SAP Focused Run.

## Architecture Overview

The central object in this context is the metric provider, an ABAP repository object that references an implementing class. The class defines a metric model for your application and implements the metric measurement. The metric model defines, for example, what kind of metrics are available in the system, how often a metric is measured, its tags, or its unit of measurement.

An application job (the generic simple metric collector) runs regularly. It calls up the `GET_METRIC_VALUES( )` method of all metric providers and stores all measured values as metrics in a generic format in the metric store. After an administrator has set up a communication arrangement based on the communication scenario `SAP_COM_0527`, the metrics are automatically pushed from the generic metric store to SAP Cloud ALM and SAP Focused Run.

## About This Documentation

In this documentation, you get information about creating your own metric providers as a developer. In addition, there's also a short information for administrators about creating an application job that calls up all created metric providers and transfers their measured values to the generic metric store.

For more information about setting up SAP Cloud ALM and SAP Focused Run, see [Central Health Monitoring Using SAP Focused Run and SAP Cloud ALM \[page 2712\]](#).

## 4.2.10.8.1 Creating a Class for Metric Providers

To create a metric model for your customer or partner application, create a class in ABAP Development Tools (ADT) that implements the interface `IF_GSM_API_PROVIDER`.

### Prerequisites

You have a developer role for creating objects with ABAP for Cloud Development.

You have created an ABAP Cloud project and a package in ABAP Development Tools.

### Context

With the class, you define the metric model and measurement.

#### Note

For code samples, see <https://github.com/SAP-samples/abap-platform-ops>.

### Procedure

1. In your ABAP Cloud project and package, create a class implementing the interface `IF_GSM_API_PROVIDER`.

As a result, you get a class with the following methods: `INITIALIZE( )`, `DEFINE_MODEL( )`, and `GET_METRIC_VALUES( )`.

2. When you edit this class, we recommend that you define constants for the metric names and values that are exactly the same for methods `DEFINE_MODEL( )` and `GET_METRIC_VALUES( )`. All metric names that do not match are ignored at runtime.

For example, your code might look as follows:

#### Sample Code

```
CONSTANTS:
  BEGIN OF e_metric_group_id,
    demo_group TYPE if_gsm_api_types=>tv_metric_group_id VALUE
'zdemo_group_01',
  END OF e_metric_group_id .
CONSTANTS:
  BEGIN OF e_metric_id,
    demo_metric_id TYPE if_gsm_api_types=>tv_metric_id VALUE
'zdemo_metric_01',
  END OF e_metric_id .
CONSTANTS:
  BEGIN OF e_attribute_id,
```

```

demo_attr_01 TYPE if_gsm_api_types=>tv_attribute_id VALUE
'zdemo_attr_01',
END OF e_attribute_id .

```

You create one metric group and assign your metrics to the group. The metric group is just for semantical grouping and holder for meta data. It has no physical impact on the metric store or the data collection for metrics later.

3. Redefine the methods `DEFINE_MODEL( )` and `GET_METRIC_VALUES( )` according to your business needs.

## Related Information

[Creating a Metric Model \[page 1090\]](#)

[Defining the Metric Measurement \[page 1091\]](#)

### 4.2.10.8.1.1 Creating a Metric Model

In the `DEFINE_MODEL( )` method, you specify your metric model, including the metric IDs, their data types, or their units of measurement.

## Prerequisites

You've created a class for metric providers (see [Creating a Class for Metric Providers \[page 1089\]](#)).

## Procedure

In the class that you've created, change the `DEFINE_MODEL( )` method according to your business needs.

For example, your method might be as follows:

### Sample Code

```

METHOD if_gsm_api_provider~define_model.
  DATA: lo_api_metric_group TYPE REF TO if_gsm_api_metric_group.
  lo_api_metric_group = io_model->add_metric_group(
    iv_metric_group_id   = me->e_metric_group_id-demo_group
    iv_metric_group_name = `Demo Client API Provider` ##NO_TEXT
    iv_category          = if_gsm_api_constants=>e_category-performance
    iv_severity          = if_gsm_api_constants=>e_severity-_2_low ).
  lo_api_metric_group->add_target(
    iv_target_type      = if_gsm_api_constants=>e_target_type-health ).
  lo_api_metric_group->add_metric(
    iv_metric_id        = me->e_metric_id-demo_metric_id
    iv_metric_name      = `Demo Client API Metric` ##NO_TEXT

```

```

iv_unit           = if_gsm_api_constants=>e_unit-seconds
iv_data_type      = if_gsm_api_constants=>e_data_type-integer
iv_period         = if_gsm_api_constants=>e_period-every_05_minutes
iv_description    = `Just a demo` ##NO_TEXT
iv_metric_type    = if_gsm_api_constants=>e_metric_type-counter )-
>add_target(
  iv_target_type  = if_gsm_api_constants=>e_target_type-health ).
ENDMETHOD.

```

Notes: For all input parameters, you can find the relevant enumerations in the released interface `IF_GSM_API_CONSTANTS`. Note, however, that there are a few additional considerations:

- The category of the metric group expresses the semantic nature of the metric, for example, whether the availability or performance of the system is affected.
- The attributes of a metric refer to the consumption of the metric:
  - **Period:** The period specifies the frequency with which the metric measurement is triggered. It implicitly derives a runtime quota. Metric providers that are executed more often must return the metrics faster. For example, metric providers running each minute must return values within 5 seconds. Otherwise, they will be banned by the framework in the future. The `period` attribute is the only control attribute. All other attributes don't have any runtime impacts.
  - **Metric type:** Metrics can be collected in different ways. Some metrics are of type *Counter*. A counter always goes up and is only reset at special events like system restart. For example, the number of processed requests is typically expressed as a counter. In contrast to a counter, a gauge metric can go up or down. The temperature or current memory usage are common examples of gauge metrics.
  - **Target type:** The target type is used to control the metric flow for different usage scenarios. Only the available target type `HEALTH` is supported. This target type registers the metric to be exported to Health Monitoring in SAP Cloud ALM and SAP Focused Run.
  - **Severity:** The severity is available, but not pushed to Health Monitoring.

## 4.2.10.8.1.2 Defining the Metric Measurement

In the `GET_METRIC_VALUES( )` method, you specify how the metrics are measured, including the requested metrics and the time frame for processing.

### Prerequisites

You've created a class for metric providers (see [Creating a Class for Metric Providers \[page 1089\]](#)).

### Context

At runtime, the generic metric provider framework calls the method `GET_METRIC_VALUES( )`. The method expects multiple input parameters like the requested metrics and the time frame for processing. If you include multiple metrics with different collection frequencies, the framework calls this method accordingly with the

corresponding metric IDs for which it requests to return data. When you provide the correct input in the `GET_METRIC_VALUES( )` implementation, you avoid wasting work for metrics not being requested.

The measurement should be fast. If a measurement takes too much time, it blocks all the other measurements. Therefore, the metric provider framework automatically monitors the runtime of each metric provider. If a metric provider exceeds the runtime quota, the framework will ban the metric provider so that all the other metric providers can be collected.

## Procedure

In the class that you've created, change the `GET_METRIC_VALUES( )` method according to your business needs.

For example, your method might be as follows:

### Sample Code

```
METHOD if_gsm_api_provider~get_metric_values.
  DATA: ls_metric_value      TYPE if_gsm_api_types=>ts_metric_value.
  DATA: lv_timestamp        TYPE timestamp.
  GET TIME STAMP FIELD lv_timestamp.
  ls_metric_value-metric_id = me->e_metric_id-demo_metric_id.
  IF iv_timestamp_start IS SUPPLIED AND iv_timestamp_start <> 0.
    ls_metric_value-value_timestamp = iv_timestamp_start.
  ELSEIF iv_timestamp_end IS SUPPLIED AND iv_timestamp_end <> 0.
    ls_metric_value-value_timestamp = iv_timestamp_end.
  ELSE.
    ls_metric_value-value_timestamp = lv_timestamp.
  ENDIF.
  ls_metric_value-value_count = 1.
  ls_metric_value-value_text = ''.
  INSERT VALUE #(
    attribute_id = me->e_attribute_id-demo_attr_01
    value        = 'None' ##NO_TEXT
  ) INTO TABLE ls_metric_value-attributes
  REFERENCE INTO DATA(lsr_mp_attr_01).
  " metric data
  "
  -----
  " Retrieval of the metric values at this point in time.
  DATA(lt_metrics) = me->mo_api_access->get_metrics( ).
  " transformation
  "
  -----
  " Transform the metric values format to the GSM data structures.
  LOOP AT lt_metrics REFERENCE INTO DATA(lrs_metric).
    lsr_mp_attr_01->value = lrs_metric->attribute.
    ls_metric_value-value_sum = lrs_metric->value.
    ls_metric_value-value_max = ls_metric_value-value_sum.
    ls_metric_value-value_min = ls_metric_value-value_sum.
    IF ls_metric_value-value_sum > 10.
      ls_metric_value-value_rating = if_gsm_api_constants=>e_rating-
      _2_warning.
    ELSE.
      ls_metric_value-value_rating = if_gsm_api_constants=>e_rating-1_ok.
    ENDIF.
    INSERT ls_metric_value INTO TABLE et_metric_values.
  ENDLOOP.
ENDMETHOD.
```

## 4.2.10.8.2 Creating a Metric Provider

You can create a metric provider in ABAP Development Tools to make your own metrics available for health monitoring of your ABAP system.

### Prerequisites

You've created a class implementing the interface `IF_GSM_API_PROVIDER`. This class defines your metric model.

### Context

With the creation of a metric provider, you register your metrics that are defined in the class for a periodic collection of values.

#### Note

For more information about creating metric providers, see the documentation in ABAP Development Tools.

### Procedure

1. To create a metric provider in ABAP Development Tools, choose **New** > **Other** > **ABAP Repository Object** > **Others** > **Metric Provider**.
2. In the wizard, enter a package, name, and description.  
A metric provider is created.
3. In the metric provider, as implementing object, enter the class that defines your metric model for this metric provider (see [Creating a Class for Metric Providers \[page 1089\]](#)).
4. Under **Execution**, select the priority with which the values of this metric provider must be collected.

#### Note

The execution mode is set to **Job**, which you can't change. The collection of metric values is executed by an application job that your administrator must schedule (see [Collect Metric Provider Values \(Administrator\) \[page 1095\]](#)). The application job runs regularly and collects the values of all metric providers using their `GET_METRIC_VALUES( )` methods.

Set a higher priority for metric providers that you consider as more important than others. A higher priority ensures that the values for these metric providers are collected first by the application job. Make sure that metric providers that are dependent on the values of other metric providers have a lower priority than the metric providers on which they depend.

5. Leave the field *Scope Dependent* set to *Yes*.

### 4.2.10.8.3 Testing the Metric Providers

You can use class `CL_GSM_API_TEST` to create unit tests for your metric providers.

#### Context

With unit tests, you can simulate the API that retrieves the lower-level raw data. You focus here on the transformation logic to the structures of the generic metric store.

#### Procedure

1. In ABAP Development Tools (ADT), you can find the class `CL_GSM_API_TEST` as released object in the package `S_GSM_API`.
2. To create unit tests, implement the methods of the class `CL_GSM_API_TEST`.

### 4.2.10.8.4 Considerations for Metric Provider Updates

When you update an existing metric provider, make sure that these updates are synchronized across the system landscape.

#### Background

With the metric provider, you define a metric model using the method `DEFINE_MODEL( )`. This code is executed each time when you activate the metric provider and when the metric provider is imported into target systems. It's important to understand these synchronization events to transport metric providers correctly.

#### Things to Consider

Please keep the following considerations in mind to ensure a consistent metric model for your applications:

- Whenever you add a metric provider to a transport request (because you changed or activated it), also add the implementing class to the transport.

- Whenever you change a metric model in an implementing class, also add the corresponding metric provider to the transport. If you forget to add the metric provider, the metric model synchronization won't be triggered when the transport is imported into another system.
- When you activate a metric provider, the metric model is synchronized. Let's assume you change the behavior of the implementing class: For example, you change the definition of a metric, add a new metric, or you change something else in the metric model of your metric provider. Then you must not only activate the implementing class, but also the metric provider again to trigger a metric model synchronization. After activating the implementing class, log off and on again to the ABAP Development Tools and then activate the metric provider.

## 4.2.10.8.5 Collect Metric Provider Values (Administrator)

As an administrator, you must create an application job to collect metric providers and their measured values for the generic metric store. From the generic metric store, they can be pushed to SAP Cloud ALM or SAP Focused Run.

### Prerequisites

You need an administration role to be able to create application jobs.

You must set up a communication arrangement based on communication scenario `SAP_COM_0527`, so that metrics stored in the generic metric store are automatically pushed to Health Monitoring in SAP Cloud ALM and SAP Focused Run.

### Procedure

1. In the SAP Fiori launchpad, open the *Schedule Metric Provider Collection* app.
2. Choose *Create* to create a new application job.

The job template for collecting metric provider values is already selected.

3. To change job settings, follow the instructions of the in-built documentation of SAP Companion.

#### Note

Enter a recurrence that is a multiple of 5 minutes. **Don't** use a recurrence pattern that's shorter than 5 minutes.

4. Schedule the job.

#### Note

Make sure that you schedule this job for the development system and all follow-up systems.

## Results

The metric provider values are collected and saved to the generic metric store.

### 4.2.10.8.6 Troubleshooting

If your own metrics for health monitoring aren't collected as expected, check for the possible error sources.

You can check the following:

- Display the log of the application job *Collect Metric Provider Values*. In the log, search for **\*GSM\*** or the name of the metric provider.  
In the log, you might find error messages saying that metric providers have been banned and the reasons for the bans.  
Background: If the metric provider framework detects any kind of runtime violation such as, for example, too many consecutive dumps, an exceeded runtime limit, or too much memory consumption during the metric value collection, the relevant metric provider is banned for 24 hours. The ban protects the metric measurement of other metric providers. Fix the issues mentioned in the log. After 24 hours, the metric provider framework attempts to execute the provider once more in a tentative mode. If the execution passes without any issues, the ban is lifted, otherwise it's extended by 24 hours.
- If the metric provider is executed, but a metric is missing, you might need to retransport the metric provider to trigger an implicit metric model synchronization.

[Considerations for Metric Provider Updates \[page 1094\]](#)

### 4.2.10.9 Accessing ABAP-Managed Data Using SQL Services for Data Integration Scenarios

As a developer in the ABAP environment, you can expose CDS view entities in an ABAP system for external consumption using SQL services.

Using the open database connectivity (ODBC) as a standard API for accessing databases, you can use SQL statements in external analytical tools to access the data of these CDS view entities from your ABAP system and formulate ad-hoc SQL queries on your data. You can also use the exposed CDS view entities from SQL services to set up data replication for further processing of the data and combining it with data from other data sources.

## Why SQL Services?

There are situations where you would like to have external SQL read access to CDS objects owned by the ABAP system. Direct SQL read access to the underlying SAP HANA database of an ABAP system isn't recommended because, for example, ABAP-level security concepts are bypassed and typecasts might not be performed as expected (see also SAP Note [2511210](#)).

Security concerns and other aspects such as authentication and authorization don't arise if you treat the ABAP system itself as a database by accessing the ABAP system directly using the SQL service exposure. In this case, authentication and authorization are done using an ABAP user. Full ABAP SQL semantics apply and even buffering on application server level can be used as well as ABAP-level access control and read access logging.

Compared to the OData interface, the SQL service exposure has the advantage that it allows for unrestricted SQL access to all exposed ABAP CDS view entities. Data from different entities can be joined in an ad-hoc fashion and data can be aggregated for analytical queries.

## Data Integration Patterns and Scenarios

Data access patterns for ABAP-managed data can be categorized into data federation and data replication, as well as privileged access and business user access. Data federation allows for live access to the source system without replicating the data, while data replication involves replicating the data to a second system for local execution. Privileged access enables communication between an SQL-based client and the ABAP system using a communication user. (The communication user is a non-restricted technical power user or represents a technical system.) Business user access applies access controls to limit data access based on authorizations of the business user.

Examples of data consumption scenarios include data consumption using external ODBC clients like Microsoft Excel and LibreOffice, which can work with both privileged and business user access. Another example is data consumption using SAP Datasphere, where data is replicated from an ABAP system to SAP Datasphere for analytical scenarios.

## Related Information

[Data Integration Patterns \[page 1098\]](#)

[Data Consumption Using External ODBC Clients \[page 1099\]](#)

[Data Consumption Using SAP Datasphere \[page 1101\]](#)

## 4.2.10.9.1 Data Integration Patterns

When you set up access to ABAP-managed data using SQL services, you can set up privileged or business user-based data access. As consumption scenarios, there's data federation and replication.

When you set up access to ABAP-managed data to be consumed using SQL services, the following dimensions can be distinguished:

- Data federation vs. data replication
- Privileged access vs. business user access

These dimensions also have interdependencies.

### Data Federation vs. Data Replication

With data federation, data remains in its source system and all requests are forwarded to the source system and executed on the original data. Data federation is used in scenarios where live access to the source system is required, for example, to access the most recent data without a time lag, or to rely on data access control mechanisms inside the source system.

With data replication, data is replicated to a second system and requests are executed locally on the replicated data like, for example, in a data warehouse. Data replication is used where it's more efficient to transfer (business) data from a source to a target system before the data is accessed within that target system.

For more information about the differences between data federation and data replication, see also [Develop Integration Services](#) in the ABAP Cloud documentation.

### Privileged Access vs. Business User Access

#### Privileged Access

With privileged access, the communication between an SQL-based client and the ABAP system is set up for a communication user. Access controls aren't applied on the ABAP side, which means that the communication user can access all data from the CDS view entities for which the communication user is authorized.

Exposure of CDS entities is controlled by service definitions and SQL service bindings. Authorizations are controlled on the level of service bindings or individual CDS view entities. The communication on the ABAP side is configured using communication scenarios and communication arrangements.

In the example used in this documentation, the communication user has read access to all data (order data from all regions).

#### Business User Access

With business user access, communication is established for a business user. Access controls for the exposed CDS view entities are active and the business user can only access data from the exposed CDS view entities filtered by the business user's authorizations.

Exposure of CDS entities is controlled by service definitions and SQL service bindings. Authorizations are controlled on the level of service bindings and the authorizations that are referenced in access controls. Authorizations are assigned using IAM apps, restriction types, and business catalogs.

In the example in this documentation, a restriction type is used to limit the access of the business user to order data from one region only.

## Dependencies Between Dimensions

The following table shows how these dimensions can be combined:

	Data Federation	Data Replication
Privileged Access	Supported	Supported
Business User Access	Supported	Not supported

## Examples

In the documentation here, you can find examples of different data access patterns: For example, the data consumption using the external ODBC clients Microsoft Excel and LibreOffice are data federation scenarios that work with privileged and business user access. Data replication is currently only supported using SAP Datasphere as replication middleware.

## Related Information

[Data Consumption Using External ODBC Clients \[page 1099\]](#)

[Data Consumption Using SAP Datasphere \[page 1101\]](#)

### 4.2.10.9.2 Data Consumption Using External ODBC Clients

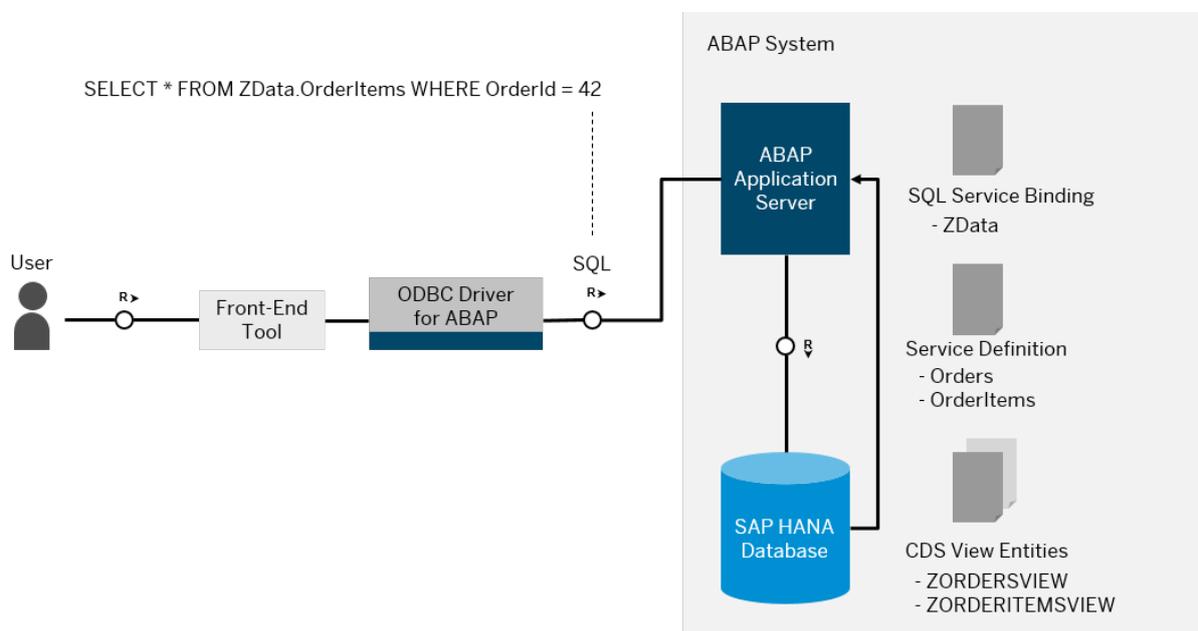

As a developer in the ABAP environment, you can access CDS view entities in an ABAP system using SQL and the open database connectivity (ODBC), a standard API for accessing databases. As a result, you can use SQL

statements in external analytical tools to access data in database tables (via CDS view entities) that reside in the ABAP environment.

## Architecture

To access CDS view entities from external ODBC-based tools, you use the SQL service binding and the ODBC driver for ABAP as follows:

- The ODBC driver for ABAP implements the ODBC API, which can be used by ODBC-enabled front-end tools to execute SQL queries on the SAP Application Server ABAP. Such a front-end tool could be a standard tool capable of loading an ODBC driver, for example, Microsoft Excel. The ODBC driver for ABAP can also be used in multiple programming languages. ODBC is primarily a C API, but other languages like node.js, Python, or Perl also provide plugins for ODBC drivers.
- Instead of directly querying the underlying ABAP-owned database objects using the SQL layer of the ABAP system database, all SQL requests are routed through the ABAP Application Server. They behave just like they would if executed from within an ABAP program.
- You create CDS view entities on top of the tables that you want to expose.
- The SQL service binding type serves to expose CDS view entities as read-only to ODBC-based SQL clients. With the SQL service, you can use an access mechanism of the ABAP Application Server that provides SQL-level access to published ABAP-managed database API objects like tables and CDS views via CDS view entities for system-external consumers.

The ODBC driver for ABAP supports the use of a communication user in the ABAP system with privileged access (no access controls applied). Only read access to the exposed ABAP CDS objects is allowed.

In addition to the communication user, the ODBC driver for ABAP also supports the use of a business user with a browser-based logon. The ABAP system forwards the user's logon request to the configured identity provider to handle it. Authorizations for business users to view data can be limited using restriction types.

The ODBC driver for ABAP is available on Windows and Linux.

You can access the data as read-only using an external ODBC-based client tool, including loading the data into the client tool and searching for data using embedded SQL queries. The ODBC-based client can be any client tool capable of loading an ODBC driver, such as Microsoft Excel or LibreOffice.

## **Additional Information**

This documentation leads you through the necessary development, installation, and configuration for the consumption of the SQL service and ODBC driver. If you prefer to follow a tutorial instead, you can also use the following (for a communication user with privileged access only):

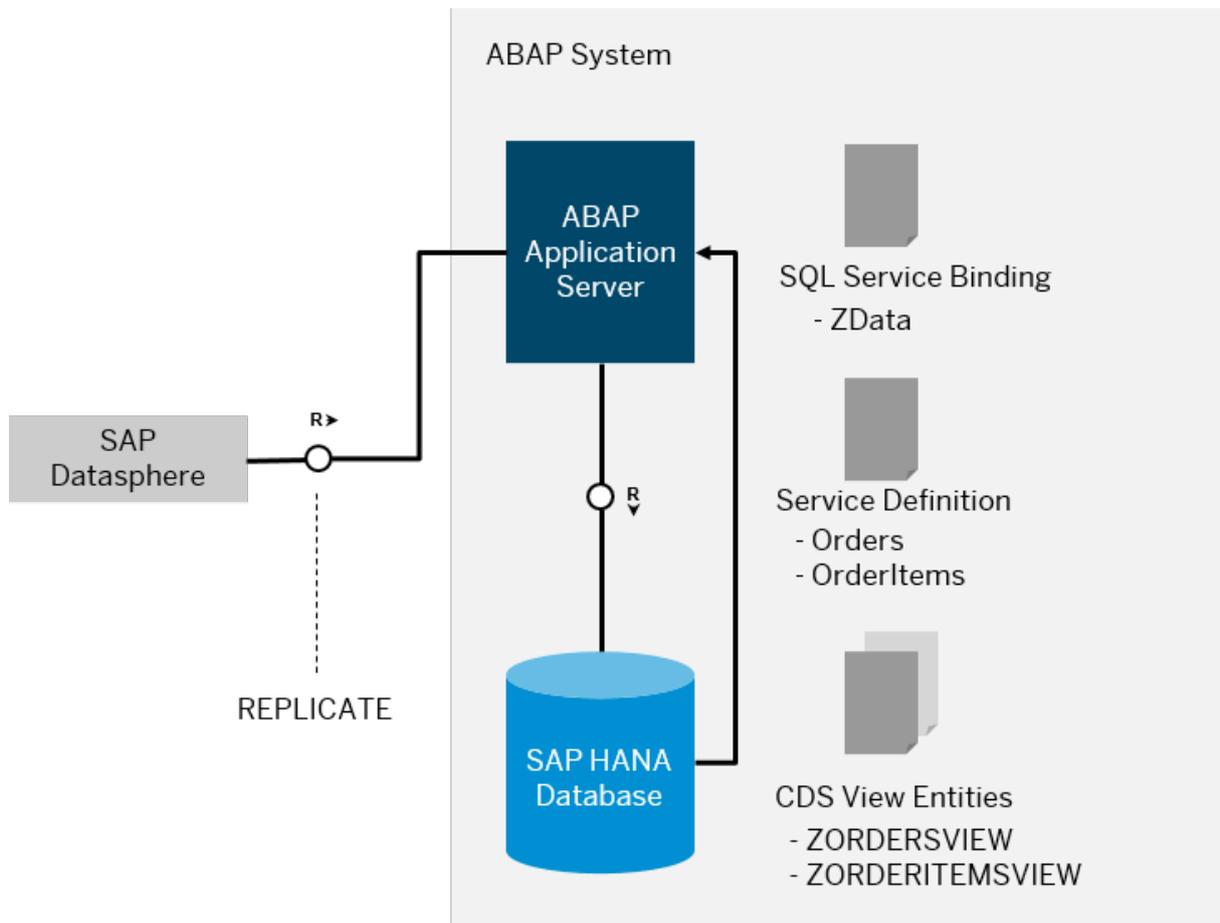

<https://developers.sap.com/tutorials/abap-environment-abap-sql.html> 

### **4.2.10.9.3 Data Consumption Using SAP Datasphere**

You can consume ABAP-managed data using SAP clients such as SAP Datasphere.

## **Architecture**

In this scenario, you use SAP Datasphere to retrieve data from your ABAP system. From a technical perspective, SAP Datasphere plays the role of a client and triggers replication of data from the ABAP system to your SAP Datasphere instance. The replicated data then forms the basis for analytical scenarios inside SAP Datasphere.

To access data from your ABAP system in SAP Datasphere, you use SQL service bindings in the ABAP systems for the data exposure and the replication flows provided by SAP Datasphere:

- You create CDS view entities on top of the tables or CDS views that you want to expose.
- The SQL service binding type serves to expose CDS view entities. With the SQL service, you can use an access mechanism of the ABAP application server that provides SQL-level access to published ABAP-managed database API objects like tables and CDS views via CDS view entities for replication.
- The replication management service of SAP Datasphere is used to replicate selected CDS view entities to SAP Datasphere.

In the replication scenario, the use of a communication user in the ABAP system with privileged access is supported (no access controls applied). Only read access to the exposed CDS view entities is allowed.

#### 4.2.10.9.4 Prerequisites and Constraints

Check the prerequisites and constraints before you start using the SQL service for accessing ABAP-managed data.

[Prerequisites \[page 1103\]](#)

Check whether you meet all prerequisites for using the SQL service.

[Constraints \[page 1104\]](#)

There are some constraints regarding functionality that can be exposed using an SQL service binding.

[Additional Prerequisites and Constraints for Replication \[page 1105\]](#)

If you want to use an SQL service for replication, additional prerequisites and constraints apply.

## 4.2.10.9.4.1 Prerequisites

Check whether you meet all prerequisites for using the SQL service.

Make sure that the following general requirements are met:

- You have a developer user in the ABAP environment.
- You have ABAP Development Tools (ADT) installed.
- You have an ABAP Cloud project configured in ADT and connected to the ABAP system.

To be able to run the ODBC driver for ABAP, the following prerequisites must be met:

- Make sure that you use a 64-bit application as an ODBC client because the ODBC driver for ABAP is only available as a 64-bit driver.
- **Linux only:** A 64-bit Linux version is required because the ODBC driver for ABAP is a 64-bit ODBC driver. To define ODBC data source names (DSN) for the ODBC driver for ABAP on Linux, you must install the unixODBC software package on your Linux system. This software package also provides some simple command-line tools to test an ODBC connection and to execute SQL queries.
- **Linux only:** Set the environment variable where the driver files reside, such as:  

```
export LD_LIBRARY_PATH=/home/<user_name>/odbc-abap
```

To avoid that you need to extend LD\_LIBRARY\_PATH manually every time the ODBC driver is used, consider adding this setting to the Linux logon scripts for the users using the ODBC driver from this location.
- **Microsoft Windows only:** The ODBC driver requires a C/C++-runtime (VCredist). Make sure that the latest version of the VCredist package is installed. For more information about VCredist, see SAP Note [1553465](#).
- If you want to use the open-source software package LibreOffice as an external ODBC client, make sure that you have LibreOffice installed.
- **Business user with browser logon only:** If you want to use the access scenario for business users with browser logon, you need at least ODBC driver version 01, patch level 2.

## Related Information

[Data Integration Patterns \[page 1098\]](#)

## 4.2.10.9.4.2 Constraints

There are some constraints regarding functionality that can be exposed using an SQL service binding.

Only CDS view entities can be exposed, for the following reasons:

- Only one name (CDS name equals SQL name)
- No table functions for views with parameters (better performance)
- Stricter checks regarding, for example, completeness of currency/unit references
- Harmonized client handling

These CDS view entities must meet **all** of the following criteria:

- They are not part of a transactional business object (BO).
  - Reason: Access on SQL-/DB-level doesn't consider the transactional buffer, so not all relevant data is considered.
  - Criteria:
    - Not part of a `ROOT-COMPOSITION` relationship OR
    - They don't contain the header annotation `@ObjectModel.transactionalProcessingEnabled`
- They don't represent an analytical query.
  - Reason: Access on SQL-/DB-level doesn't compute the correct results as query contains features that can only be interpreted by an OLAP engine.
  - Criteria: They don't contain the header annotation `@Analytical.query`.
- They don't represent an (enterprise) search model.
  - Reason: Access on SQL-/DB-level doesn't compute the correct results as only the enterprise search engine can correctly interpret/consume the view model.
  - Criteria: They don't contain the header annotation `@EnterpriseSearch.enabled`.
- They aren't implemented via a custom query.
  - Reason: Access on SQL-/DB-level doesn't compute the correct results as the query is implemented on ABAP-level.
  - Criteria: They don't contain the header annotation `@ObjectModel.query.implementedBy`.
- They aren't implemented via an ABAP-implemented analytical cube.
  - Criteria: They don't contain the header annotation `@Analytics.readClassName`.
- They are no private views.
  - Reason: Even if access on SQL-/DB-level computed the correct results, these views should only be called locally in the system.
  - Criteria: They don't contain the header annotation `@VDM.private`.
- They are no extension include views.
  - Reason: Even if access on SQL-/DB-level computed the correct results, these views should only be called locally in the system.
  - Criteria: They don't contain the header annotation `@VDM.viewType: #EXTENSION`.
- They don't represent derivation functions.
  - Reason: Even if access on SQL-/DB-level computed the correct results, these views should only be called locally in the system.
  - Criteria:

- No header annotation `@VDM.viewType: #DERIVATION_FUNCTION`
- No header annotation `@ObjectModel.derivationFunction`
- They don't contain elements that meet one of the following criteria:
  - Virtual elements
    - Criteria:
      - They are not defined via the keyword `VIRTUAL` or:
      - They don't contain the header annotations `@ObjectModel.virtualElement` or `@ObjectModel.virtualElementCalculatedBy`.
  - Private elements
    - Criteria: They don't contain the header annotation `@Consumption.hidden`.
  - Derived elements
    - Criteria: They don't contain the header annotation `@ObjectModel.value.derivedFrom`.

### 4.2.10.9.4.3 Additional Prerequisites and Constraints for Replication

If you want to use an SQL service for replication, additional prerequisites and constraints apply.

The following generally applies for replication using an SQL service:

- CDS view entities with parameters can never be replicated.
- An initial load (complete replication of all records) is possible without further restrictions.
- Every CDS view entity that is used for **delta** replication must declare this intention in its header via the annotation `@DataIntegration.deltaReplication.intended: true`.

You must perform an initial load again if **all** of the following applies:

- A table structure has been changed, which has also affected the primary key.
- The changed primary key is used in a CDS view entity that is part of a replication scenario.

In this case, a delta replication is not sufficient, but you must re-initialize the process with a full replication of the records.

For delta replication on CDS view entities, additional constraints apply. For more information and a full list of constraints, see the Knowledge Transfer Documentation for the annotation `@DataIntegration.deltaReplication.intended: true`, which can be called up in ABAP Development Tools.

## 4.2.10.9.5 Developing and Exposing an SQL Service in the ABAP System

Before you can access database tables from external ODBC-based tools, you must start with some preparatory steps such as developing and exposing an SQL service in the ABAP system.

### Context

When you want to enable the access to ABAP-managed data from external ODBC clients, you must start with some preparatory steps. These steps include the creation of CDS view entities for the tables for which you want to access, a service definition, and an SQL-typed service binding. Optionally, you can also create your own test tables. Test tables are used in this documentation as examples.

Depending on your access scenario (privileged data access with a communication user or data access with a business user), you must perform different additional steps.

### Privileged Access with a Communication User

For accessing database tables using a communication user, you must also create a communication scenario and a communication system in ABAP Development Tools. An administrator creates a corresponding communication arrangement and user. The assumption in this documentation is that the communication user gets privileged data access.

### Access with a Business User

For accessing database tables using a business user, this documentation also shows how to configure data access where access is limited to orders for a specific region. For this scenario, you must create an authorization object, access control, an IAM app, and a business catalog in ABAP Development Tools. An administrator creates a business role and assigns a business user.

### Related Information

[Data Integration Patterns \[page 1098\]](#)

## 4.2.10.9.5.1 Creating a Data Model and an SQL Service

Before you set up the data access for ODBC-based clients, you must create a data model and an SQL service in ABAP Development Tools.

In this documentation, you can find instructions how to create a few tables with sample data. These tables are used as examples to show how data access for ODBC-based clients works.

In addition, you need CDS view entities for your tables, a service definition, and an SQL-typed service binding.

### 4.2.10.9.5.1.1 Creating a Data Element

As part of the development artefacts for testing, create a data element ZREGION.

#### Context

This data element ZREGION is used as an example to illustrate data access for business users based on regions. (The data element is also part of the example data for privileged access, but won't be used.)

As part of the development artefacts, you also create a table ZORDERS (see [Creating and Filling Test Tables \[page 1108\]](#)). To use instance-level restrictions on the data, you extend the ZORDERS table by adding a region field. You can then later restrict access based on the region of an order.

#### Procedure

- Create a data element ZREGION, based on a domain ZREGIONDOM with a value table ZREGIONS.

For example, your code can look like the following:

#### Sample Code

```
@EndUserText.label : 'REGIONS'  
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE  
@AbapCatalog.tableCategory : #TRANSPARENT  
@AbapCatalog.deliveryClass : #A  
@AbapCatalog.dataMaintenance : #RESTRICTED  
define table zregions {  
    key region : zregion not null;  
}
```

## 4.2.10.9.5.1.2 Creating and Filling Test Tables

As an example, let's create and fill some test tables to illustrate how database tables can be accessed from external ODBC-based tools.

As an example, the demo table entities ZORDERS and ZORDERITEMS are used in this documentation.

The definition of the ZORDERS table in ABAP Development Tools (ADT) can look as follows:

### Sample Code

```
@EndUserText.label : 'ORDERS'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #A
@AbapCatalog.dataMaintenance : #RESTRICTED
define table zorders {
  key id          : abap.numc(10) not null;
  creationdate   : abap.datn;
  region         : zregion;
}
```

Here's the table for order items:

### Sample Code

```
@EndUserText.label : 'ORDER ITEMS'
@AbapCatalog.enhancement.category : #NOT_EXTENSIBLE
@AbapCatalog.tableCategory : #TRANSPARENT
@AbapCatalog.deliveryClass : #A
@AbapCatalog.dataMaintenance : #RESTRICTED
define table zorderitems {
  key orderid : abap.numc(10) not null;
  key pos     : abap.int4 not null;
  item       : abap.char(100) not null;
  amount     : abap.int4 not null;
}
```

You can also create some test data in the tables using the following ABAP sample code:

### Sample Code

```
class zcl_fill_orders definition
public
final
create public.
public section.
  interfaces if_oo_adt_classrun.
protected section.
private section.
endclass.
class zcl_fill_orders implementation.
method if_oo_adt_classrun~main.
  data: lt_regions type table of zregions.
  delete from zregions.
  lt_regions = value #(
    ( region = 'A' )
    ( region = 'B' )
  ).
  insert zregions from table @lt_regions.
  out->write( sy-dbcnt ).
```

```

data: lt_orders type table of zorders.
delete from zorders.
lt_orders = value #(
  ( id = '1' creationdate = '20210801' region = 'A' )
  ( id = '2' creationdate = '20210802' region = 'A' )
  ( id = '3' creationdate = '20210803' region = 'B' )
  ( id = '4' creationdate = '20210804' region = 'B' )
).
insert zorders from table @lt_orders.
out->write( sy-dbcnt ).
data: lt_orderitems type table of zorderitems.
delete from zorderitems.
lt_orderitems = value #(
  ( orderid = '1' pos = '1' item = 'Apple' amount = '5' )
  ( orderid = '1' pos = '2' item = 'Banana' amount = '5' )
  ( orderid = '1' pos = '3' item = 'Orange Juice' amount = '2' )
  ( orderid = '2' pos = '1' item = 'Orange' amount = '10' )
  ( orderid = '2' pos = '2' item = 'Apple' amount = '5' )
  ( orderid = '3' pos = '1' item = 'Bottle Water' amount = '5' )
  ( orderid = '4' pos = '1' item = 'Bottle Wine' amount = '2' )
  ( orderid = '4' pos = '2' item = 'Apple' amount = '5' )
  ( orderid = '4' pos = '3' item = 'Orange' amount = '3' )
).
insert zorderitems from table @lt_orderitems.
out->write( sy-dbcnt ).
endmethod.
endclass.

```

To be able to use regions to control data access, the ABAP class for filling the tables also fills a ZREGIONS table and includes a region in the orders.

### 4.2.10.9.5.1.3 Creating CDS View Entities for Tables

The example code gives you an idea how you create CDS view entities for data integration using an SQL service.

#### Context

In this example, you learn how you can create CDS view entities on top of the tables that you want to expose, using the ADT wizard. Only CDS view entities can be exposed to consumers using the SQL service.

#### Procedure

1. In the project explorer in ABAP Development Tools, right-click on the table and choose *New Data Definition* from the context menu.
2. Fill out the data requested in the following popup and choose *Next*.
3. On the next screen, choose *Define View Entity* and *Finish*.
4. Activate the new CDS view entities.

## Results

The definitions can look as follows:

### Sample Code

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #CHECK
@EndUserText.label: 'Orders'
@Metadata.ignorePropagatedAnnotations: true
@ObjectModel.usageType:{
  serviceQuality: #X,
  sizeCategory: #S,
  dataClass: #MIXED
}
@DataIntegration.deltaReplication.intended: true
define view entity ZORDERSVIEW as select from zorders {
  key id as Id,
  creationdate as CreationDate,
  region as Region
}
```

### Sample Code

```
@AbapCatalog.viewEnhancementCategory: [#NONE]
@AccessControl.authorizationCheck: #CHECK
@EndUserText.label: 'ORDER ITEMS'
@Metadata.ignorePropagatedAnnotations: true
@ObjectModel.usageType:{
  serviceQuality: #X,
  sizeCategory: #S,
  dataClass: #MIXED
}
@DataIntegration.deltaReplication.intended: true
define view entity ZORDERITEMSVIEW as select from zorderitems
  association [1..1] to zorders as _order on $projection.Orderid = _order.id
{
  key orderid as Orderid,
  key pos as Pos,
  item as Item,
  amount as Amount,
  _order
}
```

### Note

The original table columns have been renamed to use mixed-case names.

For business user access using a region field, the ZORDERSVIEW CDS view entity also includes the region field of the ZORDERS table. For privileged access, the region field is not needed.

For business user access, in the ZORDERITEMSVIEW CDS view entity, you make the region field of the orders accessible using an association `_order`.

For privileged access, no access control is needed, here you can replace

```
@AccessControl.authorizationCheck: #CHECK by @AccessControl.authorizationCheck:
#NOT_REQUIRED.
```

For business user access, there's a warning that no access control exists. You create this access control when you expose the SQL service for business user access.

The annotation `@DataIntegration.deltaReplication.intended: true` is only required for data replication scenarios (delta replication).

## 4.2.10.9.5.1.4 Creating a Service Definition and an SQL-Typed Service Binding

To expose CDS view entities using the SQL service, you must create a service definition and a corresponding service binding of type `SQL`.

### Procedure

1. To define a new service definition, right-click on the CDS views that you created in the project explorer and choose *New Service Definition* in the context menu.
2. Enter a name for the new service definition.
3. Open the new service definition, add the second view, and add alias names for the CDS view entities.

Adding an alias is not required but recommended because with an alias, you can exchange the CDS view entity behind the alias but keep the contract to the consuming application stable.

The service definition can look as follows, for example:

#### Sample Code

```
@EndUserText.label: 'SERVICE DEF'
define service Z_SERVICE_DEF_SQL provider contracts sql {
  expose ZORDERSVIEW as Orders;
  expose ZORDERITEMSVIEW as OrderItems;
}
```

Again, mixed-case names have been chosen for the alias names.

4. Activate the service definition.
5. To create a service binding, right-click on the service definition and choose *New Service Binding*.
6. In the following popup, enter a name and description, for example, `ZData`.

You can use a mixed-case name for the service binding. The service binding name acts as the schema name for external consumers.

7. As binding type, select *SQL – Web API* and choose *Next* and *Finish*.
8. In the *Enabled Operations* area, select all access types that you want to allow on the service.  
*SELECT* is selected by default and enables federated access. *REPLICATE* enables replicated access.
9. Activate the service binding.

## 4.2.10.9.5.2 Exposing the SQL Service for Data Federation and Replication with Privileged Access

To enable privileged data access for communication users using the SQL service exposure, you must control access to data using communication scenarios, communication systems, and communication arrangements.

### 4.2.10.9.5.2.1 Creating a Communication Scenario with Object Privileges

To be able to use a communication user in the ABAP system to access the service binding, you must create a communication scenario in ABAP Development Tools.

#### Context

This communication scenario is the basis of a communication arrangement in the ABAP environment that you also need.

#### Procedure

1. In the project explorer of the ABAP Development Tools, right-click on your project and choose ► *New* ► *Other ABAP Repository Object* .
2. In the popup, enter **Communication** in the search field and then choose *Communication Scenario* from the results.
3. Enter a name and description for the new communication scenario and choose *Next* and *Finish*.
4. In the communication scenario definition, choose the *Inbound* tab.
5. To use user/password authentication, choose *Basic* as supported authentication method. Alternatively, you can use authentication with X.509 client certificates by choosing *X.509*.
6. In the *Inbound Services* screen area, choose *Add...*, enter the S\_PRIVILEGED\_SQL1 service, and choose *Finish*.

The S\_PRIVILEGED\_SQL1 inbound service is a preconfigured service for the privileged access to CDS view entities, that is, no DCLs are applied. (DCL stands for data control language. It provides an access control mechanism to restrict the results returned by the CDS view from the database according to conditions.)

7. To add authorizations and enable access to the service binding, choose the *Authorizations* tab.
8. Under *Authorization Objects*, choose *Insert* and add the S\_SQL\_VIEW authorization object.
9. Choose the newly added authorization object and fill out the authorizations in the details, such as the following:

Field	Value
SQL_SCHEMA	The name of the service binding (exposed as a schema) that you want to grant access to
SQL_VIEW	Comma-separated list of all views to which you want to grant access or * (if you want to allow access to all views in the service definition)
SQL_VIEWOP	Choose at least one option: <i>SELECT</i> or <i>REPLICATE</i> . <i>SELECT</i> grants read access to and <i>REPLICATE</i> allows replication on the specified views.

#### Note

You can allow replication on a view here, but the replication might still not be technically possible.

We recommend that you create separate communication scenarios for *SELECT* and *REPLICATE* to give administrators more fine-grained settings.

10. Save your entries and choose *Publish Locally* to publish the communication scenario in the development system.

After publication, you can create a communication arrangement based on the communication scenario.

## Related Information

[Communication Management \[page 846\]](#)

### 4.2.10.9.5.2.2 Creating a Communication System and a Communication User

An administrator must create a communication system and a communication user for accessing ABAP-managed data from external ODBC-based clients.

## Procedure

1. Log on to the SAP Fiori launchpad of the ABAP environment as an administrator.
2. Under *Communication Management*, choose the *Communication Systems* app.
3. Choose *New*, enter a system ID and name for the communication system, and choose *Create*.
4. In the newly created communication system, select the checkbox *Inbound Only*.
5. Under *Users for Inbound Communication*, choose the + button and then *New User*.

6. Enter a user name (for example, `SQL_CLIENT_USER`), a description, and a password.

Remember the user name and password for later.

7. Choose *Create*.
8. To add the new user to the communication system, choose *OK* in the dialog.

The user is now listed in the screen area *Users for Inbound Communication*.

9. Choose *Save* to finish the creation of the communication system.

### 4.2.10.9.5.2.3 Creating a Communication Arrangement for Exposing the SQL Service

As a last step of the back-end configuration for exposing an SQL service in the ABAP system, an administrator must create a communication arrangement.

#### Context

The arrangement links the communication scenario that was created in ABAP Development Tools with the communication system and communication user.

#### Procedure

1. Log on to the SAP Fiori launchpad of the ABAP environment as an administrator.
2. In the SAP Fiori launchpad, under *Communication Management*, choose *Communication Arrangements*.
3. Choose *New*.
4. In the following popup, enter the communication scenario that you created before and choose *Create*.
5. In the newly created communication arrangement, enter the communication system that you created before (see [Creating a Communication System and a Communication User \[page 1113\]](#)).

This step completes the link between communication scenario and communication system. The system automatically adds the communication user.

6. Take note of the service URL.

It's something like `https://<hostname>/sap/bc/sql/sql1/sap/S_PRIVILEGED`.

7. Choose *Save*.

#### Results

You've now finished all preparation tasks in the ABAP system and can access the exposed objects as an SQL service.

## 4.2.10.9.5.3 Exposing the SQL Service for Data Federation with Business User Access

To enable data access for business users using ODBC-based clients, you must control access to data using IAM apps, restriction types, and business catalogs.

With the example used in this documentation, you will learn how to restrict access to order data based on an order's region.

### 4.2.10.9.5.3.1 Creating an Authorization Field and Object

Create an authorization field and object to provide access control based on a field in the relevant CDS views.

#### Context

There's a region field available in the example CDS views. Based on this example, let's create an authorization field and object.

For more information about creating authorization objects and fields, see the documentation for ABAP Development Tools.

#### Procedure

1. In ABAP Development Tools, create an authorization field.

In the example used in this documentation, create an authorization field `ZREGION` for the region, based on the `ZREGIONS` table.

2. Create an authorization object with an activity field and the authorization field that you just created.

In the example used here, this is an authorization object `ZREGIONMGT` with the authorization field `ZREGION`.

## 4.2.10.9.5.3.2 Creating Access Control

To make sure that no unauthorized users access data, create access control for your CDS views.

### Context

In the example used in this documentation, you create two access controls – one for each view – and use the `aspect pfcg_auth` clause to access the region field in the authorization object. For the sake of simplicity, we don't check the activity, that is, every activity is valid to view the records of a region.

### Procedure

Create the following access controls:

#### Sample Code

```
@EndUserText.label: 'ORDERS DCL'
@MappingRole: true
define role ZORDERSVIEW_DCL {
  grant
  select
  on
    ZORDERSVIEW
  where
    (region) = aspect pfcg_auth(ZREGIONMGT, ZREGION);
}
```

#### Sample Code

```
@EndUserText.label: 'ORDER ITEMS DCL'
@MappingRole: true
define role ZORDERITEMSVIEW_DCL {
  grant
  select
  on
    ZORDERITEMSVIEW
  where
    (_order.region) = aspect pfcg_auth(ZREGIONMGT, ZREGION);
}
```

In the second access control, you use the `_order` association to get access to the order's region field.

## 4.2.10.9.5.3.3 Creating an IAM App and a Restriction Type

To provide a data access for a business user in an ODBC scenario, you must create a restriction type and an IAM app in ABAP Development Tools (ADT).

### Prerequisites

The data that the business user needs to access already exists and there's a corresponding authorization object and authorization field available.

### Context

As a developer, you create an IAM app and a restriction type based on the available authorization field to provide access control for the data. For more information about how to create restriction types and IAM apps, see the ADT documentation.

### Procedure

1. In ABAP Development Tools, create an IAM app called, for example, `ZDATA_IAM`.
2. On the *Services* tab for the IAM app, add the SQL service that you created.  
In the example used for this documentation, this is the `ZDATA` SQL service.
3. On the *Authorizations* tab, add the authorization object that you want to use.  
In the example used for this documentation, this is the `ZREGIONMGT` authorization object.
4. For the `ACTVT` authorization field, choose the checkboxes *Add or Create*, *Change*, *Display*, and *Delete*.  
For all other authorization fields (for example, `ZREGION` in this documentation), leave the settings unchanged. You will model access control using a restriction type.
5. To create a restriction type, open the authorization object that you want to use (for example, `ZREGIONMGT` in this documentation).
6. In the *What's next* section, choose *Create restriction type based on the authorization object*.  
In the example used here, let's call the new restriction type `ZREGIONMGT_RSTR`.

## 4.2.10.9.5.3.4 Creating a Business Catalog

To provide data access to business users using ODBC-based clients, you create a business catalog and assign an IAM app to it.

### Context

For more information about creating business catalogs, assigning IAM apps and restriction types, see the ABAP Development Tools documentation.

### Procedure

1. In ABAP Development Tools, create a business catalog, for example, called ZDATA\_BC.
2. On the *Apps* tab, assign the IAM app that you have created before (see [Creating an IAM App and a Restriction Type \[page 1117\]](#)).
3. On the *Restriction Types* app, assign the restriction type that you have created before.
4. Choose the *Read* checkbox.
5. Choose *Publish Locally* to make the business catalog visible in the development system for testing.

To make the business catalog and all other development objects that you created available for productive use, transport them to the relevant production system.

## 4.2.10.9.5.3.5 Creating a Business Role and Assigning it to a Business User

To enable business users to access ABAP-managed data from ODBC clients, an administrator must create an appropriate business role and it to the business user.

### Prerequisites

#### Note

As opposed to the previous steps in this documentation that were performed by a developer, you now need an administrator role.

An appropriate business catalog for the ODBC client scenario has been created by a developer (for example, ZDATA\_BC, see [Creating a Business Catalog \[page 1118\]](#)).

## Procedure

1. Create a new business role `BR_ZDATA` and assign the business catalog `ZDATA_BC` to it.
2. On the *Assigned Business Users* tab, choose *Maintain Restrictions*.

In the example used in this documentation, the restriction type *Region Management* is shown.

3. Add a value, for example, add the value `A` for the *REGION* field.
4. Go back to the role, add a business user to it, and save the role.

## Results

The assigned business user will now be able to see data for region A only.

### 4.2.10.9.6 Installation and Configuration of the ODBC Driver for ABAP (Data Federation Only)

To be able to use an ODBC-based client to access data in the exposed CDS view entities of the ABAP environment, you must install the ODBC driver and create an ODBC data source.

#### Note

If you use the SQL service in a **replication** scenario with SAP Datasphere only, the installation of the ODBC driver for ABAP is not needed.

Proceed as follows:

1. Install the ODBC driver on your operating system (see [Installing the ODBC Driver \[page 1119\]](#)).
2. Create an ODBC data source on your operating system (see [Creating an ODBC Data Source on Windows \(Privileged Access\) \[page 1120\]](#) or [Creating an ODBC Data Source on Linux \(Privileged Access\) \[page 1121\]](#)).

#### 4.2.10.9.6.1 Installing the ODBC Driver

Get the ODBC driver from the SAP Support Portal and install it.

## Context

You need the ODBC driver for ABAP to be able to access exposed CDS entities from an ODBC-enabled client.

## Procedure

1. Go to the SAP Support Portal at <https://support.sap.com/>.
2. Choose *Software Downloads*.  
You might need to log on now.
3. Search for the components *ODBC DRIVER FOR ABAP 1.0* and *SAPCRYPTOLIB*.
4. Download the correct SAR files for your operating system. In addition, you can download *SAPCAR* to be able to unpack the SAP files.
5. Choose a directory as your ODBC driver location and unpack the SAR files there.
6. **Windows only:** To install the ODBC driver for ABAP, start the installer.

For Linux, unpacking the SAR files is sufficient.

## Results

The ODBC driver is now ready to be used in ODBC data sources.

### 4.2.10.9.6.2 Creating an ODBC Data Source on Windows (Privileged Access)

The *ODBC Data Sources (64 bit)* tool is part of a standard Windows installation. In this tool, you can create ODBC data sources and assign a data source name (DSN) to a newly created data source.

## Procedure

1. Launch the Windows ODBC data source administrator tool.
2. Choose the *User DSN* or *System DSN* tab, choose *Add*, choose the ODBC driver for ABAP as ODBC driver, and choose *Finish*.

The DSN setup dialog of the ODBC driver for ABAP starts.

3. In this dialog, choose a DSN and fill in the driver-specific parameters that are described in more detail in SAP Note [3076454](#).

#### Note

You can derive the host name and the service path from the service URL that you wrote down when you created the communication arrangement.

The user name (for example, `SQL_CLIENT_USER`) that you created in the communication system is automatically the alias name for the generated ABAP user name. Therefore, switch the user type to alias.

## 4.2.10.9.6.3 Creating an ODBC Data Source on Linux (Privileged Access)

With the settings described here, you create an ODBC data source and DSN for a communication user.

### Context

The unixODBC software package provides an ODBC driver manager that can read from multiple configuration files. You can create configuration files that define the location of the ODBC driver and DSNs.

### Procedure

1. List the locations of the configuration files by executing the command `odbcinst -j`.

You get a result such as the following, for example:

#### Sample Code

```
> odbcinst -j
unixODBC 2.3.6
DRIVERS.....: /etc/unixODBC/odbcinst.ini
SYSTEM DATA SOURCES: /etc/unixODBC/odbc. [MYDSN]>
FILE DATA SOURCES..: /etc/unixODBC/ODBCDataSources
USER DATA SOURCES..: /home/myuser/.odbc.ini
SQLULEN Size.....: 8
SQLLEN Size.....: 8
SQLSETPOSIROW Size.: 8
```

2. To define both the driver and a user-specific DSN, create the file `/home/myuser/.odbc.ini`.

You can create a system-wide driver definition and DSN in a similar way.

3. In the `/home/myuser/.odbc.ini` file, insert the DSN-specific connection parameters for the ODBC driver for ABAP as described in SAP Note [3076454](#).

For example, these parameters can look as follows:

#### Sample Code

```
[MYDSN]
; this is a comment
Driver=/home/<myuser>/ODBC_driver_for_ABAP/ODBC_driver_for_ABAP.so
HOST=<hostname>
PORT=443
CLIENT=100
LANGUAGE=EN
SERVICEPATH=/sap/bc/sql/sql11/sap/S_PRIVILEGED
TrustAll=true
CryptoLibrary=/home/<myuser>/ODBC_driver_for_ABAP/libsapcrypto.so
UidType=alias
```

In this example, the driver definition was included in the `.odbc.ini` file using the driver keyword. As connect user for the test system, you can use the user `SQL_CLIENT_USER` that you created as an alias user in the ABAP environment. It's also possible to store the UID/PWD properties in the `.odbc.ini` file. However, we don't recommend the use of a file for security reasons. In the example, for the sake of simplicity, no PSE file was created and the `TrustAll=True` property was used instead.

4. Use the unixODBC tools `isql` or `iusql` to test the ODBC connection.

If everything is configured correctly, you can see the following in the `iusql` tool, for example:

```
Sample Code

> iusql MYDSN SQL_CLIENT_USER <password> -v
+-----+

#### 4.2.10.9.6.4 Creating an ODBC Data Source on Windows (Business User Access)

You create an ODBC data source and DSN for a business user. To enable a business user to log on to the ABAP system with user name and password, you configure the browser-based logon method in the ODBC DSN.

### Context

The *ODBC Data Sources (64 bit)* tool is part of a standard Windows installation. In this tool, you can create ODBC data sources and assign a data source name (DSN) to a newly created data source.

In the example used in this documentation, you need the ODBC data source for a business user that is provided data access to the ABAP system.

### Procedure

1. Launch the Windows ODBC data source administrator tool.
2. Choose the *User DSN* or *System DSN* tab, choose *Add*, choose the ODBC driver for ABAP as ODBC driver, and choose *Finish*.

The DSN setup dialog of the ODBC driver for ABAP starts.

3. In this dialog, choose a DSN and fill in the driver-specific parameters that are described in more detail in SAP Note [3076454](#).

### Note

ServicePath must point to the SQL service that you created (in the example used here, zData):

```
ServicePath=/sap/bc/sql/sql1/sap/zdata.
```

Don't forget to configure the browser-logon method using AuthenticationType and AuthenticationURL:

```
AuthenticationType=Browser
```

```
AuthenticationURL=https://<uihost>/sap/bc/sec/reentrance
```

## 4.2.10.9.6.5 Creating an ODBC Data Source on Linux (Business User Access)

With the settings described here, you create an ODBC data source and DSN for a business user. To enable a business user to log on to the ABAP system with user name and password, you configure the browser-based logon method in the ODBC DSN.

### Context

The unixODBC software package provides an ODBC driver manager that can read from multiple configuration files. You can create configuration files that define the location of the ODBC driver and DSNs.

In the example used in this documentation, you need the ODBC data source for a business user that is provided data access to the ABAP system.

### Procedure

1. List the locations of the configuration files by executing the command `odbcinst -j`.

You get a result such as the following, for example:

#### Sample Code

```
> odbcinst -j
unixODBC 2.3.6
DRIVERS.....: /etc/unixODBC/odbcinst.ini
SYSTEM DATA SOURCES: /etc/unixODBC/odbc. [MYDSN]>
FILE DATA SOURCES..: /etc/unixODBC/ODBCDataSources
USER DATA SOURCES..: /home/myuser/.odbc.ini
SQLULEN Size.....: 8
SQLLEN Size.....: 8
SQLSETPOSIROW Size.: 8
```

2. To define both the driver and a user-specific DSN, create the file `/home/myuser/.odbc.ini`.

You can create a system-wide driver definition and DSN in a similar way.

3. In the `/home/myuser/.odbc.ini` file, insert the DSN-specific connection parameters for the ODBC driver for ABAP as described in SAP Note [3076454](#). In addition, you configure the browser-logon method using `AuthenticationType` and `AuthenticationURL`.

For example, these parameters can look as follows:

#### Sample Code

```
[MYDSN]
; this is a comment
Driver=/home/<myuser>/ODBC_driver_for_ABAP/ODBC_driver_for_ABAP.so
HOST=<hostname>
PORT=443
CLIENT=100
LANGUAGE=EN
SERVICEPATH=/sap/bc/sql/sql1/sap/zdata
TrustAll=true
CryptoLibrary=/home/<myuser>/ODBC_driver_for_ABAP/libsapcrypto.so
AuthenticationType=Browser
AuthenticationURL=https://<uihost>/sap/bc/sec/reentrance
UID=dummy
PWD=dummy
```

In this example, the driver definition was included in the `.odbc.ini` file using the driver keyword. In the example, for the sake of simplicity, no PSE file was created and the `TrustAll=True` property was used instead. The entries `UID=dummy` and `PWD=dummy` were added so that you are not forced to enter a user and password in the browser that are required by the `unixODBC` tool `iusql` for testing, but are not needed by the ODBC driver.

4. Use the `unixODBC` tools `isql` or `iusql` to test the ODBC connection.

If everything is configured correctly, you can see the following in the `iusql` tool, for example:

#### Sample Code

```
> iusql MYDSN -v
+-----+
| Connected! |
|           |
| sql-statement |
| help [tablename] |
| quit       |
|           |
+-----+
SQL>
```

## 4.2.10.9.7 Consumption of the SQL Service for Data Federation

Learn how you can use ODBC-based clients for loading and transforming data.

After the exposing an SQL service in the ABAP system and installing the ODBC driver for ABAP, the SQL service and the ODBC driver can be used to provide data access from external ODBC-based clients.

## 4.2.10.9.71 Example: Loading and Transforming Data Using Microsoft Excel

After creating a DSN, you can use this DSN in an ODBC client tool of your choice. Learn how you can use Microsoft Excel for loading and transforming data as an example.

### Procedure

1. Start Microsoft Excel.
2. In the menu, choose ► *Data* ► *Get Data* ► *From Other Sources* ► *From ODBC* ►.
3. In the following popup, enter the DSN.
4. **Communication user only:** In the *Database* section of the popup, you're prompted for user and password to log on to the ABAP system. Enter the user and password that you remember from when you created the communication system (see [Creating a Communication System and a Communication User \[page 1113\]](#)).
5. **Business user only:** In the *Database* section of the popup, you're prompted for user and password. You can enter any user or password; authentication is not checked at this point.
6. Choose *Connect*.

**Business user only:** When a connection is opened by Excel, a browser window with a logon dialog for the ABAP system appears. Depending on your system configuration, the browser logon might ask you for your credentials (user and password). Enter your business user name and password for the ABAP system.

The navigator appears and shows all exposed objects in the SQL schema that you've chosen to expose, that is, in the example used here, the SQL schema `ZORDERS`.

7. To display a preview of the data content in Excel, choose one of the CDS entities.
8. Choose either *Load* to load the data into an Excel sheet or choose *Transform Data* to switch to Power Query in Excel.

When you load the data into an Excel sheet, you can always refresh the data if needed.

9. To execute a free-style SQL query on the exposed entities, choose ► *Data* ► *Get Data* ► *From Other Sources* ► *From ODBC* ► again from the menu in Excel and then choose *Advanced Options*.
10. In the new control, you can enter a `SELECT` statement.

In the `SELECT` statement, you must prefix all view names by your schema name (in the example used here, `ZORDERS`). Apart from these necessary prefixes, you can use an ANSI-like SQL syntax. The result set shows up in an Excel preview window.

## 4.2.10.9.7.2 Example: Loading and Transforming Data Using LibreOffice

After the successful configuration of the ABAP system and the installation of the ODBC driver for ABAP, you can load and transform data from the exposed CDS view entities. You can use external tools such as LibreOffice on Linux, for example.

### Context

#### Note

**Relevant for business user access using browser logon:** If you're using unixODBC tools such as `isql` or `iisql` on command line as ODBC clients instead of LibreOffice, make sure that you work in an environment such as XWindow where a browser window can open.

### Procedure

1. Start LibreOffice.
2. In LibreOffice Calc, choose **File > New > Database**.
3. Choose the *Connect to an existing database* radio button, select *ODBC*, and choose *Next*.
4. Enter the DSN that you inserted into your `.odbc.ini` file and choose *Next*.
5. **Communication user only:** Enter a user name.

**Communication user only:** You can test your connection after providing a password.

6. Choose *Finish*.

**Business user only:** When a connection is opened by LibreOffice, a browser window with a logon dialog for the ABAP system appears. Depending on your system configuration, the browser logon might ask you for your credentials (user and password). Enter your business user name and password for the ABAP system.

LibreOffice now displays all exposed CDS view entities. You can choose these entities to get a data preview.

7. To enter an SQL query string and retrieve the result, choose *Create Query in SQL View*.

#### Note

LibreOffice automatically double-quotes all identifiers in the SQL query. Therefore, you must use the mixed case names for the CDS entities that you defined in the ABAP back end.

## 4.2.10.9.8 Consumption of the SQL Service for Data Replication

Learn how you can set up SAP Datasphere as a client for replicating data.

After you have created and exposed an SQL service for data replication (see [Creating a Communication Arrangement for Exposing the SQL Service \[page 1114\]](#)), create a communication arrangement for SAP Datasphere to be able to reach the ABAP system. In addition, create a replication flow in SAP Datasphere to connect the ABAP source system with the envisioned target environment.

After the objects exposed using the SQL service have been selected and deployed in the replication flow, you can access the replicated data in SAP Datasphere for further processing and combining it with data from other data sources.

[Creating a Communication Arrangement to Enable Replication Flows in SAP Datasphere \[page 1127\]](#)

Create a communication arrangement based the integration scenario SAP\_COM\_0532 to enable replication flows in SAP Datasphere.

[Creating a Replication Flow for SQL Service Exposure \[page 1128\]](#)

In SAP Datasphere, define a replication flow for CDS view entities using the SQL service exposure.

### 4.2.10.9.8.1 Creating a Communication Arrangement to Enable Replication Flows in SAP Datasphere

Create a communication arrangement based the integration scenario SAP\_COM\_0532 to enable replication flows in SAP Datasphere.

#### Prerequisites

You have already created a communication arrangement based on a communication scenario with object privileges so that the communication user in the ABAP system can access the service binding of the SQL service (see [Creating a Communication Scenario with Object Privileges \[page 1112\]](#) and [Creating a Communication Arrangement for Exposing the SQL Service \[page 1114\]](#)).

#### Context

You need the integration scenario SAP\_COM\_0532 if you want to use replication flows in SAP Datasphere to subscribe to CDS view entities from an ABAP system and consume data from these views. With a communication arrangement based on SAP\_COM\_0532 and with a communication arrangement for exposing the SQL service, you can now consume data from public CDS view entities released by SAP and from **custom** CDS view entities that are exposed using an ABAP SQL service.
